2. Other scheduling of new tied tasks is constrained by the set of task regions that are currently tied to the thread, and that are not suspended in a barrier region. If this set is empty, any new tied task may be scheduled. Otherwise, a new tied task may be scheduled only if it is a descendant of every task in the set. A program relying on any other assumption about task scheduling is non-conforming.

---

**NOTE**

Task scheduling points dynamically divide task regions into parts. Each part is executed from start to finish without interruption. Different parts of the same task region are executed in the order in which they are encountered. In the absence of task synchronization constructs, the order in which a thread executes parts of different schedulable tasks is unspecified.

A correct program must behave correctly and consistently with all conceivable scheduling sequences that are compatible with the rules above.

**The `omp taskwait` Pragma**

The `#pragma omp taskwait` specifies a wait on the completion of child tasks generated since the beginning of the current task. A taskwait region binds to the current task region. The binding thread set of the taskwait region is the encountering thread.

The taskwait region includes an implicit task scheduling point in the current task region. The current task region is suspended at the task scheduling point until execution of all its child tasks generated before the taskwait region are completed.

---

**Example**

```cpp
#pragma omp task
{
  ...
  #pragma omp task
  {
    do_work1();
  }
  #pragma omp task
  {
    ...
    #pragma omp task
    {
      do_work2();
    }
    ...
  }
}  ```
Example

```c
#pragma omp taskwait
...
}
```

The `omp taskyield Pragma`

The `#pragma omp taskyield` specifies that the current task can be suspended at that point and the thread may switch to the execution of a different task. You can use this pragma to provide an explicit task scheduling point at a particular point in the task.

Supported Environment Variables

Controlling Thread Allocation

The `KMP_HW_SUBSET` and `KMP_AFFINITY` environment variables allow you to control how the OpenMP* runtime uses the hardware threads on the processors. These environment variables allow you to try different thread distributions on the cores of the processors and determine how these threads are bound to the cores. You can use the environment variables to work out what is optimal for your application.

The `KMP_HW_SUBSET` variable controls the allocation of hardware resources and the `KMP_AFFINITY` variable controls how the OpenMP* threads are bound to those resources.

Controlling Thread Distribution

The `KMP_HW_SUBSET` variable controls the hardware resource that will be used by the program. This variable specifies the number of sockets to use, how many cores to use per socket and how many threads to assign per core. For example, on Intel® Xeon Phi™ coprocessors, while each coprocessor can take up to four threads, specifying fewer than four threads per core may result in a better performance. While specifying two threads per core often yields better performance than one thread per core, specifying three or four threads per core may or may not improve the performance. This variable enables you to conveniently measure the performance of up to four threads per core.

For example, you can determine the effects of assigning 24, 48, 72, or the maximum 96 OpenMP* threads in a system with 24 cores by specifying the following variable settings:

<table>
<thead>
<tr>
<th>To Assign This Number of Threads ...</th>
<th>... Use This Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>KMP_HW_SUBSET=24c,1t</td>
</tr>
<tr>
<td>48</td>
<td>KMP_HW_SUBSET=24c,2t</td>
</tr>
<tr>
<td>72</td>
<td>KMP_HW_SUBSET=24c,3t</td>
</tr>
<tr>
<td>96</td>
<td>KMP_HW_SUBSET=24c,4t</td>
</tr>
</tbody>
</table>

NOTE

Take care when using the `OMP_NUM_THREADS` variable along with this variable. Using the `OMP_NUM_THREADS` variable can result in over or under subscription.
Controlling Thread Bindings

The `KMP_AFFINITY` variable controls how the OpenMP* threads are bound to the hardware resources allocated by the `KMP_HW_SUBSET` variable. While this variable can be set to several binding or affinity types, the following are the recommended affinity types to use to run your OpenMP* threads on the processor:

- **compact**: sequentially distribute the threads among the cores that share the same cache.
- **scatter**: distribute the threads among the cores without regard to the cache.

The following table shows how the threads are bound to the cores when you want to use three threads per core on two cores by specifying `KMP_HW_SUBSET=2c,3t`:

<table>
<thead>
<tr>
<th>Affinity</th>
<th>OpenMP* Threads on Core 0</th>
<th>OpenMP* Threads on Core 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_AFFINITY=compact</td>
<td>0, 1, 2</td>
<td>3, 4, 5</td>
</tr>
<tr>
<td>KMP_AFFINITY=scatter</td>
<td>0, 2, 4</td>
<td>1, 3, 5</td>
</tr>
</tbody>
</table>

Determining the Best Setting

To determine the best thread distribution and bindings using these variables, use the following:

1. Ensure that your OpenMP* code is working properly before using these environment variables.
2. Establish a baseline with your current OpenMP* code to compare to the performance when you allocate the threads to a processor.
3. Measure the performance of distributing one, two, three, or four threads per core by use the `KMP_HW_SUBSET` variable.
4. Measure the performance of binding the threads to the cores by using the `KMP_AFFINITY` variable.

Supported Environment Variables

OpenMP* Pragmas Summary

This is a summary of the OpenMP* pragmas supported in the Intel® C++ Compiler. For detailed information about the OpenMP* API, see the *OpenMP Application Program Interface* Version TR4: Version 5.0 specification, which is available from the OpenMP* web site.

**PARALLEL Pragma**

Use this pragma to form a team of threads and execute those threads in parallel.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp parallel</td>
<td>Specifies that a structured block should be run in parallel by a team of threads.</td>
</tr>
</tbody>
</table>

**TASKING Pragma**

Use this pragma for deferring execution.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp task</td>
<td>Specifies the beginning of a code block whose execution may be deferred.</td>
</tr>
</tbody>
</table>
Pragma | Description
--- | ---
omp taskloop | Specifies that the iterations of one or more associated for loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.

**WORKSHARING Pragmas**

Use these pragmas to share work among a team of threads.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp for</td>
<td>Specifies a parallel loop. Each iteration of the loop is executed by one of the threads in the team.</td>
</tr>
<tr>
<td>omp sections</td>
<td>Defines a region of structured blocks that will be distributed among the threads in a team.</td>
</tr>
<tr>
<td>omp single</td>
<td>Specifies that a block of code is to be executed by only one thread in the team at a time.</td>
</tr>
</tbody>
</table>

**SYNCHRONIZATION Pragmas**

Use these pragmas to synchronize between threads.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp atomic</td>
<td>Specifies a computation that must be executed atomically.</td>
</tr>
<tr>
<td>omp barrier</td>
<td>Specifies a point in the code where each thread must wait until all threads in the team arrive.</td>
</tr>
<tr>
<td>omp critical</td>
<td>Specifies a code block that is restricted to access by only one thread at a time.</td>
</tr>
<tr>
<td>omp flush</td>
<td>Identifies a point at which the view of the memory by the thread becomes consistent with the memory.</td>
</tr>
<tr>
<td>omp master</td>
<td>Specifies the beginning of a code block that must be executed only once by the master thread of the team.</td>
</tr>
<tr>
<td>omp ordered</td>
<td>Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.</td>
</tr>
<tr>
<td>omp taskgroup</td>
<td>Causes the program to wait until the completion of all enclosed and descendant tasks.</td>
</tr>
<tr>
<td>omp taskwait</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>omp taskyield</td>
<td>Specifies that the current task can be suspended at this point in favor of execution of a different task.</td>
</tr>
</tbody>
</table>

**Data Environment Pragma**

Use this pragma to give threads global private data.
Pragma | Description
---|---
omp threadprivate | Specifies a list of globally-visible variables that will be allocated private to each thread.

**Offload Target Control Pragmas**

Use these pragmas to control execution on one or more offload targets.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp declare target</td>
<td>Specifies functions and variables that are created or mapped to a device. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp distribute</td>
<td>Specifies that the iterations of one or more loops should be distributed among the master threads of all thread teams in a league.</td>
</tr>
<tr>
<td>omp target</td>
<td>Creates a device data environment and executes the construct on that device. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>omp target data</td>
<td>Specifies that variables are mapped to a device data environment for the extent of the region. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>omp target enter data</td>
<td>Specifies that variables are mapped to a device data environment. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>omp target exit data</td>
<td>Specifies that variables are unmapped from a device data environment. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>omp target update</td>
<td>Makes the items listed in the device data environment consistent between the device and host, in accordance with the motion clauses on the pragma. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp teams</td>
<td>Creates a league of thread teams inside a target region to execute a structured block in the master thread of each team.</td>
</tr>
</tbody>
</table>

**Vectorization Pragmas**

Use these pragmas to control execution on vector hardware.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp simd</td>
<td>Transforms the loop into a loop that will be executed concurrently using SIMD instructions. The <code>early_exit</code> clause is an Intel-specific extension of the OpenMP® specification.</td>
</tr>
<tr>
<td></td>
<td>The <code>early_exit</code> clause is an Intel-specific extension of the OpenMP® specification.</td>
</tr>
<tr>
<td></td>
<td><code>early_exit</code> Allows vectorization of multiple exit loops. When this clause is specified:</td>
</tr>
<tr>
<td></td>
<td>• Each operation before last lexical early exit of the loop may be executed as if early exit were not triggered within the SIMD chunk.</td>
</tr>
</tbody>
</table>
Pragma Description

- After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
- Each list item specified in the linear clause is computed based on the last iteration number upon exiting the loop.
- The last value for linear clauses and conditional lastprivates clauses are preserved with respect to scalar execution.
- The last value for reductions clauses are computed as if the last iteration in the last SIMD chunk was executed up on exiting the loop.
- The shared memory state may not be preserved with regard to scalar execution.
- Exceptions are not allowed.

omp declare simd

Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.

omp inclusive_scan

Specifies a boundary between definitions and uses. This pragma should be used with the scan clause and must not be used in nested loops.

Cancellation Constructs

Pragma Description

omp cancel

Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering task to proceed to the end of the cancelled construct.

omp cancellation point

Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.

User-Defined Reduction Pragma

Use this pragma to define reduction identifiers that can be used as reduction operators in a reduction clause.

Pragma Description

omp declare reduction

Declares User-Defined Reduction (UDR) functions (reduction identifiers) that can be used as reduction operators in a reduction clause.

Combined Pragmas

Use these pragmas as shortcuts for multiple pragmas in sequence. A combined construct is a shortcut for specifying one construct immediately nested inside another construct. A combined construct is semantically identical to that of explicitly specifying the first construct containing one instance of the second construct and no other statements.
A composite construct is composed of two constructs but does not have identical semantics to specifying one of the constructs immediately nested inside the other. A composite construct either adds semantics not included in the constructs from which it is composed or the nesting of the one construct inside the other is not conforming.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp distribute parallel for ^</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>omp distribute parallel for simd</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp distribute simd ^</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp for simd ^</td>
<td>Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp parallel for ^</td>
<td>Provides an abbreviated way to specify a parallel region containing a single FOR construct.</td>
</tr>
<tr>
<td>omp parallel for simd ^</td>
<td>Specifies a parallel construct that contains one for simd construct and no other statement.</td>
</tr>
<tr>
<td>omp parallel sections ^</td>
<td>Specifies a parallel construct that contains a single sections construct.</td>
</tr>
<tr>
<td>omp target parallel ^</td>
<td>Creates a device data environment and executes the parallel region on that device. This directive only applies to Intel® MIC Architecture. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp target parallel for ^</td>
<td>Provides an abbreviated way to specify a target construct that contains a n omp target parallel for construct and no other statement between them.</td>
</tr>
<tr>
<td>omp target parallel for simd ^</td>
<td>Specifies a target construct that contains a n omp target parallel for simd construct and no other statement between them.</td>
</tr>
<tr>
<td>omp target simd ^</td>
<td>Specifies a target construct that contains a n omp simd construct and no other statement between them.</td>
</tr>
<tr>
<td>omp target teams ^</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp target teams distribute ^</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a teams construct. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>

It will be executed concurrently using SIMD instructions. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp taskloop simd</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.</td>
</tr>
<tr>
<td>omp teams distribute</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a teams construct.</td>
</tr>
<tr>
<td>omp teams distribute parallel for</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>omp teams distribute parallel for simd</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp teams distribute simd</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams.</td>
</tr>
</tbody>
</table>

**Footnotes:**

1 This directive specifies a composite construct.

**OpenMP** Library Support
Intel® C++ Compiler 19.0 Developer Guide and Reference

OpenMP* Run-time Library Routines
OpenMP* provides run-time library routines to help you manage your program in parallel mode. Many of
these run-time library routines have corresponding environment variables that can be set as defaults. The
run-time library routines let you dynamically change these factors to assist in controlling your program. In all
cases, a call to a run-time library routine overrides any corresponding environment variable.
Caution
Running OpenMP runtime library routines may initialize the OpenMP runtime environment, which might
cause a situation where subsequent programmatic setting of OpenMP environment variables has no
effect. To avoid this situation, you can use the Intel extension routine kmp_set_defaults() to set
OpenMP environment variables.
The compiler supports all the OpenMP* run-time library routines. Refer to the OpenMP* API specification for
detailed information about using these routines.
Include the appropriate declarations of the routines in your source code by adding a statement similar to the
following:
Example

#include <omp.h>
The header files are provided in the ../include (Linux* and macOS*) or ..\include (Windows*) directory
of your compiler installation.
NOTE
Some of the routines interfaces have offload equivalents. The offload equivalent takes two additional
arguments to specify the target type and target number. For more information, see Calling Functions
on the CPU to Modify the Coprocessor's Execution Environment.

Execution Environment Routines
Use these routines to monitor and influence threads and the parallel environment.
Routine

Description

void omp_set_num_threads(int nthreads)

Sets the number of threads to use for
subsequent parallel regions created by
the calling thread.

void omp_set_dynamic(int dynamic_threads)

Enables or disables dynamic adjustment
of the number of threads used to
execute a parallel region. If
dynamic_threads is TRUE, dynamic
threads are enabled. If dynamic_threads
is FALSE, dynamic threads are disabled.
Dynamic threads are disabled by default.

void omp_set_nested(int nested)

Enables or disables nested parallelism. If
nested is TRUE, nested parallelism is
enabled. If nested is FALSE, nested
parallelism is disabled. Nested
parallelism is disabled by default.

</tbody>
</table>
### Routine

<table>
<thead>
<tr>
<th>Routine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int omp_target_memcpy_rect(void *dst, void *src, size_t element_size, int num_dims, const size_t *volume, const size_t *dst_offsets, const size_t *srcOffsets, const size_t *dst_dimensions, const size_t *src_dimensions, int dst_device_num, int src_device_num)</code></td>
<td><code>src_device_num</code> to <code>dst</code>, starting at offset <code>dst_offset</code> in the device data environment of the device specified by <code>dst_device_num</code>. Returns zero on success and a non-zero value on failure. Use <code>omp_get_initial_device</code> to return a the device number you can use to reference the host device and host device data environment. This routine includes a task scheduling point. The effect of this routine is unspecified when it is called from within a target region. This routine copies a rectangular subvolume of <code>src</code>, in the device data environment of the device specified by <code>src_device_num</code>, to <code>dst</code>, in the device data environment of the device specified by <code>dst_device_num</code>. Specify the volume in terms of the size of an element, the number of its dimensions, and constant arrays of length <code>num_dims</code>. The maximum number of dimensions supported is three or more. The volume array specifies the length, in number of elements, to copy in each dimension from <code>src</code> to <code>dst</code>. The <code>dst_offsets</code> and <code>src_offsets</code> parameters specify the number of elements from the origin of <code>dst</code> and <code>src</code>, in elements. The <code>dst_dimensions</code> and <code>src_dimensions</code> parameters specify the length of each dimension of <code>dst</code> and <code>src</code>. The routine returns zero if successful. If both <code>dst</code> and <code>src</code> are NULL pointers, the routine returns the number of dimensions supported by the implementation for the specified device numbers. You can use the device number returned by <code>omp_get_initial_device</code> to reference the host device and host device data environment. Otherwise, it returns a non-zero value. This routine contains a task scheduling point. The effect of this routine is unspecified when called from within a target region.</td>
</tr>
<tr>
<td><code>int omp_target_associate_ptr(void *host_ptr, void *device_ptr, size_t size, size_t device_offset, int device_num)</code></td>
<td>Maps a device pointer, which might be returned by <code>omp_target_alloc</code>, to a host pointer.</td>
</tr>
</tbody>
</table>
Lock Routines

Use these routines to affect OpenMP* locks.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void omp_init_lock(omp_lock_t svar)</td>
<td>Initializes the lock associated with the simple lock variable svar for use in subsequent calls.</td>
</tr>
<tr>
<td>void omp_init_lock_with_hint(omp_lock_t *svar, omp_lock_hint_t hint)</td>
<td>Initializes the lock associated with svar to the unlocked state, optionally choosing a specific lock implementation based on hint.</td>
</tr>
<tr>
<td>void omp_destroy_lock(omp_lock_t svar)</td>
<td>Causes the lock specified by svar to become undefined or uninitialized.</td>
</tr>
<tr>
<td>void omp_set_lock(omp_lock_t svar)</td>
<td>Forces the executing thread to wait until the lock associated with svar is available. The thread is granted ownership of the lock when it becomes available.</td>
</tr>
<tr>

Intel® Compiler Extension Routines to OpenMP*

The Intel compiler implements the following group of routines as extensions to the OpenMP* run-time library:

- Get and set the execution environment
- Get and set the stack size for parallel threads
- Memory allocation
- Get and set the thread sleep time for the throughput execution mode

The Intel extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in the other compiler. To execute these OpenMP* routines, use the [Q]openmp-stubs option.

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the OMP_STACKSIZE environment variable rather than the kmp_set_stacksize_s() library routine.

**NOTE**

A run-time call to an Intel extension routine takes precedence over the corresponding environment variable setting.

Execution Environment

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void kmp_set_defaults(char const *)</td>
<td>Sets OpenMP* environment variables defined as a list of variables separated by &quot;</td>
</tr>
<tr>
<td>void kmp_set_library_throughput()</td>
<td>Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.</td>
</tr>
</tbody>
</table>
### Function and Description

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void kmp_set_library_turnaround()</td>
<td>Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.</td>
</tr>
<tr>
<td>void kmp_set_library_serial()</td>
<td>Sets execution mode to serial.</td>
</tr>
</tbody>
</table>
| void kmp_set_library(int) | Sets execution mode indicated by the value passed to the function. Valid values are:  
• 1 - serial mode  
• 2 - turnaround mode  
• 3 - throughput mode  
Call this routine before the first parallel region is executed. |

| int kmp_get_library() | Returns a value corresponding to the current execution mode:  
• 1 - serial  
• 2 - turnaround  
• 3 - throughput |

### Stack Size

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t kmp_get_stacksize_s()</td>
<td>Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with kmp_set_stacksize_s() routine, prior to the first parallel region or via the KMP_STACKSIZE environment variable.</td>
</tr>
<tr>
<td>int kmp_get_stacksize()</td>
<td>Provided for backwards compatibility only. Use kmp_get_stacksize_s() routine for compatibility across different families of Intel processors.</td>
</tr>
<tr>
<td>void kmp_set_stacksize_s(size_t size)</td>
<td>Sets to size the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can also be set via the KMP_STACKSIZE environment variable. In order for kmp_set_stacksize_s() to have an effect, it must be called before the beginning of the first (dynamically executed) parallel region in the program.</td>
</tr>
<tr>
<td>void kmp_set_stacksize(int size)</td>
<td>Provided for backward compatibility only. Use kmp_set_stacksize_s() for compatibility across different families of Intel® processors.</td>
</tr>
</tbody>
</table>

### Memory Allocation

The Intel compiler implements a group of memory allocation routines as an extension to the OpenMP* run-time library to enable threads to allocate memory from a heap local to each thread. These routines are: kmp_malloc(), kmp_calloc(), and kmp realloc().
The memory allocated by these routines must also be freed by the `kmp_free()` routine. While you can allocate memory in one thread and then free that memory in a different thread, this mode of operation incurs a slight performance penalty.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void* kmp_malloc(size_t size)</code></td>
<td>Allocate memory block of <code>size</code> bytes from thread-local heap.</td>
</tr>
<tr>
<td><code>void* kmp_calloc(size_t nelem, size_t elsize)</code></td>
<td>Allocate array of <code>nelem</code> elements of size <code>elsize</code> from thread-local heap.</td>
</tr>
<tr>
<td><code>void* kmp_realloc(void* ptr, size_t size)</code></td>
<td>Reallocate memory block at address <code>ptr</code> and <code>size</code> bytes from thread-local heap.</td>
</tr>
<tr>
<td><code>void* kmp_free(void* ptr)</code></td>
<td>Free memory block at address <code>ptr</code> from thread-local heap. Memory must have been previously allocated with <code>kmp_malloc()</code>, <code>kmp_calloc()</code>, or <code>kmp_realloc()</code>.</td>
</tr>
</tbody>
</table>

### Thread Sleep Time

In the throughput OpenMP* Support Libraries, threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the `KMP_BLOCKTIME` environment variable or by the `kmp_set_blocktime()` function.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int kmp_get_blocktime(void)</code></td>
<td>Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the <code>KMP_BLOCKTIME</code> environment variable or by <code>kmp_set_blocktime()</code>.</td>
</tr>
<tr>
<td><code>void kmp_set_blocktime(int msec)</code></td>
<td>Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP* team threads formed by the calling thread. The routine does not affect the block time for any other threads.</td>
</tr>
</tbody>
</table>

OpenMP* Run-time Library Routines

OpenMP* Support Libraries

### OpenMP* Support Libraries

The Intel® Compiler provides support libraries for OpenMP*. There are several kinds of libraries:

- **Performance**: supports parallel OpenMP* execution.
- **Stubs**: supports serial execution of OpenMP* applications.

Each kind of library is available for both dynamic and static linking on Linux* and macOS* operating systems. Only dynamic linking is supported on Windows* operating systems.
Performance Libraries

To use these libraries, specify the \texttt{[Q]openmp} compiler option.

Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Dynamic Link</th>
<th>Static Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>libiomp5.so</td>
<td>libiomp5.a</td>
</tr>
<tr>
<td>macOS*</td>
<td>libiomp5.dylib</td>
<td>libiomp5.a</td>
</tr>
<tr>
<td>Windows*</td>
<td>libiomp5md.lib</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>libiomp5md.dll</td>
<td></td>
</tr>
</tbody>
</table>

Many routines in the OpenMP* support libraries are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Stubs Libraries

To use these libraries, specify \texttt{[Q]openmp-stubs} compiler option. These allow you to compile OpenMP* applications in serial mode and provide stubs for OpenMP* routines and extended Intel-specific routines.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Dynamic Link</th>
<th>Static Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>libiompstubs5.so</td>
<td>libiompstubs5.a</td>
</tr>
<tr>
<td>macOS*</td>
<td>libiompstubs5.dylib</td>
<td>libiompstubs5.a</td>
</tr>
<tr>
<td>Windows*</td>
<td>libiompstubs5md.lib</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>libiompstubs5md.dll</td>
<td></td>
</tr>
</tbody>
</table>

Execution modes

The Intel® Compiler enables you to run an application under different execution modes specified at run time; the libraries support the turnaround, throughput, and serial modes. Use the \texttt{KMP_LIBRARY} environment variable to select the modes at run time.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>throughput</td>
<td>The throughput mode allows the program to yield to other running programs and adjust resource usage to produce efficient execution in a dynamic environment. In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work. After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, the threads wait for more parallel work to become available.</td>
</tr>
<tr>
<td>Mode</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications.</td>
</tr>
<tr>
<td></td>
<td>The amount of time to wait before sleeping is set either by the KMP_BLOCKTIME environment variable or by the kmp_set_blocktime() function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP* execution, but may penalize other concurrently-running OpenMP* or threaded applications.</td>
</tr>
<tr>
<td></td>
<td>The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads (although they are still subject to KMP_BLOCKTIME control). In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong> Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at run time. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.</td>
</tr>
<tr>
<td></td>
<td>The serial mode forces parallel applications to run as a single thread.</td>
</tr>
</tbody>
</table>

openmp-stubs, Qopenmp-stubs compiler option

**Using the OpenMP* Libraries**
This section describes the steps needed to set up and use the OpenMP* Libraries from the command line. On Windows* systems, you can also build applications compiled with the OpenMP libraries in the Microsoft Visual Studio* development environment.
For a summary of the support provided by the libraries provided with Intel compilers, see OpenMP* Source Compatibility and Interoperability with Other Compilers.
For a list of the options and libraries used by the OpenMP* libraries, see OpenMP* Support Libraries.
Set up your environment for access to the Intel® C++ Compiler to ensure that the appropriate OpenMP* library is available during linking. On Windows* systems, you can either execute the appropriate batch (.bat) file or use the command-line window supplied in the compiler program folder that already has the environment set up. On Linux* and macOS* systems, you can source the appropriate script file (compilervars file).
During compilation, ensure that the version of omp.h used when compiling is the version provided by that compiler. For example, use the omp.h provided with gcc when you compile on Linux* systems.
Caution
Be aware that when using the gcc* or Microsoft* compiler, you may inadvertently use inappropriate
header/module files. To avoid this, copy the header/module file(s) to a separate directory and put it in
the appropriate include path using the -I option.

If a program uses data structures or classes that contain members with data types defined in omp.h file,
then source files that use those data structures should all be compiled with the same omp.h file.

The following table lists the commands used by the various command-line compilers for both C and C++
source files:.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>C Source Module</th>
<th>C++ Source Module</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>gcc</td>
<td>g++</td>
</tr>
<tr>
<td></td>
<td>Intel: icc</td>
<td>Intel: icpc</td>
</tr>
<tr>
<td>macOS* [prior to</td>
<td>gcc</td>
<td>g++</td>
</tr>
<tr>
<td>v10.9]</td>
<td>Intel: icc</td>
<td>Intel: icpc</td>
</tr>
<tr>
<td>macOS* [v10.9 and</td>
<td>clang</td>
<td>clang++</td>
</tr>
<tr>
<td>later]</td>
<td>Intel: icc</td>
<td>Intel: or icpc</td>
</tr>
<tr>
<td>Windows*</td>
<td>Visual C++*: cl</td>
<td>Visual C++*: cl</td>
</tr>
<tr>
<td></td>
<td>Intel: icl</td>
<td>Intel: icl</td>
</tr>
</tbody>
</table>

For information on the OpenMP* libraries and options used by the Intel® C++ Compiler, see OpenMP*
Support Libraries.

Command-Line Examples, Windows*
To compile and link (build) the entire application with one command using the Compatibility libraries, specify
the following Intel® C++ Compiler command:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source, dynamic link</td>
<td>icl /MD /Qopenmp hello.c</td>
</tr>
<tr>
<td>C++ source, dynamic link</td>
<td>icl /MD /Qopenmp hello.cpp</td>
</tr>
</tbody>
</table>

When using the Microsoft* Visual C++* compiler, you should link with the Intel OpenMP compatibility library.
You need to avoid linking the Microsoft* OpenMP run-time library (vcomp) and explicitly pass the name of the
Intel OpenMP compatibility library as linker options (following /link):

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source, dynamic link</td>
<td>cl /MD /openmp hello.c /link /nodefaultlib:vcomp \ libiomp5md.lib</td>
</tr>
<tr>
<td>C++ source, dynamic link</td>
<td>cl /MD /openmp hello.cpp /link /nodefaultlib:vcomp \ libiomp5md.lib</td>
</tr>
</tbody>
</table>

You can also use the Intel® C++ Compiler with the Visual C++* compiler to compile parts of the application
and create object files (object-level interoperability). In this example, the Intel® C++ Compiler compiles and
links the entire application:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source, dynamic link</td>
<td>cl /MD /openmp /c f1.c f2.c</td>
</tr>
</tbody>
</table>
The first command produces two object files compiled by Visual C++* compiler, and the second command produces two more object files compiled by the Intel® C++ Compiler. The final command links all four object files into an application.

Alternatively, the third line below uses the Visual C++* linker to link the application and specifies the Compatibility library `libiomp5md.lib` at the end of the third command:

### Using Intel OpenMP* Libraries from Visual Studio*

When using systems running Windows*, you can make certain changes in the Visual C++* Visual Studio* development environment to allow you to use the Intel® C++ Compiler and Visual C++* to create applications that use the Intel OpenMP libraries.

**NOTE**

Microsoft® Visual C++* must have the symbol `_OPENMP_NOFORCE_MANIFEST` defined or it will include the manifest for the `vcomp90` dlls. While this may not appear to cause a problem on the build system, it will cause a problem when the application is moved to another system that does not have this DLL installed.

Set the project **Property Pages** to indicate the Intel OpenMP run-time library location:

1. Open the project's property pages in from the main menu: **Project > Properties** (or right click the Project name and select **Properties**).
2. Select **Configuration Properties > Linker > General > Additional Library Directories**.
3. Enter the path to the Intel® Compiler libraries. For example, for an IA-32 architecture system, enter:

```<Intel_compiler_installation_path>\IA32\LIB```

Make the Intel OpenMP dynamic run-time library accessible at run-time; you must specify the corresponding path:

1. Open the project's property pages in from the main menu: **Project > Properties** (or right click the Project name and select **Properties**).
2. Select **Configuration Properties > Debugging > Environment**.
3. Enter the path to the Intel® Compiler libraries. For example, for an IA-32 architecture system, enter:

```PATH=%PATH%;<Intel_compiler_installation_path>\IA32\Bin```

Add the Intel OpenMP run-time library name to the linker options and exclude the default Microsoft* OpenMP run-time library:

1. Open the project's property pages in from the main menu: **Project > Properties** (or right click the Project name and select **Properties**).
2. Select **Configuration Properties > Linker > Command Line > Additional Options**.
3. Enter the OpenMP* library name and the Visual C++* linker option, `/nodefaultlib`.

**Command-Line Examples, Linux**

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® C++ Compiler command on Linux* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td>icc -qopenmp hello.c</td>
</tr>
<tr>
<td>C++ source</td>
<td>icpc -qopenmp hello.cpp</td>
</tr>
</tbody>
</table>

By default, the Intel® C++ Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The Intel® C++ Compiler option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and macOS* systems (default is `-qopenmp-link=dynamic`).

You can also use the Intel® C++ Compiler icc/icpc with gcc/g++ compilers to compile parts of the application and create object files (object-level interoperability).

In this example, gcc compiles the C file foo.c (the gcc option `-fopenmp` enables OpenMP* support), and the Intel® C++ Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td>gcc -fopenmp -c foo.c</td>
</tr>
<tr>
<td>C++ source</td>
<td>g++ -fopenmp -c foo.cpp</td>
</tr>
</tbody>
</table>

When using gcc or g++ compiler to link the application with the Intel® C++ Compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP library name using the `-l` option, the Linux* pthread library using the `-l` option, and path to the Intel® libraries where the Intel® C++ compiler is installed using the `-L` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td>gcc -fopenmp -c foo.c bar.c</td>
</tr>
<tr>
<td></td>
<td>gcc foo.o bar.o -liomp5 -lpthread -L&lt;icc_dir&gt;/lib</td>
</tr>
</tbody>
</table>
You can mix object files, but it is easier to use the Intel® C++ Compiler to link the application so you do not need to specify the `gcc-l` option, `-L` option, and the `-lpthread` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -qopenmp -c bar.c (Linux* and macOS*)</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -qopenmp foo.o bar.o (Linux* and macOS*)</code></td>
</tr>
</tbody>
</table>

You can mix OpenMP* object files compiled with gcc, the Intel® C++ Compiler, and the Intel® Fortran Compiler.

**NOTE**
You cannot mix object files compiled by the Intel® Fortran compiler and the gfortran compiler.

The table illustrates examples of using the Intel® Fortran compiler to link all the objects:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td><code>icc -qopenmp -c ibar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>gcc -fopenmp -c gbar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -qopenmp -c foo.f</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -qopenmp foo.o ibar.o gbar.o</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and GNU Fortran sources</td>
<td><code>icc -qopenmp -c ibar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>gcc -fopenmp -c gbar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>gfortran -fopenmp -c foo.f</code></td>
</tr>
<tr>
<td></td>
<td><code>gfortran foo.o ibar.o gbar.o -lirc -lomp5 -lpthread -lc -L&lt;icc_dir&gt;/lib</code></td>
</tr>
</tbody>
</table>

Alternatively, you could use the Intel® C++ Compiler to link the application, but need to pass multiple gfortran libraries using the `-l` options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td><code>gfortran -fopenmp -c foo.f</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -qopenmp -c ibar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -qopenmp foo.o ibar.o -lgfortranbegin -lgfortran</code></td>
</tr>
</tbody>
</table>

**Command-Line Examples, macOS***

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® C++ Compiler command on macOS* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>icc -qopenmp hello.c</code></td>
</tr>
</tbody>
</table>
By default, the Intel® C++ Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The Intel® C++ Compiler option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and macOS* systems (default is `-qopenmp-link=dynamic`).

You can also use the Intel® C++ Compiler icc/icpc/icl with gcc/g++ compilers to compile parts of the application and create object files (object-level interoperability).

**NOTE**
Mixed compiling using Intel® C++ Compiler with GCC compilers is possible only on older macOS* platforms. The latest macOS* v10.x platforms do not include the GCC compiler, and the Clang compiler included in the latest macOS* 10.x does not support OpenMP* implementation. Future versions of Clang compiler may support OpenMP* implementation.

In this example, icl or icc compiles the C file foo.c, icpc compiles the file ifoo.cpp, the option Qopenmp (Windows*) or qopenmp (Linux* or macOS*) enables OpenMP* support, and the Intel® C++ Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td>icc -qopenmp -c foo.c</td>
</tr>
<tr>
<td>C++ source</td>
<td>icpc -qopenmp -c ifoo.cpp</td>
</tr>
</tbody>
</table>

**NOTE**
GCC is absent on macOS* v10.9 and later (that is, Xcode 5.x and later). However, you may install GCC along with the Intel® C++ Compiler.

You can mix object files, but it is easier to use the Intel compiler to link the application so you do not need to specify the gcc-l option, -L option, and the -lpthread option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td>icc -qopenmp -c bar.c</td>
</tr>
<tr>
<td></td>
<td>icc -qopenmp foo.o bar.o</td>
</tr>
</tbody>
</table>

Alternatively, you could use the Intel® C++ Compiler to link the application, but need to pass multiple gfortran libraries using the -l options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td>icc -qopenmp -c ibar.c</td>
</tr>
<tr>
<td></td>
<td>icc -qopenmp foo.o bar.o -lgfortranbegin -lgfortran</td>
</tr>
</tbody>
</table>

Thread Affinity Interface (Linux* and Windows*)

The Intel® runtime library has the ability to bind OpenMP* threads to physical processing units. The interface is controlled using the KMP_AFFINITY environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

Thread affinity restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows* systems and versions of Linux* systems that have kernel support for thread affinity, but is not supported by macOS*.

The Intel OpenMP runtime library has the ability to bind OpenMP* threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP* threads to the processors based upon their physical location in the machine. This interface is controlled entirely by the KMP_AFFINITY environment variable.
- The mid-level affinity interface uses an environment variable to explicitly specifies which processors (labeled with integer IDs) are bound to OpenMP* threads. This interface provides compatibility with the gcc* GOMP_AFFINITY environment variable, but you can also invoke it by using the KMP_AFFINITY environment variable. The GOMP_AFFINITY environment variable is supported on Linux* systems only, but users on Windows* or Linux* systems can use the similar functionality provided by the KMP_AFFINITY environment variable.
- The low-level affinity interface uses APIs to enable OpenMP* threads to make calls into the OpenMP* runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to sched_setaffinity and related functions on Linux* systems or to SetThreadAffinityMask and related functions on Windows* systems. In addition, you can specify certain options of the KMP_AFFINITY environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type KMP_AFFINITY to disabled, which disables the low-level affinity interface, or you could use the KMP_AFFINITY or GOMP_AFFINITY environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section:

- The total number of processing elements on the machine is referred to as the number of OS thread contexts.
- Each processing element is referred to as an Operating System processor, or OS proc.
- Each OS processor has a unique integer identifier associated with it, called an OS proc ID.
- The term package refers to a single or multi-core processor chip.
- The term OpenMP* Global Thread ID (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then n-threads-var - 1 new threads are created with GTIDs ranging from 1 to nthreads-var - 1, and each thread's GTID is equal to the OpenMP* thread number returned by function omp_get_thread_num(). The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID, and can be used by programs containing arbitrarily many levels of parallelism.

Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.
The **KMP_AFFINITY** Environment Variable

**NOTE**
You must set the **KMP_AFFINITY** environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

The **KMP_AFFINITY** environment variable uses the following general syntax:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_AFFINITY=[&lt;modifier&gt;,...]&lt;type&gt;[,&lt;permute&gt;][,&lt;offset&gt;]</td>
</tr>
</tbody>
</table>

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a modifier of verbose and a type of none.

The following table describes the supported specific arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>modifier</td>
<td>noverbose, respect, granularity=core</td>
<td>Optional. String consisting of keyword and specifier.</td>
</tr>
<tr>
<td>type</td>
<td>none</td>
<td>Required string. Indicates the thread affinity to use.</td>
</tr>
</tbody>
</table>

The syntax for `<proc-list>` is explained in mid-level affinity interface.

**NOTE**
On Windows* with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows*). Otherwise, the respect affinity modifier is used.

Required string. Indicates the thread affinity to use.

- balanced
- compact
- disabled
Affinity Types

Type is the only required argument.

**type = none (default)**

Does not bind OpenMP* threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP* thread affinity interface to determine machine topology. Specify KMP_AFFINITY=verbose,none to list a machine topology map.

**type = balanced**

Places threads on separate cores until all cores have at least one thread, similar to the scatter type. However, when the runtime must use multiple hardware thread contexts on the same core, the balanced type ensures that the OpenMP* thread numbers are close to each other, which scatter does not do. This affinity type is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.

**NOTE**

The OpenMP* environment variable OMP_PROC_BIND=spread is similar to KMP_AFFINITY=balanced and is available on all platforms, including multi-socket CPU systems.

**type = compact**

Specifying compact assigns the OpenMP* thread \(<n>\)+1 to a free thread context as close as possible to the thread context where the \(<n>\) OpenMP* thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

**type = disabled**
Specifying disabled completely disables the thread affinity interfaces. This forces the OpenMP* run-time library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as kmp_set_affinity and kmp_get_affinity, which have no effect and will return a nonzero error code.

**type = explicit**

Specifying explicit assigns OpenMP* threads to a list of OS proc IDs that have been explicitly specified by using the proclist= modifier, which is required for this affinity type. See Explicitly Specifying OS Proc IDs (GOMP_CPU_AFFINITY).

**type = scatter**

Specifying scatter distributes the threads as evenly as possible across the entire system. scatter is the opposite of compact; so the leaves of the node are most significant when sorting through the machine topology map.

**Deprecated Types: logical and physical**

Types logical and physical are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

For logical and physical affinity types, a single trailing integer is interpreted as an offset specifier instead of a permute specifier. In contrast, with compact and scatter types, a single trailing integer is interpreted as a permute specifier.

- Specifying logical assigns OpenMP* threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to compact, except that the permute specifier is not allowed. Thus, KMP_AFFINITY=logical,n is equivalent to KMP_AFFINITY=compact,0,n (this equivalence is true regardless of the whether or not a granularity=fine modifier is present).

- Specifying physical assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to logical. For systems where multiple thread contexts exist per core, physical is equivalent to compact with a permute specifier of 1; that is, KMP_AFFINITY=physical,n is equivalent to KMP_AFFINITY=compact,1,n (regardless of the whether or not a granularity=fine modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the permute specifier.

**Examples of Types compact and scatter**

The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Intel® Hyper-Threading Technology (Intel® HT Technology) enabled.

The following figure also illustrates the binding of OpenMP* thread to hardware thread contexts when specifying KMP_AFFINITY=granularity=fine,compact.
Specifying scatter on the same system as shown in the figure above, the OpenMP* threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying KMP_AFFINITY=granularity=fine,scatter.

```
permute and offset combinations
For both compact and scatter, permute and offset are allowed; however, if you specify only one integer, the compiler interprets the value as a permute specifier. Both permute and offset default to 0.

The permute specifier controls which levels are most significant when sorting the machine topology map. A value for permute forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The offset specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying KMP_AFFINITY=granularity=fine,compact,0,3.
Consider the hardware configuration from the previous example, running an OpenMP* application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP* threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using `KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.

The OpenMP* thread $n+1$ is bound to a thread context as close as possible to OpenMP* thread $n$, but on a different core. Once each core has been assigned one OpenMP* thread, the subsequent OpenMP* threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.
Modifier Values for Affinity Types

Modifiers are optional arguments that precede type. If you do not specify a modifier, the `noverbose`, `respect`, and `granularity=core` modifiers are used automatically.

Modifiers are interpreted in order from left to right, and can negate each other. For example, specifying `KMP_AFFINITY=verbose,noverbose,scatter` is therefore equivalent to setting `KMP_AFFINITY=noverbose,scatter`, or just `KMP_AFFINITY=scatter`.

**modifier = noverbose** (default)

Does not print verbose messages.

**modifier = verbose**

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP* thread bindings to physical thread contexts.

Information about binding OpenMP* threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP* thread is printed as a set of OS processor IDs.

For example, specifying `KMP_AFFINITY=verbose,scatter` on a dual core system with two processors, with Intel® Hyper-Threading Technology (Intel® HT Technology) disabled, results in a message listing similar to the following when then program is executed:

**Verbose, scatter message**

```
...
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{0,1,2,3}
KMP_AFFINITY: 4 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0]
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0]
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {1}
```

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

<table>
<thead>
<tr>
<th>Message String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;affinity capable&quot;</td>
<td>Indicates that all components (compiler, operating system, and hardware)</td>
</tr>
<tr>
<td>&quot;using global cpuid info&quot;</td>
<td>support affinity, so thread binding is possible.</td>
</tr>
<tr>
<td>&quot;using local cpuid info&quot;</td>
<td>Indicates that the machine topology was discovered by binding a thread to each operating system processor and decoding the output of the cpuid instruction.</td>
</tr>
<tr>
<td></td>
<td>Indicates that compiler is decoding the output of the cpuid instruction, issued by only the initial thread, and is assuming a machine topology using the number of operating system processors.</td>
</tr>
</tbody>
</table>
Message String | Description
--- | ---
"using /proc/cpuinfo" | Linux* only. Indicates that cpuinfo is being used to determine machine topology.
"using flat" | Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.
"uniform topology of" | The machine topology map is a full tree with no missing leaves at any level.

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP* thread context ID is printed next unless the affinity type is none. The thread level is contained in brackets (in the listing shown above). This implies that there is no representation of the thread context level in the machine topology map. For more information, see Determining Machine Topology.

**modifier = granularity**

Binding OpenMP* threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled; however, it is usually not beneficial to bind each OpenMP* thread to a particular thread context on a specific core. Granularity describes the lowest levels that OpenMP* threads are allowed to float within a topology map.

This modifier supports the following additional specifiers.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>core</td>
<td>Default. Allows all the OpenMP* threads bound to a core to float between the different thread contexts.</td>
</tr>
<tr>
<td>fine or thread</td>
<td>The finest granularity level. Causes each OpenMP* thread to be bound to a single thread context. The two specifiers are functionally equivalent.</td>
</tr>
<tr>
<td>tile</td>
<td>Allows all the OpenMP* threads bound to a tile to float between the different thread contexts of cores the tile consists of.</td>
</tr>
</tbody>
</table>

Specifying KMP_AFFINITY=verbose,granularity=core,compact on the same dual core system with two processors as in the previous section, but with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, results in a message listing similar to the following when the program is executed:

**Verbose, granularity=core,compact message**

KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{0,1,2,3,4,5,6,7}
KMP_AFFINITY: 8 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0,4}
The affinity mask for each OpenMP* thread is shown in the listing (above) as the set of operating system processor to which the OpenMP* thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP* thread bindings.

In contrast, specifying `KMP_AFFINITY=verbose,granularity=fine,compact` or `KMP_AFFINITY=verbose,granularity=thread,compact` binds each OpenMP* thread to a single hardware thread context when the program is executed:
The OpenMP* to hardware context binding for this example was illustrated in the first example.

Specifying `granularity=fine` will always cause each OpenMP* thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

**modifier = respect (default)**

Respect the process' original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP* run-time library. The behavior differs between Linux* and Windows*:

- On Windows*: Respect original affinity mask for the process.
- On Linux*: Respect the affinity mask for the thread that initializes the OpenMP* run-time library.

Specifying `KMP_AFFINITY=verbose,compact` for the same system used in the previous example, with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, and invoking the library with an initial affinity mask of `{4,5,6,7}` (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with Intel® HT Technology disabled.

Because there are eight thread contexts on the machine, by default the compiler created eight threads for an OpenMP* parallel construct.

The brackets around thread 1 indicate that the thread context level is ignored, and is not present in the topology map. The following figure illustrates the corresponding machine topology map.
When using the local `cpuid` information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Intel® Hyper-Threading Technology (Intel® HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.

modifier = norespect

Do not respect original affinity mask for the process. Binds OpenMP* threads to all operating system processors.

In early versions of the OpenMP* run-time library that supported only the physical and logical affinity types, norespect was the default and was not recognized as a modifier.

The default was changed to respect when types compact and scatter were added; therefore, thread bindings for the logical and physical affinity types may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

modifier = nowarnings

Do not print warning messages from the affinity interface.

modifier = warnings (default)

Print warning messages from the affinity interface (default).

Determining Machine Topology

On IA-32 and Intel® 64 architecture systems, if the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the `cpuid` instruction to obtain the package id, core id, and thread context id. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the `cpuid` instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the package ID, core ID, and thread context ID.

There are two ways to specify the APIC ID in the `cpuid` instruction - the legacy method in leaf 4, and the more modern method in leaf 11. Only 256 unique APIC IDs are available in leaf 4. Leaf 11 has no such limitation.

Normally, all core ids on a package and all thread context ids on a core are contiguous; however, numbering assignment gaps are common for package ids, as shown in the figure above.
If the compiler cannot determine the machine topology using any other method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be flat. For example, a flat topology assumes the operating system process $N$ maps to package $N$, and there exists only one thread context per core and only one core for each package.

If the machine topology cannot be accurately determined as described above, the user can manually copy `/proc/cpuinfo` to a temporary file, correct any errors, and specify the machine topology to the OpenMP* runtime library via the environment variable KMP_CPUINFO_FILE=<temp_filename>, as described in the section KMP_CPUINFO_FILE and `/proc/cpuinfo`.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.

**KMP_CPUINFO_FILE and `/proc/cpuinfo**

One of the methods the Intel® C++ Compiler OpenMP runtime library can use to detect the machine topology on Linux* systems is to parse the contents of `/proc/cpuinfo`. If the contents of this file (or a device mapped into the Linux* file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file `<temp_file>`, correct it or extend it with the necessary information, and set KMP_CPUINFO_FILE=`<temp_file>`.

If you do this, the OpenMP* runtime library will read the `<temp_file>` location pointed to by KMP_CPUINFO_FILE instead of the information contained in `/proc/cpuinfo` or attempting to detect the machine topology by decoding the APIC IDs. That is, the information contained in the `<temp_file>` overrides these other methods. You can use the KMP_CPUINFO_FILE interface on Windows* systems, where `/proc/cpuinfo` does not exist.

The content of `/proc/cpuinfo` or `<temp_file>` should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in `<temp_file>` or `/proc/cpuinfo`:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processor</td>
<td>Specifies the OS ID for the processing element. The OS ID must be unique. The processor and physical id fields are the only ones that are required to use the interface.</td>
</tr>
<tr>
<td>physical id</td>
<td>Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the Intel compiler OpenMP run-time library's model of the machine topology.</td>
</tr>
<tr>
<td>core id</td>
<td>Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core level will not exist in the machine topology map (even if some of the core ID fields are non-zero).</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
thread id : | Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).
node_n id : | This is an extension to the normal contents of /proc/cpuinfo that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels $n$ are supported. The node_0 level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on.

Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.

**NOTE**
It is common for the thread id field to be missing from /proc/cpuinfo on many Linux* variants, and for a field labeled siblings to specify the number of threads per node or number of nodes per package. However, the Intel OpenMP runtime library ignores fields labeled siblings so it can distinguish between the thread id and siblings fields. When this situation arises, the warning message Physical node/pkg/core/thread ids not unique appears (unless the type specified is nowarnings).

**Windows* Processor Groups**

On a 64-bit Windows* operating system, it is possible for multiple processor groups to accommodate more than 64 processors. Each group is limited in size, up to a maximum value of sixty-four (64) processors.

If multiple processor groups are detected, the default is to model the machine as a 2-level tree, where level 0 are for the processors in a group, and level 1 are for the different groups. Threads are assigned to a group until there are as many OpenMP* threads bound to the groups as there are processors in the group. Subsequent threads are assigned to the next group, and so on.

By default, threads are allowed to float among all processors in a group, that is to say, granularity equals the group [granularity=group]. You can override this binding and explicitly use another affinity type like compact, scatter, and so on. If you do so, the granularity must be sufficiently fine to prevent a thread from being bound to multiple processors in different groups.

**Using a Specific Machine Topology Modeling Method (KMP_TOPOLOGY_METHOD)**

You can set the KMP_TOPOLOGY_METHOD environment variable to force OpenMP* to use a particular machine topology modeling method.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpuid_leaf11</td>
<td>Decodes the APIC identifiers as specified by leaf 11 of the cpuid instruction.</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
cpuid_leaf4 | Decodes the APIC identifiers as specified in leaf 4 of the cpuid instruction.
cpuinfo | If KMP_CPUINFO_FILE is not specified, forces OpenMP* to parse /proc/cpuinfo to determine the topology (Linux* only).
If KMP_CPUINFO_FILE is specified as described above, uses it (Windows* or Linux*).
group | Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows* 64-bit only).
flat | Models the machine as a flat (linear) list of processors.
hwloc | Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows* processor groups.

Explicitly Specifying OS Processor IDs (GOMP_CPU_AFFINITY)

NOTE
You must set the GOMP_CPU_AFFINITY environment variable before the first parallel region, or certain API calls including omp_get_max_threads(), omp_get_num_procs() and any affinity API calls, as described in Low Level Affinity API, below.

Instead of allowing the library to detect the hardware topology and automatically assign OpenMP* threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

This list may either be specified by using the proclist modifier along with the explicit affinity type in the KMP_AFFINITY environment variable, or by using the GOMP_AFFINITY environment variable (for compatibility with gcc) when using the OpenMP* Source Compatibility and Interoperability with Other Compilers.

On Linux* systems, when using the Intel OpenMP compatibility libraries enabled by the compiler option -qopenmp-lib compat, you can use the GOMP_AFFINITY environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by libgomp (assume that <proc_list> produces the entire GOMP_AFFINITY environment string):

Value | Description
--- | ---
<proc_list> := | <entry> | <elem> | <list> | <elem> | whitespace | <list>
<elem> := | <proc_spec> | <range>
<proc_spec> := | <proc_id>
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;range&gt; :=</td>
<td>&lt;proc_id&gt; - &lt;proc_id&gt;</td>
</tr>
<tr>
<td>&lt;proc_id&gt; :=</td>
<td>&lt;positive_int&gt;</td>
</tr>
</tbody>
</table>

OS processors specified in this list are then assigned to OpenMP* threads, in order of OpenMP* Global Thread IDs. If more OpenMP* threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP* Global Thread ID \( n \) is bound to list element \( n \mod <list\_size> \).

Consider the machine previously mentioned: a dual core, dual-package machine without Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates six OpenMP* threads instead of 4 (the default), oversubscribing the machine. If GOMP_AFFINITY=3,0-2, then OpenMP* threads are bound as shown in the figure below, just as should happen when compiling with gcc and linking with libgomp:

![Diagram](image)

The same syntax can be used to specify the OS proc ID list in the proclist=[<proc_list>] modifier in the KMP_AFFINITY environment variable string. There is a slight difference: in order to have strictly the same semantics as in the gcc OpenMP* runtime library libgomp: the GOMP_AFFINITY environment variable implies granularity=fine. If you specify the OS proc list in the KMP_AFFINITY environment variable without a granularity= specifier, then the default granularity is not changed. That is, OpenMP* threads are allowed to float between the different thread contexts on a single core. Thus GOMP_AFFINITY=<proc_list> is an alias for KMP_AFFINITY="granularity=fine,proclist=[<proc_list>],explicit".

In the KMP_AFFINITY environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP* thread may execute ("œfloat") enclosed in brackets:
This allows functionality similarity to the `granularity=` specifier, but it is more flexible. The OS processors on which an OpenMP* thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the previous example, we may allow OpenMP* threads 2 and 3 to "œfloat" between OS processor 1 and OS processor 2 by using `KMP_AFFINITY="granularity=fine,proclist=[3,0,{1,2},{1,2}],explicit"`, as shown in the figure below:

[Diagram showing machine/node structure with OS processor and core mappings]

If `verbose` were also specified, the output when the application is executed would include:

```
KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected: {0,1,2,3}
KMP_AFFINITY: 4 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0]
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0]
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {1,2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {1,2}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {0})
```
Low Level Affinity API

Instead of relying on the user to specify the OpenMP* thread to OS proc binding by setting an environment variable before program execution starts (or by using the kmp_settings interface before the first parallel region is reached), each OpenMP* thread can determine the desired set of OS procs on which it is to execute and bind to them with the kmp_set_affinity API call.

Caution
When you use this affinity interface you take complete control of the hardware resources on which your threads run. To do that sensibly you need to understand in detail how the logical CPUs, the enumeration of hardware threads controlled by the OS, map to the physical hardware of the specific machine on which you are running. That mapping can be, and likely is, different on different machines, so you risk binding machine-specific information into your code, which can result in explicitly forcing bad affinities when your code runs on a different machine. And if you are concerned with optimization at this level of detail, your code is probably valuable, and therefore will probably move to another machine.

This interface may also allow you to ignore the resource limitations that were set by the program startup mechanism, such as MPI, specifically to prevent multiple OpenMP processes on the same node from using the same hardware threads. Again, this can result in explicitly forcing affinities that cause bad performance, and the OpenMP runtime will neither prevent this from happening, nor warn you when it does. These are expert interfaces and you must use them with caution.

It is recommended, therefore, to use the higher level affinity settings if you possibly can, because they are more portable and do not require this low level knowledge.

The C/C++ API interfaces follow, where the type name kmp_affinity_mask_t is defined in omp.h:

NOTE
Some of these interfaces have offload equivalents. The offload equivalent takes two additional arguments to specify the target type and target number. For more information, see Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int kmp_set_affinity (kmp_affinity_mask_t *mask)</td>
<td>Sets the affinity mask for the current OpenMP* thread to *mask, where *mask is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td>int kmp_get_affinity (kmp_affinity_mask_t *mask)</td>
<td>Retrieves the affinity mask for the current OpenMP* thread, and stores it in *mask, which must have previously been initialized with a call to kmp_create_affinity_mask(). Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td>int kmp_get_affinity_max_proc (void)</td>
<td>Returns the maximum OS proc ID that is on the machine, plus 1. All OS proc IDs are guaranteed to be between 0 (inclusive) and kmp_get_affinity_max_proc() (exclusive).</td>
</tr>
</tbody>
</table>
### Syntax and Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void kmp_create_affinity_mask (kmp_affinity_mask_t *mask)</td>
<td>Allocates a new OpenMP* thread affinity mask, and initializes *mask to the empty set of OS procs. The implementation is free to use an object of kmp_affinity_mask_kind either as the set itself, a pointer to the actual set, or an index into a table describing the set. Do not make any assumption as to what the actual representation is.</td>
</tr>
<tr>
<td>void kmp_destroy_affinity_mask (kmp_affinity_mask_t *mask)</td>
<td>Deallocates the OpenMP* thread affinity mask. For each call to kmp_create_affinity_mask(), there should be a corresponding call to kmp_destroy_affinity_mask().</td>
</tr>
<tr>
<td>int kmp_set_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)</td>
<td>Adds the OS proc ID proc to the set *mask, if it is not already. Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td>int kmp_unset_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)</td>
<td>If the OS proc ID proc is in the set *mask, it removes it. Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td>int kmp_get_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)</td>
<td>Returns 1 if the OS proc ID proc is in the set *mask; if not, it returns 0.</td>
</tr>
</tbody>
</table>

Once an OpenMP* thread has set its own affinity mask via a successful call to kmp_set_affinity(), then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to kmp_set_affinity().

Between parallel regions, the affinity mask (and the corresponding OpenMP* thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP* Application Program Interface. For more information, see the OpenMP* API specification (http://www.openmp.org), some relevant parts of which are provided below:

In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions."

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, you can mimic the behavior of the KMP_AFFINITY environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP* specification.

The following example shows how these low-level interfaces can be used. This code binds the executing thread to the specified logical CPU:

### Example

```c
// Force the executing thread to execute on logical CPU i
// Returns 1 on success, 0 on failure.
int forceAffinity(int i)
{
    kmp_affinity_mask_t mask;
    ...
} 
```
Example

```c
kmp_create_affinity_mask(&mask);
kmp_set_affinity_mask_proc(i, &mask);
return (kmp_set_affinity(&mask) == 0);
```

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP* thread to physical processing element bindings could differ and you might be explicitly force a bad distribution.

OpenMP* Advanced Issues

This topic discusses how to use the OpenMP* library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP*.

OpenMP* provides specific function calls, and environment variables. See the following topics to refresh you memory about the primary functions and environment variable used in this topic:

- OpenMP* Run-time Library Routines
- OpenMP* Environment Variables

To use the function calls, include the `omp.h` header file. This file is installed in the `INCLUDE` directory during the compiler installation, and compile the application using the `-Qopenmp` option.

The following example, which demonstrates how to use the OpenMP* functions to print the alphabet, also illustrates several important concepts:

1. When using functions instead of pragmas, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.
2. It becomes difficult to compile without OpenMP* support.
3. It is very easy to introduce simple bugs, as in the loop (below) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.
4. You lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.

Example

```c
#include <stdio.h>
#include <omp.h>

int main(void) {
    int i;
    omp_set_num_threads(4);

    #pragma omp parallel private(i) {
        // OMP_NUM_THREADS is not a multiple of 26,
        // which can be considered a bug in this code.
        int LettersPerThread = 26 / omp_get_num_threads();
        int ThisThreadNum = omp_get_thread_num();
        int StartLetter = 'a'+ThisThreadNum*LettersPerThread;

    }

    printf("Hello, World\n");
}
```
Example

```c
int EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread;
for (i=StartLetter; i<EndLetter; i++) { printf("%c", i); }
printf("\n");
return 0;
```

Debugging threaded applications is a complex process because debuggers change the run-time performance, which can mask race conditions. Even print statements can mask issues, because they use synchronization and operating system functions. OpenMP* itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables, and inserts additional code. A debugger that supports OpenMP* can help you to examine variables and step through threaded code. You can use Intel® Inspector to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.

Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs. By default, variables declared on the stack are private, but the C/C++ keyword static changes the variable to be placed on the global heap and therefore shared for OpenMP* loops.

The default(none) clause, shown below, can be used to help find those hard-to-spot variables. If you specify default(none), then every variable must be declared with a data-sharing attribute clause.

Example

```c
#pragma omp parallel for default(none) private(x,y) shared(a,b)
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the firstprivate and lastprivate clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can't find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Force parallel sections to be serial again with if(0) on the parallel construct or commenting out the pragma altogether. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn't work, try setting the entire program to run in serial by setting the compiler-specific environment variable KMP_LIBRARY=serial.

If the code is still not working, and you are not using any OpenMP* API function calls, compile it without the [Q]openmp option to make sure the serial version works. If you are using OpenMP* API function calls, use the [Q]openmp-stubs option.

Performance

OpenMP* threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.
Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on \( n \) CPUs. With OpenMP*, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the \( \texttt{openmp} \) option to generate a single-threaded version, or build with the \( \texttt{openmp-stubs} \) option, and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code. If the overhead of a parallel region is large compared to the compute time, you may want to use an \( \texttt{if} \) clause to execute the section serially.

</tbody>
</table>

**OpenMP* Examples**

The following examples show how to use several OpenMP* features.
A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The `for` has a `nowait` because there is an implicit barrier at the end of the parallel region.

```
Example

void for1(float a[], float b[], int n) {
    int i, j;
    #pragma omp parallel shared(a,b,n) {
        #pragma omp for schedule(dynamic,1) private (i,j) nowait
        for (i = 1; i < n; i++)
            for (j = 0; j < i; j++)
                b[j + n*i] = (a[j + n*i] + a[j + n*(i-1)]) / 2.0;
    }
}
```

Two Difference Operators: for Loop Version

The example uses two parallel loops fused to reduce fork/join overhead. The first `omp for` pragma has a `nowait` clause because all the data used in the second loop is different than all the data used in the first loop.

```
Example

void for2(float a[], float b[], float c[], float d[], int n, int m) {
    int i, j;
    #pragma omp parallel shared(a,b,c,d,n,m) private(i,j) {
        #pragma omp for schedule(dynamic,1) nowait
        for (i = 1; i < n; i++)
            for (j = 0; j < i; j++)
                b[j + n*i] = (a[j + n*i] + a[j + n*(i-1)])/2.0;
        #pragma omp for schedule(dynamic,1) nowait
        for (i = 1; i < m; i++)
            for (j = 0; j < i; j++)
                d[j + m*i] = (c[j + m*i] + c[j + m*(i-1)])/2.0;
    }
}
```

Two Difference Operators: sections Version

The example demonstrates the use of the `omp sections` pragma. The logic is identical to the preceding `omp for` example, but uses `omp sections` instead of `omp for`. Here the speedup is limited to two because there are only two units of work whereas in the example above there are \((n-1) + (m-1)\) units of work.

```
Example

void sections1(float a[], float b[], float c[], float d[], int n, int m) {
    int i, j;
    #pragma omp parallel shared(a,b,c,d,n,m) private(i,j) {
        #pragma omp sections nowait {
            #pragma omp section
            for (i = 1; i < n; i++)
                for (j = 0; j < i; j++)
                    b[j + n*i] = (a[j + n*i] + a[j + n*(i-1)])/2.0;
            #pragma omp section
        }
    }
}
```
Updating a Shared Scalar

This example demonstrates how to use a single construct to update an element of the shared array `a`. The optional nowait clause after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the single construct.

Example

```c
void sp_1a(float a[], float b[], int n) {
  int i;
  #pragma omp parallel shared(a,b,n) private(i) {
    #pragma omp for
    for (i = 0; i < n; i++)
      a[i] = 1.0 / a[i];
    #pragma omp single
    a[0] = MIN( a[0], 1.0 );
    #pragma omp for nowait
    for (i = 0; i < n; i++)
      b[i] = b[i] / a[i];
  }
}
```

Intel(R) Cilk(TM) Plus

Intel® Cilk™ Plus – an extension to the C and C++ languages to support data and task parallelism – is being deprecated in the 2018 release of Intel® Software Development Tools. It will remain in deprecation mode in the Intel® C++ Compiler for an extended period of two years. It is highly recommended that you start migrating to standard parallelization models such as OpenMP® and Intel® Threading Building Blocks (Intel® TBB). For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Intel® Cilk™ Plus, included in the Intel® C++ Compiler, allows you to improve performance by adding parallelism to new or existing C or C++ programs.

Most of the information pertains to all platforms; differences are noted in the text.

For a description of Intel® Cilk™ Plus features, see the section: Intel® Cilk™ Plus.

Target Audience

Application developers who use Intel® Cilk™ Plus need at least a working knowledge of C or C++ programming; expert-level knowledge of C or C++ is optimal.

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.
Getting Started

Intel® Cilk™ Plus adds fine-grained task support to C and C++, making it easy to add parallelism to both new and existing software to efficiently exploit multiple processors and the vector instructions available on modern CPUs. It provides simple language extensions to express data and task parallelism to the C and C++ language implemented by the Intel® C++ Compiler.

Intel® Cilk™ Plus is made up of these main features:

- **Task Parallelism**
  - **keywords**, for expression of task parallelism. For more information on supplied keywords, see Introduction to Keywords.
  - **reducers**, which eliminate contention for shared variables among tasks by automatically creating views of them for each task and reducing them back to a shared value after task completion. For more information on reducers, see Introduction to Reducers.

- **Data Parallelism**
  - **array notations**, which provide data parallelism for sections of arrays or whole arrays. For more information on array notations, see C/C++ Extensions for Array Notations Overview.
  - **SIMD-enabled functions**, which enable data parallelism of whole functions or operations which can then be applied to whole or parts of arrays or scalars. SIMD-enabled functions were formerly called elemental functions. For more information on SIMD-enabled functions, see SIMD-Enabled Functions.
  - the **simd pragma**, which is used to guide the compiler to vectorize more loops. Vectorization using the simd pragma complements (but does not replace) the fully automatic approach. For more information on #pragma simd, see simd.

Intel® Cilk™ Plus is particularly well suited for, but not limited to,"divide and conquer" algorithms. This strategy solves problems by breaking them into sub-problems (tasks) that can be solved independently, then combining the results. Recursive functions are often used for divide and conquer algorithms, and are well supported.

Tasks can either be implemented in separate functions or in iterations of a loop. Certain keywords identify function calls and loops that can run in parallel. The runtime schedules these tasks to run efficiently on the available processors.

In the following sections, the term **worker** is used to mean an operating system thread used to execute a task in a program.

## Summary of Intel® Cilk™ Plus Language Features

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Intel® Cilk™ Plus provides a number of related elements such as keywords, command line options, environment variables and pragmas. The following table provides a summary.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Cilk_spawn</td>
<td>Modifies a function call statement to tell the runtime system that the function may (but is not required to) run in parallel with the caller. See cilk_spawn.</td>
</tr>
<tr>
<td>_Cilk_sync</td>
<td>Indicates that the current function cannot continue past this point in parallel with its spawned children. See cilk_sync.</td>
</tr>
<tr>
<td>_Cilk_for</td>
<td>Specifies a loop that permits loop iterations to run in parallel; is a replacement for the normal C/C++ for loop.</td>
</tr>
</tbody>
</table>
This statement divides a loop into chunks containing one or more loop iterations. Each chunk is executed serially, and is spawned as a chunk during the execution of the loop.

See `cilk_for`.

**Pragmas:**

```plaintext
cilk grainsize

Specifies the grain size for one `cilk_for` loop.
See `cilk_for`.

simd

Expresses vector parallelism for utilizing hardware SIMD parallelism.
See `simd`.
```

**Predefined Macro:**

```plaintext
__cilk

Specifies the supported Intel® Cilk™ Plus version number. The value is set at 200 for this release. If this macro is not defined, the compiler does not support Intel® Cilk™ Plus.
```

**Environment Variables:**

```plaintext
CILK_NWORKERS

Specifies the number of worker threads.
See [Debugging an Intel® Cilk™ Plus Program](#).

CILK_VERSION

If defined, specifies a file to receive information on the version of the Cilk runtime. The special values "stdout" or "stderr" will cause the version information to be written to the specified stream.
```

**SIMD-Enabled Function:**

```plaintext
__declspec(vector)
__attribute__((vector))

Used to write a SIMD-enabled function.
See [SIMD-Enabled Functions](#).
```

**Compiler Options:**

```plaintext
[Q]cilk-serialize

Specifies that an Intel® Cilk™ Plus program should be serialized.
See the section on serialization on [Debugging an Intel® Cilk™ Plus Program](#) and `cilk-serialize/Qcilk-serialize`.

[Q]intel-extensions

Enables Intel language extensions (which include Intel® Cilk™ Plus). Intel language extensions are on by default. To disable, use the negative form of the compiler option.
See `intel-extensions/Qintel-extensions`.
```

**Header files (located in include/cilk):**

```plaintext
cilk/cilk.h

Defines macros that provide names with simpler conventions (`cilk_spawn`, `cilk_sync` and `cilk_for`).

cilk/cilk_api.h

Declares the runtime functions and classes.

cilk/cilk_stub.h

Can be used to serialize an Intel® Cilk™ Plus application.
```
cilk/holder.h
Contains the definition of the cilk::holder template.
See Introduction to Holders.

cilk/reducer.h
Contains common reducer definitions.
See Introduction to Reducers.

reducer_list.h reducer_max.h
reducer_min.h reducer_opadd.h
reducer_opand.h reducer_opor.h
reducer_opxor.h reducer_ostream.h
reducer_string.h reducer_vector.h
Reducers provided in the reducer library.
See Reducer Library.

vector attribute

Debugging an Intel® Cilk™ Plus Program

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

By default, the number of worker threads is set to the number of cores on the host system. In most cases, the default value works well. Additionally, on systems that support simultaneous multithreading on each core, Intel® Cilk™ Plus uses all available hardware threads—except on Intel® Xeon Phi™ processors and coprocessors where it uses half the number of available hardware threads.

You can increase or decrease the number of workers under program control or via the environment. You may want to use fewer workers than the number of processor cores available in order to run tests or to reserve resources for other programs. In some cases, you may want to oversubscribe by creating more workers than the number of available processor cores. This may be useful if you have workers waiting on locks, or if you want to test a parallel program on a single-core computer.

Environment
You can specify the number of worker threads using the environment variable CILK_NWORKERS.

Windows*: set CILK_NWORKERS=4
Linux* and macOS*: export CILK_NWORKERS=4

Program Control
Prior to the first call to a function that performs a spawn (cilk_spawn or cilk_for) within a program, you may set the desired number of workers by calling __cilkrts_set_param("nworkers","N"), where N is a number expressed in decimal or, with a leading 0x or 0, in hexadecimal or octal. This call to set the worker count overrides the value set in the CILK_NWORKERS environment variable. To use __cilkrts_set_param, make sure to specify #include <cilk/cilk_api.h> in your program.

Example:

```c
if (0!= __cilkrts_set_param("nworkers","4"))
{
    printf("Failed to set worker count\n");
    return 1;
}
```

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.
Serialization
The provided keywords are designed to have serial semantics. In other words, every Intel® Cilk™ Plus program corresponds to an equivalent C/C++ program. Such a C/C++ program is referred to as the serialization of the program. The serialization is particularly useful when debugging Intel® Cilk™ Plus programs.

How to Create a Serialization
The header file `cilk_stub.h` contains macros that redefine the Intel® Cilk™ Plus keywords and library calls into an equivalent serial form. To build a serialization do one of the following:

- include `cilk/cilk_stub.h` before any other headers in your source file(s)
- specify the header on the command line: `-include cilk/cilk_stub.h` for Linux* and macOS*
  or `/FI cilk/cilk_stub.h` for Windows*
- Use the equivalent command line option: `-cilk-serialize` for Linux* and macOS*
  or `/Qcilk-serialize` for Windows*

Debugging Strategies
Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Debugging a parallel program can be more difficult than debugging a serial program. Use of Intel® Cilk™ Plus is designed to simplify the challenge of parallel debugging as much as possible. Start by debugging the serialization first.

Follow these guidelines to minimize the problem of debugging parallel programs:

- If you are converting an existing C/C++ program, debug and test the serial version first.
- Once you have a parallel Intel® Cilk™ Plus program, test and debug the serialization. Because both the serial base program and the serialization of the Intel® Cilk™ Plus program are serial C/C++ programs, you can use existing serial debug tools and techniques.
- Run with one worker. This can help detect problems occurring in the parallelized code or detect an algorithmic problem.
- You can use the standard debuggers (gdb for Linux* and macOS*; the Microsoft Visual Studio* debugger for Windows*) for debugging.
- If your program works correctly as a serialization or when run with only one worker, but behaves incorrectly when run with multiple workers, you probably have a data race. You can use Intel® Cilk™ screen race detector (part of the Intel® Cilk™ Plus SDK on the cilkplus.org website) or Intel® Inspector to detect data races. If you detect a data race, do one or more of the following:
  - Restructure the code to remove the race
  - Use a reducer
  - Use a mutual-exclusion lock (such as one of the mutex locks available as part of Intel® Threading Building Blocks), other lock, or atomic operation

It may be simpler to debug programs built without optimizations. Debugging without optimizations turns off inlining, resulting in a more accurate call stack; additionally, the compiler does not attempt to reorder instructions and optimize register usage.

Intel® Cilk Plus™ Keywords
Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

There are three supported keywords: `_Cilk_spawn`, `Cilk_sync` and `Cilk_for`.

The header file `<cilk/cilk.h>` defines macros that allow alternative spellings (`cilk_spawn`, `cilk_sync` and `cilk_for`). This document uses the alternative spellings as defined in `cilk.h`. 

2105
cilk_spawn

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The keyword spelling is _Cilk_spawn. The header file <cilk/cilk.h> defines macros that allow an alternative spelling (in this case, cilk_spawn). This document uses the alternative spelling as defined in cilk.h.

The cilk_spawn keyword modifies a function call statement to tell the runtime system that the function may (but is not required to) run in parallel with the caller. A cilk_spawn statement can take one of the following forms:

- type var = cilk_spawn func(args); // func () returns a value
- var = cilk_spawn func(args); // func () returns a value
- cilk_spawn func(args); // func () may return void

func is the name of a function which may run in parallel with the current strand. A strand is a serial sequence of instructions without any parallel control. The code following the cilk_spawn in the current routine can execute in parallel with func. func(args) may be a call to a normal (C-style) function, a member function, a lambda function, or a function object that overloads operator().

var is a variable that can be initialized or assigned from the return value of func. (It is the same type or a type convertible from the return value.) It is known as the receiver because it receives the function call result. The receiver must be omitted for void functions.

args are the arguments to the function being spawned. These arguments are evaluated before the spawn takes effect. Be careful to ensure that pass-by-reference and pass-by-address arguments have life spans that extend at least until the next cilk_sync or else the spawned function may outlive the variable and attempt to use it after it has been destroyed. This is an example of a data race.

A cilk_spawn expression must be the only expression in the right side of an assignment and cannot be part of a larger expression. For example, the following is disallowed and will cause the compiler to issue an error diagnostic:

- var = var2 + cilk_spawn func(args);

A spawned function is called a child of the function that spawned it. Conversely, the function that executes the cilk_spawn statement is known as the parent of the spawned function.

A function can be spawned using any expression that is a function. For instance, you can use a function pointer or member function pointer, as in:

- var = cilk_spawn (object.*pointer) (args);

You cannot spawn a function as an argument to another function:

- g(cilk_spawn f()); // Not allowed

The correct approach is to spawn a function that calls both f() and g(). This is easily accomplished using a C++11 lambda:

- cilk_spawn [&] { g(f()); }();

Note that the above is different from the following:

- cilk_spawn g(f());

In the latter statement, f() is executed in the parent before spawning g() whereas with the lambda, f() and g() are both executed in the child.
When spawning named lambda functions, be careful that the lifespan of the lambda extends at least until the next sync, or else the destructor for the lambda will race with the spawned call. For example:

```cpp
double i = g();
if (some condition) {
    // named lambda with value capture of i
    auto f = [=i] () { double d = sin(i); f(d); };
    cilk_spawn f();
} // Ouch! destructor for f is in parallel with spawned call.
```

cilk_sync

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The keyword spelling is _Cilk_sync. The header file <cilk/cilk.h> defines macros that allow an alternative spelling (in this case, cilk_sync). This document uses the alternative spelling as defined in cilk.h.

The cilk_sync statement applies to a task block, which, in most cases, is a function. It indicates that the current function cannot continue in parallel with its spawned children, and must wait. After all the children complete, the current function can continue.

An exception to this is when the cilk_sync statement occurs in the body of a cilk_for loop. In this case, the cilk_sync applies only to child tasks spawned from inside the cilk_for loop and not from the same function outside the cilk_for body.

The syntax is as follows:

```cpp
cilk_sync;
```

cilk_sync only syncs with children spawned by this function. Children of other functions are not affected.

There is an implicit cilk_sync at the end of every function and every try block that contains a cilk_spawn. The sync is needed for these reasons:

- To ensure that program resource use does not grow out of proportion to the program’s parallelism.
- To ensure that a race-free parallel program has the same behavior as the corresponding serial program.
  - An ordinary non-spawn call to a function works the same regardless of whether the called function spawns internally.
- There will be no strands left running that might have side effects or fail to free resources.
- The called function will have completed all operations when it returns.

The implicit cilk_sync occurs after destructors are invoked.

cilk_for

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The keyword spelling is _Cilk_for. The header file <cilk/cilk.h> defines macros that allow an alternative spelling (in this case, cilk_for). This document uses the alternative spelling as defined in cilk.h.

A cilk_for loop is a replacement for the normal C/C++ for loop that permits loop iterations to run in parallel.

The general cilk_for syntax is:

```cpp
cilk_for (declaration and initialization;
    conditional expression;
    increment expression)
    body
```
The following rules apply to the `cilk_for` statement:

- The declaration must initialize a single variable, called the loop control variable. In C++ (but not C), the variable must also be declared in the `cilk_for` statement, rather than before it. The constructor’s syntactic form does not matter. If the variable type has a default constructor, no explicit initial value is needed.
- The conditional expression must compare the loop control variable to a "termination expression" using one of the following comparison operators:
  - `<`
  - `<=`
  - `!=`
  - `>=`
  - `>`
- The termination expression and loop control variable can appear on either side of the comparison operator, but the loop control variable cannot occur within the termination expression. The termination expression value must not change from one iteration to the next.
- The increment expression must add to or subtract from the loop control variable using one of the following supported operations:
  - `+=`
  - `-=`
  - `++` (prefix or postfix)
  - `--` (prefix or postfix)

  The value added to (or subtracted from) the loop control variable, like the loop termination expression, must not change from one iteration to the next.
- The body of a `cilk_for` loop body is executed in parallel, so it must not modify the loop control variable.

**Sample `cilk_for` loops include:**

```cpp
cilk_for (int i = begin; i < end; i += 2)
    f(i);

cilk_for (T::iterator i(vec.begin()); i != vec.end(); ++i)
    g(i);
```

In C, but not C++, the loop control variable can be declared in advance:

```cpp
int i;

cilk_for (i = begin; i < end; i += 2)
    f(i);
```

`cilk_for` is compatible with vectorization using the `simd` pragma or `_Simd` keyword:

```cpp
#pragma simd
cilk_for (int i = 0; i < N; ++i) {
    // Loop body
}
```

```cpp
cilk_for _Simd (int i = 0; i < N; ++i) {
    // Loop body
}
```

This combination of `cilk_for` and use of `_Simd` or the `simd` pragma works like a SIMD loop nested within a parallel loop, with the outer loop executing chunks in parallel (using a chunk size chosen by the compiler and runtime system) and the inner loop iterating through a single chunk at a time using vectorization. When using both `cilk_for` and SIMD vectorization you should obey all restrictions for both constructs. If you are familiar with vectorization, but new to threading, remember that while vectorization chunks the work and operates left-to-right, it is unlikely that combined parallel/vector code will execute the chunks in that same order. In a phrase: heed the union of the restrictions to enjoy the intersection of the guarantees.
For the best results, the use of both `cilk_for` parallelism and SIMD vectorization should be employed only when there is a substantial amount of total work: either a significant number of iterations or a significant amount of work per iteration. In the case of nested loops, it's generally best to vectorize only the innermost loop and use `cilk_for` to parallelize only the one or two outermost loops. If the loops are even more deeply nested, the intermediate nesting levels should generally be serial. The parallel/vector combined loop should, therefore, be used only when the outermost and innermost loops are the same loop—that is, when there is no nesting. Ultimately, the best test of whether both methods are useful is to try a loop with and without parallelization and use a profiler to determine which way yields better performance.

The serialization of a valid Intel® Cilk™ Plus program has the same behavior as the similar C/C++ program, where the serialization of `cilk_for` is the result of replacing `cilk_for` with `for`. Therefore, a `cilk_for` loop must be a valid C/C++ `for` loop, but `cilk_for` loops have several constraints compared to C/C++ `for` loops.

### Serial/parallel structure of `cilk_for`

Using `cilk_for` is not the same as spawning each loop iteration. In fact, the Intel compiler converts the loop body to a function that is called recursively using a divide-and-conquer strategy; this provides significantly better performance. The difference can be seen clearly in the Directed Acyclic Graph (DAG) for the two strategies.

First, consider the DAG for a `cilk_for`, assuming N=8 iterations and a grain size of 1. The numbers label the serial sequence of instructions, known as strands; these numbers indicate which loop iteration is handled by each strand.

![DAG for cilk_for](image)

At each division of work, half of the remaining work is done in the child and half in the continuation. Importantly, the overhead of both the loop itself and of spawning new work is divided evenly along with the cost of the loop body.

If each iteration takes the same amount of time T to execute, then the span, which is the most expensive path extending from the beginning to the end of the program, is \( \log_2(N) \times T \), or 3 * T for 8 iterations. The run-time behavior is well balanced, regardless of the number of iterations or number of workers.

### Serial/parallel structure when spawning within a serial loop

Here is the DAG for a serial loop that spawns each iteration. In this case, the work is not well balanced, because each child does the work of only one iteration before incurring the scheduling overhead inherent in entering a sync. For a short loop, or a loop in which the work in the body is much greater than the control and spawn overhead, there will be little measurable performance difference. However, for a loop of many cheap iterations, the overhead cost will overwhelm any advantage provided by parallelism.

![DAG for serial loop](image)
The body of a `cilk_for` loop defines a special region that limits the scope of `cilk_for` and `cilk_sync` statements within it. A `cilk_sync` statement within a `cilk_for` waits for completion only of the children that were spawned within the same loop iteration. It will not sync with any other iteration, nor will it sync with any other children of the surrounding function. In addition, there is an implicit `cilk_sync` at the end of every loop iteration (after block-scoped variable destructors are invoked). As a result, if a function has outstanding children when entering a `cilk_for` loop, it will have the same outstanding children when exiting the `cilk_for` loop. Any children that were spawned within the `cilk_for` loop are guaranteed to have synchronized before the loop terminates. Conversely, none of the children that existed before entering the loop will be synchronized during loop execution. This quality of a `cilk_for` loop can be used to your advantage (see Exception Handling).

If an exception is thrown from within a `cilk_for` loop body (and not handled within the same iteration), then some of the loop iterations may not run. Unlike a serial execution, it is not completely predictable which iterations will run and which will not. No iteration (other than the one throwing the exception) is aborted in the middle.

Windows*: There are restrictions when using Microsoft structured exception handling (specifically, the /EHa compiler option and the __try, __except, __finally and __leave extensions to C/C++). See Windows* Structured Exception Handling in Exception Handling.

**cilk_for Type Requirements**

With care, you may use custom C++ data types for the `cilk_for` control variable. For each custom data type, you need to provide some methods to help the runtime system compute the loop range size so that it can be divided. Types such as integer types and STL random-access iterators have an integral difference type already, and so require no additional work.

Suppose the control variable is declared with type `variable_type` and the loop termination expression has type `termination_type`, as shown here:

```cpp
extern termination_type end;
extern int incr;
cilk_for (variable_type var; var != end; var += incr) ;
```

You must provide one or two functions to tell the compiler how many times the loop executes; these functions allow the compiler to compute the integer difference between `variable_type` and `termination_type` variables:

```cpp
difference_type operator-(termination_type, variable_type);
difference_type operator-(variable_type, termination_type);
```

The following applies:

- The argument types need not be exact, but must be convertible from `termination_type` or `variable_type`.
- The first form of `operator-` is required if the loop could count up; the second is required if the loop could count down.
- The arguments may be passed by const reference or value.
- The program will call one or the other function at run time depending on whether the increment is positive or negative.
- You can pick any integral type as the `difference_type` return value, but it must be the same for both functions.
- It does not matter if the `difference_type` is signed or unsigned.

Also, you need to tell the system how to add to the control variable by defining:

```cpp
variable_type::operator+=(difference_type);
```

If you wrote `-=` or `--` instead of `+=` or `++` in the loop, define `operator-=` instead of `operator+=`.

These operator functions must be consistent with ordinary arithmetic. The compiler assumes that adding one twice is the same as adding two once, and if

```
X - Y == 10
```
then
\[ Y + 10 = X \]

\textbf{cilk\_for Restrictions}

In order to parallelize a loop using the divide and conquer technique, the compiler must pre-compute the total number of iterations and must be able to pre-compute the value of the loop control variable at every iteration. To enable this computation, the control variable must act as an integer with respect to addition, subtraction, and comparison, even if it is a user-defined type. Integers, pointers, and random access iterators from the standard template library all have integer behavior and thus satisfy this requirement.

In addition, a \texttt{cilk\_for} loop has the following limitations, which are not present for a standard C/C++ for loop. The compiler will report an error or warning for violations of the following.

- There must be exactly one loop control variable, and the loop initialization clause must assign the value. The following form is not supported:
  \begin{verbatim}
  cilk_for (unsigned int i, j = 42; j < 1; i++, j++)
  \end{verbatim}
- The loop control variable must not be modified in the loop body. The following form is not supported:
  \begin{verbatim}
  cilk_for (unsigned int i = 1; i < 16; ++i) i = f();
  \end{verbatim}
- The termination and increment values are evaluated once before starting the loop and will not be re-evaluated at each iteration. Therefore, modifying either value within the loop body will not add or remove iterations. The following form is not supported:
  \begin{verbatim}
  cilk_for (unsigned int i = 1; i < x; ++i) x = f();
  \end{verbatim}
- In C++, the control variable must be declared in the loop header, not outside the loop. The following form is supported for C, but not C++:
  \begin{verbatim}
  int i; cilk_for (i = 0; i < 100; i++)
  \end{verbatim}
- A break or return statement will not work within the body of a \texttt{cilk\_for} loop; the compiler will generate an error message.
- A \texttt{goto} can only be used within the body of a \texttt{cilk\_for} loop if the target is within the loop body. The compiler will generate an error message if there is a \texttt{goto} transfer into or out of a \texttt{cilk\_for} loop body. Similarly, a \texttt{goto} cannot jump into the body of a \texttt{cilk\_for} loop from outside the loop.
- A \texttt{cilk\_for} loop may not "wrap around." For example, in C/C++ you can write:
  \begin{verbatim}
  for (unsigned int i = 0; i != i; i += 0)
  \end{verbatim}
  and this has well-defined, if surprising, behavior. It means execute the loop \(2,863,311,531\) times. Such a loop produces unpredictable results when converted to a \texttt{cilk\_for} loop.
- A \texttt{cilk\_for} loop may not be an infinite loop such as:
  \begin{verbatim}
  cilk_for (unsigned int i = 0; i != i; i += 0);
  \end{verbatim}

\textbf{cilk\_for Grain Size}

The \texttt{cilk\_for} statement divides the loop into chunks containing one or more loop iterations. Each chunk is executed serially, and is spawned as a chunk during the execution of the loop. The maximum number of iterations in each chunk is the \textit{grain size}.

In a loop with many iterations, a relatively large grain size can significantly reduce overhead. Alternately, with a loop that has few iterations, a small grain size can increase the parallelism of the program and thus improve performance as the number of processors increases.

\textbf{Setting the Grain Size}

Use the \texttt{cilk\_grainsize} pragma to specify the grain size for one \texttt{cilk\_for} loop:

\begin{verbatim}
#pragma cilk grainsize = expression
\end{verbatim}

For example, you can write:
\begin{verbatim}
#pragma cilk grainsize = 1

cilk_for (int i=0; i<IMAX; ++i) { . . . }
\end{verbatim}

If you do not specify a grain size, the system calculates a default that works well for most loops. The default value is set as if the following pragma were in effect:
```c
#pragma cilk grainsize = min(2048, N / (8*p))
```

where N is the number of loop iterations, and p is the number of workers created during the current program run. This formula will generate parallelism of at least 8 and at most 2048. For loops with few iterations (less than 8 * workers) the grain size will be set to 1, and each loop iteration may run in parallel. For loops with more than (16484 * p) iterations, the grain size will be set to 2048.

The `cilk grainsize` pragma is usually used to reduce the grain size (often to 1) for particularly large loops or loops where the amount of work varies widely between iterations. Smaller grain sizes increase parallelism and improve load balancing, at the cost of increased scheduling and function-call overhead.

The `cilk grainsize` pragma can also be used to increase the grain size and thus, reduce overhead, especially when the loop body is short. However, once the grain size reaches about 1000 to 2000 iterations, the overhead of the `cilk_for` becomes inconsequential, even when the amount of work per iteration is very small. At that point, there is no benefit to increasing the grain size any further. In fact, using a grain size that is too large will reduce parallelism and impede load balancing. In general, the larger and more unbalanced the loop iterations, the smaller the grain size should be.

If you specify a grain size of zero, the default formula will be used. The result is undefined if you specify a grain size less than zero.

The expression in the pragma is evaluated at run time. For example, here is an example that sets the grain size based on the number of workers:

```c
#pragma cilk grainsize = n/(4*__cilkrts_get_nworkers())
```

**Loop Partitioning at Run Time**

The number of chunks that are executed is approximately the number of iterations N divided by the grain size K.

The Intel compiler generates a divide and conquer recursion to execute the loop. In pseudo-code, the control structure looks like this:

```c
void run_loop(first, last)
{
    if (last - first) < grainsize)
    {
        for (int i=first; i<last ++i) LOOP_BODY;
    }
    else
    {
        int mid = (last+first)/2;
        cilk_spawn run_loop(first, mid);
        run_loop(mid, last);
    }
}
```

In other words, the loop is split in half repeatedly until the chunk remaining is less than or equal to the grain size. The actual number of iterations run as a chunk will often be less than the grain size.

For example, consider a `cilk_for` loop of 16 iterations:

```c
cilk_for (int i=0; i<16; ++i) { ... }
```

With grain size of 4, this will execute exactly 4 chunks of 4 iterations each. However, if the grain size is set to 5, the division will result in 4 unequal chunks consisting of 5, 3, 5 and 3 iterations.

If you work through the algorithm in detail, you will see that for the same loop of 16 iterations, a grain size of 2 and 3 will both result in exactly the same partitioning of 8 chunks of 2 iterations each.

**Selecting a Good Grain Size Value**

The default grain size usually performs well. Use the following guidelines to select a different value:
• If the amount of work per iteration varies widely and if the longer iterations are likely to be unevenly
distributed, it might make sense to reduce the grain size. This will decrease the likelihood that there is a
time-consuming chunk that continues after other chunks have completed, which would result in idle
workers with no work to steal.
• If the amount of work per iteration is uniformly small, then it might make sense to increase the grain size.
However, the default usually works well in these cases, and you don't want to risk reducing parallelism.
• If you change the grain size, carry out performance testing to ensure that you have made the loop faster,
not slower.

Intel(R) Cilk(TM) Plus Execution Model

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more
information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Programming with Intel® Cilk™ Plus is a departure from traditional serial programming. Certain key concepts
require explanation in order for you to write programs that perform and scale well.

The following concepts are key:
  • **strands**: the structure of an Intel® Cilk™ Plus program is best understood as a graph of strands connecting
    parallel control points.
  • **pedigrees**: each strand in an Intel® Cilk™ Plus program can be assigned a pedigree, a sequence of
    integers that identifies the strand.
  • **work, span, and parallelism**: the expected performance of an Intel® Cilk™ Plus program can be analyzed
    in terms of work, span, and parallelism.

Strands

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more
information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Traditional serial programs are often described using call graphs or class hierarchies. Parallel programming
adds another layer on top of the serial analysis. To diagram, understand and analyze the parallel
performance of an Intel® Cilk™ Plus program, you need to distinguish between sections of code that run
serially, and sections that may run in parallel.

The term **strand** describes a serial section of the program. More precisely, the definition of a strand is "any
sequence of instructions without any parallel control structures."

According to this definition, a serial program can be made up of many sequential strands as short as a single
instruction each, a single strand consisting of the entire program, or any other partitioning. A **maximal strand** is a strand that is not part of a longer strand, that is, a strand whose start and end points are parallel
control structures.

An Intel® Cilk™ Plus program contains two kinds of parallel control structures - spawn and sync. (A parallel
loop, such as _Cilk_for, is just a convenient notation for decomposing a problem into spawns and syncs.)
The following illustrates 4 strands (1, 2, 3, 4), a spawn (A) and a sync (B). In this figure, only strands (2)
and (3) may execute in parallel.

In this diagram, the strands are represented by lines and arcs (edges), while the parallel control structures
are represented by the circular nodes (vertices). The strand diagram represents a Directed Acyclic Graph
(DAG) that represents the serial/parallel structure of a program.

An Intel® Cilk™ Plus program fragment that reflects the structure in the diagram is as follows:

```c
...
do_stuff_1();       // execute strand 1
cilk_spawn func_3(); // spawn strand 3 at A
do_stuff_2();        // execute strand 2
```
cilk_sync;          // sync at B
do_stuff_4();        // execute strand 4
...

In an Intel® Cilk™ Plus program, a spawn has exactly one input strand and two output strands. A sync has two or more input strands and exactly one output strand. The following diagram shows a DAG with two spawns (labeled A and B) and one sync (labeled C). In this program, the strands labeled (2) and (3) may execute in parallel, while strands (3), (4), and (5) may execute in parallel.

A DAG represents the serial/parallel structure of the execution of an Intel® Cilk™ Plus program. With different input, the same program may have a different DAG. For example, a spawn may execute conditionally.

Most Intel® Cilk™ Plus programs are **strand-invariant**, that is, for a given input, every execution of the program generates the same DAG, independent of the number of processors used to run the program. To determine the DAG of a strand-invariant program, it is sufficient to run the program on a single processor. A later section will describe the execution model and explain how work is divided among the number of available processors.

Mapping Strands to Workers

**Pedigrees**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

In an execution of an Intel® Cilk™ Plus program, each maximal strand is identified by its **pedigree**, a variable-length sequence of 64-bit integers. Intel® Cilk™ Plus provides an API that enables you to query the pedigree of a currently executing strand.

Conceptually, as a program executes, the pedigree for the currently executing strand changes at the boundaries of maximal strands. Recall that maximal strand boundaries occur at each `cilk_spawn`, `cilk_sync`, and at each grain of a `cilk_for`.

Pedigrees satisfy three key properties:

- **Uniqueness**: Every maximal strand in an execution DAG has a distinct pedigree.
- **Lexicographic ordering**: In any serial execution of an Intel® Cilk™ Plus program, the pedigrees of strands increase in a "dictionary" ordering.
- **Determinism**: For any execution DAG generated by a strand-invariant program, the pedigree for each strand in the DAG is always the same across multiple runs of the program.

For example, consider following Intel® Cilk™ Plus program.

```cpp
int fib(int n) {
  if (n < 2) {
    return n;
  }
  else {
    int x, y;
    x = cilk_spawn fib(n-1);
    y = fib(n-2);
    cilk_sync;
    return x+y;
  }
}
```
This program generates the following execution DAG, which has 13 strands, labeled A through M. One valid way of assigning pedigrees to strands is shown below. Strand H has a pedigree of [0, 0, 2]. The first term of 0 is the most-significant term, and the last term of 2 is the least-significant term. Property 1 is satisfied because each strand has a unique pedigree. Property 2 is satisfied because a serial execution of the program executes strands in alphabetical order (from A to M), and the pedigrees for each strand are increasing lexicographically. Finally, since this program is strand-invariant, Property 3 guarantees that every execution of the program assigns the same pedigree to each strand each the program runs.

**Pedigrees for strands**

A: [0, 0]
B: [0, 0, 0]
C: [0, 0, 0, 0]
D: [0, 0, 0, 0, 0]
E: [0, 0, 0, 1]
F: [0, 0, 0, 2]
G: [0, 0, 1]
H: [0, 0, 2]
I: [0, 1]
J: [0, 1, 0]
K: [0, 2]
L: [0, 3]
M: [0, 4]

**Work and Span**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Once you have a method of describing the serial/parallel structure of an Intel® Cilk™ Plus program, you can begin to analyze the program's performance and scalability.

Consider a more complex program, represented in the following diagram:
This DAG represents the parallel structure of some Intel® Cilk™ Plus program. To construct a program that has this DAG, it is useful to add labels to the strands to indicate the number of milliseconds it takes to execute each strand:

**Work**

The total amount of processor time required to complete the program is the sum of all the numbers. This value is defined as the *work*.

In this DAG, the work is 181 milliseconds for the 25 strands shown, and if the program runs on a single processor, the program should run for 181 milliseconds.

**Span**

The *span*, sometimes called the critical path length, is the most expensive path that extends from the beginning to the end of the program. In this DAG, the span is 68 milliseconds, as shown in the following diagram:

Under ideal circumstances (for instance, when there is no scheduling overhead) and when an unlimited number of processors are available, this program should run for 68 milliseconds.

You can use the work and span to predict how an Intel® Cilk™ Plus program will speed up and scale on multiple processors.

When analyzing an Intel® Cilk™ Plus program, you need to consider the running time of the program on various numbers of processors. The following notations are helpful:

- $T(P)$ is the execution time of the program on $P$ processors.
- $T(1)$ is the Work
- $T(\infty)$ is the Span

On 2 processors, the execution time can never be less than $T(1) / 2$. In general, the Work Law can be stated as:

$$T(P) \geq T(1) / P$$

Similarly, for $P$ processors, the execution time is never less than the execution time on an infinite number of processors. Therefore, the Span Law can be stated as:

$$T(P) \geq T(\infty)$$
Speed up and Parallelism

If a program runs twice as fast on 2 processors, then the speedup is 2. Therefore, speedup on \( P \) processors can be stated as:

\[
T(1)/T(P)
\]

An interesting consequence of the speedup formula is that if \( T(1) \) increases faster than \( T(P) \), then speedup increases as the work increases. Some algorithms, for example, do extra work in order to take advantage of additional processors. Such algorithms are typically slower than a corresponding serial algorithm on one or two processors, but begin to show speedup on three or more processors. This situation is not common, but is worth noting.

The maximum possible speedup would occur using an infinite number of processors. Parallelism is defined as the hypothetical speedup on an infinite number of processors. Therefore, parallelism can be defined as:

\[
T(1)/T(\infty)
\]

Parallelism puts an upper bound on the speedup you can expect. If the code you are parallelizing has a parallelism of 2.7, for example, then you will achieve reasonable speedup on 2 or three processors, but no additional speedup on four or more processors. Thus, algorithms that are tuned to a small number of cores do not scale to larger machines. In general, if parallelism is less than 5-10 times the number of available processors, then you should expect less than linear speedup because the scheduler will not always be able to keep all of the processors busy.

Mapping Strands to Workers

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

An earlier DAG illustrated the serial/parallel structure of an Intel® Cilk™ Plus program. Recall that the DAG does not depend on the number of processors. The execution model describes how the runtime scheduler maps strands to workers.

When parallelism is introduced, multiple strands may execute in parallel. However, in an Intel® Cilk™ Plus program, strands that may execute in parallel are not required to execute in parallel. The scheduler makes this decision dynamically.

Consider the following program fragment:

```c
do_init_stuff(); // execute strand 1
cilk_spawn func3(); // spawn strand 3 (the "child")
do_more_stuff(); // execute strand 2 (the "continuation")
cilk_sync;
do_final_stuff; // execute strand 4
```

Here is the simple DAG for the code:

Recall that a worker is an operating system thread that executes an Intel® Cilk™ Plus program. If there is more than one worker available, there are two ways that this program may execute:

- The entire program may execute on a single worker
- The scheduler may choose to execute strands (2) and (3) on different workers

In order to guarantee serial semantics, the function that is spawned (the child, or strand (3) in this example) is always executed on the same worker that is executing the strand that enters the spawn. Thus, in this case, strand (1) and strand (3) are guaranteed to run on the same worker.

If there is a worker available, then strand (2) (the "continuation") may execute on a different worker. This is known as a steal, and the situation can be described by saying that the continuation was stolen by the new worker.
To illustrate these two execution options, a new diagram is helpful. The diagram illustrates the execution on a single worker:

![Diagram of single worker execution]

If a second worker is scheduled, the second worker will begin executing the continuation, strand (2). The first worker will proceed to the sync at (B). In the following diagram, the second worker is indicated by showing strand (2) as a dotted line. After the sync, strand (4) may continue on either worker. In the current implementation, strand (4) will execute on the last worker that reaches the sync.

![Diagram of execution with second worker]

The details of the execution model have several implications that will be described in the section on the interaction between workers and system threads, and also the section on reducers. For now, the key ideas are:

- After a `cilk_spawn`, the child will always execute on the same worker (the system thread) as the caller.
- After a `cilk_spawn`, the continuation may execute on a different worker. If this occurs, the continuation is said to be stolen by another worker.
- After a `cilk_sync`, execution may proceed on any worker that executed a strand that entered the sync.

As a program executes on multiple workers, each worker tracks the pedigree of the strand it is currently executing. Intel® Cilk™ Plus provides an API that enables each worker to query the pedigree of its currently executing strand. The API also provides a call for creating a new maximal strand boundary. This call terminates the current maximal strand, and begins a new maximal strand with a different pedigree.

**Exception Handling**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Intel® Cilk™ Plus attempts to reproduce, as closely as possible, the semantics of C++ exception handling. This generally requires limiting parallelism while exceptions are pending, and programs should not depend on parallelism during exception handling. The exception handling logic is as follows:

- If an exception is thrown and not caught in a spawned child, then that exception is rethrown in the parent at the next sync point.
- If the parent or another child also throws an exception, then the first exception that would have been thrown in the serial execution order takes precedence. The logically-later exceptions are discarded. There is currently no mechanism for collecting multiple exceptions thrown in parallel.

Throwing an exception does not abort existing children or siblings of the strand in which the exception is thrown; these strands will run normally to completion.

If a try block contains a `cilk_spawn` and/or a `cilk_sync`, then there is an implicit `cilk_sync` just before entering the try block and an implicit `cilk_sync` at the end of the try block (after destructors are invoked). A sync is executed automatically before exiting a try block, function block, or `cilk_for` body via an exception. (Note that the scope of a sync within a `cilk_for` is limited to spawns within the same loop.) A function has no active children when it begins execution of a catch block. These implicit syncs exist to ensure that the same catch clauses run as would have run in a serial execution of the program.

Implicit syncs may limit the parallelism of your program. The sync before a try block, in particular, may prematurely sync a spawn that occurs before the try block as in the following example:

```c
void func() {
    cilk_spawn f();
    try { // oops! implicit sync prevents parallel execution of f()
        cilk_spawn g();
        h();
    }
}
```
catch (...) {
    // Handle exceptions from g() or h(), but not f()
}
}

If this is a problem for your program, there are two ways to prevent the implicit sync. One way is to move the body of your try block into a separate function. By moving the cilk_spawn lexically out of the try block, you eliminate the automatic generation of cilk_sync at both the start and end of the try block. The previous example could be rewritten as follows:

```c
void gh()
{
    cilk_spawn g();
    h();
}

void func() {
    cilk_spawn f();
    try { // no cilk_spawn in body, so no implicit sync
        gh();
    }
    catch (...) { // Handle exceptions from gh(), but not f()
    }
}
```

Another way to prevent an implicit sync is to enclose the body of the try block or the entire try/catch statement in a cilk_for loop that executes only once. The body of a cilk_for loop is an isolated context such that spawns and syncs do not interact with the surrounding function. If you do this a lot, a macro can come in handy. The above example could be rewritten as follows:

```c
#define CILK_TRY cilk_for (int _temp = 0; _temp < 1; ++_temp) try

void func() {
    cilk_spawn f();
    CILK_TRY { // try is within cilk_for, so does not sync f()
        cilk_spawn g();
        h();
    }
    catch (...) { // Handle exceptions from g() or h(), but not f()
    }
}
```

### Windows* Structured Exception Handling

There are restrictions when using Microsoft Windows* structured exception handling (specifically, the /EHa compiler option and the __try, __except, __finally and __leave extensions to C/C++). Structured exception handling (SEH) will fail if an SEH exception is thrown after a steal occurs and before the corresponding cilk_sync. The runtime recognizes this condition and terminates the program with an appropriate error code.

---

**Reducers**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.
Reducers address the problem of computing a value by incrementally updating a variable in parallel code without data races on that variable. Conceptually, a reducer is a variable that can be safely used by multiple strands running in parallel. The runtime ensures that each worker has access to a private copy of the variable, eliminating the possibility of races without requiring locks. When the strands synchronize, the variable instances are merged—or reduced—into a single variable.

Reducers have several attractive properties:

- Reducers allow reliable access to nonlocal variables without races.
- Reducers do not require locks and therefore avoid the problem of lock contention (and subsequent loss of parallelism) that arises from using locks to protect nonlocal variables.
- Defined and used correctly, reducers retain serial semantics. The result of a program that uses reducers is the same as the serial version, and the result does not depend on the number of processors or how the workers are scheduled.
- Reducers are implemented efficiently, incurring minimal overhead.
- Reducers can be used independently of the program’s control structure, unlike constructs that are defined over specific control structures such as loops.
- Reducers can be used without significantly restructuring existing code.

Reducers are defined by writing C++ templates that provide an interface to the runtime system.

At some point, you may want to write your own reducer. Advanced Topic: How to Write a New Reducer provides more information.

Using Reducers - A Simple Example

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

This example illustrates use of reducers in accumulating a sum in parallel. Consider the following serial program, which repeatedly calls a compute() function and accumulates the answers into the total variable.

```cpp
#include <iostream>

unsigned int compute(unsigned int i)
{
    return i; // return a value computed from i
}

int main(int argc, char* argv[])
{
    unsigned long long int n = 1000000;
    unsigned long long int total = 0;

    // Compute the sum of integers 1..n
    for(unsigned int i = 1; i <= n; ++i)
    {
        total += compute(i);
    }

    // the sum of the first n integers should be n * (n+1) / 2
    unsigned long long int correct = (n * (n+1)) / 2;

    if (total == correct)
        std::cout << "Total (" << total << ") is correct" << std::endl;
    else
        std::cout << "Total (" << total << ") is WRONG, should be "
```

2120
Converting this program to an Intel® Cilk™ Plus program and changing the for to a cilk_for causes the loop to run in parallel, but creates a data race on the total variable. To resolve the race, you can make total a reducer; specifically, a reducer<op_add>, defined for types that have an associative + operator. The changes are shown below.

```cpp
#include <cilk/cilk.h>
#include <cilk/reducer_opadd.h>
#include <iostream>

unsigned int compute(unsigned int i)
{
    return i; // return a value computed from i
}

int main(int argc, char* argv[])
{
    unsigned long long int n = 1000000;
    cilk::reducer< cilk::op_add<unsigned long long int> > total (0);
    // Compute 1..n
    cilk_for(unsigned int i = 1; i <= n; ++i)
    {
        *total += compute(i);
    }
    // the sum of the first N integers should be n * (n+1) / 2
    unsigned long long int correct = (n * (n+1)) / 2;
    if (total.get_value() == correct)
        std::cout << "Total (" << total.get_value() << ") is correct" << std::endl;
    else
        std::cout << "Total (" << total.get_value() << ") is WRONG, should be "
        << correct << std::endl;
    return 0;
}
```

The following changes in the serial code show how to use a reducer:

1. Include the appropriate reducer header file (cilk/reducer_opadd.h).
2. Declare the reduction variable as a reducer<op_kind<TYPE>> rather than as a TYPE.
3. Introduce parallelism, in this case by changing the for loop to a cilk_for loop.
4. In the parallel code, change references to the original variable to dereferences of the reducer variable (*total).
5. Retrieve the reducer's final value after all parallel strands have synchronized; in this case, after the cilk_for loop is complete (total.get_value()).

**NOTE**
Reducers are C++ class objects that cannot be copied or assigned.
How Reducers Work

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

An explanation of the mechanisms and semantics of reducers should help the more advanced programmer understand the rules governing the use of reducers as well as provide the background needed to write custom reducers.

Reducers are designed to support the parallel execution of a "reduction" algorithm:

1. There is an accumulator variable x with an initial value $a_0$.
2. There is a reduction operation OP.
3. OP is an associative operation, i.e., $x \text{ OP } y = y \text{ OP } x$.
4. OP has an identity value $I$, i.e., $x \text{ OP } I = I \text{ OP } x = x$.
5. The code repeatedly updates the variable, with each update having the form $x = x \text{ OP } a_i$. After $N$ updates, $x$ contains $a_0 \text{ OP } a_1 \text{ OP } a_2 \text{ OP } \ldots \text{ OP } a_N$.

Common operations that fit this pattern include addition and multiplication, bitwise AND and OR, set union, list append, and string concatenation. (In mathematics, the combination of a type, an associative operation on that type, and an identity for that operation is called a monoid.)

A reducer object automatically manages multiple copies of an accumulator variable, called the "view," as parallel strands of execution are spawned and synced. Each strand executing in parallel gets its own view, so there cannot be data races between modifications of the accumulator variable in different strands:

1. Initially, a reducer contains a single view, called the "leftmost" view.
2. The reducer creates a new instance of the view for each strand that executes in parallel with the leftmost strand. The new view instance is initialized to the reduction operation's identity value by the reducer's identity() function.
3. All accesses to the reducer's view in a strand apply to the view instance that the reducer created for that strand.
4. When a spawned strand finishes executing and merges back into its parent, the reducer's reduce() function combines the values of the two strands' views with the reduction operation, leaving the result in the surviving strand's view instance. The reducer then destroys the terminated strand's view.
5. When all spawned strands have finished executing, the final result of the computation remains in the leftmost view.

As a result of this process, each strand computes a subsequence of the total sequence of operations $(I \text{ OP } a_i \text{ OP } a_{i+1} \text{ OP } \ldots \text{ OP } a_{i+m} = a_i \text{ OP } a_{i+1} \text{ OP } \ldots \text{ OP } a_{i+m})$ in its view, and when the computation is finished, the leftmost view contains the expected result $(a_0 \text{ OP } a_1 \text{ OP } a_2 \text{ OP } \ldots \text{ OP } a_N)$. The order of the values is the same as in the serial computation, and since the operation is associative, it doesn't matter what order the subsequence totals are combined in.

Lazy View Creation

The reason for creating private view instances for strands is to eliminate data races. A strand needs its own instance of a view only if it accesses the view and also executes in parallel with some other strand. Creating, managing, and merging views is not expensive, but it isn't free, so the scheduler avoids creating views unnecessarily. The rule is that:

1. A reducer does not create a new view instance for a strand unless the strand has been stolen. If the strand is not stolen, it can safely use the same view as its child.
2. The reducer does not create a new view instance until the first time the view is accessed in a stolen strand. If the view is never accessed in the strand, a new instance is not created.

Example: Using reducer<op_list_append>

This example is a simple program that uses reducer<op_list_append> to accumulate a list of strings in parallel. For list appends, the identity value is the empty list, and the reduction function concatenates the left and right lists.

```
1 #include <cilk/cilk.h>
2 #include <cilk/reducer_list.h>
3```
4 cilk::reducer< cilk::op_list_append<std::string> > lr();
5
6 void depart()
7 {
8   lr->push_back("leave");
9 }
10
11 int main()
12 {
13   lr->push_back("Don't ");
14   cilk_spawn depart();
15   lr->push_back(" the path!");
16   cilk_sync;
17   std::list<std::string> result = list.get_value();
18 }

First, consider the serial case when the execution occurs on a single processor.

1. The leftmost view is initialized to an empty list when the reducer is created.
2. The string "Don't " is appended to the list at line 13.
3. At the spawn, execution continues in the depart() strand, and "leave" is appended to the list at line 8.
4. With only one worker, there is no steal, so a new view is not created for the continuation strand, and " the path!" is appended to the list at line 15.
5. Since there is only one view, there is nothing to do at the sync, and the final content of the leftmost view is {"Don't ", "leave", " the path!"}.

Now consider what happens when the program is run with two workers.

1. The leftmost view is initialized to an empty list when the reducer is created.
2. The string "Don't " is appended to the list at line 13.
3. At the spawn, execution continues in the depart() strand, and "leave" is appended to the list at line 8.
4. Meanwhile, the second worker steals the continuation strand, so when the view is accessed at line 15, the reducer creates a new view and initializes it to the empty list.
5. " the path!" is appended to the list in the private view of the continuation strand at line 15.
6. At the sync, the content of the right view, {"the path!"}, is appended to the content of the left view, {"Don't ", "leave" }, so the content of the left most view becomes {"Don't ", "leave", " the path!" }, and the right view is deleted.

Safety, Correctness, and Performance

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

When developing your program, be aware of the following safety, correctness, and performance considerations.

The Reducer and the View

A reducer manages instances of a view; code in a parallel reduction computation updates the view instance for the current parallel strand. The current view instance is accessed by dereferencing the reducer: *r = *r OP a.

In other words, you can think of the reducer as being like a (smart) pointer to the view.

Safety

If a properly written reducer is used as described above, no data races will occur between accesses to the reducer's view in different parallel strands.

Floating-Point Operations
Floating-point arithmetic operations are not strictly associative because of overflow, underflow, and loss of precision resulting from the way that floating-point numbers are represented in a computer. This is a consideration that potentially affects any optimization that reassociates floating-point arithmetic, including reducers.

Before using a floating-point reducer, you should carefully consider the characteristics of your data and what the possible effects on the results may be.

**Initial and Final Values**

You can specify an initial value for a reducer with an argument to the reducer constructor, or you can set its initial value by calling the reducer `set_value()` function. If you do not give a reducer an initial value, its identity value will be used.

You can retrieve the final value of the computation by calling the reducer `get_value()` function after the computation is complete.

Alternatively, you can move the value of a variable into the reducer, leaving the variable undefined, but calling the reducer `move_in()` function, or move the value of the reducer out into a variable, leaving the reducer value undefined, by calling the reducer `move_out()` function.

`get_value()`, `set_value()`, `move_in()`, and `move_out()` always access the view instance of the current strand. You can call them in the middle of a parallel computation, but the results will almost always be meaningless. The best policy is to use `set_value()` and `move_in()` only to initialize a reducer, and `get_value()` and `move_out()` only to retrieve its final value.

**Permitted Operations**

A reducer computes the correct result in a parallel computation (in other words, the same result as the serial computation) because its reduction operation is associative. Reassociating a non-associative computation will lead to undesired results. In other words, the only modifications that are permitted on a reducer's view are updates using its reduction operation (`view = view OP value`), or something that is semantically equivalent. (For example, permissible operations on an addition reducer include `view = view + value`, `view += value` (equivalent to `view = view + value`), `view++` (equivalent to `view = view + 1`), and `view = view - value` (equivalent to `view = view + (- value)`).)

All library reducer class views enforce this restriction: `view = view * value` or `view = 3` won't even compile if `view` is the view of an addition reducer. Custom reducer classes may or may not enforce similar restrictions. If you use a reducer class that does not syntactically restrict the operations you can perform on its view, then it is up to you to understand and follow its operator restrictions.

**Performance**

When used judiciously, reducers can incur little or no runtime performance cost. However, there are some performance considerations to keep in mind:

- There is a small overhead cost for accessing the view of a reducer. Remember that an assignment `*reducer = *reducer + x` has to access the view twice, while a direct modification such as `*reducer += x` only accesses it once.
- The efficiency of reducers relies on the assumption that creating and merging view instances is cheap. If the identity and reduce operations do not have small constant execution times, then the performance benefits of parallel execution may be lost in the overhead of view management.
- There is some overhead at a `cilk_sync` for every reducer in the strands being synched, regardless of whether new views instances were created for them. This can be important if you use many reducers (for example, a large array of reducers).

**Reducer Library**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The provided reducer library contains the reducers shown in the following table. Note that the name in the first column is the name of the monoid class; the corresponding reducer would be written as `reducer<monoid>`.

A description of each reducer is described in the comments that appear in the corresponding header file.
In the following table, the second column shows each reducer’s identity element and the third column shows the Update operation (there may be several).

<table>

**Using Reducers - More Examples**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The following shows how to use a variety of reducers, including the String and List reducers.

**String Reducer**

To build strings of 8-bit characters, use `reducer<op_string>` as the update operation. For strings of 16-bit or 32-bit characters, use `reducer<op_basic_string>` or `reducer<op_wstring>`.

This example demonstrates how reducers work with the runtime to preserve serial semantics. In a serial for loop, the reducer concatenates each of the characters 'A' to 'Z', and then prints out:

The result string is: ABCDEFGHIJKLMNOPQRSTUVWXYZ

The `cilk_for` loop uses a divide-and-conquer algorithm to break this into two halves, and then break each half into two halves, until it gets down to a reasonable size chunk of work. Therefore, the first worker might build the string "ABCDEF", the second might build "GHIJKLM", the third might build "NOPQRS", and the fourth might build "TUVWXYZ". The runtime system calls the reducer's reduce method so that the final result is a string containing the letters of the English alphabet in order.

String concatenation is associative (but not commutative); the order of operations is not important. For instance, the following two expressions are equal:

- "ABCDEF" concat ("GHIJKLM" concat ("NOPQRS" concat "TUVWXYZ"))
- ("ABCDEF" concat "GHIJKLM") concat ("NOPQRS" concat "TUVWXYZ")

The result is always the same, regardless of how `cilk_for` creates the work chunks.
The call to `get_value()` performs the reduce operation and concatenates the substrings into a single output string. Why use `get_value()` to fetch the string? It makes you think about whether fetching the value at this time makes sense. You could fetch the value whenever you want, but, in general, you should not. The result might be an unexpected intermediate value, and, in any case, the intermediate value is meaningless. In this example, the result might be "GHijklmnopqrs", the concatenation of "GHIJklm" and "nopqrs".

Intel® Cilk™ Plus reducers provide serial semantics; these serial semantics are only guaranteed at the end of the parallel calculation, such as at the end of a `cilk_for` loop, after the runtime system has performed all the reduce operations. You should not call `get_value()` within the `cilk_for` loop; the value is unpredictable and meaningless since results from other loop iterations are being combined (reduced) with the results in the calling iteration.

Unlike the previous example, which adds integers, the reduce operation is not commutative. You could use similar code to append (or prepend) elements to a list using the reducer library's `reducer_list_append`, as is shown in the example in the next section.

```c++
#include <cilk/cilk.h>
#include <cilk/reducer_string.h>
#include <iostream>

int main()
{
  //...
  cilk::reducer<cilk::op_string> result;
  cilk_for (std::size_t i = 'A'; i < 'Z'+1; ++i){
    *result += (char)i;
  }
  std::cout << "The result string is: "
            << result.get_value() << std::endl;
  return 0;
}
```

In this and other examples, each loop iteration only updates the reducer once; however, you can have several updates in each iteration. For example:

```c++
#include <cilk/cilk.h>
#include <cilk/reducer_list.h>
#include <iostream>

int main()
{
  //...
  cilk::reducer<op_list_append<char> > result;
  cilk_for (std::size_t i = 'A'; i < 'Z'+1; ++i){
    *result += (char)i;
    *result += tolower((char)i);
  }
  std::cout << "String = ";
  std::list<char> r;
  r = result.get_value();
```

This is valid and produces the following string:

AaBb...Zz

**List Reducer (With User-Defined Type)**

`reducer<op_list_append>` creates lists, using the STL list append method as the update operation. The identity is the empty list. The example here is almost identical to the previous string example. The `reducer<op_list_append>` declaration does, however, require a type, as shown in the following code.

```c++
#include <cilk/cilk.h>
#include <cilk/reducer_list.h>
#include <iostream>

int main()
{
  //...
  cilk::reducer<op_list_append<char> > result;
  cilk_for (std::size_t i = 'A'; i < 'Z'+1; ++i){
    result->push_back ((char)i);
  }
  std::cout << "String = ";
  std::list<char> r;
  r = result.get_value();
```
for (std::list<char>::iterator i = r.begin();
     i != r.end(); ++i){
    std::cout << *i;
}
std::cout << std::endl;
}

Reducers in Recursive Functions

Reducers are not limited to update operations within a cilk_for loop. Reducers can work with arbitrary control flow, such as recursively spawned functions. This example illustrates how a reducer can be used to create an in-order list of elements in a tree. The final list will always contain the elements in the same order as in a serial execution, regardless of the number of cores or how the computation is scheduled.

```
#include <cilk/reducer_list.h>
Node *target;
cilk::reducer<op_list_append<int> > output_list;
...
// Output the tree with an in-order walk
void walk (Node *x)
{
    if (NULL == x)
        return;
    cilk_spawn walk (x->left);
    output_list->push_back (x->value);
    walk (x->right);
}
```

Advanced Topic: How to Write a New Reducer

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

You can write a custom reducer if none of the supplied reducers satisfies your requirements.

Any of the supplied reducers can be used as models for developing new reducers, although some of these examples are relatively complex. The implementations are found in the reducer_*\.h header files in the include/cilk directory of the installation.

Additional examples are provided in the following sections.

The basic reducer infrastructure is in include/cilk/reducer.h.

Monoids

In mathematics, a monoid comprises a set of values $T$, an associative operation $OP$ on those values, and an identity $I$ value with respect to the operation. That is, $(T, OP, I)$ is a monoid if:

- $OP$ is associative: for every $x, y, \text{ and } z$ in $T$, $x OP (y OP z) = (x OP y) OP z$
- $I$ is the identity for $OP$: for every $x$ in $T$, $x OP I = I op x = x$

Examples of monoids include the following:

- Values = the set of all integers; Operation = addition; Identity = 0.
- Values = the set of all 32-bit unsigned integers; Operation = addition modulo $2^{32}$; Identity = 0.
- Values = the set of all strings; Operation = concatenation; Identity = the empty string.

A reducer is always built around a monoid. That is, it computes a final value by combining a set of values with an operator; it relies on the associativity of the operator to be able to recombine parts of the combination in parallel; and it relies on having an identity value to be able to initialize the accumulator variables for the partial computations.

Components of a Reducer

A reducer can be broken into these logical parts:
• The "value type" is the type of the value computed by the reducer.
• The "view" class represents the accumulator variable within the reducer. In many cases, the view class is (or contains) just a value of the value type. For example, the view class of a reducer<op_add> that computes the sum of a collection of int values just contains an int value. However, the view class may also contain additional information to represent aspects of the computation that are not part of the final computed value. For example, the view class of a reducer<op_string> that computes the concatenation of a collection of strings contains a list of substrings that haven’t yet been combined.

The reducer directly contains one instance of the view class (the "leftmost view"); other view instances are created and destroyed as strands start and finish executing in parallel.
• The "monoid" class represents the mathematical monoid that the reducer is built around. It defines the value type and provides the identity() and reduce() functions used by the reducer when creating and merging views, as well as some functions to handle memory allocation of views. See the discussion below.
• The "reducer" class is the cilk::reducer class template, instantiated with the monoid (cilk::reducer<Monoid>). A reducer object contains a monoid object and the leftmost view, manages the interaction with the runtime system, and provides access to the view instance for the current strand during execution.

The Monoid Class
A monoid class provides the information needed by the reducer class to create, initialize, merge, and destroy view instances. It must define types value_type, the value type of the reducer, and view_type, the view class for the reducer, and the following functions which may be either static or const:

<table>
<thead>
<tr>
<th>Monoid Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reduce(value_type *left, value_type *right)</td>
<td>evaluates *left = *left OP *right; leaves *right in an unspecified, but valid state</td>
</tr>
<tr>
<td>identity(value_type *p)</td>
<td>constructs the identity value into the uninitialized memory pointed to by p</td>
</tr>
<tr>
<td>destroy(value_type *p)</td>
<td>calls the value_type destructor on the object pointed to by p</td>
</tr>
<tr>
<td>allocate(size)</td>
<td>returns a pointer to size bytes of raw memory</td>
</tr>
<tr>
<td>deallocate(p)</td>
<td>deallocates the raw memory at p</td>
</tr>
</tbody>
</table>

Any class that provides these definitions can be used as a monoid class, but in practice, a monoid class is always defined as a subclass of cilk::monoid_base<Value, View=Value>, which defines view and value types to be View and Value and defines the allocate(), destroy(), and deallocate() functions using the new operator. A class derived from monoid_base needs to declare and implement only the identity() and reduce() functions.

The reduce() function is not required to leave any particular value in its right argument view, but it must leave it in a valid state so that it can be destructed following the reduce().

Why Associativity Is Necessary
For a reducer to deterministically reproduce the serial semantics, the reduce function and the permitted operations on the view must implement an associative operation. (It does not need to be commutative.)

The serial execution of reduction computes the expression \((a_0 \ OP \ a_1 \ OP \ a_2 \ OP \ ... \ OP \ a_N)\). When the reduction is performed in parallel, that expression is broken up into a set of subexpressions which are then combined; for example, \(((a_0 \ OP \ a_1) \ OP \ ((a_2 \ OP \ a_3) \ OP \ (a_4))) \ OP \ (a_5 \ OP \ a_6 \ OP \ ... \ OP \ a_{10}) \ OP \ ...\). The partitioning into subexpressions, and the order in which the subexpressions are combined, is unpredictable, and can vary from one run of the program to another. However, If OP is associative, it does not matter: regardless of how the expression is broken up, and in what order the subexpressions are associated, the result will be the same.
WritingReducers - A Singly-Linked List

Here is a simple singly-linked list created in a loop. The example shows code to make the loop parallel by using a cilk_for, but it will not work, because there will be data races between the list node updates. To create a value incrementally in parallel, use of a reducer is required.

```cpp
#include <cilk/cilk.h>
#include <iostream>

// Singly-linked list.

struct IntListNode {
    int data;
    IntListNode* link;
};

// Compute a value. (Probably does something more interesting in
// a real program.)

int compute(int i) {
    return i;
}

// Create a list.

IntListNode* make_list(int n) {
    IntListNode* list = 0;
    for (int i = 0; i < n; ++i) {
        IntListNode* node = new IntListNode;
        node->data = compute(i);
        if (list) { list->link = node; }
        list = node;
    }
    return list;
}
```

Conceptual Behavior

<table>
<thead>
<tr>
<th>original</th>
<th>equivalent</th>
<th>equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = 0;</td>
<td>x1 = 0;</td>
<td>x1 = 0;</td>
</tr>
<tr>
<td>x += 3;</td>
<td>x1 += 3;</td>
<td>x1 += 3;</td>
</tr>
<tr>
<td>x++;</td>
<td>x1++;</td>
<td>x1++;</td>
</tr>
<tr>
<td>x += 4;</td>
<td>x1 += 4;</td>
<td>x2 = 0;</td>
</tr>
<tr>
<td>x++;</td>
<td>x1++;</td>
<td>x2 += 4;</td>
</tr>
<tr>
<td>x += 5;</td>
<td>x1 += 5;</td>
<td>x2 += 5;</td>
</tr>
<tr>
<td>x += 9;</td>
<td>x2 = 0;</td>
<td>x2 += 5;</td>
</tr>
<tr>
<td>x += 2;</td>
<td>x2 += 9;</td>
<td>x2 += 9;</td>
</tr>
<tr>
<td>x += 6;</td>
<td>x2 += 2;</td>
<td>x2 += 2;</td>
</tr>
<tr>
<td>x += 5;</td>
<td>x2 += 6;</td>
<td>x2 += 6;</td>
</tr>
<tr>
<td>x = x1 + x2;</td>
<td>x = x1 + x2;</td>
<td></td>
</tr>
</tbody>
</table>

If you don’t “look” at the intermediate values, the result is determinate, because addition is associative.
node->link = list;
    list = node;
}
return list;
}

// Use a list. (Probably does something more interesting in a
// real program.)
//
void print_list(IntListNode* list)
{
    for (IntListNode* node = list; node; node = node->link)
        std::cout << node->data << "\n";
}

int main()
{
    IntListNode* list = make_list(20);
    print_list(list);
    // Code to deallocate list should go here
}

The first step in creating a reducer is to identify the monoid. The data type here is a singly-linked list of integers, represented by \texttt{IntListNode} objects. Since parallelizing the computation will result in creating and combining multiple sublists, the associative operation must be list concatenation. The identity value for list concatenation is the empty list. Adding an object at the beginning of a list is equivalent to concatenating a new singleton list containing the object to be added at the front of the list (\texttt{list = \{x\} || list}), so the reduce operation must be "left = right || left".

How is the list to be represented? Is the view type different from the value type? A singly-linked list can be uniquely represented by a pointer to its first node (or a null pointer for an empty list), and this is what is returned from the \texttt{make_list} function and passed to the \texttt{print_list} function. However, there is no efficient way to concatenate two lists represented just by pointers to their heads, so the view type needs both a head and a tail pointer.

So this is the structure of a monoid. The value type is a pointer to the first node in the list, or \texttt{null} for an empty list. The view is a (head, tail) pointer pair, and provides an operation to add a new value to the list. The monoid's identity function initializes an empty-list view, and its \texttt{reduce()} function concatenates the lists represented by two views.

Here is the resulting parallel code using the new reducer:

```cpp
#include <cilk/cilk.h>
#include <cilk/reducer.h>
#include <iostream>

//  Singly-linked list.
//
struct IntListNode {
    int data;
    IntListNode* link;
};

class IntListMonoid;          // forward declaration

//  View class.
//
class IntListView {
    friend class IntListMonoid; // for the identity and reduce functions
```
IntListNode* head;
IntListNode* tail;
public:
  void add_value(int x) {
    IntListNode* node = new IntListNode;
    node->data = x;
    node->link = head;
    head = node;
    if (!tail) tail = node;
  }
  IntListNode* get_value() const { return head; }
};

// Monoid class.
//
struct IntListMonoid : public cilk::monoid_base<IntListNode*, IntListView> {  
  // Set *view to the empty list.
  //
  static void identity(IntListView* view) {
    view->head = view->tail = 0;
  }

  // Move the right list to the beginning of the left list.
  // Leave the right list empty.
  //
  static void reduce(IntListView* left, IntListView* right) {
    if (right->head) {
      right->tail->link = left->head;
      left->head = right->head;
      right->head = right->tail = 0;
    }
  }
};

// Compute a value. (Probably does something more interesting in
// a real program.)
//
int compute(int i)
{
  return i;
}

// Create a list.
//
IntListNode* make_list(int n)
{
  cilk::reducer<IntListMonoid> list;
  cilk_for (int i = 0; i < n; ++i) {
    list->add_value(i); // "list->" accesses the view
  }
  return list.get_value(); // get_value() is a reducer function
}

// Use a list. (Probably does something more interesting in a
// real program.)
void print_list(IntListNode* list)
{
    for (IntListNode* node = list; node; node = node->link)
        std::cout << node->data << "\n";
}

int main()
{
    IntListNode* list = make_list(20);
    print_list(list);
    // Code to deallocate list should go here
}

For reducers with simple views like this one, the coding can be simplified further. In the view class:

- Define `value_type`.
- Ensure that the default view constructor initializes the view with the identity value.
- Define a `reduce()` function to merge the value of another view with the value of this view.

Then use the `monoid_with_view` class instead of `monoid_base`, and you do not need to specialize the monoid class at all:

```cpp
// View class.
//
class IntListView {
    IntListNode* head;
    IntListNode* tail;

public:
    typedef IntListNode* value_type;
    IntListView() : head(0), tail(0) {};
    void reduce(IntListView* right) {
        if (right->head) {
            right->tail->link = this->head;
            this->head = right->head;
            right->head = right->tail = 0;
        }
    }
    void add_value(int x) {
        IntListNode* node = new IntListNode;
        node->data = x;
        node->link = head;
        head = node;
        if (!tail) tail = node;
    }
    IntListNode* get_value() const { return head; }
};

// Monoid class.
//
typedef cilk::monoid_with_view<IntListView> IntListMonoid;
```

**Holders**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.
A holder is a hyperobject that isolates parallel uses of a common variable in cases where it is not necessary to preserve changes from different parallel strands. Each parallel strand will see and manipulate a different view of the holder, just as in the case of a reducer.

A holder is similar to thread-local storage but is specifically designed to work with the fork-join structure of Intel® Cilk™ Plus.

A holder has the following characteristics:

- The view of a holder before the first spawn within a function is the same as the view after each sync (as in the case of a reducer).
- The view of a holder within the first spawned child of a function (or the first child spawned after a sync) is the same as the view on entry to the function.
- The view of a holder before entering a cilk_for loop is the same as the view during the first iteration of the loop and the view at the end of the loop.
- The value stored in the view of a holder in the continuation of a spawn or at the beginning of an arbitrary iteration of a cilk_for loop is non-deterministic. It is generally recommended that the holder be explicitly placed into a known state in these situations.

A holder can be used as an alternative to parameter passing because it can replace non-local variables without massive refactoring. A holder takes advantage of the fact that, most of the time, a holder view does not change after a spawn or from one iteration of a parallel for loop to the next (stealing is the exception). When the holder view is a large object that is expensive to construct, this optimization can save significant time by avoiding the creation of a separate local object for each view.

In addition, a holder using the "keep last" policy has the same value after a sync as the serialization of the same program. This characteristic often allows the program to avoid recomputing a value.

Using Holders - An Example

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

This example illustrates the use of a holder.

Function compute() is a complex function that computes a value using a memoized algorithm, storing intermediate results in a hash table. compute() calls several other functions, each of which calls several other functions, all of which share a global hash table. In all, there are over a dozen functions with a total of about sixty references to the hash table.

```cpp
hash_table<int, X> memos;
void h(const X& x);  // Uses memos
double compute(const X& x)
{
    memos.clear();
    // ...
    memos[i] = x;
    ...  
    g(i); // Uses memos
    // ...
    std::for_each(c.begin(), c.end(), h); // Call h for each element of c
}
int main()
{
    const std::size_t ARRAY_SIZE = 1000000;
    extern X myArray[ARRAY_SIZE];
    for (std::size_t i = 0; i < ARRAY_SIZE;++i)
    {
        compute(myArray[i]);
    }
}
```

To use Intel® Cilk™ Plus in the above example, replace the for loop in main with a cilk_for.
Although the hash table is cleared on entry to each call to `compute()`, and although the values stored in the hash table are no longer used after `compute()` returns, the use of the hash table as a global variable prevents `compute()` from being called safely in parallel. One way to remedy this is to make `memos` a private variable within the `cilk_for` loop and pass it down to the actual computation, so that each loop iteration has its own private copy:

```cpp
cilk_for (std::size_t i = 0; i < ARRAY_SIZE; ++i)
{
    hash_table<int,X> memos;
    compute(myArray[i], memos);
}
```

This approach requires changing the signature of `compute`, `h`, `g` and every other function that references `memos` as well as any function that calls those functions. This change to `compute` and other functions might expose an implementation detail that was not part of the original abstract interface. In addition, the function `h` is called through a templated algorithm, `for_each`, which requires a fixed interface. Finally, there is constructor and destructor overhead for `hash_table` each time through the loop.

The alternative approach is to replace `memos` with a holder. The holder will be available to all of the functions involved, but will not cause a race between parallel loop iterations. For this to work, you need to replace each use of the `memos` variable with use of the holder:

```cpp
cilk::holder<hash_table<int, X>> memos_h;
void h(const X x); // Uses memos_h
double compute(const X& x)
{
    *memos_h->clear(); // dereference the holder to access its content

    (*memos_h)[i] = x; // dereference the holder to access its content

    g(i); // Uses memos_h

    std::for_each(c.begin(), c.end(), h); // Call h for each element of c
}
```

Like a reducer, a holder must be "dereferenced" to access the value it holds. If this requires too much recoding, it is possible to wrap the holder in a class that has the same interface as `hash_table` but redirects all calls to the holder:

```cpp
template <typename K, typename V>
class hash_table_holder
{
private:
    cilk::holder<hash_table<K, V>> m_holder;
public:
    void clear() { m_holder()->clear(); }
    V& operator[](const K& x) { return (*m_holder)[x]; }
    std::size_t size() const { return m_holder->size(); }
    // etc. ...
};
```

Using the above wrapper, the original code can be left unchanged except for replacing `hash_table` with `hash_table_holder` and replacing `for` with `cilk_for`:

```cpp
hash_table_holder<int, X> memos;
void h(const X& x); // Uses memos
double compute(const X& x)
{
    ```
memos.clear(); // Calls hash_table_holder::clear().
   // ...
}

All of the changes shown above have no benefit over the use of thread-local storage (except, perhaps for
portability). However, consider the case where one of the functions uses cilk_spawn:

```cpp
void h(const X& x) {
    Y y = x.nested();
    double d, w;
    if (y) {
        w = cilk_spawn compute_width(y); // May use 'memos'
        d = compute_depth(y); // Does not use 'memos'
        cilk_sync;
        compute(y); // recursive call. Uses 'memos'
    }
}
```

In the above, the view of the holder within compute_width is the same as the view on entry to h. More
importantly, the view of the holder within the recursive call to compute is the same as the view on entry to
h, even if a different worker is executing the recursive call. Thus, the holder view within an Intel® Cilk™ Plus
program has benefits not achieved using thread-local storage.

**Holder Syntax**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more
information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Holder syntax is as follows:

```cpp
#include <cilk/holder.h>
enum holder_policy {
    holder_keep_indeterminate,
    holder_keep_last,
    holder_keep_last_copy,
    holder_keep_last_swap,
    holder_keep_last_move
};
template <typename Type,
    holder_policy Policy = holder_keep_indeterminate,
    typename Allocator = std::allocator<Type> >
class holder
{
    // Default constructor uses default-initialization for both the
    // leftmost view and each identity view.
    holder(const Allocator& alloc = Allocator());

    // Construct from an exemplar that is used to initialize both the
    // leftmost view and each identity view.
    holder(const Type& v, const Allocator& alloc = Allocator());

    // Construct from a functor that is used to initialize both the
    // leftmost view and each identity view. The functor, 'f', must be be
    // invokable using the expression 'Type x = f()'.
    template <typename Func>
    holder(const Func& f, const Allocator& alloc = Allocator());

    // Return the current view
```
```cpp
Type& view();
Type const& view() const;
Type& operator()();
Type const& operator()() const;
};
```

**Template Parameters:**

- **Type**: The type of object held in the holder
- **Policy**: The policy for deciding the value of the holder after a sync. Valid keywords are the following:
  - `holder_keep_indeterminate`: The value of the holder is indeterminate (most efficient.)
  - `holder_keep_last`: The value of the holder is the last value that would have been set in the program serialization. The Intel® Cilk™ Plus library will choose one of the policies below using compile-time heuristics that attempt to pick the most efficient.
  - `holder_keep_last_copy`: The value of the holder is set by copy-assigning the last value that would have been set in the program serialization.
  - `holder_keep_last_swap`: The value of the holder is set by invoking the `Type::swap(Type&)` member function.
  - `holder_keep_last_move`: The value of the holder is set by move-assigning the last value that would have been set in the program serialization (C++11-mode only.)
- **Allocator**: A memory allocator used to allocate each holder view.

---

**Operating System Considerations**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

**Using Other Tools with Intel® Cilk™ Plus Programs**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Because Intel® Cilk™ Plus programs have a stack layout that is different from the standard C and C++ conventions, tools that understand the binary program executable (including memory checkers such as valgrind and code coverage tools) may not work with the parallel Intel® Cilk™ Plus programs. Often, it is sufficient to run your program using only one worker (by setting the `CILK_NWORKERS` environment variable to 1). If that doesn't work, you can use such tools on the serialization of the Intel® Cilk™ Plus program.

**General Interaction with OS Threads**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

When working with OS threads, be aware of the following.

**A worker thread is an OS thread.**

The runtime system allocates a set of "worker" threads using native OS facilities.

**Intel® Cilk™ Plus programs do not always use 100% of all available processors.**

When running an Intel® Cilk™ Plus program, you may observe that the program appears to consume all the resources of all the processors in the system, even when there is no parallel work to perform. This effect is apparent with programs such as the Windows* Task Manager "Performance" tab; all CPUs may appear to be busy, even if only one strand is executing.
In fact, the runtime scheduler does yield the CPUs to other programs. If there are no other programs requesting the processor, then the worker will be immediately run again to look for work to steal, and this is what makes the CPUs appear to be busy. Therefore, the program appears to consume all the processors all the time, but there is no adverse effect on the system or other programs.

**Use caution when using native threading interfaces.**

Intel® Cilk™ Plus strands are not operating-system threads. A strand never migrates between workers while running. However, the worker may change after a `cilk_spawn`, `cilk_sync` or `cilk_for` statement, since these statements terminate one or more strands and create one or more new strands. Furthermore, you do not have any control over which worker will run a specific strand.

This can impact a program in several ways, most importantly:

- Do not use Windows* thread local storage or Linux*/macOS* Pthreads thread-specific data, because the OS thread may change at a `cilk_spawn`, `cilk_sync`, or `cilk_for` (including within called functions). Instead, use other programming techniques, such as the holder reducer described earlier.
- Do not use operating system locks or mutexes across `cilk_spawn`, `cilk_sync` or `cilk_for` statements, because only the locking thread can unlock the object.

**Microsoft Foundation Classes and Intel® Cilk™ Plus Programs**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

---

**NOTE** This topic is for Windows* programmers only.

The Microsoft Foundation Classes (MFC) library depends upon thread local storage to map from its class wrappers to the GDI handles for objects. Because an Intel® Cilk™ Plus strand is not guaranteed to run on any specific OS thread, parallel code using Intel® Cilk™ Plus cannot safely call MFC functions.

There are two methods typically used to perform a computationally-intensive task in an MFC-based application:

- The user interface (UI) thread creates a computation thread to run the computationally-intensive task. The compute thread posts messages to the UI thread to update it, leaving the UI thread free to respond to UI requests.
- The computationally-intensive code is run on the UI thread, updating the UI directly and occasionally running a "message pump" to handle other UI requests.

Since the runtime system can switch operating system threads, Intel® Cilk™ Plus code must be isolated from code such as MFC that depends on Thread Local Storage.

To add a computation thread to an MFC program:

1. Create a computation thread using operating-system facilities (`_beginthreadex` or `AfxBeginThread`). All the C++ code that is to be converted to Intel® Cilk™ Plus should run in this thread. The computation thread leaves the main (UI) thread available to run the message pump for processing window messages and updating the UI.
2. Pass the handle (`HWND`) for the UI windows to the computation thread. When the computation thread needs to update the UI, it should send a message to the UI thread by calling `PostMessage`. `PostMessage` marshals and queues the message into the message queue associated with the thread that created the window handle. Do not use `SendMessage`. `SendMessage` is run on the currently executing thread, which is not the correct (UI) thread.
3. Test the C++ program to ensure that the logic and thread management are correct.
4. Add Intel® Cilk™ Plus constructs to the logic in the computation thread.
5. Before terminating, the main (UI) thread should wait for the computation thread to complete, using `WaitForSingleObject()`.
The QuickDemo sample program, supplied with the product, illustrates an Intel® Cilk™ Plus application using MFC.

Additional recommendations:

- When the main UI thread creates the computation thread, it should not wait for the thread to complete. The function that creates the computation thread should return to allow the message pump to run.
- Be sure that none of the data passed to the computation thread is allocated on the stack. If it is, it will quickly be invalidated as the computation-thread creation function returns, releasing the data.
- A data block passed to the computation thread should be freed by the computation thread when it is done, just before it sends a completion message to the UI.
- Use the PostMessage function instead of CWnd::PostMessage, as a primary reason for creating a computation thread is to avoid the MFC thread-local variables in Intel® Cilk™ Plus code.
- A (short) computation using Intel® Cilk™ Plus constructs can be called directly from the UI thread, as long as the computation behaves as a "black box" and does not attempt to communicate with the message pump or any other threads. This feature allows you to call non-interactive functions without regard to whether they use Intel® Cilk™ Plus.

Intel® Cilk™ Plus Run Time System API

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Intel® Cilk™ Plus programs require the runtime system and libraries, which are automatically linked into any program that uses Intel® Cilk™ Plus. The runtime system provides a small number of user-accessible functions for controlling details of the program's behavior.

Include cilk/cilk_api.h to declare the Intel® Cilk™ Plus runtime functions and classes. The entry points defined in this header file are described below. This header file does not define the interface to reducers. For more information on reducers, see Reducers.

__cilkrts_bump_loop_rank

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

int __cilkrts_bump_loop_rank(void);

This function ensures that no two loop iterations share a pedigree.

Each iteration of a cilk_for loop should start with a different pedigree. However, because of the way that the runtime breaks cilk_for loops into grains (see cilk_for), the pedigree can remain unchanged over consecutive iterations within a grain. Calling __cilkrts_bump_loop_rank() at the end of each loop iteration ensures that no two loop iterations will share a pedigree.

The following guidelines apply to __cilkrts_bump_loop_rank():

- Do not call __cilkrts_bump_loop_rank() unless you intend to read the pedigree during the loop; doing so may inhibit vectorization of the loop.
- Do not call __cilkrts_bump_loop_rank() more than once within the loop; doing so will create overlapping pedigrees across grains.

__cilkrts_bump_worker_rank

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

int __cilkrts_bump_worker_rank(void);

This function advances the current pedigree (see __cilkrts_get_pedigree). It returns 0 if the call was successful, non-zero if it failed.
Normally, there is a one-to-one mapping between pedigrees and strands.
You can think of a call to this function as either:
• mapping multiple pedigrees to the current strand, or
• ending the current strand and beginning a new strand with a different pedigree

__cilkrts_end_cilk
Intel Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

void __cilkrts_end_cilk(void);
This function shuts down and deallocates all Intel® Cilk™ Plus states. The runtime system will abort the application if Intel® Cilk™ Plus is still in use by this thread. Otherwise, the runtime system will wait for all other threads using Intel® Cilk™ Plus to exit.

Use of __cilkrts_end_cilk() will allow you to change the number of workers. With no spawning function executing, call __cilkrts_end_cilk(), then call __cilkrts_set_param() to set the desired number of workers. The runtime system will automatically restart when needed to execute a cilk_spawn or cilk_for statement, or when you call __cilkrts_init().

__cilkrts_get_nworkers
Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

int __cilkrts_get_nworkers(void);
This function returns the number of worker threads assigned to handle Intel® Cilk™ Plus tasks. If called in serialized code, it will return 1.

The range of valid worker IDs is 0 to __cilkrts_get_nworkers()-1.

__cilkrts_get_pedigree
Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

__cilkrts_get_pedigree(void);
This function returns the latest significant node in the current pedigree.

Intel® Cilk™ Plus identifies a strand of execution by a pedigree, a sequence of 64-bit integers that reflects the history of spawns and syncs in the computation leading up to that strand. Two strands always have distinct pedigrees. The current pedigree for a strand will change at each cilk_spawn, cilk_sync, or cilk_for, and will be different in each grain of a cilk_for loop. The current pedigree also changes after any call to __cilkrts_bump_worker_rank().

The pedigree is represented as a linked list of pedigree nodes, each of type __cilkrts_pedigree. This list is singly linked and stores the pedigree nodes in reverse order, that is, from the least significant node to the most significant node. Each pedigree node is a structure containing a 64-bit integer rank and a const "parent" pointer to the next (more significant) pedigree node, or null if the node is the end of the list. The return value of this function is a copy of the least significant node of the current pedigree, that is, the head of the list.

In a serial execution of a program, the pedigrees increase lexicographically at each strand transition. In any parallel execution of the same program that generates the same set of strands as the serial execution, the pedigrees of the corresponding strands in the two executions should match.

The following guidelines apply to __cilkrts_get_pedigree():

2140
Applications that want to inspect the pedigree should walk the linked list of `__cilkrts_pedigree` nodes, saving the rank values.

Applications should never modify the entries in the `__cilkrts_pedigree` list. The list remains valid for traversal until the end of the function that called `__cilkrts_get_pedigree()`.

Applications should never save pointers to `__cilkrts_pedigree` entries. To save the pedigree, applications should copy the pedigree rank values into their own structures.

For an Intel® Cilk™ Plus program that executes using multiple OS threads not created by the Intel® Cilk™ Plus runtime, strands that execute on different OS threads differ in their most significant pedigree node. The runtime makes no guarantees that the most significant pedigree node will be the same across multiple runs of a such a program.

Applications should generally rely only on the results of comparing two pedigrees, rather than the specific rank values in a pedigree. The rank values of pedigrees may change slightly if a program is compiled using different flags, in part because redundant or implicit `cilk_sync` statements may be eliminated during optimizations.

---

`__cilkrts_get_total_workers`

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

```c
int __cilkrts_get_total_workers (void);
```

In order to allow more than one user-created thread to share the same set of workers, the runtime system may allocate more worker slots than are active at a given time. The function `__cilkrts_get_total_workers` returns the total number of worker slots, including those that are not actively in use. If called in serialized code, `__cilkrts_get_total_workers` returns 1.

---

`__cilkrts_get_worker_number`

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

```c
int __cilkrts_get_worker_number (void);
```

The function `__cilkrts_get_worker_number` returns a small integer indicating the Intel® Cilk™ Plus worker on which the function is executing. The return value is in the range 0 to "__cilkrts_get_nworkers()-1. You can simulate “worker-local storage” by creating an array of size `__cilkrts_get_nworkers()`, with each element indexed by a worker ID. If more than one user-created thread calls `__cilkrts_get_worker_number`, they may get identical results (since worker IDs are not unique across user threads). If called in serialized code, `__cilkrts_get_worker_number` returns zero.

---

`__cilkrts_init`

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

```c
void __cilkrts_init(void);
```

This function allocates Intel® Cilk™ Plus data structures, starting the runtime. This function is documented for completeness; it should never be necessary to call this function explicitly, as the runtime system calls it automatically when needed (for example, to execute the first `cilk_spawn` or `cilk_for` in a program).

After the Intel® Cilk™ Plus runtime has been started, any attempts to change the number of workers using `__cilkrts_set_param()` will return an error.
**Intel Cilk™ Plus** is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel Cilk™ Plus.

```c
int __cilkrts_set_param(const char* name, const char* value);
```

This function controls parameters of the Intel Cilk™ Plus runtime system. The two string parameters form a name/value pair. The following name argument is recognized:

- **nworkers**: The value argument specifies the number of worker threads to use, as a decimal number or, if prefixed by 0x or 0, as a hexadecimal or octal number, respectively. If this function is not called, the worker count is obtained from the CILK_NWORKERS environment variable, if present. Otherwise, the worker count defaults to the number of processors available. This function is effective only before the first call to a function containing a `cilk_spawn` or `cilk_for`. If you need precise control over the number of workers, exit the parallel region, shut down the Intel Cilk™ Plus runtime using `__clkrts_end_cilk()`, then set the number of workers.

The return value is zero on success and a non-zero value on failure. Failures may be caused by a variety of conditions including an unrecognized argument, an illegal value, or calling at an incorrect time.

For an example using `__cilkrts_set_param`, see Debugging an Intel® Cilk™ Plus Program.

Windows* only: `__cilkrts_set_param_w()` provides a wide character interface for Windows programmers. Its parameters are the same as `__cilkrts_set_param()`.

### Understanding Race Conditions

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

**Data Races**

A determinacy race occurs when two parallel strands access the same memory location and at least one strand performs a write operation. The program result depends on which strand "wins the race" and accesses the memory first.

A data race is a special case of a determinacy race. A data race is a race condition that occurs when two parallel strands, holding no locks in common, access the same memory location and at least one strand performs a write operation. The program result depends on which strand "wins the race" and accesses the memory first.

If the parallel accesses are protected by locks, there is no data race. However, a program using locks may not produce deterministic results. A lock can ensure consistency by protecting a data structure from being visible in an intermediate state during an update, but does not guarantee deterministic results.

For example, consider the following program:

```c
int a = 2; // declare a variable that is
           // visible to more than one worker

void Strand1()
{
    a = 1;
}
```
Because Strand1(), Strand2() and Strand3() may run in parallel, the final value of $a$ and result can vary, depending on the order in which they run.

Strand1() may write the value of $a$ before or after Strand2() reads $a$, so there is a read/write race between Strand1() and Strand2().

Strand3() may write the value of $a$ before or after Strand1() writes $a$, so there is a write/write race between Strand3() and Strand1().

Some data races are benign. In other words, although there is a race, the race does not affect the output of the program.

Here is a simple example:

```c
bool bFlag = false;
cilk_for (int i=0; i<N; ++i) {
  if (some_condition()) bFlag = true;
}
if (bFlag) do_something();
```

This program has a write/write race on the $bFlag$ variable. However, all of the write operations are writing the same value (true) and the value is not read until after the `cilk_sync` that is implicit at the end of the `cilk_for` loop.

In this example, the data race is benign. No matter what order the loop iterations execute, the program produces the same result.

### Resolving Data Races

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

There are a number of ways to resolve a race condition:

- Fix a bug in your program
- Use local variables instead of global variables
- Restructure your code
- Change your algorithm
- Use reducers
- Use a lock
Fix a bug in your program

A race condition can be caused by a bug in the program logic. For instance, a race can occur if a recursive sort calls use an overlapping region, and, therefore, references the same memory location in parallel. The solution is to fix the application.

Use local variables instead of global variables

Consider the following program:

```cpp
#include <cilk/cilk.h>
#include <iostream>
const int IMAX=5;
const int JMAX=5;
int a[IMAX * JMAX];

int main()
{
    int idx;

cilk_for (int i=0; i<IMAX; ++i)
    {
        for (int j=0; j<JMAX; ++j)
        {
            idx = i*JMAX + j; // This is a race.
            a[idx] = i+j;
        }
    }

    for (int i=0; i<IMAX*JMAX; ++i)
        std::cout << i << " " << a[i] << std::endl;

    return 0;
}
```

This program has a race on the `idx` variable, because it is accessed in parallel in the `cilk_for` loop. Because `idx` is only used inside the loop, it is easy to resolve the race by making `idx` local within the loop:

```cpp
int main()
{
    // int idx;                  // Remove global
    cilk_for (int i=0; i<IMAX; ++i)
    {
        for (int j=0; j<JMAX; ++j)
        {
            int idx = i*JMAX + j; // Declare idx locally
            a[idx] = i+j;
        }
    }

    ...  
}
```

Restructure your code

In some cases, you can eliminate the race by a simple rewrite. Here is another way to resolve the race in the previous program:

```cpp
int main()
{
    // int idx;                // Remove global
    cilk_for (int i=0; i<IMAX; ++i)
    {
        for (int j=0; j<JMAX; ++j)
        {
            int idx = i*JMAX + j; // Declare idx locally
            a[idx] = i+j;
        }
    }
```
Change your algorithm

One of the best solutions, although not always easy or even possible, is to find an algorithm that partitions your problem such that the parallelism is restricted to calculations that cannot race.

Use reducers

Reducers are designed to be race-free objects that can be safely used in parallel. See Reducers for more information.

Use locks

Locks can be used to resolve data race conditions. The drawbacks to this approach are described in Introductions to Using Locks. There are several kinds of locks, including:

- `tbb::mutex` objects from the Intel® Threading Building Blocks library
- System locks on Windows®, Linux®, and macOS® operating systems
- Atomic instructions that are effectively short-lived locks that protect a read-modify-write sequence of instructions

The following program contains a race on `sum`, because the statement `sum=sum+i` both reads and writes `sum`:

```c
#include <cilk/cilk.h>

int main()
{
    int sum = 0;
    cilk_for (int i=0; i<10; ++i)
    {
        sum = sum + i;  // THERE IS A RACE ON SUM
    }
}
```

Using a lock to resolve the race:

```c
#include <cilk/cilk.h>
#include <tbb/mutex.h>
#include <iostream>

int main()
{
    tbb::mutex mut;
    int sum = 0;
    cilk_for (int i=0; i<10; ++i)
    {
        mut.lock();
        sum = sum + i; // PROTECTED WITH LOCK
        mut.unlock();
    }
    std::cout << "Sum is " << sum << std::endl;
    return 0;
}
```
This example is for illustration only. A reducer is typically a better way to solve this kind of race.

# Using Locks

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

You can use various synchronization mechanisms in the hardware or operating system.

The following lock terms and facts are useful:

- The following terms are interchangeable: "acquiring", "entering", or "locking" a lock (or "mutex").
- A strand (or thread) that acquires a lock is said to "own" the lock.
- Only the owning strand can "release", "leave", or "unlock" the lock.
- Only one strand can own a lock at a time.
- `tbb::mutex` is implemented using underlying OS mutex operations.

Lock contention can create performance problems in parallel programs. Additionally, while locks can resolve data races, programs using locks are often non-deterministic. Avoiding locks whenever possible is recommended.

These problems (and others) are described in detail in the following sections.

## Locks Cause Determinancy Races

Even if you properly use a lock to protect a resource (such as a simple variable or a list or other data structure), the actual order that two strands modify the resource is not deterministic. For example, suppose the following code fragment is part of a function that is spawned, so that several strands may be executing the code in parallel.

```
// Update is a function that modifies a global variable, gv.
sm.lock();
Update(gv);
sm.unlock();
```

Multiple strands will race to acquire the lock, `sm`, so the order in which `gv` is updated will vary from one program execution to the next, even with identical program input. This is the source of non-determinism, but it is not a data race as defined in Understanding Data Races.

This non-determinacy may not cause a different final result if the update is a commutative operation, such as integer addition. However, many common operations, such as appending an element to the end of a list, are not commutative, and so the result varies based on the order in which the lock is acquired.

## Deadlocks

A deadlock can occur when using two or more locks and different strands acquire the locks in different orders. It is possible for two or more strands to become deadlocked when each strand acquires a mutex that the other strand attempts to acquire.

Following is a simple example, with two strand fragments, where the aim is to move a list element from one list to another in such a way that the element is always in exactly one of the two lists. `L1` and `L2` are the two lists, and `sm1` and `sm2` are two `tbb::mutex` objects, protecting `L1` and `L2`, respectively.

```
// Code Fragment A. Move the beginning of L1 to the end of L2.
sm1.lock();
```
The deadlock would occur if one strand, executing Fragment A, were to lock \texttt{sm1} and, in another strand, Fragment B were to lock \texttt{sm2} before Fragment A locks \texttt{sm2}. Neither strand could proceed.

The common solution is to acquire the locks in exactly the same order in both fragments; for example, switch the first two lines in Fragment B. You can release the locks in the opposite order, but doing so is not necessary to avoid deadlocks.

**Lock Contention**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Parallel strands are not able to run in parallel if they concurrently attempt to access a shared lock. In some programs, locks can eliminate virtually all of the performance benefit of parallelism. In extreme cases, such programs can even run significantly slower than the corresponding single-processor serial program. Consider using a reducer if possible.

If you must use locks, consider observing these guidelines:

- Hold a synchronization object (lock) for as short a time as possible. Acquire the lock, update the data, and release the lock. Do not perform extraneous operations while holding the lock. If the application must hold a synchronization object for a long time, then reconsider whether it is a good candidate for parallelization. This guideline also helps to ensure that the acquiring strand always releases the lock.
- Release a lock at the same scope level as it was acquired. Separating the acquisition and release of a synchronization object obfuscates the duration that the object is being held and can lead to failure to release a synchronization object and deadlocks. This guideline also ensures that the acquiring strand also releases the lock.
- Do not hold a lock across a \texttt{cilk_spawn} or \texttt{cilk_sync} boundary. This includes across a \texttt{cilk_for} loop. See the following section for more explanation.
- Avoid deadlocks by ensuring that a lock sequence is always acquired in the same order. Releasing the locks in the opposite order is not necessary but can improve performance.

**Holding a Lock Across a Strand Boundary**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The best and easiest practice is to avoid holding a lock across strand boundaries. Sibling strands can use the same lock, but there are potential problems if a parent shares a lock with a child strand. The issues are as follows:

- There is no guarantee that a strand created after a \texttt{cilk_spawn} or \texttt{cilk_sync} boundary will continue to execute on the same OS thread as the parent strand. Most locking synchronization objects, such as a Windows® CRITICAL_SECTION, must be released on the same thread that allocated them.
- \texttt{cilk_sync} exposes the application to Intel® Cilk™ Plus runtime synchronization objects. These can interact with the application in unexpected ways. Consider the following code:
Consider the following code:

```cpp
#include <cilk/cilk.h>
#include <tbb/mutex.h>
#include <iostream>

void child (tbb::mutex &m, int &a)
{    m.lock();
    a++;
    m.unlock();
}

void parent(int a, int b, int c)
{    tbb::mutex m;
    try
    {
        cilk_spawn child (m, a);
        m.lock();
        throw a;
    }
    catch (...) { m.unlock(); }
}
```

There is an implied `cilk_sync` at the end of a `try` block that contains a `cilk_spawn`. In the event of an exception, execution cannot continue until all children have completed. If the parent acquires the lock before a child, the application is deadlocked since the catch block cannot be executed until all children have completed, and the child cannot complete until it acquires the lock. Using a "guard" or "scoped lock" object won’t help, because the guard object’s destructor will not run until the catch block is exited.

To make the situation worse, invisible `try` blocks are present. Any compound statement that declares local variables with non-trivial destructors has an implicit `try` block around it. Therefore, by the time the program spawns or acquires a lock, it is probably already in a `try` block.

If a function holds a lock that could be acquired by a child, the function should not do anything that might throw an exception before it releases the lock. However, since most functions cannot guarantee that they won’t throw an exception, follow these rules:

- Do not acquire a lock that might be acquired by a child strand. In other words, lock against your siblings, but not against your children.
- If you need to lock against a child, put the code that acquires the lock, performs the work, and releases the lock into a separate function and call it rather than putting the code in the same function as the spawn.
- If a parent strand needs to acquire a lock, set the values of one or more primitive types, perhaps within a data structure, then release the lock. This is safe, provided there are no try blocks, function calls that may throw (including overloaded operators), spawns or syncs involved while holding the lock. Be sure to pre-compute the primitive values before acquiring the lock.

**Performance Considerations for Intel(R) Cilk(TM) Plus Programs**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Parallel programs have numerous additional performance considerations and opportunities for tuning and improvement.
In general, the Intel® Cilk™ Plus runtime uses processor resources efficiently using a scheduling algorithm called work stealing. The work stealing algorithm is designed to minimize the number of times that work is moved from one processor to another.

Additionally, the algorithm ensures that space use is bounded linearly by the number of workers. In other words, an Intel® Cilk™ Plus program running on N workers will use no more than N times the amount of memory that is used when running on one worker.

**Granularity**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Divide and conquer is an effective parallelization strategy, creating a good mix of large and small subproblems. The work-stealing scheduler can allocate chunks of work efficiently to the cores, provided that there are not too many very large chunks or too many very small chunks. If the work is divided into just a few large chunks, there may not be enough parallelism to keep all the cores busy. If the chunks are too small, then scheduling overhead may overwhelm the advantages of parallelism.

Granularity can be an issue with parallel programs using cilk_for or cilk_spawn. If you are using cilk_for, you can control the granularity by setting the grain size of the loop. In addition, if you have nested loops, the nature of your computation will determine whether you achieve the best performance using cilk_for for inner or outer loops, or both. If you are using cilk_spawn, be careful not to spawn very small chunks of work. While the overhead of cilk_spawn is relatively small, performance will suffer if you spawn very small amounts of work.

**Optimize the Serial Program**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

The first step is to ensure that the C/C++ serial program has good performance and that normal optimization methods, including compiler optimization, have already been used.

As one simple, and limited, illustration of the importance of serial program optimization, consider the matrix_multiply example, which organizes the loop with the intent of minimizing cache line misses. The resulting code is:

```c
    cilk_for(unsigned int i = 0; i < n; ++i) {
        for (unsigned int k = 0; k < n; ++k) {
            for (unsigned int j = 0; j < n; ++j) {
                A[i*n + j] += B[i*n + k] * C[k*n + j];
            }
        }
    }
```

In multiple performance tests, this organization has resulted in a significant performance advantage compared to the same program with the two inner loops (the k and j loops) interchanged. This performance difference shows up in both the serial and Intel® Cilk™ Plus parallel programs. The matrix example has a similar loop structure. Be aware, however, that such performance improvements cannot be assured on all systems as there are numerous architectural factors that can affect performance.

**Timing Programs and Program Segments**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.
You should measure performance to find and understand bottlenecks. Even small changes in a program can lead to large and sometimes surprising performance differences. The only reliable way to tune performance is to measure frequently—preferably on a mix of different systems. Use any tool or technique at your disposal, but only true measurements will determine if your optimizations are effective.

Performance measurements can be misleading, however, so it is important to take a few precautions and be aware of potential performance anomalies. Most of these precautions are straightforward but may be overlooked in practice.

- Other running applications can affect performance measurements. Even an idle version of a common desktop application can consume processor time and distort measurements.
- If you are measuring time between points in the program, be careful not to measure elapsed time between two points if other strands could be running in parallel with the function containing the starting point.
- Dynamic frequency scaling on multicore laptops and other systems can produce unexpected results, especially when you increase worker count to use additional cores. As you add workers and activate cores, the system may adjust clock rates to reduce power consumption and therefore reduce overall performance.

**Common Performance Pitfalls**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

If a program has sufficient parallelism and burdened parallelism but still doesn't achieve good speedup, the performance could be affected by other factors. Here are a few common factors, some of which are discussed elsewhere.

- **cilk_for Grainsize Setting.** If the grain size is too large, the program's logical parallelism decreases. If the grain size is too small, overhead associated with each spawn could compromise the parallelism benefits. The Intel compiler and runtime system use a default formula to calculate the grain size. The default works well under most circumstances. If your program uses cilk_for, experiment with different grain sizes to tune performance.
- **Lock contention.** Locks generally reduce program parallelism and therefore affect performance. Lock usage can be analyzed using performance and profiling tools.
- **Cache efficiency and memory bandwidth.** Covered later in this section.
- **False sharing.** Covered later in this section.
- **Atomic operations.** Atomic operations, provided by compiler intrinsics, lock cache lines. Therefore, these operations can impact performance the same way that lock contention does. Also, since an entire cache line is locked, there can be false sharing.

**Cache Efficiency and Bandwidth**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

Good cache efficiency is important for serial programs, and it becomes even more important for parallel programs running on multicore machines. The cores contend for bus bandwidth, limiting how quickly data that can be transferred between memory and the processors. Therefore, consider cache efficiency and data and spatial locality when designing and implementing parallel programs. For example code that considers these issues, see the matrix and matrix_multiply examples cited in Optimize the Serial Program.

A simple way to identify bandwidth problems is to run multiple copies of the serial program simultaneously, one for each core on your system. If the average running time of the serial programs is much larger than the time of running just one copy of the program, it is likely that the program is saturating system bandwidth. The cause could be memory bandwidth limits or, perhaps, disk or network I/O bandwidth limits.
These bandwidth performance effects are frequently system-specific. For example, when running the matrix example on a specific system with two cores (call it "S2C"), the "iterative parallel" version may be considerably slower than the "iterative sequential" version (4.431 seconds compared to 1.435 seconds). On other systems, however, the iterative parallel version may show nearly linear speedup when tested with as many as 16 cores and workers. Here are the results on S2C:

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Sequential version</th>
<th>Parallel version</th>
<th>Speedup</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iterative Sequential</td>
<td>1.435 seconds</td>
<td>4.431 seconds</td>
<td>0.323855</td>
</tr>
<tr>
<td>Parallel Speedup</td>
<td></td>
<td></td>
<td>0.323855</td>
</tr>
</tbody>
</table>

There are multiple, often complex and unpredictable, reasons that memory bandwidth is better on one system than another (including DRAM speed, number of memory channels, cache and page table architecture, number of CPUs on a single die). Be aware that such effects are possible and may cause unexpected and inconsistent performance results. This situation is inherent to parallel programs and is not unique to Intel® Cilk™ Plus programs.

**False Sharing**

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP* or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP* or Intel® TBB Instead of Intel® Cilk™ Plus.

Multiple levels of cache, divided into cache lines, speed access to memory in modern computers. False sharing is a common problem in shared memory parallel processing. It occurs when two or more cores hold a copy of the same memory cache line.

If one core writes to a variable in a cache line, that entire cache line is invalidated on all other cores. Even though another core may not be using that data (reading or writing), it may be using another element of data on the same cache line. The second core will need to reload the line before it can access its own data again.

The cache hardware ensures data coherency, but at a potentially high performance cost if false sharing is frequent. A good technique to identify false sharing problems is to catch unexpected sharp increases in last-level cache misses using hardware counters or other performance tools.

As a simple example, consider the following:

```c
int a, b, c;
cilk_spawn f(&b);
c++;
```

The compiler will likely place the variables `a`, `b`, and `c` in the same cache line. If the variables are placed in the same cache line, false sharing will occur between variable `b` and `c` when the spawned function `f` accesses `b`, while the parent accesses `c`. Use the `avoid_false_share` attribute/declspec here; otherwise, restructure the declaration using alignment directives or by placing the variables in structs with field alignment to avoid cache line sharing.

Here’s the same code using the `avoid_false_share` attribute:

```c
__attribute__((avoid_false_share)) int b;
// For Windows* use __declspec(avoid_false_share) int b;
```
In another simple example, consider a spawned function with a for loop that increments array values. The array is volatile to force the compiler to generate store instructions rather than hold values in registers or optimize the loop.

```c
volatile int x[32];
void f(volatile int *p)
{
  for (int i = 0; i < 100000000; i++)
  {
    ++p[0];
    ++p[16];
  }
}
int main()
{
  cilk_spawn f(&x[0]);
  cilk_spawn f(&x[1]);
  cilk_spawn f(&x[2]);
  cilk_spawn f(&x[3]);
  cilk_sync;
  return 0;
}
```

The x[] elements are four bytes wide, and a 64-byte cache line would hold 16 elements. There are no data races, and the results will be correct when the loop completes. However, cache line contention as the individual strands update adjacent array elements can degrade performance, sometimes significantly.

avoid_false_share attribute

Memory Allocation Bottlenecks
Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

The memory allocation system used by default on some Linux*, macOS*, and Windows* operating systems is known to be a bottleneck in parallel programs. When the program allocates or deallocates memory from the heap (e.g., using malloc, free, new, or delete) on these systems, the runtime library uses a mutex lock to prevent corruption of the heap data structures. Even on a single processor, this lock is quite expensive. However, when multiple strands try to allocate or deallocate memory simultaneously, the resulting contention on the lock can effectively kill much of the parallelism in the program. This means that the heap allocator does not scale to multiple processors.

One solution to this problem is to use a scalable memory allocator, such as the one provided by the Intel® Threading Building Blocks library (Intel® TBB). The TBB Scalable Memory Allocator is recommended for use with Intel® Cilk™ Plus programs.

Glossary

Intel® Cilk™ Plus is a deprecated feature. Use OpenMP® or Intel® Threading Building Blocks instead. For more information see Migrate Your Application to use OpenMP® or Intel® TBB Instead of Intel® Cilk™ Plus.

The Glossary is an alphabetical list of important terms used in this programmer’s guide and gives brief explanations and definitions.

atomic
Indivisible. An instruction sequence executed by a strand is atomic if it appears at any moment to any other strand as if either no instructions in the sequence have been executed or all instructions in the sequence have been executed.

**chip multiprocessor**

A general-purpose multiprocessor implemented as a single multicore chip.

**cilk_for**

A keyword that indicates a for loop whose iterations can be executed independently in parallel.

**cilk_spawn**

A keyword that indicates that the named subroutine can execute independently and in parallel with the caller.

**cilk_sync**

A keyword that indicates that all functions spawned within the current function must complete before statements following the cilk_sync can be executed.

**commutative operation**

An operation (op), over a type (T), is commutative if a op b = b op a for any two objects, a and b, of type T. Integer addition and set union are commutative, but string concatenation is not.

**concurrent agent**

A processor, process, thread, or other entity that executes a program instruction potentially simultaneously with other similar concurrent agents.

**core**

A single processor unit of a multicore chip. The terms "processor" and "CPU" are often used in place of "core", although industry usage varies.

**CPU**

"Central Processing Unit"; a synonym for "core", or a single processor of a multicore chip.

**critical section**

The code executed by a strand while holding a lock.

**critical-path length**

See span.

**data race**

A race condition that occurs when two or more parallel strands, holding no lock in common, access the same memory location and at least one of the strands performs a write. Compare with determinacy race.

**deadlock**

A situation when two or more strand instances are each waiting for another to release a resource, and the "waiting-for" relation forms a cycle so that none can ever proceed.

**determinacy race**

A race condition that occurs when two parallel strands access the same memory location and at least one strand performs a write.

**determinism**

The property of a program when it behaves identically from run to run when executed on the same inputs. Deterministic programs are usually easier to debug.

**distributed memory**

Computer storage that is partitioned among several processors. A distributed-memory multiprocessor is a computer in which processors must send messages to remote processors to access data in remote processor memory. Contrast with shared memory.

**execution time**
How long a program takes to execute on a given computer system. Also called running time.

**false sharing**
The situation that occurs when two strands access different memory locations residing on the same cache block, thereby contending for the cache block.

**global variable**
A variable that is bound outside of all local scopes. See also nonlocal variable.

**hyperobject**
An object which interacts with the Intel® Cilk™ Plus runtime to manage the creation, interaction, and destruction of a set of related data structures as parallel strands are spawned and synced. Hyperobjects include reducers and holders.

**instruction**
A single operation executed by a processor.

**linear speedup**
Speedup proportional to the processor count. See also perfect linear speedup.

**lock**
A synchronization mechanism for providing atomic operation by limiting concurrent access to a resource. Important operations on locks include acquire (lock) and release (unlock). Many locks are implemented as a mutex, whereby only one strand can hold the lock at any time.

**lock contention**
The situation wherein multiple strands vie for the same lock.

**multicore**
A semiconductor chip containing more than one processor core.

**multiprocessor**
A computer containing multiple general-purpose processors.

**mutex**
A "mutually exclusive" lock that only one strand can acquire at a time, thereby ensuring that only one strand executes the critical section protected by the mutex at a time. Windows* supports several types of locks, including the CRITICAL_SECTION. Linux* supports Pthreads pthread_mutex_t objects.

**nondeterminism**
The property of a program when it behaves differently from run to run when executed on exactly the same inputs. Nondeterministic programs are usually hard to debug.

**nonlocal variable**
A program variable that is bound outside of the scope of the function, method, or class in which it is used. In Intel® Cilk™ Plus programs, this term refers to variables with a scope outside a cilk_for loop.

**parallel loop**
A for loop all of whose iterations can be run independently in parallel. The cilk_for keyword designates a parallel loop.

**parallelism**
The ratio of work to span, which is the largest speedup an application could possibly attain when run on an infinite number of processors.

**pedigree**
A sequence of 64-bit integers used to uniquely identify a maximal strand.

**perfect linear speedup**
Speedup equal to the processor count. See also linear speedup.

**process**
A concurrent agent that has its own address space and is managed by the operating system. Memory can be shared among processes only through the use of explicit operating system calls.

**processor**
A processor implements the logic to execute program instructions sequentially; the term "core" is used as a synonym.

**race condition**
A source of nondeterminism whereby the result of a concurrent computation depends on the timing or relative order of the execution of instructions in each individual strand.

**receiver**
A variable to receive the result of the function call.

**reducer**
A hyperobject used in place of an ordinary variable to allow a parallel associative computation such as an arithmetic sum, string concatenation, or list creation without data races.

**response time**
The time it takes to execute a computation from the time a human user provides an input to the time the user gets the result.

**running time**
How long a program takes to execute on a given computer system. Also called execution time.

**scale down**
The ability of a parallel application to run efficiently on one or a small number of processors.

**scale out**
The ability to run multiple copies of an application efficiently on a large number of processors.

**scale up**
The ability of a parallel application to run efficiently on a large number of processors. See also linear speedup.

**sequential consistency**
The memory model for concurrency wherein the effect of concurrent agents is as if their operations on shared memory were interleaved in a global order consistent with the orders in which each agent executed them.

**serial execution**
Execution of the serialization of an Intel® Cilk™ Plus program.

**serial semantics**
A deterministic Intel® Cilk™ Plus program will produce the same results as the serialization of the program. This is referred to as "serial semantics."

**serialization**
The C/C++ program that results from stubbing out the Intel® Cilk™ Plus keywords of a program, where `cilk_spawn` and `cilk_sync` are elided and `cilk_for` is replaced with an ordinary `for`. The serialization can be used for debugging and, in the case of a converted C/C++ program, will behave exactly as the original C/C++ program. The term "serial elision" is used in some of the literature.

**shared memory**
Computer storage that is shared among several processors. A shared-memory multiprocessor is a computer in which each processor can directly address any memory location. Contrast with distributed memory.
span
The theoretically fastest execution time for a parallel program when run on an infinite number of processors, discounting overheads for communication and scheduling. Often denoted by $T_\infty$ in the literature, and sometimes called critical-path length.

spawn
To call a function without waiting for it to return, as in a normal call. The caller can continue to execute in parallel with the called function. See also cilk_spawn.

speedup
How many times faster a program is when run in parallel than when run on one processor. Speedup can be computed by dividing the running time $T_P$ of the program on $P$ processors by its running time $T_1$ on one processor.

strand
A serial chain of instructions containing no spawns, syncs, returns from spawn, or other parallel control.

sync
To wait for a set of spawned functions to return before proceeding. The current function is dependent upon the spawned functions and cannot proceed in parallel with them. See also cilk_sync.

thread
A concurrent agent that shares an address space with other threads within the same process. Scheduling of threads is typically managed by the operating system.

throughput
A number of operations performed per unit time.

view
The state of a hyperobject as seen by a given strand.

work
The running time of a program when run on one processor, sometimes denoted by $T_1$.

work stealing
A scheduling strategy where processors post parallel work locally and, when a processor runs out of local work, it steals work from another processor. Work-stealing schedulers are notable for their efficiency, because they incur no communication or synchronization overhead when there is ample parallelism. The Intel® Cilk™ Plus runtime system employs a work-stealing scheduler.

worker
A concurrent agent that executes the instructions in one strand, possibly at the same time that another worker executes instructions in a parallel strand. Workers are managed by the Intel® Cilk™ Plus runtime system's work stealing scheduler. A worker is implemented as an operating system thread.

Automatic Parallelization

The auto-parallelization feature of the Intel® C++ Compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP* directives. The OpenMP* and auto-parallelization features provide the performance gains from shared memory on multiprocessor and dual core systems.
The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel.

This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.

The guided auto-parallelization feature of the Intel® C++ Compiler helps you locate portions in your serial code that can be parallelized further. You can invoke guidance for parallelization, vectorization, or data transformation using specified compiler options of the [Q]guide series.

Automatic parallelization frees developers from having to:

- Find loops that are good worksharing candidates.
- Perform the dataflow analysis to verify correct parallel execution.
- Partition the data for threaded code generation as is needed in programming with OpenMP* directives.

Although OpenMP* directives enable serial applications to transform into parallel applications quickly, you must explicitly identify specific portions of your application code that contain parallelism and add the appropriate compiler directives. Auto-parallelization, which is triggered by the [Q]parallel option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort is needed.

**NOTE** In order to execute a program that uses auto-parallelization on Linux* or macOS* systems, you must include the -parallel compiler option when you compile and link your program.

**NOTE**
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.

### Example 1: Original Serial Code

```c
void ser(int *a, int *b, int *c) {
    for (int i=0; i<100; i++)
        a[i] = a[i] + b[i] * c[i];
}
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

### Example 2: Transformed Parallel Code

```c
void par(int *a, int *b, int *c) {
    int i;
    // Thread 1
    for (i=0; i<50; i++)
        a[i] = a[i] + b[i] * c[i];
    // Thread 2
    for (i=50; i<100; i++)
        a[i] = a[i] + b[i] * c[i];
}
```
**Auto-vectorization and Parallelization**

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts the sequential program to process 2, 4, 8, or (up to) 16 elements in one operation, depending on the data type. In some cases, auto-parallelization and vectorization can be combined for better performance results.

The following example demonstrates how code can be designed to explicitly benefit from parallelization and vectorization. Assuming you compile the code shown below using the `[Q]`parallel option, the compiler will parallelize the outer loop and vectorize the innermost loop.

```c
#include <stdio.h>
#define ARR_SIZE 500 //Define array
int main() {
    int matrix[ARR_SIZE][ARR_SIZE];
    int arrA[ARR_SIZE]={10};
    int arrB[ARR_SIZE]={30};
    int i, j;
    for(i=0;i<ARR_SIZE;i++) {
        for(j=0;j<ARR_SIZE;j++) { matrix[i][j] = arrB[i]*(arrA[i]%2+10); }
    }
    printf("%d\n",matrix[0][0]);
}
```

Compiling the example code with the correct options, the compiler should report results similar to the following:

```
vectorization.c(18) : (col. 6) remark: LOOP WAS VECTORIZED.
vectorization.c(16) : (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.
```

With the relatively small effort of adding OpenMP* directives to existing code you can transform a sequential program into a parallel program. The `[Q]openmp` option must be specified to enable the OpenMP directives. The following example demonstrates one method of using the OpenMP* pragmas within code.

```c
#include <stdio.h>
#define ARR_SIZE 100 //Define array
void foo(int ma[][ARR_SIZE], int mb[][ARR_SIZE], int *a, int *b, int *c);
int main() {
    int arr_a[ARR_SIZE];
    int arr_b[ARR_SIZE];
    int arr_c[ARR_SIZE];
    int i,j;
    int matrix_a[ARR_SIZE][ARR_SIZE];
    int matrix_b[ARR_SIZE][ARR_SIZE];
    #pragma omp parallel for
    // Initialize the arrays and matrices.
    for(i=0;i<ARR_SIZE; i++) {
        arr_a[i]= i;
        arr_b[i]= i;
        arr_c[i]= ARR_SIZE-i;
        for(j=0; j<ARR_SIZE; j++) {
            matrix_a[i][j]= j;
            matrix_b[i][j]= i;
        }
    }
    foo(matrix_a, matrix_b, arr_a, arr_b, arr_c);
}
```
Example

```c
void foo(int ma[][ARR_SIZE], int mb[][ARR_SIZE], int *a, int *b, int *c)
{
    int i, num, arr_x[ARR_SIZE];
    #pragma omp parallel for private(num)
    // Expresses the parallelism using the OpenMP pragma: parallel for.
    // The pragma guides the compiler generating multi-threaded code.
    // Array arr_X, mb, b, and c are shared among threads based on OpenMP
    // data sharing rules. Scalar num si specifed as private
    // for each thread.
    for(i=0;i<ARR_SIZE;i++) {
        num = ma[b[i]][c[i]];
        arr_x[i]= mb[a[i]][num];
        printf("Values: %d\n", arr_x[i]); // prints values 0-ARR_SIZE-1
    }
}
```

NOTE
Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Using Parallelism Reports
To generate a parallelism report, use the -opt-report-phase=par (Linux* and macOS*) or the /Qopt-report-phase:par option along with the -opt-report=n or /Qopt-report:n option. By default the auto-parallelism report generates a medium level of detail, where \( n = 2 \). You can use the [Q]opt-report option along with the [Q]opt-report-phase option if you want a greater or lesser level of detail. Specifying a value of '5' generates the maximum diagnostic details.

Run the report by entering commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>icpc -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
<tr>
<td>macOS*</td>
<td>icl++ -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /c /Qparallel /Qopt-report-phase:par /Qopt-report:5 sample.cpp</td>
</tr>
</tbody>
</table>

NOTE The -c (Linux* and macOS*) or /c (Windows*) prevents linking and instructs the compiler to stop compilation after the object file is generated. The example is compiled without generating an executable.

The output, by default, produces a file with the same name as the object file, with .optrpt extension, and is written into the same directory as the object file. Using the above command-line entries, you will obtain an output file called sample.optrpt. Use the [Q]opt-report-file option to specify any other name for the output file that captures the report results. Use the arguments stdout or stderr to send the optimization report to stdout or stderr.
For example, assume you want a full diagnostic report on the following example code:

```c
void no_par(void) {
  int i;
  int a[1000];
  for (i=1; i<1000; i++) {
    a[i] = (i * 2) % i * 1 + sqrt(i);
    a[i] = a[i-1] + i;
  }
}
```

The following example output illustrates the diagnostic report generated by the compiler for the example code shown above. In most cases, the comment listed next to the line is self-explanatory.

```c
procedure: no_par
sample.c(13):(3) remark #15048: DISTRIBUTED LOOP WAS AUTO-PARALLELIZED
sample.c(13):(3) remark #15050: loop was not parallelized: existence of parallel dependence
sample.c(19):(5) remark #15051: parallel dependence: proven FLOW dependence between a line 19, and a line 19
```

For more information on options to generate reports see the Optimization Report Options topic.

Optimization Report Options

---

**Enabling Auto-parallelization**

To enable the auto-parallelizer, use the `[Q]parallel` option. This option detects parallel loops capable of being executed safely in parallel, and automatically generates multi-threaded code for these loops.

**NOTE**

You may need to set the KMP_STACKSIZE environment variable to an appropriately large size to enable parallelization with this option.
**NOTE**

Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

An example of the command using auto-parallelization is as follows:

<table>
<thead>
<tr>
<th>Commanding auto-parallelization in Linux*</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icc -c -parallel prog.cpp</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Commanding auto-parallelization in Windows*</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icl /c /Qparallel prog.cpp</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Commanding auto-parallelization in macOS*</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icc -c -parallel prog.cpp</code></td>
</tr>
</tbody>
</table>

Auto-parallelization uses two specific pragmas: `#pragma parallel` and `#pragma noparallel`.

The format of an auto-parallelization compiler pragma is below:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;prefix&gt; &lt;pragma&gt;</code></td>
</tr>
</tbody>
</table>

where `<prefix>` indicates `#pragma, the `<prefix>` is followed by the pragma name, as in:

```plaintext
#pragma parallel
```

The `#pragma parallel` pragma instructs the compiler to ignore dependencies that it assumes may exist and that would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored. In addition, `parallel [always]` overrides the compiler heuristics that estimate the likelihood that parallelization of a loop increases performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the `ASSERT` keyword is added, as in `#pragma parallel [always [assert]]`, the compiler generates an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

The `#pragma noparallel` pragma disables auto-parallelization.

`parallel, Qparallel` compiler option

**Programming with Auto-parallelization**

The auto-parallelization feature implements some concepts of OpenMP*, such as the worksharing construct (with the `PARALLEL for` directive). This section provides details on auto-parallelization.

**Guidelines for Effective Auto-parallelization Usage**

A loop can be parallelized if it meets the following criteria:
• The loop is countable at compile time: This means that an expression representing how many times the loop will execute (loop trip count) can be generated just before entering the loop.
• There are no FLOW (READ after WRITE), OUTPUT (WRITE after WRITE) or ANTI (WRITE after READ) loop-carried data dependencies. A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler’s discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by run-time dependency testing.

The compiler may generate a run-time test for the profitability of executing in parallel for loop, with loop parameters that are not compile-time constants.

Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:
• Expose the trip count of loops whenever possible; use constants where the trip count is known and save loop parameters in local variables.
• Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.

Auto-parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:
1. Data flow analysis: Computing the flow of data through the program.
2. Loop classification: Determining loop candidates for parallelization based on correctness and efficiency, as shown by Enabling Auto-parallelization.
3. Dependency analysis: Computing the dependency analysis for references in each loop nest.
4. High-level parallelization: Analyzing the dependency graph to determine loops that can execute in parallel, and computing run-time dependency.
5. Data partitioning: Examining data reference and partition based on the following types of access: SHARED, PRIVATE, and FIRSTPRIVATE.
6. Multithreaded code generation: Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel run-time routines for thread creation and synchronization.

NOTE
Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Enabling Further Loop Parallelization for Multicore Platforms

Parallelizing loops for multicore platforms is subject to certain conditions. Three requirements must be met for the compiler to parallelize a loop:
• The number of iterations must be known before entry into a loop to insure that the work can be divided in advance. A do while loop, for example, usually cannot be made parallel.
• There can be no jumps into or out of the loop.
• The loop iterations must be independent (no cross-iteration dependencies).
Correct results must not logically depend on the order in which the iterations are executed. There may be slight variations in the accumulated rounding error, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location, for example, if they depend on function arguments, run-time data, or the results of complex calculations.

If the compiler cannot prove that pointers or array references are safe, it will not parallelize the loop, except in limited cases when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at run-time.

An alternative way in C to assert that a pointer is not aliased is to use the restrict keyword in the pointer declaration, along with the \[Q\]\texttt{restrict} command-line option. The compiler will never parallelize a loop that it can prove to be unsafe.

If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the \#pragma parallel pragma.

**Parallelizing Loops with Cross-iteration Dependencies**

Before the compiler can auto-parallelize a loop, it must prove that the loop does not have potential cross-iteration dependencies that prevent parallelization. A cross-iteration dependency exists if a memory location is written to in an iteration of a loop and accessed (read from or written to) in another iteration of the loop. Cross-iteration dependencies often occur in loops that access overlapping array ranges, such as a loop that reads from a(1:100) and writes to a(0:99).

Sometimes, even though a loop does not have cross-iteration dependencies, the compiler does not have enough information to prove it and does not parallelize the loop. In such cases, you can assist the compiler by providing additional information about the loop using the \#pragma parallel pragma. Adding the \#pragma parallel pragma before a for loop informs the compiler that the loop does not have cross-iteration dependencies. Auto-parallelization analysis ignores potential dependencies that it assumes could exist; however, the compiler still may not parallelize the loop if heuristics estimate parallelization is unlikely to increase performance of the loop.

The \#pragma parallel always pragma has the same effect to ignore potential dependencies as the \#pragma parallel pragma, but it also overrides the compiler heuristics that estimate the likelihood that parallelization of a loop would increase performance. It allows a loop to be parallelized even when the compiler estimates that parallelization might not improve performance.

The \#pragma noparallel pragma prevents auto-parallelization of the immediately following for loop. Unlike \#pragma parallel, which is a hint, the noparallel pragma is guaranteed to prevent parallelization of the following loop.

These pragmas take effect only if auto-parallelization is enabled by the option \[Q\]parallel.

**Parallelizing Loops with Private Clauses**

When you use the Guided Auto Parallelism feature, the compiler's auto-parallelizer gives you advice on where to alter your program to enhance parallelization. For instance, you may get advice to check if a condition (that the compiler could not prove) is true, and if true, to insert \#pragma parallel in your source code so that the associated loop is parallelized when you recompile.

To specify that it is legal for each thread to create a new, private copy (not visible by other threads) of a variable, and replace the original variable in the loop with the new private variable, use the \#pragma parallel pragma with the private clause. The private clause allows you to list scalar and array type variables and specify the number of array elements to privatize.

Use the firstprivate clause to specify private variables that need to be initialized with the original value before entering the parallel loop.
Use the `lastprivate` clause to specify those variables with a value you want to reuse after it exits a parallelized loop. When you use the `lastprivate` clause to handle a particular privatized variable, the value is copied to the original variable when it exits from the parallelized loop.

**NOTE**
Do not use the same variable in both `private` and `lastprivate` clauses for the same loop. You will get an error message.

**Parallelizing Loops with External Function Calls**

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependencies. You can invoke interprocedural optimization with the `[`ipo`]` option. Using this option gives the compiler the opportunity to analyze the called function for side effects.

**Parallelizing Loops with OpenMP**

When the compiler is unable to automatically parallelize loops you know to be parallel, use OpenMP*. OpenMP* is the preferred solution because you understand the code better than the compiler and can express parallelism at a coarser granularity. Alternatively, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

**Threshold Parameter to Parallelize Loops**

If a loop can be parallelized, it does not necessarily mean that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `[par-threshold` compiler option adjusts this behavior. The threshold ranges from 0 to 100, where 0 instructs the compiler to always parallelize a safe loop and 100 instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `[par-report` option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized and indicate probable reason(s) why. See OpenMP* and Parallel Processing Options for more information on the using these compiler options.

The following example illustrates using the options in combination.

### Example code

```c
void add (int k, float *a, float *b) {
    for (int i = 1; i < 10000; i++) {
        a[i] = a[i+k] + b[i];
    }
}
```

Entering a command-line compiler command similar to the following will result in the compiler issuing parallelization messages:

```
// Linux* and macOS*
icpc -c -parallel -opt-report-phase=par -opt-report=3 add.cpp
```

The compiler might report results similar to those listed below:
Sample results

add.cpp

procedure:
add serial loop: line 2
anti data dependence assumed from line 2 to line 2, due to "a"
flow data dependence assumed from line 2 to line 2, due to "a"
flow data dependence assumed from line 2 to line 2, due to "a"

Because the compiler does not know the value of \( k \), the compiler assumes the iterations depend on each other, for example if \( k \) equals -1, even if the actual case is otherwise. You can override the compiler by inserting the \#pragma parallel pragma.

Example

```c++
void add(int k, float *a, float *b) {
    #pragma parallel
    for (int i = 0; i < 10000; i++) {
        a[i] = a[i+k] + b[i];
    }
}
```

Caution

Do not call this function with a value of \( k \) that is less than 10000; passing a value less than 10000 could lead to incorrect results.

Language Support for Auto-parallelization

This topic addresses specific C++ language features that better help to parallelize code.

Annotating Functions with Declarations

Annotating functions with the declaration:

```c++
// (Windows* OS)
__declspec(concurrency_safe(cost(cycles) | profitable)) -OR-// (Linux* OS)
__attribute__((concurrency_safe(cost(cycles) | profitable)))
```

guides the compiler to parallelize more loops and straight-line code.
Using the `concurrency_safe` attribute indicates to the compiler that there are no unaffected side-effects and no illegal (or improperly synchronized) memory access interferences among multiple invocations of the annotated function or between an invocation of this annotated function and other statements in the program, if they are executed concurrently.

**NOTE**

For every function that is annotated with the `concurrency_safe` attribute, it is your responsibility to ensure that its side effects (if any) are acceptable (or expected), and the memory access interferences are properly synchronized.

The `cost` clause specifies the execution cycles of the annotated function for the compiler to perform parallelization profitability analysis while compiling its enclosing loops or blocks. The `profitable` clause indicates that the loops or blocks that contain calls to the annotated function are profitable to parallelize.

**NOTE**

The value of `cycles` is a 2-byte unsigned integer (unsigned short), its maximal value is $2^{16}-1$. If the cycle count is greater than $2^{16}-1$, the user should use `profitable` clause.

The following example illustrates the use of this declaration.

```
Example using __declspec(concurrency_safe(cost(cycles) | profitable))

#define N 10
#define M 40
#define NValue N

#if defined(COSTLOW)
    // The function cost is ~5 cycles, the loop calling "foo" will not be parallellized
    __declspec(concurrency_safe(cost(5)))
#elif defined(COSTHIGH)
    // The function cost is ~100 cycles, so the loop calling "foo" will be parallellized
    __declspec(concurrency_safe(cost(200)))
#else defined(PROFITABLE)
    // The function is profitable to be executed in parallel, so the loop calling "foo"
    // should be parallellized.
    __declspec(concurrency_safe(profitable))
#endif

__declspec(noinline)
int foo(float A[], float B[]) {
    for (int i = 0; i < N; i++) {
        B[i] = A[i];
    }
    return N;
}

int testp(float A[], float B[], float In[], float Out[]) {
    int i, j;
    for (i = 0; i < M; i++) {
        foo (A, B);
        ...
Example using __declspec(concurrency_safe(cost(cycles) | profitable))

```c
for (j = 0; j < N; j++) {
    Out[i][j] = In[i][j] + (NValue*j);
}
return N;
```

[C:/temp] icl -c -DCOSTLOW -Qparallel -Qpar-report2 -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: loop was not parallelized: insufficient computational work.

[C:/temp] icl -c -DCOSTHIGH -Qparallel -Qpar-report -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.

[C:/temp] icl -c -DPROFITABLE -Qparallel -Qpar-report -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.

Vectorization

Automatic Vectorization

Automatic Vectorization Overview

The automatic vectorizer (also called the auto-vectorizer) is a component of the Intel® compiler that automatically uses SIMD instructions in the Intel® Streaming SIMD Extensions (Intel® SSE, Intel® SSE2, Intel® SSE3 and Intel® SSE4), Suplemental Streaming SIMD Extensions (SSSE3) instruction sets, and the Intel® Advanced Vector Extensions (Intel® AVX, Intel® AVX2) instruction sets. The vectorizer detects operations in the program that can be done in parallel and converts the sequential operations to parallel; for example, the vectorizer converts the sequential SIMD instruction that processes up to 16 elements into a parallel operation, depending on the data type.

Automatic vectorization occurs when the Intel® Compiler generates packed SIMD instructions to unroll a loop. Because the packed instructions operate on more than one data element at a time, the loop executes more efficiently. This process is referred to as auto-vectorization only to emphasize that the compiler identifies and optimizes suitable loops on its own, without requiring any special action by you. However, it is useful to note that in some cases, certain keywords or directives may be applied in the code for auto-vectorization to occur.

The compiler supports a variety of auto-vectorizing hints that can help the compiler to generate effective vector instructions. Automatic vectorization is supported on IA-32 and Intel® 64 architectures. Intel® Advisor XE, a separate tool included in some editions of Intel® Parallel Studio XE, provides a Vectorization Advisor feature that can analyze the compiler's optimization reports and make recommendations for enhancing vectorization.
### Programming Guidelines for Vectorization

The goal of including the vectorizer component in the Intel® C++ Compiler is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help by supplying the compiler with additional information; for example, by using auto-vectorizer hints or pragmas.

### Guidelines to Vectorize Innermost Loops

Follow these guidelines to vectorize innermost loop bodies.

**Use:**
- straight-line code (a single basic block).
- vector data only; that is, arrays and invariant expressions on the right hand side of assignments.
  - Array references can appear on the left hand side of assignments.
- only assignment statements.

**Avoid:**
- function calls (other than math library calls).
- non-vectorizable operations (either because the loop cannot be vectorized, or because an operation is emulated through a number of instructions).
- mixing vectorizable types in the same loop (leads to lower resource utilization).
- data-dependent loop exit conditions (leads to loss of vectorization).

To make your code vectorizable, you will often need to make some changes to your loops. You should only make changes needed to enable vectorization, and avoid these common changes:
- loop unrolling, which the compiler performs automatically.
- decomposing one loop with several statements in the body into several single-statement loops.

### Restrictions

There are a number of restrictions that you should consider. Vectorization depends on two major factors: hardware and style of source code.

<table>
<thead>
<tr>
<th>Factor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware</td>
<td>The compiler is limited by restrictions imposed by the underlying hardware. In the case of Intel® Streaming SIMD Extensions (Intel® SSE), the vector memory operations are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.</td>
</tr>
</tbody>
</table>
The style in which you write source code can inhibit vectorization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, pointer arithmetic, and memory operations within the loop bodies.

By understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization.

**Guidelines for Writing Vectorizable Code**

Follow these guidelines to write vectorizable code:

- Use simple `for` loops. Avoid complex loop termination conditions – the upper iteration limit must be invariant within the loop. For the innermost loop in a nest of loops, you could set the upper limit iteration to be a function of the outer loop indices.
- Write straight-line code. Avoid branches such as `switch`, `goto`, or `return` statements; most function calls; or `if` constructs that can not be treated as masked assignments.
- Avoid dependencies between loop iterations or at the least, avoid read-after-write dependencies.
- Try to use array notations instead of the use of pointers. C programs in particular impose very few restrictions on the use of pointers; aliased pointers may lead to unexpected dependencies. Without help, the compiler often cannot tell whether it is safe to vectorize code containing pointers.
- Wherever possible, use the loop index directly in array subscripts instead of incrementing a separate counter for use as an array address.
- Access memory efficiently:
  - Favor inner loops with unit stride.
  - Minimize indirect addressing.
  - Align your data to 16-byte boundaries (for Intel® SSE instructions).
- Choose a suitable data layout with care. Most multimedia extension instruction sets are rather sensitive to alignment. The data movement instructions of Intel® SSE, for example, operate much more efficiently on data that is aligned at a 16-byte boundary in memory. Therefore, the success of a vectorizing compiler also depends on its ability to select an appropriate data layout which, in combination with code restructuring (like loop peeling), results in aligned memory accesses throughout the program.
- Use aligned data structures: Data structure alignment is the adjustment of any data object in relation with other objects.
  
  You can use the declaration `__declspec(align).`

**Caution**

Use this hint with care. Incorrect usage of aligned data movements result in an exception when using Intel® SSE.

- Use structure of arrays (SoA) instead of array of structures (AoS): An array is the most common type of data structure that contains a contiguous collection of data items that can be accessed by an ordinal index. You can organize this data as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization is excellent for encapsulation it can be a hindrance for use of vector processing. To make vectorization of the resulting code more effective, you can also select appropriate data structures.
Dynamic Alignment Optimizations

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

To enable or disable dynamic data alignment optimizations, specify the option `Qopt-dynamic-align[-]` (Windows) or `[no-]qopt-dynamic-align[-]` (Linux).

Using Aligned Data Structures

Data structure alignment is the adjustment of any data object with relation to other objects. The Intel® C++ Compiler may align individual variables to start at certain addresses to speed up memory access. Misaligned memory accesses can incur large performance losses on certain target processors that do not support them in hardware.

Alignment is a property of a memory address, expressed as the numeric address modulo of powers of two. In addition to its address, a single datum also has a size. A datum is called 'naturally aligned' if its address is aligned to its size, otherwise it is called 'misaligned'. For example, an 8-byte floating-point datum is naturally aligned if the address used to identify it is aligned to eight (8).

A data structure is a way of storing data in a computer so that it can be used efficiently. Often, a carefully chosen data structure allows a more efficient algorithm to be used. A well-designed data structure allows a variety of critical operations to be performed, using as little resources - both execution time and memory space - as possible.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| struct MyData{
|   short Data1;
|   short Data2;
|   short Data3;
|}; |

In the example data structure above, if the type `short` is stored in two bytes of memory then each member of the data structure is aligned to a boundary of two bytes. `Data1` would be at offset 0, `Data2` at offset 2 and `Data3` at offset 4. The size of this structure is six bytes. The type of each member of the structure usually has a required alignment, meaning that it is aligned on a pre-determined boundary, unless you request otherwise. In cases where the compiler has taken sub-optimal alignment decisions, you can use the declaration `declspec(align(base,offset))`, where 0 <= offset < base and base is a power of two, to allocate a data structure at offset from a certain base.

Consider as an example, that most of the execution time of an application is spent in a loop of the following form:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| double a[N], b[N];
| ...
| for (i = 0; i < N; i++) { a[i+1] = b[i] * 3; } |

If the first element of both arrays is aligned at a 16-byte boundary, then either an unaligned load of elements from `b` or an unaligned store of elements into `a` must be used after vectorization.

**NOTE**

In this case, peeling off an iteration will not help.
However, you can enforce the alignment shown below, which results in two aligned access patterns after vectorization (assuming an 8-byte size for doubles):

### Example: Alignment Enforcement

```cpp
__declspec(align(16, 8)) double a[N];
__declspec(align(16, 0)) double b[N];
/* or simply "align(16)" */
```

If pointer variables are used, the compiler is usually not able to determine the alignment of access patterns at compile time. Consider the following simple `fill()` function:

### Example

```cpp
void fill(char *x) {
    int i;
    for (i = 0; i < 1024; i++) { x[i] = 1; }
}
```

Without more information, the compiler cannot make any assumption on the alignment of the memory region accessed by the above loop. At this point, the compiler may decide to vectorize this loop using unaligned data movement instructions or, generate the run-time alignment optimization shown here:

### Example

```cpp
peel = x & 0x0f;
if (peel != 0) {
    peel = 16 - peel;
    /* runtime peeling loop */
    for (i = 0; i < peel; i++) { x[i] = 1; }
}
/* aligned access */
for (i = peel; i < 1024; i++) { x[i] = 1; }
```

Run-time optimization provides a generally effective way to obtain aligned access patterns at the expense of a slight increase in code size and testing. If incoming access patterns are guaranteed to be aligned at a 16-byte boundary, you can avoid this overhead with the hint `__assume_aligned(x, 16)` in the function to convey this information to the compiler.

For example, suppose you can introduce an optimization in the case where a block of memory with address `n2` is aligned on a 16-byte boundary. You could use `__assume(n2%16==0)`.

### Caution

Use this hint with care. Incorrect use of aligned data movements result in an exception for Intel® SSE.

### Using Structure of Arrays versus Array of Structures

The most common and well-known data structure is the array that contains a contiguous collection of data items, which can be accessed by an ordinal index. This data can be organized as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization works excellently for encapsulation, for vector processing it works poorly.

You can select appropriate data structures to make vectorization of the resulting code more effective. To illustrate this point, compare the traditional array of structures (AoS) arrangement for storing the `r, g, b` components of a set of three-dimensional points with the alternative structure of arrays (SoA) arrangement for storing this set.
With the AoS arrangement, a loop that visits all components of an RGB point before moving to the next point exhibits a good locality of reference because all elements in the fetched cache lines are utilized. The disadvantage of the AoS arrangement is that each individual memory reference in such a loop exhibits a non-unit stride, which, in general, adversely affects vector performance. Furthermore, a loop that visits only one component of all points exhibits less satisfactory locality of reference because many of the elements in the fetched cache lines remain unused.

In contrast, with the SoA arrangement the unit-stride memory references are more amenable to effective vectorization and still exhibit good locality of reference within each of the three data streams. Consequently, an application that uses the SoA arrangement may ultimately outperform an application based on the AoS arrangement when compiled with a vectorizing compiler, even if this performance difference is not directly apparent during the early implementation phase.

Before you start vectorization, try out some simple rules:

- Make your data structures vector-friendly.
- Make sure that inner loop indices correspond to the outermost (last) array index in your data (row-major order).
- Use structure of arrays over array of structures.

For instance when dealing with three-dimensional coordinates, use three separate arrays for each component (SoA), instead of using one array of three-component structures (AoS). To avoid dependencies between loops that will eventually prevent vectorization, use three separate arrays for each component (SoA), instead of one array of three-component structures (AoS). When you use the AoS arrangement, each iteration produces one result by computing XYZ, but it can at best use only 75% of the SSE unit because the forth component is not used. Sometimes, the compiler may use only one component (25%). When you use the SoA arrangement, each iteration produces four results by computing XXXX, YYYY and ZZZZ, using 100% of the SSE unit. A drawback for the SoA arrangement is that your code will likely be three times as long. On the other hand, the compiler might not be able to vectorize AoS arranged code at all.
If your original data layout is in AoS format, you may even want to consider a conversion to SoA on the fly, before the critical loop. If it gets vectorized, it may be worth the effort!

To summarize:

• Use the smallest data types that gives the needed precision to maximize potential SIMD width. (If only 16-bits are needed, using a \texttt{short} rather than an \texttt{int} can make the difference between 8-way or four-way SIMD parallelism, respectively.)
• Avoid mixing data types to minimize type conversions.
• Avoid operations not supported in SIMD hardware.
• Use all the instruction sets available for your processor. Use the appropriate command line option for your processor type, or select the appropriate IDE option (Windows* only):
  • \texttt{Project > Properties > C/C++ > Code Generation > Intel Processor-Specific Optimization}, if your application runs only on Intel\textsuperscript{®} processors.
  • \texttt{Project > Properties > C/C++ > Code Generation > Enable Enhanced Instruction Set}, if your application runs on compatible, non-Intel processors.
• Vectorizing compilers usually have some built-in efficiency heuristics to decide whether vectorization is likely to improve performance. The Intel\textsuperscript{®} C++ Compiler disables vectorization of loops with many unaligned or non-unit stride data access patterns. If experimentation reveals that vectorization improves performance, you can override this behavior using the \texttt{#pragma vector always} hint before the loop; the compiler vectorizes any loop regardless of the outcome of the efficiency analysis (provided, of course, that vectorization is safe).

\textbf{Vectorization and Loops}

\textbf{Loop Constructs}

\texttt{opt-dynamic-align, Qopt-dynamic-align}

\texttt{compiler option}

\textbf{Using Automatic Vectorization}

Automatic vectorization is supported on IA-32 and Intel\textsuperscript{®} 64 architectures. The information below will guide you in setting up the auto-vectorizer.

\textbf{Vectorization Speed-up}

Where does the vectorization speedup come from? Consider the following sample code fragment, where \( a \), \( b \) and \( c \) are integer arrays:

\begin{verbatim}
Sample Code Fragment
for (I=0;i<=MAX;i++)
c[i]=a[i]+b[i];
\end{verbatim}

If vectorization is not enabled (that is, you compile using \texttt{O1} or \texttt{[Q]vec-} options), for each iteration, the compiler processes the code such that there is a lot of unused space in the SIMD registers, even though each of the registers could hold three additional integers. If vectorization is enabled (compiled using \texttt{O2} or higher options), the compiler may use the additional registers to perform four additions in a single instruction. The compiler looks for vectorization opportunities whenever you compile at default optimization (\texttt{O2}) or higher.
NOTE
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

Tip
To allow comparisons between vectorized and not-vectorized code, disable vectorization using the /Qvec- (Windows*) or -no-vec (Linux* or macOS*) option; enable vectorization using the O2 option.

To get information on whether a loop was vectorized or not, enable generation of the optimization report using the options Qopt-report:1 Qopt-report-phase:vec (Windows) or qopt-report=1 qopt-report-phase=vec (Linux and macOS*) options. These options generate a separate report in an *.optrpt file that includes optimization messages. In Visual Studio, the program source is annotated with the report's messages, or you can read the resulting .optrpt file using a text editor. A message appears for every loop that is vectorized, such as:

Example: Vectorization Report

```
> icl /Qopt-report:1 /Qopt-report-phase:vec Multiply.c
Multiply.c(92): (col. 5) remark: LOOP WAS VECTORIZED.
```

The source line number (92 in the above example) refers to either the beginning or the end of the loop.

To get details about the type of loop transformations and optimizations that took place, use the [Q]opt-report-phase option by itself or along with the [Q]opt-report option.

To get information on whether the loop was vectorized using the Visual Studio* IDE, select Project > Properties > C/C++ > Diagnostics > Optimization Diagnostic Level as Level 1 (/Qopt-report:1) and Optimization Diagnostic Phase as Loop Nest Optimization (/Qopt-report-phase:loop). To get a diagnostic message for every loop that was not vectorized, with a brief explanation of why the loop was not vectorized, select /Qopt-report-phase:vec.

How significant is the performance enhancement? To evaluate performance enhancement yourself, run vec_samples:

1. Open an Intel® Compiler command line window.
   - On Windows*: Under the Start menu item for your Intel product, select an icon under Compiler and Performance Libraries > Command Prompt with Intel Compiler
   - On Linux* and macOS*: Source an environment script such as compilervars.sh or the compilervars.csh in the <installdir>/bin directory and use the attribute appropriate for the architecture.
2. Navigate to the <install-dir>/Samples/<locale>/C++ directory. On Windows, unzip the sample project vec_samples.zip to a writable directory. This small application multiplies a vector by a matrix using the following loop:

Example: Vector Matrix Multiplication

```
for (j = 0; j < size2; j++) { b[i] += a[i][j] * x[j]; }
```

3. Build and run the application, first without enabling auto-vectorization. The default O2 optimization enables vectorization, so you need to disable it with a separate option. Note the time taken for the application to run.
4. Now build and run the application, this time with auto-vectorization. Note the time taken for the application to run.

```
Example: Building and Running an Application with Auto-vectorization

// (Linux* and macOS*)
vicc -O2 -qopt-report=1 -qopt-report-phase=vec Multiply.c -o VectMult
./VectMult

// (Windows*)
icl /O2 /Qopt-report:1 /Qopt-report-phase:vec Multiply.c /FeVectMult
VectMult
```

When you compare the timing of the two runs, you may see that the vectorized version runs faster. The time for the non-vectorized version is only slightly faster than would be obtained by compiling with the O1 option.

### Obstacles to Vectorization

The following do not always prevent vectorization, but frequently either prevent it or cause the compiler to decide that vectorization would not be worthwhile.

- **Non-contiguous memory access:** Four consecutive integers or floating-point values, or two consecutive doubles, may be loaded directly from memory in a single SSE instruction. But if the four integers are not adjacent, they must be loaded separately using multiple instructions, which is considerably less efficient. The most common examples of non-contiguous memory access are loops with non-unit stride or with indirect addressing, as in the examples below. The compiler rarely vectorizes such loops, unless the amount of computational work is large compared to the overhead from non-contiguous memory access.

```
Example: Non-contiguous Memory Access

// arrays accessed with stride 2
for (int I=0; i<SIZE; I+=2)  b[i] += a[i] * x[i];

// inner loop accesses a with stride SIZE
for (int j=0; j<SIZE; j++) {
  for (int I=0; i<SIZE; I++)   b[i] += a[i][j] * x[j];
}

// indirect addressing of x using index array
for (int I=0; i<SIZE; I+=2)  b[i] += a[i] * x[index[i]];
```

The typical message from the vectorization report is: vectorization possible but seems inefficient, although indirect addressing may also result in the following report: Existence of vector dependence.

- **Data dependencies:** Vectorization entails changes in the order of operations within a loop, since each SIMD instruction operates on several data elements at once. Vectorization is only possible if this change of order does not change the results of the calculation.
• The simplest case is when data elements that are written (stored to) do not appear in any other iteration of the individual loop. In this case, all the iterations of the original loop are independent of each other, and can be executed in any order, without changing the result. The loop may be safely executed using any parallel method, including vectorization. All the examples considered so far fall into this category.

• When a variable is written in one iteration and read in a subsequent iteration, there is a "read-after-write" dependency, also known as a flow dependency, as in this example:

```
Example: Flow Dependency

A[0]=0;
   // this is equivalent to:
```

So the value of j gets propagated to all A[j]. This cannot safely be vectorized: if the first two iterations are executed simultaneously by a SIMD instruction, the value of A[1] is used by the second iteration before it has been calculated by the first iteration.

• When a variable is read in one iteration and written in a subsequent iteration, this is a write-after-read dependency, also known as an anti-dependency, as in the following example:

```
Example: Write-after-read Dependency

    // this is equivalent to:
```

This write-after-read dependency is not safe for general parallel execution, since the iteration with the write may execute before the iteration with the read. However, for vectorization, no iteration with a higher value of j can complete before an iteration with a lower value of j, and so vectorization is safe (that is, it gives the same result as non-vectorized code) in this case. The following example, however, may not be safe, since vectorization might cause some elements of A to be overwritten by the first SIMD instruction before being used for the second SIMD instruction.

```
Example: Unsafe Vectorization

for (j=1; j<MAX; j++)  {
   B[j]=A[j]*2;
}
   // this is equivalent to:
```

• Read-after-read situations are not really dependencies, and do not prevent vectorization or parallel execution. If a variable is unwritten, it does not matter how often it is read.

• Write-after-write, or 'output', dependencies, where the same variable is written to in more than one iteration, are in general unsafe for parallel execution, including vectorization.

• One important exception, that apparently contains all of the above types of dependency:
**Example: Dependency Exception**

```
sum=0;
for (j=1; j<MAX; j++)  sum = sum + A[j]*B[j]
```

Although `sum` is both read and written in every iteration, the compiler recognizes such reduction idioms, and is able to vectorize them safely. The loop in the first example was another example of a reduction, with a loop-invariant array element in place of a scalar.

These types of dependencies between loop iterations are sometimes known as loop-carried dependencies.

The above examples are of proven dependencies. The compiler cannot safely vectorize a loop if there is even a potential dependency. Consider the following example:

**Example: Potential Dependency**

```
for (I = 0; I < size; I++) { c[i] = a[i] * b[i]; }
```

In the above example, the compiler needs to determine whether, for some iteration `I`, `c[i]` might refer to the same memory location as `a[i]` or `b[i]` for a different iteration. Such memory locations are sometimes said to be *aliased*. For example, if `a[i]` pointed to the same memory location as `c[i-1]`, there would be a read-after-write dependency as in the earlier example. If the compiler cannot exclude this possibility, it will not vectorize the loop unless you provide the compiler with hints.

**Helping the Intel® C++ Compiler to Vectorize**

Sometimes the Intel® C++ Compiler has insufficient information to decide to vectorize a loop. There are several ways to provide additional information to the compiler:

- **Pragmas:**
  - `#pragma ivdep:` may be used to tell the compiler that it may safely ignore any potential data dependencies. (The compiler will not ignore proven dependencies). Use of this pragma when there are dependencies may lead to incorrect results.

There are cases where the compiler cannot tell by a static dependency analysis that it is safe to vectorize. Consider the following loop:

**Loop Example**

```
void copy(char *cp_a, char *cp_b, int n) {
    for (int I = 0; I < n; I++) { cp_a[i] = cp_b[i]; }
}
```

Without more information, a vectorizing compiler must conservatively assume that the memory regions accessed by the pointer variables `cp_a` and `cp_b` may (partially) overlap, which gives rise to potential data dependencies that prohibit straightforward conversion of this loop into SIMD instructions. At this point, the compiler may decide to keep the loop serial or, as done by the Intel® C++ compiler, generate a run-time test for overlap, where the loop in the true-branch can be converted into SIMD instructions:

**Example: True-branch Loop**

```
if (cp_a + n < cp_b || cp_b + n < cp_a)
    /* vector loop */
    for (int I = 0; I < n; I++) cp_a[i] = cp_b [i];
```
Example: True-branch Loop

```c
else
    /* serial loop */
    for (int I = 0; I < n; I++) cp_a[i] = cp_b[i];
```

Run-time data-dependency testing provides a generally effective way to exploit implicit parallelism in C or C++ code at the expense of a slight increase in code size and testing overhead. If the function copy is only used in specific ways, however, you can assist the vectorizing compiler as follows:

- If the function is mainly used for small values of \( n \) or for overlapping memory regions, you can simply prevent vectorization and, hence, the corresponding run-time overhead by inserting a \#pragma novector hint before the loop.
- Conversely, if the loop is guaranteed to operate on non-overlapping memory regions, you can provide this information to the compiler by means of a \#pragma ivdep hint before the loop, which informs the compiler that conservatively assumed data dependencies that prevent vectorization can be ignored. This results in vectorization of the loop without run-time data-dependency testing.

Example: Ignoring Data Dependencies with \#pragma ivdep

```c
#pragma ivdep
void copy(char *cp_a, char *cp_b, int n) {
    for (int I = 0; I < n; I++) { cp_a[i] = cp_b[i]; }
}
```

**NOTE**
You can also use the restrict keyword.

- \#pragma loop count (n): may be used to advise the compiler of the typical trip count of the loop. This may help the compiler to decide whether vectorization is worthwhile, or whether or not it should generate alternative code paths for the loop.
- \#pragma vector always: asks the compiler to vectorize the loop if it is safe to do so, whether or not the compiler thinks that will improve performance.
- \#pragma vector align: asserts that data within the following loop is aligned (to a 16-byte boundary, for Intel® SSE instruction sets).
- \#pragma novector: asks the compiler not to vectorize a particular loop.
- \#pragma vector nontemporal: gives a hint to the compiler that data will not be reused, and therefore to use streaming stores that bypass cache.
- **Keywords:** The restrict keyword may be used to assert that the memory referenced by a pointer is not aliased, i.e. that it is not accessed in any other way. The keyword requires the use of either the [Q]restrict or [Q]c99 compiler options. The example under \#pragma ivdep above can also be handled using the restrict keyword.

You may use the restrict keyword in the declarations of \( cp_a \) and \( cp_b \), as shown below, to inform the compiler that each pointer variable provides exclusive access to a certain memory region. The restrict qualifier in the argument list lets the compiler know that there are no other aliases to the memory to which the pointers point. In other words, the pointer for which it is used provides the only means of accessing the memory in question in the scope in which the pointers live. Even if the code gets vectorized without the restrict keyword, the compiler checks for aliasing at run-time, if the restrict keyword was used. You may have to use an extra compiler option, such as [Q]restrict option for the Intel® C++ Compiler.
Example: Restrict Keyword

```c
void copy(char * __restrict cp_a, char * __restrict cp_b, int n) {
    for (int I = 0; I < n; I++) cp_a[I] = cp_b[I];
}
```

This method is convenient in case the exclusive access property holds for pointer variables that are used in a large portion of code with many loops because it avoids the need to annotate each of the vectorizable loops individually. Note, however, that both the loop-specific `#pragma ivdep` hint, as well as the pointer variable-specific restrict hint must be used with care because incorrect usage may change the semantics intended in the original program.

Another example is the following loop that may also not get vectorized because of a potential aliasing problem between pointers `a`, `b` and `c`:

Example: Potential Unsupported Loop Structure

```c
void add(float *a, float *b, float *c) {
    for (int I=0; i<SIZE; I++) { c[i] += a[i] + b[i]; }
}
```

If the restrict keyword is added to the parameters, the compiler will trust you, that you will not access the memory in question with any other pointer and vectorize the code properly:

Example: Using Pointers with the Restrict Keyword

```c
// let the compiler know, the pointers are safe with restrict
void add(float * __restrict a, float * __restrict b, float * __restrict c) {
    for (int I=0; i<SIZE; I++) { c[i] += a[i] + b[i]; }
}
```

The down-side of using restrict is that not all compilers support this keyword, so your source code may lose portability. If you care about source code portability you may want to consider using the [Q]ansi-alias compiler option instead. However, compiler options work globally, so you have to make sure they do not cause harm to other code fragments.

- **Options/switches**: You can use options to enable different levels of optimizations to achieve automatic vectorization:
  - **Interprocedural optimization (IPO)**: Enable IPO using [Q]ip option within a single source file, or using [Q]ipo across source files. You provide the compiler with additional information (trip counts, alignment, or data dependencies) about a loop. Enabling IPO may also allow inlining of function calls.
  - **Disambiguation of pointers and arrays**: Use the options /Oa (Windows*) or -fno-alias (Linux* or macOS*) to assert there is no aliasing of memory references, that is, the same memory location is not accessed via different arrays or pointers. Other options make more limited assertions, for example, /Qalias-args- (Windows*) or -fargument-noalias (Linux* or macOS*) asserts that function arguments cannot alias each other (that is, they cannot overlap). The /Qansi-alias (-fargument-alias) options allow the compiler to assume strict adherence to the aliasing rules in the ISO C standard. Use these options responsibly; if you use these options when memory is aliased it may lead to incorrect results.

**NOTE**

When you specify the [Q]ansi-alias option, the ansi-alias checker is enabled by default. To disable the ansi-alias checker, you must specify -no-ansi-alias-check (Linux* and macOS*) or /Qansi-alias-check (Windows*).
Use the \texttt{ansi-alias-check} option to enable the ansi-alias checker. The ansi-alias checker checks the source code for potential violations of ANSI aliasing rules and disables unsafe optimizations related to the code for those statements that are identified as potential violations.

- **High-level optimizations (HLO):** Enable HLO with option \texttt{O3}. This will enable additional loop optimizations that make it easier for the compiler to vectorize the transformed loops. The HLO report, obtained using the \texttt{opt-report-phase[::]loop} option or the corresponding IDE selection, tells you whether some of these additional transformations occurred.

### Vectorization and Loops

This topic provides more information on the interaction between the auto-vectorizer and loops.

#### Interactions with Loop Parallelization

Combine the \texttt{parallel} and \texttt{x} options to instruct the Intel® C++ Compiler to attempt both Auto-Parallelization and automatic loop vectorization in the same compilation.

**NOTE**
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as \texttt{/arch} (Windows*), \texttt{-m} (Linux* and macOS*), or \texttt{x}.

**NOTE**
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as \texttt{/arch} (Windows*), \texttt{-m} (Linux* and macOS*), or \texttt{x}.

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

In some rare cases, a successful loop parallelization (either automatically or by means of OpenMP* directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where the \texttt{opt-report:2 opt-report-phase:vec} (Windows) or \texttt{-opt-report=2 -opt-report-phase=vec} (Linux and macOS*) options indicate that loops were not successfully vectorized.

#### Types of Vectorized Loops

For integer loops, the 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) and the Intel® Advanced Vector Extensions (Intel® AVX) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types, with limited support for the 64-bit integer data type.
Vectorization may proceed if the final precision of integer wrap-around arithmetic is preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the Intel® SSE and the Intel® AVX instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators:

- addition (+)
- subtraction (-)
- multiplication (*)
- division (/)

Additionally, Intel® SSE provide SIMD instructions for the binary MIN and MAX and unary SQRT operators. SIMD versions of several other mathematical operators (like the trigonometric functions SIN, COS, and TAN) are supported in software in a vector mathematical run-time library that is provided with the Intel® C++ Compiler.

To be vectorizable, loops must be:

- **Countable**: The loop trip count must be known at entry to the loop at runtime, though it need not be known at compile time (that is, the trip count can be a variable but the variable must remain constant for the duration of the loop). This implies that exit from the loop must not be data-dependent.
- **Single entry and single exit**: as is implied by stating that the loop must be countable. Consider the following example of a loop that is not vectorizable, due to a second, data-dependent exit:

  **Example 1: Non-vectorizable Loop**

  ```c
  void no_vec(float a[], float b[], float c[]){
    int i = 0.;
    while (i < 100) {
      a[i] = b[i] * c[i];
      // this is a data-dependent exit condition:
      if (a[i] < 0.0)
        break;
      ++i;
    }
  }
  > icc -c -O2 -qopt-report=2 -qopt-report-phase=vec two_exits.cpp
  two_exits.cpp(4) (col. 9): remark: loop was not vectorized: nonstandard loop is not a
  vectorization candidate.
  ```

- **Contain straight-line code**: SIMD instruction perform the same operation on data elements from multiple iterations of the original loop, therefore, it is not possible for different iterations to have different control flow; that is, they must not branch. It follows that switch statements are not allowed. However, if statements are allowed if they can be implemented as masked assignments, which is usually the case. The calculation is performed for all data elements but the result is stored only for those elements for which the mask evaluates to true. To illustrate this point, consider the following example that may be vectorized:

  **Example 2: Evaluation of a Vectorizable Loop**

  ```c
  #include <math.h>
  void quad(int length, float *a, float *b, float *c, float *restrict x1, float *restrict x2)
  {
    for (int i=0; i<length; i++) {
      float s = b[i]*b[i] - 4*a[i]*c[i];
      if ( s >= 0 )
        
  
  
```
Example 2: Evaluation of a Vectorizable Loop

```c
s = sqrt(s); 
for (i=0;i<nx;i++)
{ 
  x2[i] = (-b[i]+s)/(2.*a[i]);
  x1[i] = (-b[i]-s)/(2.*a[i]);
} else 
{ 
  x2[i] = 0.;
  x1[i] = 0.;
}

> icc -c -restrict -qopt-report=2 -qopt-report-phase=vec quad.cpp
quad5.cpp(5) (col. 3): remark: LOOP WAS VECTORIZED.
```

- **Innermost loop of a nest:** The only exception is if an original outer loop is transformed into an inner loop as a result of some other prior optimization phase, such as unrolling, loop collapsing or interchange, or an original outermost loop is transformed to an innermost loop due to loop materialization.
- **Without function calls:** Even a `printf` statement is sufficient to prevent a loop from getting vectorized.

The vectorization report message is typically: non-standard loop is not a vectorization candidate. The two major exceptions are for intrinsic math functions and for functions that may be inlined.

Intrinsic math functions are allowed, because the compiler runtime library contains vectorized versions of these functions. See the table below for a list of these functions; most exist in both float and double versions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>acos</td>
<td>ceil</td>
<td>fabs</td>
</tr>
<tr>
<td>acosh</td>
<td>cos</td>
<td>floor</td>
</tr>
<tr>
<td>asin</td>
<td>cosh</td>
<td>fmax</td>
</tr>
<tr>
<td>asinh</td>
<td>erf</td>
<td>sinh</td>
</tr>
<tr>
<td>atan</td>
<td>erfnc</td>
<td>sqrt</td>
</tr>
<tr>
<td>atan2</td>
<td>log</td>
<td>tan</td>
</tr>
<tr>
<td>atanh</td>
<td>log2</td>
<td>trunc</td>
</tr>
<tr>
<td>cbrt</td>
<td>exp2</td>
<td>pow</td>
</tr>
</tbody>
</table>

The loop in the following example may be vectorized because `sqrt()` is vectorizable and `func()` gets inlined. Inlining is enabled at default optimization for functions in the same source file. An inlining report may be obtained by setting the options `/Qopt-report:2 /Qopt-report-phase:ipo (Windows) or -qopt-report=2 -qopt-report-phase=ipo (Linux).

Example 3: Inlining of a Vectorizable Loop

```c
float func(float x, float y, float xp, float yp) {
  float denom; 
  denom = (x-xp)*(x-xp) + (y-yp)*(y-yp); 
  denom = 1./sqrtf(denom); 
  return denom; 
}

float trap_int(float y, float x0, float xn, int nx, float xp, float yp) {
  float x, h, sumx; 
  int i; 
  h = (xn-x0) / nx; 
  sumx = 0.5*(func(x0,y,xp,yp) + func(xn,y,xp,yp));
  for (i=1;i<nx;i++)
  { 
```
Example 3: Inlining of a Vectorizable Loop

```c
x = x0 + i*h;
sumx = sumx + func(x,y,xp,yp);
}
sumx = sumx * h;
return sumx;
}
```

// Command line
> icc -c -qopt-report=2 -qopt-report-phase=vec trap_integ.c

trap_int.c(16) (col. 3): remark: LOOP WAS VECTORIZED.

**Statements in the Loop Body**

The vectorizable operations are different for floating-point and integer data.

**Integer Array Operations**

The statements within the loop body may contain `char`, `unsigned char`, `short`, `unsigned short`, `int`, and `unsigned int`. Calls to functions such as `sqrt` and `fabs` are also supported. Arithmetic operations are limited to addition, subtraction, bitwise `AND`, `OR`, and `XOR` operators, division (via run-time library call), multiplication, `min`, and `max`. You can mix data types but this may potentially cost you in terms of lowering efficiency. Some example operators where you can mix data types are multiplication, shift, or unary operators.

**Other Operations**

No statements other than the preceding floating-point and integer operations are allowed. In particular, note that the special `__m64`, `m128`, and `__m256` data types are not vectorizable. The loop body cannot contain any function calls. Use of Intel® SSE intrinsics (for example, `_mm_add_ps`) or Intel® AVX intrinsics (for example, `_mm256_add_ps`) are not allowed.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Loop Constructs

Loops can be formed with the usual for and while constructs. Loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized.

Example: Vectorizable structure

```c
void vec(float a[], float b[], float c[]) {
    int i = 0;
    while (i < 100) {
        // The if branch is inside body of loop.
        a[i] = b[i] * c[i];
        if (a[i] < 0.0)
            a[i] = 0.0;
        i++;
    }
}
```

The following example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.

Example: Non-vectorizable structure

```c
void no_vec(float a[], float b[], float c[]) {
    int i = 0;
    while (i < 100) {
        if (a[i] < 50)
            // The next statement is a second exit
            // that allows an early exit from the loop.
            break;
        ++i;
    }
}
```

Loop Exit Conditions

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable; in other words, the number of iterations must be expressed as one of the following:

- A constant.
- A loop invariant term.
- A linear function of outermost loop indices.

In the case where a loops exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable.

Example: Countable Loop

```c
void cnt1(float a[], float b[], float c[],
           int n, int lb) {
    // Exit condition specified by "N-lb+1"
    int cnt=n, i=0;
    while (cnt >= lb) {
        // lb is not affected within loop.
        a[i] = b[i] * c[i];
        cnt--;
    }
}
```
Example: Countable Loop

```c
void cnt2(float a[], float b[], float c[],
    int m, int n)
{
    // Number of iterations is "(n-m+2)/2".
    int i=0, l;
    for (l=m; l<n; l+=2) {
        a[i] = b[i] * c[i];
        i++;
    }
}
```

The following example demonstrates a different countable loop construct.

Example: Countable Loop

```c
void no_cnt(float a[], float b[], float c[]) {
    int i=0;
    // Iterations dependent on a[i].
    while (a[i]>0.0) {
        a[i] = b[i] * c[i];
        i++;
    }
}
```

The following examples demonstrates a loop construct that is non-countable due to dependency loop variant count value.

Example: Non-Countable Loop

**Strip-mining and Cleanup**

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encodings of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- By increasing the temporal and spatial locality in the data cache if the data are reusable in different passes of an algorithm.
- By reducing the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. In the case of Intel® Streaming SIMD Extensions, this vector or strip-length is reduced by four times: four floating-point data items per single Intel® SSE single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the following loop:
The compiler might handle the strip mining and loop cleaning by restructuring the loop in the following manner:

### Example: After Vectorization

```c
// The vectorizer generates the following two loops
i=0;
while(i<(n-n%4)) {
    // Vector strip-mined loop
    // Subscript [i:i+3] denotes SIMD execution
    a[i:i+3]=b[i:i+3]+c[i:i+3];
    i=i+4;
}
while(i<n) {
    // Scalar clean-up loop
    a[i]=b[i]+c[i];
    ++i;
}
```

**Loop Blocking**

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, thereby maximizing data reuse.

Consider the following example, loop blocking allows arrays `A` and `B` to be blocked into smaller rectangular chunks so that the total combined size of two blocked (`A` and `B`) chunks is smaller than cache size, which can improve data reuse.

### Example: Original loop

```c
#include <time.h>
#include <stdio.h>
#define MAX 7000

void add(int a[][MAX], int b[][MAX]);
int main() {
    int i, j;
    int A[MAX][MAX];
    int B[MAX][MAX];
time_t start, elaspe;
    int sec;

    //Initialize array
    for(i=0;i<MAX;i++) {
        for(j=0;j<MAX; j++) {
            A[i][j]=j;
        }
    }
    return 0;
}
```
The following example illustrates loop blocking the `add` function (from the previous example). In order to benefit from this optimization you might have to increase the cache size.

### Example: Original loop

```c
B[i][j]=j;
} 
}

start= time(NULL);
add(A, B);
elaspe=time(NULL);
sec = elaspe - start;
printf("Time %d",sec); //List time taken to complete add function
}
void add(int a[][MAX], int b[][MAX]) {
  int i, j;
  for(i=0;i<MAX;i++) {
    for(j=0; j<MAX;j++ {
      a[i][j] = a[i][j] + b[j][i]; //Adds two matrices
    }
  }
}
```

### Example: Transformed Loop after Blocking

```c
#include <stdio.h>
#include <time.h>
define MAX 7000
void add(int a[][MAX], int b[][MAX]);

int main() {
  #define BS 8 //Block size is selected as the loop-blocking factor.
  int i, j;
  int A[MAX][MAX];
  int B[MAX][MAX];
  time_t start, elaspe;
  int sec;

  //initialize array
  for(i=0;i<MAX;i++) {
    for(j=0; j<MAX;j++) {
      A[i][j]=j;
      B[i][j]=j;
    }
  }
  start= time(NULL);

  add(A, B);
elaspe=time(NULL);
sec = elaspe - start;
printf("Time %d",sec); //Display time taken to complete loop Blocking function
}
void add(int a[][MAX], int b[][MAX]) {
  int i, j, ii, jj;
```
Example: Transformed Loop after Blocking

```
for(i=0; i<MAX; i+=BS) {
    for(j=0; j<MAX; j+=BS) {
        for(ii=i; ii<i+BS; ii++) {   //outer loop
            for(jj=j; jj<j+BS; jj++) {  //Array B experiences one cache miss
                //for every iteration of outer loop
                a[ii][jj] = a[ii][jj] + b[jj][ii]; //Add the two arrays
            }
        }
    }
}
```

Loop Interchange and Subscripts: Matrix Multiply

Loop interchange is often used for improving memory access patterns. Matrix multiplication is commonly written as shown in the following example:

Example: Typical Matrix Multiplication

```
void matmul_slow(float *a[], float *b[], float *c[]) {
    int N = 100;
    for (int i = 0; i < N; i++)
        for (int j = 0; j < N; j++)
            for (int k = 0; k < N; k++)
                c[i][j] = c[i][j] + a[i][k] * b[k][j];
}
```

The use of $B(K,J)$ is not a stride-1 reference and therefore will not be vectorized efficiently.

If the loops are interchanged, however, all the references will become stride-1 as shown in the following example.

Example: Matrix Multiplication with Stride-1

```
void matmul_fast(float *a[], float *b[], float *c[]) {
    int N = 100;
    for (int i = 0; i < N; i++)
        for (int k = 0; k < N; k++)
            for (int j = 0; j < N; j++)
                c[i][j] = c[i][j] + a[i][k] * b[k][j];
}
```

Interchanging is not always possible because of dependencies, which can lead to different results.

Explicit Vector Programming

User-Mandated or SIMD Vectorization

User-mandated or SIMD vectorization supplements automatic vectorization just like OpenMP* parallelization supplements automatic parallelization. The following figure illustrates this relationship. User-mandated vectorization is implemented as a single-instruction-multiple-data (SIMD) feature and is referred to as SIMD vectorization.
NOTE
The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or /Qx.

The following figure illustrates how SIMD vectorization is positioned among various approaches that you can take to generate vector code that exploits vector hardware capabilities. The programs written with SIMD vectorization are very similar to those written using auto-vectorization hints. You can use SIMD vectorization to minimize the amount of code changes that you may have to go through in order to obtain vectorized code.

SIMD vectorization uses the #pragma omp simd pragma to effect loop vectorization. You must add this pragma to a loop and recompile to vectorize the loop using the option -qopenmp-simd (Linux and macOS*) or Qopenmp-simd (Windows*).

Consider an example in C++ where the function add_floats() uses too many unknown pointers for the compiler’s automatic runtime independence check optimization to kick in. You can give a data dependence assertion using the auto-vectorization hint via #pragma ivdep and let the compiler decide whether the auto-vectorization optimization should be applied to the loop. Or you can now enforce vectorization of this loop by using #pragma omp simd.
### Example: without `#pragma omp simd`

```c
[D:/simd] cat example1.c
void add_floats(float *a, float *b, float *c, float *d, float *e, int n) {
    int i;
    for (i=0; i<n; i++){
        a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
    }
}
```

```c
example1.c
```

Begin optimization report for: `add_floats(float *, float *, float *, float *, float *, int)`

Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example1.c(3,2)
 remark #15344: loop was not vectorized: vector dependence prevents vectorization. First dependence is shown below. Use level 5 report for details
 remark #15346: vector dependence: assumed FLOW dependence between a[i] (4:3) and b[i] (4:3)
LOOP END

LOOP BEGIN at C:\Users\test\run\example1.c(4,2)
 LOOP END
===========================================================================

### Example: with `#pragma omp simd`

```c
[D:/simd] cat example1.c
void add_floats(float *a, float *b, float *c, float *d, float *e, int n) {
    int i;
    #pragma omp simd
    for (i=0; i<n; i++){
        a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
    }
}
```

```c
example1.c
```

Begin optimization report for: `add_floats(float *, float *, float *, float *, float *, int)`

Report from: Vector optimizations [vec]

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
 remark #15301: OpenMP SIMD LOOP WAS VECTORIZED
LOOP END
The one big difference between using `#pragma omp simd` and auto-vectorization hints is that with `#pragma omp simd`, the compiler generates a warning when it is unable to vectorize the loop. With auto-vectorization hints, actual vectorization is still under the discretion of the compiler, even when you use the `#pragma vector always` hint.

`#pragma omp simd` has optional clauses to guide the compiler on how vectorization must proceed. Use these clauses appropriately so that the compiler obtains enough information to generate correct vector code. For more information on the clauses, see the `#pragma omp simd` description.

### Additional Semantics

Note the following points when using the `omp simd` pragma.

- A variable may belong to zero or one of the following: private, linear, or reduction.
- Within the vector loop, an expression is evaluated as a vector value if it is private, linear, reduction, or it has a sub-expression that is evaluated to a vector value. Otherwise, it is evaluated as a scalar value (that is, broadcast the same value to all iterations). Scalar value does not necessarily mean loop invariant, although that is the most frequently seen usage pattern of scalar value.
- A vector value may not be assigned to a scalar L-value. It is an error.
- A scalar L-value may not be assigned under a vector condition. It is an error.
- The `switch` statement is not supported.

**NOTE**
You may find it difficult to describe vector semantics using the SIMD pragma for some auto-vectorizable loops. One example is `MIN/MAX` reduction in C since the language does not have `MIN/MAX` operators.

### Using vector Declaration

Consider the following C++ example code with a loop containing the math function, `sinf()`.

**NOTE** All code examples in this section are applicable for C/C++ on Windows* only.
Example: Loop with math function is auto-vectorized

```c
for (i=0; i<n; i++) {
    a[i] = sinf(b[i]);
}
```

[D:/simd] icl -nologo -c -Qrestrict -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-phase=vec example2.c

Begin optimization report for: vsin(float *restrict, float *restrict, int)

```
Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
<Peeled loop for vectorization>
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
    remark #15300: LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
    <Alternate Alignment Vectorized Loop>
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
    <Remainder loop for vectorization>
LOOP END
```

When you compile the above code, the loop with `sinf()` function is auto-vectorized using the appropriate Short Vector Math Library (SVML) library function provided by the Intel® C++ Compiler. The auto-vectorizer identifies the entry points, matches up the scalar math library function to the SVML function and invokes it.

However, within this loop if you have a call to your function, `foo()`, that has the same prototype as `sinf()`, the auto-vectorizer fails to vectorize the loop because it does not know what `foo()` does unless it is inlined to this call site.

Example: Loop with user-defined function is NOT auto-vectorized

```c
[D:/simd] cat example2.c
float foo(float);
void vfoo(float *restrict a, float *restrict b, int n){
    int i;
    for (i=0; i<n; i++){
        a[i] = foo(b[i]);
    }
}
```

[D:/simd] icl -nologo -c -Qrestrict -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-phase=vec example2.c

Begin optimization report for: vsin(float *restrict, float *restrict, int)
Example: Loop with user-defined function is NOT auto-vectorized

Report from: Vector optimizations [vec]

Non-optimizable loops:

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
  remark #15543: loop was not vectorized: loop with function call not considered an optimization candidate.
LOOP END

In such cases, you can use the __declspec(vector) (Windows*) or __attribute__((vector)) (Linux*) declaration to vectorize the loop. All you need to do is add the vector declaration to the function declaration, and recompile both the caller and callee code, and the loop and function are vectorized.

Example: Loop with user-defined function with simd declaration is vectorized

[D:/simd] cat example3.c
// foo() and vfoo() do not have to be in the same compilation unit as long
// as both see the same "#pragma omp declare simd" lines.
#pragma omp declare simd
float foo(float);
void vfoo(float * restrict a, float * restrict b, int n){
  int i;
  for (i=0; i<n; i++) { a[i] = foo(b[i]); }
}

float foo(float x) { ... }

example3.c
Begin optimization report for: vfoo(float *restrict, float *restrict, int)

Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
  <Peeled loop for vectorization>
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
  remark #15300: LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
  <Alternate Alignment Vectorized Loop>
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
  <Remainder loop for vectorization>
LOOP END

===========================================================================

Optimization and Programming Guide

2193
Restrictions on Using #pragma omp declare simd declaration

Vectorization depends on two major factors: hardware and the style of source code. When using the vector declaration, the following features are not allowed:

- Thread creation and joining through `_Cilk_spawn, _Cilk_for, OpenMP* parallel/for/sections/task/target/teams, and explicit threading API calls.

**NOTE**

- Locks, barriers, atomic construct, critical sections (These are allowed inside #pragma omp ordered simd blocks).
- Inline ASM code, VM and Vector Intrinsics (for example, SVML intrinsics).
- Using setjmp, longjmp, SHE and computed GOTO.
- EH is not allowed and all vector functions are considered noexcept.
- The switch statement (in some cases this may be supported and converted to if statements, but this is not reliable).
- The exit()/abort() calls.

Non-vector function calls are generally allowed within vector functions but calls to such functions are serialized lane-by-lane and so might perform poorly. Also for SIMD-enabled functions it is not allowed to have side effects except writes by their arguments. This rule can be violated by non-vector function calls, so be careful executing such calls in SIMD-enabled functions.

Formal parameters must be of the following data types:

- (un)signed 8, 16, 32, or 64-bit integer
- 32- or 64-bit floating point
- 64- or 128-bit complex
- A pointer (C++ reference is considered a pointer data type)

__declspec(vector) declaration

Function Annotations and the SIMD Directive for Vectorization

`omp simd pragma` is described in the OpenMP* spec at www.openmp.org.
**SIMD-Enabled Functions**

SIMD-enabled functions (formerly called elemental functions) are a general language construct to express a data parallel algorithm. A SIMD-enabled function is written as a regular C/C++ function, and the algorithm within describes the operation on one element, using scalar syntax. The function can then be called as a regular C/C++ function to operate on a single element or it can be called in a data parallel context to operate on many elements. In Intel® Cilk™ Plus, the data parallel context is provided as an array.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

If you are using SIMD-enabled functions and need to link a compiler object file with an object file from a previous version of the compiler (for example, 13.1), you need to use the [Q]vecabi compiler option, specifying the legacy keyword.

**How SIMD-Enabled Functions Work**

When you write a SIMD-enabled function, the compiler generates short vector variants of the function that you requested, which can perform your function's operation on multiple arguments in a single invocation. The short vector variant may be able to perform multiple operations as fast as the regular implementation performs a single one by utilizing the vector instruction set architecture (ISA) in the CPU. When a call to a SIMD-enabled function occurs in a SIMD loop or another SIMD-enabled function, the compiler replaces the scalar call with the best fit from the available short-vector variants of the function.

In addition, when invoked from a cilk_for or pragma omp construct, the compiler may assign different copies of the SIMD-enabled functions to different threads (or workers), executing them concurrently. The end result is that your data parallel operation executes on the CPU utilizing both the parallelism available in the multiple cores and the parallelism available in the vector ISA. In other words, if the short vector function is called inside a parallel loop, a cilk_for loop, or an auto-parallelized loop that is vectorized, you can achieve both vector-level and thread-level parallelism.

**Declaring a SIMD-Enabled Function**

In order for the compiler to generate the short vector function, you need to use the appropriate syntax from below in your code:

**Windows***:
Use the _declspec(vector (clauses)) declaration, as follows:

```c
_declspec(vector (clauses)) return_type simd_enabled_function_name(parameters)
```

**Linux*** and **macOS***:
Use the __attribute__((vector (clauses))) declaration, as follows:

```c
__attribute__((vector (clauses))) return_type simd_enabled_function_name(parameters)
```

Alternately, you can use the following OpenMP* pragma, which requires the [q or Q]openmp or [q or Q]openmp-simd compiler option:

```c
#pragma omp declare simd clauses
```

The clauses in the vector declaration may be used for achieving better performance by overriding defaults. These clauses at SIMD-enabled function definition declare one or several short vector variants for a SIMD-enabled functions. Multiple vector declarations with different set of clauses may be attached to one function in order to declare multiple different short vector variants available for a SIMD-enabled function.

The clauses are defined as follows:
**processor(cpuid)**

Tells the compiler to generate a vector variant using the instructions, the caller/callee interface, and the default vectorlength selection scheme suitable to the specified processor. Use of this clause is highly recommended, especially for processors with wider vector register support (i.e., core_2nd_gen_avx and newer).

*cpuid* takes one of the following values:

- mic_avx512
- core_4th_gen_avx_tsx
- core_4th_gen_avx
- mic
- core_3rd_gen_avx
- core_2nd_gen_avx
- core_aes_pclmulqdq
- core_17_sse4_2
- atom
- core_2_duo_sse4_1
- core_2_duo_ssse3
- pentium_4_sse3
- pentium_m
- pentium_4
- haswell
- broadwell
- skylake
- skylake_avx512
- knl
- knm

**vectorlength(n) / simdlen(n) (for omp declare simd)**

Where *n* is a vector length that is a power of 2, no greater than 32.

The *simdlen* clause tells the compiler that each routine invocation at the call site should execute the computation equivalent to *n* times the scalar function execution. When omitted the compiler selects the vector length automatically depending on the routine return value, parameters, and/or the processor clause. When multiple vector variants are called from one vectorization context (for example, two different functions called from the same vector loop), explicit use of identical *simdlen* values are advised to achieve good performance.

**linear(list_item[,, list_item...])**

where *list_item* is one of:

- *param*:step
- *val(param*:step)
- *ref(param*:step)
- *uval(param*:step)

The *linear* clause tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of *param* is incremented by *step*, where *param* is a formal parameter of the specified function or the C++ keyword *this*. The *linear* clause can be used on parameters that are either scalar (non-arrays and of non-structured types), pointers, or C++ references. *step* is a compile-time integer constant expression, which defaults to 1 if omitted.

If more than one step is specified for a particular parameter, a compile-time error occurs.

Multiple *linear* clauses will be merged as a union.

The meaning of each variant of the clause is as follows:
linear(param[:step])  For parameters that are not C++ references: the clause tells the compiler that on each iteration of the loop from which the routine is called the value of the parameter will be incremented by step. The clause can also be used for C++ references for backward compatibility, but it is not recommended.

linear(val(param[:step])))  For parameters that are C++ references: the clause tells the compiler that on each iteration of the loop from which the routine is called the referenced value of the parameter will be incremented by step.

linear(uval(param[:step])))  For C++ references: means the same as linear(val()). It differs from linear(val()) so that in case of linear(val()) a vector of references is passed to vector variant of the routine but in case of linear(uval()) only one reference is passed (and thus linear(uval()) is better to use in terms of performance).

linear(ref(param[:step])))  For C++ references: means that the reference itself is linear, i.e. the referenced values (that form a vector for calculations) are located sequentially, like in array with the distance between elements equal to step.

uniform(param [, param,]...)  Where param is a formal parameter of the specified function or the C++ keyword this.

The uniform clause tells the compiler that the values of the specified arguments can be broadcast to all iterations as a performance optimization. It is often useful in generating more favorable vector memory references. On the other hand, lack of uniform clause may allow broadcast operations to be hoisted out of the caller loop. Evaluate carefully the performance implications. Multiple uniform clauses are merged as a union.

mask / nomask  The mask and nomask clauses tell the compiler to generate only masked or unmasked (respectively) vector variants of the routine. When omitted, both masked and unmasked variants are generated. The masked variant is used when the routine is called conditionally.

inbranch / notinbranch  The inbranch and notinbranch clauses are used with #pragma omp declare simd. The inbranch clause works the same as the mask clause above and the notinbranch clause works the same as the nomask clause above.

Write the code inside your function using existing C/C++ syntax and relevant built-in functions (see the section on __intel_simd_lane() below).

Usage of Vector Function Specifications

You may define several vector variants for one routine with each variant reflecting a possible usage of the routine. Encountering a call, the compiler matches vector variants with actual parameter kinds and chooses the best match. Matching is done by priorities. In other words, if an actual parameter is the loop invariant and the uniform clause was specified for the corresponding formal parameter, then the variant with the uniform clause has a higher priority. Linear specifications have the following order, from high priority to low: linear(uval()), linear(), linear(val()), linear(ref()). Consider the following example loops with the calls to the same routine.
Example: OpenMP*

```c
// routine prototype
#pragma omp declare simd // universal but slowest definition matches the use in all three loops
#pragma omp declare simd linear(in1) linear(ref(in2)) uniform(mul) // matches the use in the first loop
#pragma omp declare simd linear(ref(in2)) // matches the use in the second and the third loops
#pragma omp declare simd linear(ref(in2)) linear(mul) // matches the use in the second loop
#pragma omp declare simd linear(val(in2:2)) // matches the use in the third loop
extern int func(int* in1, int& in2, int mul);

int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
for (int i = 0; i < nn; i++) {
    c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed linearly,
                                        // the second reference is changed linearly too
                                        // the third parameter is not changed
}

#pragma omp simd
for (int i = 0; i < nn; i++) {
    c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is unpredictable,
                                        // the second reference is changed linearly
                                        // the third parameter is changed linearly
}
```

Example: Intel® Cilk™ Plus

```c
// routine prototype
__declspec(vector) // universal but slowest definition matches the use in all three loops
__declspec(vector(linear(in1), linear(ref(in2)), uniform(mul))) // matches the use in the first loop
__declspec(vector(linear(ref(in2)))) // matches the use in the second and the third loops
__declspec(vector(linear(ref(in2)), linear(mul))) // matches the use in the second loop
__declspec(vector(linear(val(in2:2)))) // matches the use in the third loop
```

Example: Intel® C++ Compiler 19.0 Developer Guide and Reference
Example: Intel® Cilk™ Plus

extern int func(int* in1, int& in2, int mul);
int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
for (int i = 0; i < nn; i++) {
    c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed linearly,
    // the second reference is changed linearly too
    // the third parameter is not changed
}
for (int i = 0; i < nn; i++) {
    c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is unpredictable,
    // the second reference is changed linearly
    // the third parameter is changed linearly
}
#pragma simd private(k)
for (int i = 0; i < nn; i++) {
    int k = i * 2; // during vectorization, private variables are transformed into arrays:
    c[i] = func(&a[ndx[i]], b[i], i); // the value of the first parameter is unpredictable,
    // the second reference and value can be considered linear
    // the third parameter has unpredictable value
    // {the __declspec(vector(linear(val(in2:2)))) will be chosen from the two matching variants}
}

SIMD-Enabled Functions and C++

You should use SIMD-enabled functions in modern C++ with caution: C++ imposes strict requirements on compilation and execution environments which may not compose well with semantically-rich language extensions such as SIMD-enabled functions. There are 3 key aspects of C++ that interrelate with SIMD-enabled functions concept: exception handling, dynamic polymorphism, and the C++ type system.

SIMD-Enabled Functions and Exception Handling

Exceptions are currently not supported in SIMD contexts: exceptions cannot be thrown and/or caught in SIMD loops and SIMD-enabled functions. Therefore, all SIMD-enabled functions are considered noexcept in C++11 terms. This affects not only short vector variants of a function, but its original scalar routine as well. This is enforced when the function is compiled: it is checked against throw construct and against function calls throwing exceptions. It is also enforced when the SIMD-enabled function call is compiled.

SIMD-Enabled Functions and Dynamic Polymorphism

Vector attributes can be applied to virtual functions of classes with some limitations and taken into account during polymorphic virtual function calls. The syntax of vector declarations is the same as for regular SIMD-enabled class methods: just attach vector declarations as described above to the method declarations inside the class declaration.
Vector function attributes for virtual methods are inherited. If a vector attribute is specified for an overriding virtual function, it must match that of the overridden function. Even if the virtual method implementation is overridden in a derived class the vector declarations are inherited and applied. A set of vector variants is produced for the override according to vector variants set on parent. This rule also applies when the parent does not have any vector variants. If some virtual method is introduced as non-SIMD-enabled (no vector declarations supplied) it cannot become SIMD-enabled in the derived class even if the derived class contains its own implementation of the virtual method.

Matching vector variants for a virtual methods is done by the declared (static) type of an object for which the method is called. The actual (dynamic) type of an object may either coincide with the static type or be inherited from it.

Unlike regular function calls which transfer control to one target function, the call target of a virtual function depends on the dynamic type of the object for which the method is called and accomplished indirectly via the virtual function table of a class. In a single SIMD chunk, the virtual method may be invoked for objects of multiple classes, for example, elements of a polymorphic collection. This requires multiple calls to different targets within a single SIMD chunk. This works as follows:

1. If a SIMD-enabled virtual function call is matched to a variant with a uniform this parameter, multiple calls are not needed. The compiler makes an indirect call to the matched vector variant of a virtual method of the object's dynamic class.
2. If a SIMD-enabled virtual function call is matched to a variant with a non-uniform this parameter, all objects in a SIMD chunk may still share the same virtual method implementation. This is checked and a single, indirect call to the matched vector variant of the target virtual method implementation is invoked.
3. Otherwise, lanes sharing virtual call targets are masked-in and a masked vector variant corresponding to the match is invoked in a loop for each unique virtual call target. If a masked variant is not provided for matching a vector variant and a this parameter is not declared uniform, the match will be rejected.

The following example illustrates SIMD-enabled virtual functions:

```c++
Example: OpenMP*

struct Base {
    #pragma omp declare simd
    #pragma omp declare simd uniform(this)
    virtual int process(int);
};

struct Child1 : Base {
    // int process(int); is inherited
};

struct Child11 : Child1 {
    int process(int); // Overrides implementation, inherits vector declarations
};

struct Child2 : Base {
    int process(int); // Overrides implementation, inherits vector declarations
};

int main() {
    int arr[100];
    Base* c2 = new Child2();
    Base* objs[100];
    int res = 0;

    // SIMD-enabled virtual function call for uniform object
```
Example: OpenMP*

```c
#pragma omp simd reduction(+:res)
for (int i = 0; i < 100; i++) {
    res += c2->process(arr[i]); // Variant with uniform this is matched
    // call to vector variant of
    // Child2::process() is invoked
}

// Initialize polymorphic array of objects
for (int i = 0; i < 100; i++) {
    if (i % 16 < 4) objs[i] = new Base();
    else if (i % 16 < 8) objs[i] = new Child1();
    else if (i % 12 < 12) objs[i] = new Child11();
    else_objs[i] = new Child2();
}

// SIMD-enabled virtual function call for non-uniform objects
#pragma omp simd reduction(+:res) simdlen(8)
for (int i = 0; i < 100; i++) {
    res += objs[i]->process(arr[i]); // Variant with non-uniform this is matched
    // Base and Child1 share the same 'process' implementation, so call
    // targets for each even chunk [i*16:i*16+7] are the same even though
    // this pointers are different for all elements of objs[] array.
    // Odd chunks [i*16+8:i*16+15] consist of objects of classes Child11
    // and Child2 and so require calls to their respective implementations
    // of process() virtual functions. Masked vector variant for
    // Child11::process() is called with mask 0b00001111 (lower lanes of a
    // chunk) and masked vector variant for Child2::process() is called
    // with mask 0b11110000 (upper lanes of a chunk).
}
return res;
```

Example: Intel® Cilk™ Plus

```c
struct Base {
    __declspec(vector)
    __declspec(vector(uniform(this)))
    virtual int process(int);
};

struct Child1 : Base {
    // int process(int); is inherited
};

struct Child11 : Child1 {
    int process(int); // Overrides implementation, inherits vector declarations
};

struct Child2 : Base {
    int process(int); // Overrides implementation, inherits vector declarations
};
```
Example: Intel® Cilk™ Plus

```cpp
int main() {
    int arr[100];
    Base* c2 = new Child2();
    Base* objs[100];
    int res = 0;

    // SIMD-enabled virtual function call for uniform object
    #pragma simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += c2->process(arr[i]);  // Variant with uniform this is matched
        // call to vector variant of
        // Child2::process() is invoked
    }

    // Initialize polymorphic array of objects
    for (int i = 0; i < 100; i++) {
        if (i % 16 < 4) objs[i] = new Base();
        else if (i % 16 < 8) objs[i] = new Child1();
        else if (i % 12 < 12) objs[i] = new Child11();
        else objs[i] = new Child2();
    }

    // SIMD-enabled virtual function call for non-uniform objects
    #pragma simd reduction(+:res) vectorlength(8)
    for (int i = 0; i < 100; i++) {
        res += objs[i]->process(arr[i]);  // Variant with non-uniform this is matched
        // Base and Child1 share the same 'process' implementation, so call
        // targets for each even chunk [i*16:i*16+7] are the same even though
        // this pointers are different for all elements of objs[] array.

        // Odd chunks [i*16+8:i*16+15] consist of objects of classes Child11
        // and Child2 and so require calls to their respective implementations
        // of process() virtual functions. Masked vector variant for
        // Child11::process() is called with mask 0b00001111 (lower lanes of a
        // chunk) and masked vector variant for Child2::process() is called
        // with mask 0b11110000 (upper lanes of a chunk).
    }

    return res;
}
```

The following are limitations to SIMD-enabled virtual function support:

- Multiple inheritance, including virtual inheritance, is not supported for classes having SIMD-enabled virtual methods. This is because calls to virtual functions in multiple inheritance cases may be done through special functions called thunks which adjust the 'this' pointer and/or virtual function table pointer. The current implementation doesn't support thunks for SIMD-enabled virtual calls because in this case thunks should themselves become SIMD-enabled functions which is not implemented.

- It is not possible to get the address of a SIMD-enabled virtual method. Support of SIMD-enabled virtual functions would require additional information, so their binary representation is different. Such cases will not be handled properly by code expecting a regular pointer to the virtual member.
### SIMD-Enabled Functions and the C++ Type System

Vector attributes are attributes in the C++11 sense and so are not part of a functional type of SIMD-Enabled functions. Vector attributes are bound to the function itself, an instance of a functional type. This has the following implications:

- Template instantiations having SIMD-enabled functions as template parameters won’t catch vector attributes, so it is currently impossible to reliably preserve vector attributes in function wrapper templates like `std::bind` which add indirection. This indirection may sometimes be optimized away by compiler and the resulting direct call will have all vector attributes associated.
- There is no way to overload or specialize templates by vector attributes.
- There is no way to write functional traits to capture vector attributes for the sake of template metaprogramming.

The example below depicts various situations where this situation may be observed:

**Example: OpenMP**

```cpp
// Function value template - captures exact function
// not a function type
template <int f(int)>   // Function value template – captures exact function
    int caller1(int x[100]) {  // Exact function put here upon instantiation
    int res = 0;
    #pragma omp simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]);
    }
    return res;
}

// Generic functional type template – captures
// object type for functors or entire functional type
// for functions. If vector attributes were part of
// a functional type they might be captured and applied
// but currently they are not.
template <typename F>  // Generic functional type template – captures
    int caller2(F f, int x[100]) {  // Will call matching function 'f' indirectly
    int res = 0;
    #pragma omp simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]);
        // Will call matching f.operator() directly
    }
    return res;
}

// Type-decomposing template
// captures argument and return types.
// Vector attributes would be lost
// even if they were part of a
// functional type.
template <typename RET, typename ARG>  // Type-decomposing template
    int caller3(RET (*f)(ARG), int x[100]) {  // Type-decomposing template
    int res = 0;
    #pragma omp simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]);
        // Will call matching function 'f' indirectly
    }
    return res;
}
```
Example: OpenMP*

```cpp
#pragma omp declare simd
int function(int x); // SIMD-enabled function
int nv_function(int x); // Regular scalar function

struct functor {
               // Functor class with
#pragma omp declare simd // SIMD-enabled operator()
    int operator()(int x);
};

int arr[100];

int main() {
    int res;
#pragma noinline
    res = caller1<function>(arr); // This will be instantiated for
    // function() and call short vector variant
#pragma noinline
    res += caller1<nv_function>(arr); // This will be separately instantiated
    // for nv_function()
#pragma noinline
    res += caller2(function, arr); // This will be instantiated for
    // int(*)(int) type and will call scalar
    // function() indirectly
#pragma noinline
    res += caller2(nv_function, arr); // This will call the same
    // instantiation as above on nv_function
#pragma noinline
    res += caller2(functor(), arr); // This will be instantiated for
    // functor type and will call short vector
    // variant of functor::operator()
#pragma noinline
    res += caller3(function, arr); // This will be instantiated for
    // <int, int> types and will call scalar
    // function() indirectly
#pragma noinline
    res += caller3(nv_function, arr); // This will call the same
    // instantiation as above on nv_function

    return res;
}
```

Example: Intel® Cilk™ Plus

```cpp
template <int f(int)> // Function value template – captures exact function
    // not a function type
int caller1(int x[100]) {
    int res = 0;
#pragma simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]); // Exact function put here upon instantiation
    }
    return res;
}
```

```cpp
template <typename F> // Generic functional type template – captures
```
Example: Intel® Cilk™ Plus

```c
// object type for functors or entire functional type
// for functions. If vector attributes were part of
// a functional type they might be captured and applied
// but currently they are not.

int caller2(F f, int x[100]) {
    int res = 0;
    #pragma simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]);  // Will call matching function 'f' indirectly
                        // Will call matching f.operator() directly
    }
    return res;
}

template <typename RET, typename ARG>  // Type-decomposing template
// captures argument and return types.
// Vector attributes would be lost
// even if they were part of a
// functional type.

int caller3(RET (*f)(ARG), int x[100]) {
    int res = 0;
    #pragma simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
        res += f(x[i]);  // Will call matching function 'f' indirectly
    }
    return res;
}

__declspec(vector) int function(int x); // SIMD-enabled function
int nv_function(int x);                 // Regular scalar function

struct functor {
    __declspec(vector) // SIMD-enabled operator()
    int operator()(int x);
};

int arr[100];

int main() {
    int res;
    #pragma noinline
    res = caller1<function>(arr); // This will be instantiated for
                                   // function() and call short vector variant
    #pragma noinline
    res += caller1<nv_function>(arr); // This will be separately instantiated
                                      // for nv_function()
    #pragma noinline
    res += caller2(function, arr); // This will be instantiated for
                                    // int(*)(int) type and will call scalar
                                    // function() indirectly
    #pragma noinline
    res += caller2(nv_function, arr); // This will call the same
                                      // instantiation as above on nv_function
```
## Example: Intel® Cilk™ Plus

```cpp
#pragma noinline
res += caller2(functor(), arr); // This will be instantiated for
    // functor type and will call short vector
    // variant of functor::operator()

#pragma noinline
res += caller3(function, arr); // This will be instantiated for
    // <int, int> types and will call scalar
    // function() indirectly

#pragma noinline
res += caller3(nv_function, arr); // This will call the same
    // instantiation as above on nv_function

return res;
```

### NOTE
If calls to `caller1`, `caller2` and `caller3` are inlined, the compiler is able to replace indirect calls by direct calls in all cases. In this case `caller2(function, arr)` and `caller3(function, arr)` both call short vector variants of a function as result of the usual replacement of direct calls to `function()` by matching short vector variants in the SIMD loop.

## Invoking a SIMD-Enabled Function with Parallel Context

Typically, the invocation of a SIMD-enabled function provides arrays wherever scalar arguments are specified as formal parameters. Use the array notation syntax available in Intel® Cilk™ Plus to provide the arrays succinctly. Alternatively, you can invoke the function from a `_Cilk_for` loop.

The following two invocations will give instruction-level parallelism by having the compiler issue special vector instructions.

```cpp
a[:] = ef_add(b[:],c[:]);    //operates on the whole extent of the arrays a, b, c

a[0:n:s] = ef_add(b[0:n:s],c[0:n:s]); //use the full array notation construct to also specify n as an extend and s as a stride
```

To invoke the SIMD-enabled function in a data parallel context and use multiple cores and processors use `_Cilk_for`:

```cpp
_Cilk_for (j = 0; j < n; ++j) {
    a[j] = ef_add(b[j],c[j]);
}
```

### NOTE
Only the calling code using the `_Cilk_for` calling syntax is able to use all available parallelism. The array notation syntax, as well as calling the SIMD-enabled function from the regular `for` loop, results in invoking the short vector function in each iteration and utilizing the vector parallelism but the invocation is done in a serial loop, without utilizing multiple cores.

Use of array notation syntax and SIMD-enabled functions in a regular `for` loop results in invoking the short vector function in each iteration and utilizing the vector parallelism, but the invocation is done in a serial loop without utilizing multiple cores. To use all available parallelism one should explore the use of Intel® Cilk™ Plus keywords (e.g., `cilk_for` or `cilk_spawn`) or OpenMP*.
Using the __intel_simd_lane() Built-in Function

When called from within a vectorized loop, the __intel_simd_lane() built-in function will return a number between 0 and vectorlength - 1 that reflects the current "lane id" within the SIMD vector. __intel_simd_lane() will return zero if the loop is not vectorized. Calling __intel_simd_lane() outside of an explicit vector programming construct is discouraged. It may prevent auto-vectorization and such a call often results in the function returning zero instead of a value between 0 and vectorlength-1.

To see how __intel_simd_lane() can be used, consider the following example:

```c
void accumulate(float *a, float *b, float *c, d){
  *a+=sin(d);
  *b+=cos(d);
  *c+=log(d);
}

for (i=low; i<high; i++){
  accumulate(&suma, &sumb, &sumc, d[i]);
}
```

A first-run conversion to Intel® Cilk™ Plus vector code without __intel_simd_lane() might look like this:

**Example: OpenMP**

```c
#define VL 16
#pragma omp declare simd uniform(a,b,c) linear(i)
void accumulate(float *a, float *b, float *c, d, i){
  a[i & (VL-1)]+=sin(d);
  b[i & (VL-1)]+=cos(d);
  c[i & (VL-1)]+=log(d);
}

float a[VL] = {0.0f};
float b[VL] = {0.0f};
float c[VL] = {0.0f};
#pragma omp simd for simdlen(VL)
for (i=low; i<high; i++){
  accumulate(a, b, c, d[i], i);
}
for(i=0;i<VL;i++){ 
  suma += a[i];
  sumb += b[i];
  sumc += c[i];
}
```

**Example: Intel® Cilk™ Plus**

```c
#define VL 16
__declspec(vector(uniform(a,b,c), linear(i)))
void accumulate(float *a, float *b, float *c, d, i){
  a[i & (VL-1)]+=sin(d);
  b[i & (VL-1)]+=cos(d);
  c[i & (VL-1)]+=log(d);
}

float a[VL] = {0.0f};
float b[VL] = {0.0f};
float c[VL] = {0.0f};
#pragma omp simd for safelen(VL)
```
The gather-scatter type memory addressing caused by the references to arrays A, B, and C in the SIMD-enabled function `accumulate()` will significantly hurt performance making the whole conversion useless. To avoid this penalty you may use the `__intel_simd_lane()` built-in function as follows:

**Example: Intel® Cilk™ Plus**

```cpp
for (i=low; i<high; i++){  
    accumulate(a, b, c, d[i], i); 
}
for(i=0;i<VL;i++){  
    suma += a[i];  
    sumb += b[i];  
    sumc += c[i]; 
}
```

**Example: OpenMP**

```cpp
#pragma omp declare simd uniform(a,b,c) aligned(a,b,c)  
void accumulate(float *a, float *b, float *c, float d){  
    a[__intel_simd_lane()] += sin(d);  
    b[__intel_simd_lane()] += cos(d);  
    c[__intel_simd_lane()] += log(d);  
}
#define VL 16 // actual SIMD code may use vectorlength of 4 but it's okay.  
float a[VL] = {0.0f};  
float b[VL] = {0.0f};  
float c[VL] = {0.0f};  
#pragma omp simd for simdlen(VL)  
for (i=low; i<high; i++){  
    if (low is known to be zero at compile time, “i & (VL-1)”  
    would accomplish what __intel_simd_lane() is intended for,  
    but only on the caller side.  
    accumulate(a, b, c, d[i]);  
}
for(i=0;i<VL;i++){  
    suma += a[i];  
    sumb += b[i];  
    sumc += c[i]; 
}
```

**Example: Intel® Cilk™ Plus**

```cpp
__declspec(vector(uniform(a,b,c),aligned(a,b,c)))  
void accumulate(float *a, float *b, float *c, d){  
    a[__intel_simd_lane()] += sin(d);  
    b[__intel_simd_lane()] += cos(d);  
    c[__intel_simd_lane()] += log(d);  
}
#define VL 16 // actual SIMD code may use vectorlength of 4 but it's okay.  
float a[VL] = {0.0f};  
float b[VL] = {0.0f};  
float c[VL] = {0.0f};
```
Example: Intel® Cilk™ Plus

```c
#pragma omp simd for safe_veclen(VL)
for (i=low; i<high; i++){
    // If low is known to be zero at compile time, "i & (VL-1)"
    // would accomplish what __intel_simd_lane() is intended for,
    // but only on the caller side.
    accumulate(a, b, c, d[i]);
}
for(i=0;i<VL;i++){
    suma += a[i];
    sumb += b[i];
    sumc += c[i];
}
```

With use of __intel_simd_lane() the references to the arrays in accumulate() will have unit-stride.

Limitations

The following language constructs are not allowed within SIMD-enabled functions:

- The GOTO statement.
- The switch statement with 16 or more case statements.
- Operations on classes and structs (other than member selection).
- The _Cilk_spawn keyword and any update to the Intel® Cilk™ Plus pedigree.
- Any OpenMP* construct.

SIMD-Enabled Function Pointers

SIMD-enabled functions (formerly called elemental functions) are a general language construct to express a data parallel algorithm. A SIMD-enabled function is written as a regular C/C++ function, and the algorithm within describes the operation on one element, using scalar syntax. The function can then be called as a regular C/C++ function to operate on a single element or it can be called in a data parallel context to operate on many elements. In Intel® Cilk™ Plus, the data parallel context is a SIMD loop.

NOTE Intel® Cilk™ Plus is a deprecated feature.

In some cases it is desirable to have a pointer for SIMD-enabled functions, but without special effort, the vector nature of a function will be lost: function pointers will point to the scalar function and there will be no way to call the short vector variants existing for this scalar function.

In order to support indirect calls to vector variants of SIMD-enabled functions, SIMD-enabled function pointers were introduced. A SIMD-enabled function pointer is a special kind of pointer incompatible with a regular function pointer. They refer to an entire set of short vector variants as well as the scalar function. This incompatibility incurs the risk of inappropriate misuse, especially in C++ code. Therefore vector function pointer support is disabled by default.

To enable support of SIMD-enabled function pointers use the following compiler switches:
- Qsimd-function-pointers on Windows* or simd-function-pointers on Linux*/macOS*.

Such pointers may hold the address of a SIMD-enabled function in a way that enables indirect calls to the appropriate vector variants of the function from a SIMD loop or another SIMD-enabled function.
When disabled with Qsimd-function-pointers on Windows* or no-simd-function-pointers on Linux*/macOS*, vector attributes (__declspec(vector) or __attribute__((vector)) or #pragma omp declare simd) can only be placed on function declarations and definitions. Other placements will result in a warning message and then be ignored.

**How SIMD-Enabled Function Pointers Work**

When you write a SIMD-enabled function, the compiler generates short vector variants of the function that you requested, which can perform your function's operation on multiple arguments in a single invocation. The short vector variants may be able to perform multiple operations as fast as the regular implementation performs just one such operation by utilizing the vector instruction set architecture (ISA) in the CPU. When a call to SIMD-enabled function occurs in a SIMD loop or another SIMD-enabled function, the compiler replaces the scalar call with the best fit short vector variant of the function among those available.

Indirect SIMD-enabled function calls are handled similarly, but the set of available variants should be associated with the function pointer variable, not the target function, because actual call targets are unknown at the indirect call. That means all SIMD-enabled functions to be referenced by a SIMD-enabled function pointer should have a set of variants that match the set of variants declared for the pointer.

**Declaring a SIMD-Enabled Function Pointer Variable**

In order for the compiler to generate a pointer to a SIMD-enabled function, you need to provide an indication in your code.

**Windows***:

Use the __declspec(vector (clauses)) attribute, as follows:

```c
__declspec(vector (clauses)) return_type (*function_pointer_name) (parameters)
```

**Linux** and **macOS**:

Use the __attribute__((vector (clauses))) attribute, as follows:

```c
__attribute__((vector (clauses))) return_type (*function_pointer_name) (parameters)
```

Alternately, you can use OpenMP* #pragma omp declare simd, which requires the [q or Q]openmp or [q or Q]openmp-simd compiler option.

The clauses are described in the previous topic on SIMD-enabled functions.

**Usage of Vector Function Attributes on Pointers**

You may associate several vector attributes with one SIMD-enabled function pointer which reflects all the variants available for the target functions to be called through the pointer. The attributes usually reflect a possible use of the function pointer in the loops. Encountering an indirect call, the compiler matches the vector variants declared on the function pointer with the actual parameter kinds and chooses the best match. Matching is done exactly the same way as with direct calls (see the previous topic on SIMD-enabled functions). Consider the following example of the declaration of vector function pointers and loops with indirect calls.

**Example: OpenMP**

```c
// pointer declaration
#pragma omp declare simd                                   // universal but slowest definition matches
the use in all three loops
#pragma omp declare simd linear(in1) linear(ref(in2)) uniform(mul) // matches the use in the first loop
#pragma omp declare simd linear(ref(in2))                   // matches the use in the second and the third loops
#pragma omp declare simd linear(ref(in2)) linear(mul)       // matches the use in the
```
Example: OpenMP*

second loop
#pragma omp declare simd linear(val(in2:2))                          // matches the use in the third loop
int (*func)(int* in1, int& in2, int mul);

int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
for (int i = 0; i < nn; i++) {
    c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed linearly,
                                      // the second reference is changed linearly too
                                      // the third parameter is not changed
}

for (int i = 0; i < nn; i++) {
    c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is unpredictable,
                                           // the second reference is changed linearly
                                           // the third parameter is changed linearly
}

#pragma omp simd
for (int i = 0; i < nn; i++) {
    int k = i * 2;  // during vectorization, private variables are transformed into arrays:
    k->k_vec[vector_length]
    c[i] = func(&a[ndx[i]], k, b[i]); // the value of the first parameter is unpredictable,
                                       // the second reference and value can be considered linear
                                       // the third parameter has unpredictable value
                                       // (the __declspec(vector(linear(val(in2:2)))) will be chosen from the two matching variants)
}

Example: Intel® Cilk™ Plus

// pointer declaration
__declspec(vector) // universal but slowest definition matches the use in all three loops
__declspec(vector(linear(in1), linear(ref(in2)), uniform(mul))) // matches the use in the first loop
__declspec(vector(linear(ref(in2)))) // matches the use in the second and the third loops
__declspec(vector(linear(ref(in2)), linear(mul))) // matches the use in the second loop
__declspec(vector(linear(val(in2:2)))) // matches the use in the third loop
int (*func)(int* in1, int& in2, int mul);

int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
for (int i = 0; i < nn; i++) {
    c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed
Example: Intel<sup>®</sup> Cilk™ Plus

```c
linearly,
    // the second reference is changed linearly too
    // the third parameter is not changed
}

for (int i = 0; i < nn; i++) {
    c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is unpredictable,
        // the second reference is changed linearly
        // the third parameter is changed linearly
}

#pragma simd private(k)
for (int i = 0; i < nn; i++) {
    int k = i * 2; // during vectorization, private variables are transformed into arrays:
    k->k_vec[vector_length]
    c[i] = func(&a[ndx[i]], k, b[i]); // the value of the first parameter is unpredictable,
        // the second reference and value can be considered linear
        // the third parameter has unpredictable value
        // (the __declspec(vector(linear(val(in2:2)))) will be chosen from the two matching variants)
}
```

Before any use in a call, the function pointer should be assigned either the address of a function or another function pointer. Just as with function pointers, vector function pointers should be compatible at assignment and initialization. The compatibility rules are described below.

**Vector Function Pointer Compatibility**

Pointer assignment compatibility is defined as following:

1. If a SIMD-enabled function pointer is assigned the address of a function, the function should be compatible with the pointer in the usual C/C++ sense, it should be SIMD-enabled, and the set of vector variants declared for the function should be a superset of those declared for the pointer. This includes initializations and passing addresses of SIMD-enabled functions as parameters.

2. If a SIMD-enabled function pointer is assigned another function pointer, the source pointer should be compatible with the destination function pointer in the general C/C++ sense, it should be SIMD-enabled, and the set of vector variants declared for the source pointer should be exactly the same as those declared for destination pointer. This includes initializations and passing SIMD-enabled function pointers as parameters.

3. If a regular (non-SIMD-enabled) function pointer is assigned the address of a SIMD-enabled function, the address of a scalar function is assigned. Vector variants cannot be called through the pointer and it cannot be reinterpreted as or converted into a SIMD-enabled function pointer as discussed in rule 2.

4. If a regular (non-SIMD-enabled) function pointer is assigned a SIMD-enabled function pointer matching in the C/C++ sense, the implicit dynamic casting of the right-hand side of the assignment (RHS) is performed by extracting the address of a scalar function and this address is assigned. Vector variants cannot be called through these pointers and it cannot be reinterpreted as or converted into a SIMD-enabled function pointer as discussed in rule 2.
**NOTE** SIMD-enabled function pointers and regular function pointers are binary-incompatible and handled differently. Mixing them may lead to severe unpredictable results. The compiler does its best to check compatibility where it is allowed by C/C++ language standards, but in certain cases it cannot check, such as passing function pointers to undeclared functions or as variable arguments. It is best to refrain from using SIMD-enabled function pointers in these contexts. Additional complexities with respect to the C++ type system are described in the *SIMD-Enabled Function Pointers and the C++ Type System* section below.

**NOTE** A SIMD-enabled function pointer may be assigned to a scalar function pointer with a cast as described in rule 4 above, but a SIMD-enabled function pointer cannot refer to a scalar function pointer.

ptr3 = func1; // scalar pointer with same prototype - use scalar func1
ptr3 = func2; // scalar pointer with same prototype - use scalar func2
ptr3 = ptr1; // scalar pointer with same prototype - implicit conversion from vector to scalar pointer
ptr3 = ptr2; // scalar pointer with same prototype - implicit conversion from vector to scalar pointer

// disallowed assignments
Examples of Declarations and Assignments: Intel® Cilk™ Plus

```c
ptr2 = func1; // vector spec on function does not have all specs on pointer
ptr2 = func3; // prototype mismatch although vector spec matched
ptr1 = func3; // prototype mismatch although vector spec matched
ptr3 = func3; // prototype mismatch
ptr1 = ptr2; // pointers should have the same vector spec
ptr2 = ptr3; // pointers should have the same vector spec
```

**Call Sequence**

Unlike regular function calls, which transfer control to a target function, the call target of an indirect call depends on the dynamic content of the function pointer. In a loop, call targets may be different on different iterations of a vectorized loop or on different lanes of a SIMD-enabled function executing the call. When vectorized, such an indirect call may involve multiple calls to different targets within a single SIMD chunk. This works as follows:

1. If the vector function pointer is uniform by the Intel® Cilk™ Plus or OpenMP* specification, or if it can be determined to be uniform by the compiler, then multiple calls are not needed. The compiler makes a single indirect call to a matched vector variant accessible by the pointer.
2. If the vector function pointer is not known to be uniform at compile time, all values of the pointer in a SIMD chunk may still be the same. This is checked at run time and a single indirect call to a matched vector variant is invoked.
3. Otherwise, lanes sharing the same function pointer value (call target) are masked-in and a masked vector variant corresponding to the matched one is invoked in the loop for each unique call target. If the masked variant is not provided for the matching vector variant and the function pointer is not proven to be uniform by compiler the match will be rejected and the compiler may serialize the call, or in other words, generate several scalar calls.

**Example: OpenMP**

```
// pointer typedefs
#pragma omp declare simd
typedef int (*fptr_t1)(int*, int);

// function declarations
#pragma omp declare simd
int func1(int* x, int b);

// uses of vector function pointers
fptr_t1 *fptr_array; // array of vector function pointers
void foo(int N, int *x, int y){
  fptr_t1 ptr1 = func1;
  #pragma omp simd
  for (int i = 0; i < N; i++) {
    ptr1(x+i, y); // ptr1 is uniform by OpenMP rule.
    fptr_t1 ptr1a = ptr1;
    ptr1a(x+i, y); // compiler can prove ptr1a is uniform.
    fptr_t1 ptr1b = fptr_array[i];
    ptr1b(x+i,y); // ptr1b may or may not be uniform.
  }
}
```
SIMD-Enabled Function Pointers and the C++ Type System

Use caution when using SIMD-enabled function pointers in modern C++: C++ imposes strict requirements on compilation and execution environments which may not compose well with semantically-rich language extensions such as SIMD-enabled function pointers. Vector specifications on SIMD-enabled function pointers are attributes in C++11 sense and so are not part of a pointer type even though they make that pointer binary incompatible with another pointer of the same type but without the attribute. Vector specifications are not bound to a pointer type, but instead are bound to the variable or function argument (which is an instance of a pointer type) itself. For a given function pointer, the type of the pointer is the same with or without SIMD-enabled function pointer decoration. This has the following important implications:

- Vector attributes put on a function argument are not reflected in C++ name mangling, so the functions differ only in the vector attributes of a functional pointer argument (or lack thereof) will have the same name and will be treated the same by the C++ linker. This may result in a parameter of incorrect vectorness (having the vector attribute or not) being passed into the function. In some cases there is no way for the compiler to detect this situation, so you’re strongly encouraged to distinctly name functions having SIMD-enabled function pointers as parameters.

- The incorrect interpretation of function pointers is extremely dangerous because it may lead to the execution of unwanted code or non-code. To identify these situations the compiler issues the following warning if a vector function pointer is used as a C++ function parameter: Warning #3757: this use of a vector function type is not fully supported. If you are sure that no ambiguity is possible—for example, the function accepting the vector function pointer has a distinct name and is fully declared before all uses—you may ignore this warning. Otherwise, ensure that no ambiguity is possible. To prevent such situations the warning can be converted to an error using the command line switch -diag-error=3757.

- Template instantiations having SIMD-enabled pointer types as template parameters won’t catch vector attributes. The template will be instantiated a parameter matching the non-SIMD-enabled pointer type. All variables, class members, and function arguments bound to the template argument type will be regular function pointers. The use of such templates with a SIMD-enabled function pointer as a template function parameter, template class method parameter, or RHS of template class member assignment will lead to a dynamic cast to the non-SIMD-enabled function pointer and loss of vectorness.
- There is no way to overload or achieve template specialization by the vector attributes of a functional pointer
- There is no way to write functional traits to capture vector attributes for the sake of template metaprogramming.

**Examples: OpenMP**

```cpp
// pointer typedefs and pointer declarations
typedef int (*fptr_t)(int*, int);

#pragma omp declare simd
typedef int (*fptr_t1)(int*, int);

#pragma omp declare simd
#pragma omp declare simd linear(x)
typedef int (*fptr_t2)(int* a, int b);

fptr_t ptr
fptr_t1 ptr1
fptr_t2 ptr2

// function prototype that only differs in SIMD-enabled function decoration
// All these will have identical mangled names.
void foo(fptr_t);
void foo(fptr_t1);
void foo(fptr_t2);

// template instantiation
template <typename T>
void bar(T);

... bar(fptr);       // bar<fptr_t>
bar(fptr1);        // bar<fptr_t>
bar(fptr2);        // bar<fptr_t>
```

**Examples: Intel® Cilk™ Plus**

```cpp
// pointer typedefs and pointer declarations
typedef int (*fptr_t)(int*, int);

typedef int
__declspec(vector)
(*fptr_t1)(int*, int);

__declspec(vector)
__declspec(vector(linear(a)))
(*fptr_t2)(int* a, int b);

fptr_t ptr
fptr_t1 ptr1
fptr_t2 ptr2

// function prototype that only differs in SIMD-enabled function decoration
// All these will have identical mangled names.
```
Examples: Intel® Cilk™ Plus

```c
void foo(fptr_t);
void foo(fptr_t1);
void foo(fptr_t2);

// template instantiation
template <typename T>
void bar(T);
...
bar(fptr);    // bar<fptr_t>
bar(fptr1);   // bar<fptr_t>
bar(fptr2);   // bar<fptr_t>
```

Indirect Invocation of a SIMD-Enabled Function with Parallel Context

Typically, the invocation of a SIMD-enabled function directly or indirectly provides arrays wherever scalar arguments are specified as formal parameters. Use the array notation syntax available in Intel® Cilk™ Plus to provide the arrays succinctly. Alternatively, you can invoke the function from a _Cilk_for loop.

The following two invocations will give instruction-level parallelism by having the compiler issue special vector instructions.

Example: OpenMP*

```c
#pragma omp declare simd
float (**vf_ptr)(float, float);

// operates on the whole extent of the arrays a, b, c
a[:] = vf_ptr[:] (b[:],c[:]);

// use the full array notation construct to also specify n
// as an extend and s as a stride
a[0:n:s] = vf_ptr[0:n:s] (b[0:n:s],c[0:n:s]);
```

Example: Intel® Cilk™ Plus

```c
__declspec(vector)
float (**vf_ptr)(float, float);

// operates on the whole extent of the arrays a, b, c
a[:] = vf_ptr[:] (b[:],c[:]);

// use the full array notation construct to also specify n
// as an extend and s as a stride
a[0:n:s] = vf_ptr[0:n:s] (b[0:n:s],c[0:n:s]);
```

To invoke the SIMD-enabled function in a data parallel context and use multiple cores and processors use _Cilk_for:

```c
_Cilk_for (j = 0; j < n; ++j) {
    a[j] = vf_ptr[j](b[j],c[j]);
}
```
**NOTE** Only use of the _Cilk for calling syntax is able to use all available parallelism. The array notation syntax, as well as calling the SIMD-enabled function from the regular for loop, results in invoking the short vector variant in each iteration and utilizing the vector parallelism but the invocation is done in a serial loop, without utilizing multiple cores.

### Vectorizing a Loop Using the _Simd Keyword

Vectorization is a key component of Intel® Cilk™ Plus technology. SIMD vectorization is discussed in some depth in the User-Mandated or SIMD Vectorization section of the Auto-Vectorization key feature chapter and the simd pragma is documented in the Pragmas section of the Compiler Reference Chapter.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

In this section we introduce the _Simd keyword, which provides an alternative to the simd pragma. Just like the simd pragma, the _Simd keyword modifies a serial for loop for vectorization. The syntax is as follows:

```
_Simd [_Safelen(constant-expression)][_Reduction (reduction-identifier : list)]
```

The _Simd keyword and any clauses should come after the for keyword as in this example:

```
for _Simd (int i=0; i<10; i++){  
    // loop body
}
```

The _Simd keyword can also be used with cilk_for. See the cilk_for keyword documentation for a discussion of the cases where they are most effectively used together.

**Differences between the simd pragma and _Simd keyword:**

- **Omission of the private and lastprivate clauses of the simd pragma construct** because C and C++ already have variable-scoping rules that allow a programmer to cleanly declare a private variable within the scope of a loop iteration
- **The linear clause is omitted** because the ability to increment multiple variables makes it unnecessary. See the following example:

```
float add_floats(float *a, float *b, int n){
    int i=0;
    int j=0;
    float sum=0;

    for _Simd _Reduction(+:sum) (i=0; i<n; i++, j+=2){  
        a[i] = a[i] + b[j];
        sum += a[i];
    }
    return sum;
}
```

To ensure that your loop is vectorized keep the following in mind:

- **The countable loop for the _Simd keyword has to conform to the for-loop style of an OpenMP* canonical loop form except that multiple variables may be incremented in the incr-expr** (See the OpenMP specification at www.openmp.org).
• The loop control variable must be a signed integer type.
• The vector values should be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating point numbers, or single or double-precision complex numbers.
• You cannot use any control constructs to jump into or out of a SIMD loop. That includes the break, return, goto, and throw constructs.
• A SIMD loop may contain another loop (for, while, do-while) in it, but goto out of such inner loops is not supported. You may use break and continue with the inner loop.
• A SIMD loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

simd Enforces vectorization of loops.

Function Annotations and the SIMD Directive for Vectorization
This topic presents specific C++ language features that better help to vectorize code.

NOTE
The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

The __declspec(align(n)) declaration enables you to overcome hardware alignment constraints. The auto-vectorization hints address the stylistic issues due to lexical scope, data dependency, and ambiguity resolution. The SIMD feature’s pragma allows you to enforce vectorization of loops.

You can use the __declspec(vector)__attribute__(vector) and the __declspec(vector[clauses])__attribute__(vector(clauses)) declarations to vectorize user-defined functions and loops. For SIMD usage, the vector function is called from a loop that is being vectorized.

The C/C++ extensions for array notations map operations can be defined to provide general data parallel semantics, where you do not express the implementation strategy. Using array notations, you can write the same operation regardless of the size of the problem, and let the implementation use the right construct, combining SIMD, loops, and tasking to implement the operation. With these semantics, you can choose more elaborate programming and express a single dimensional operation at two levels, using both task constructs and array operations to force a preferred parallel and vector execution.

The usage model of the vector declaration is that the code generated for the function actually takes a small section (vectorlength) of the array, by value, and exploits SIMD parallelism, whereas the implementation of task parallelism is done at the call site.

The following table summarizes the language features that help vectorize code.

<table>
<thead>
<tr>
<th>Language Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>__declspec(align(n))</td>
<td>Directs the compiler to align the variable to an n-byte boundary. Address of the variable is address mod n=0.</td>
</tr>
<tr>
<td>__declspec(align(n,off))</td>
<td>Directs the compiler to align the variable to an n-byte boundary with offset off within each n-byte boundary. Address of the variable is address mod n=off.</td>

</tbody>
</table>
Auto-Vectorization Hints

| #pragma novector | Specifies that the loop should never be vectorized. |

**NOTE**
Some pragmas are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

User-MandatedPragma

| #pragma simd | Enforces vectorization of loops. |
| omp simd | Transforms the loop into a loop that will be executed concurrently using SIMD instructions. |

Array Notations

**C/C++ Extensions for Array Notations Overview**
The C/C++ language extensions for array notations are Intel-specific language extensions that are part of the Intel® Cilk™ Plus feature.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

The C/C++ extensions provide data parallel array notations with the following major benefits:

- Allows you to use array notation to program vector operations in a familiar language
- Achieves predictable performance based on mapping parallel constructs to the underlying SIMD hardware
- Enables compiler vectorization with less reliance on alias and dependence analysis

When you use the array notations, the compiler implements them using vector code.

**Usage Recommendations**
Use the array notations when your algorithm requires operations on arrays and where it does not require a specific order of operations among the elements of the array(s).

The C/C++ language extensions for array notations are enabled by default. To disable them, use the negative form of the [Q]intel-extensions- compiler option.

To use the array notations in your application, do the following:
1. Insert the array notations language extensions into your application source code.
2. Compile the application at optimization level O2 and above to enable vectorization. By default, the compiler generates SIMD vector instructions in the Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instruction set. To generate SIMD vector instructions beyond SSE2, you can add target/architecture-specific compiler options to the compile command.

If you compile your application using -O0 or -O1 (Linux* and macOS*) or /Od or /O1 (Windows*), you generate serialized scalar code without vectorization.

By default, the compiler accepts the array notations language extensions to generate vector code based on the data parallel constructs in the program.

The array notations work at all optimization levels. Specifying the -O0 (Linux and macOS*) or /Od (Windows) compiler options serializes the array operations into sequential loops and helps to debug applications using array notations.

### C/C++ Extensions for Array Notations Programming Model

This section provides the syntax and semantics for the C/C++ language extensions for array notations.

#### Array Section Notation

In your application code, introduce a section operator in the standard C/C++ language, as follows:

section_operator ::= [<lower bound> : <length> : <stride>]

where the <lower bound>, <length>, and <stride> are of integer types, representing a set of integer values as follows:

<lower bound>, <lower bound + <stride>>, …, <lower bound> + (<length> - 1) * <stride>

A section operator can occur in place of a subscript operator. The following example is an array section with len elements: a[lb], a[lb + str], a[lb + 2*str], …, a[lb + (len-1)*str].

```
a[lb:len:str]
```

Length is chosen instead of upper bound because, in declarations, C/C++ deals with lengths of arrays and not upper bounds. Use of length also makes it easier to ensure that array sections match in size.

Successive section operators designate a sub-array of a multidimensional array object. When absent, the <stride> defaults to 1. If the <length> is less than 1, the array section is undefined. You can also use [:] as a short hand for a whole array dimension if the size of the dimension is known from the array declaration. If either <lower bound> or <length> must be specified, you must specify both.

**Example**

```
a[0:3][0:4] // refers to 12 elements in the 2D array a, starting at // row 0, column 0, and ending at row 2, column 3.
b[0:2:3]   // refers to elements 0 and 3 of the 1D array b b[:]    // refers to the entire array b
```

### Array Declarations for Array Notations

For the array section notation—[:]—to be useful, the compiler must know the shape and size of an array object. The table below summarizes the different ways of declaring arrays and pointers to array objects in C/C++.
### Length
- **Fixed**
- **Auto**
- **Parameter**
- **Heap**

### Storage Class
- **Static**
- **Auto**
- **Variable (C99)**

<table>
<thead>
<tr>
<th>Length</th>
<th>Storage Class</th>
<th>Declaration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed</td>
<td>Static</td>
<td><code>static int a[16][128]</code></td>
</tr>
<tr>
<td></td>
<td>Auto</td>
<td><code>void foo(void) { int a[16][128]; }</code></td>
</tr>
<tr>
<td></td>
<td>Parameter</td>
<td><code>void bar(int a[16][128]);</code></td>
</tr>
<tr>
<td></td>
<td>Heap</td>
<td><code>int (*p2d)[128];</code></td>
</tr>
<tr>
<td>Auto</td>
<td>Auto</td>
<td><code>void foo(int m, int n) { int a[m][n]; }</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Parameter</td>
<td><code>void bar(int m, int n, int a[m][n]);</code></td>
</tr>
<tr>
<td></td>
<td>Heap</td>
<td><code>void bar(int m, int n) { int (*p2d)[n]; }</code></td>
</tr>
</tbody>
</table>

The variable length array (VLA) notation is a C99 [ISO/IEC 9899] feature and a compiler specific-extension of C++. It is supported by the GNU GCC and Intel® C++ compilers.

**NOTE** You must use the `/Qstd=c99` compiler option for the compiler to accept the C99 extensions.

If the base of an array section has incompletely specified dimensions (such as a pointer variable), you must explicitly specify the length of the array section. This is illustrated in the following example.

**Example**

```c
typedef int (*p2d)[128];
p2d p = (p2d) malloc(sizeof(int)*rows*128);
p[:][:]      // error
p[0:rows][:] // ok
```

**Operator Maps**

Most C/C++ operators are available for array sections: `+`, `-`, `*`, `/`, `%`, `<`, `<=`, `>`, `>=`, `!=`, `==`, `++`, `--`, `|`, `&`, `^`, `&&`, `||`, `!`, -(unary), +(unary), `+=`, `-=` `*=` `/=`, `*`(pointer de-referencing).

Operators are implicitly mapped to all elements of the array section operands. The operations on different elements can be executed in parallel without any ordering constraints.

Array operands in an operation must have the same rank and size. Rank is defined as the number of array section operators, and size is the length of each array section. A scalar operand is automatically filled to the whole array section of any rank.

**Example**

```c
a[:] * b[:]; // element-wise multiplication
a[0:4] + b[1:2][0:4] // starting at a[3][3] and b[5][5]
a[0:4][1:2] + b[0][1] // adds a scalar b[0][1] to an array section.
```
Assignment Maps

The assignment operator applies in parallel to every element of the array section on the left hand side (LHS).

**Example**

\[
\begin{align*}
a[:][:] &= b[:][2][:] + c; \\
e[] &= d; \\
e[] &= b[:][1][:]; \quad // \text{error, different rank} \\
a[:][:] &= e[:]; \quad // \text{error, different rank}
\end{align*}
\]

If there is an overlap between the RHS and the LHS, the behavior is undefined. There is no guarantee that the RHS will be evaluated before assignment to the LHS. If there is aliasing between the LHS and the RHS, the programmer must introduce a temporary array section to evaluate the RHS before assigning to the LHS. One exception is when there is an exact overlap and the stride is the same, then the assignment is well defined. This semantic allows for the most efficient code to be generated.

**Example**

\[
\begin{align*}
a[1:s] &= a[0:s] + 1; \quad // \text{due to overlap the behavior is undefined} \\
temp[0:s] &= a[0:s] + 1; \quad // \text{introduce temporary section to resolve} \\
a[1:s] &= temp[0:s]; \quad // \text{the aliasing} \\
a[:] &= b[:]; \quad // \text{well-defined: there is exact overlap and stride 1} \\
& \quad // a[:] = a[:] + b[:];
\end{align*}
\]

Gather and Scatter

When an array section occurs directly under a subscript expression, it designates a set of elements indexed by the values of the array section.

**Example**

```
unsigned index[10] = {0,1,2,3,4,5,6,7,8,9};
float out[10], in[10] = {9,8,7,6,5,4,3,2,1,0};
out[0:5] = in[index[0:5]]; // gather
out[index[5:5]] = in[0:5]; // scatter
for(int i = 0; i < 5; i++){
  cerr << "out[" << i << "]" << out[i] << endl;
}
```

If the index values in a scatter array section overlap with each other, the values for the duplicated locations must be the same, otherwise, the final stored value after the scatter is undefined.

Depending on the target architecture option chosen, and if the scatter/gather support is available on the target architecture, the compiler may map the array notations operations to the appropriate hardware.

Array Implicit Index

In writing code that uses array sections, you may find it useful to explicitly reference the indices of the individual elements in a section. For example, you may decide to fill an array with a function of the element index, rather than with a single value. Conceptually, an array section operation can be thought of as expanding into a loop with an implicit index variable for each relative rank of the section. For each relative rank, the value of the implicit index variable ranges between zero and one less than the length of the triplet with that relative rank. The \_sec_implicit_index operation returns the value of the implicit index variable for a specified relative rank. It behaves as a function with the following declaration:

\[
\text{intptr_t} \_\text{sec}_\text{implicit}_\text{index}(\text{int relative_rank});
\]
The argument must be an integer constant expression. For purposes of rank checking, the rank of an implicit index operation is zero, although it is reevaluated for each element, similar to an expression of rank one.

**Example**

```cpp
int A[10], B[10][10];

A[:] = __sec_implicit_index(0);

// Assign B[i][j] = i+j:
B[:][:] = __sec_implicit_index(0) + __sec_implicit_index(1);

// The value of __sec_implicit_index is independent of the starting value
// of the section. In this example, the values are either 0 or 1, even though the
// actual indices are x+i and y+j.
// B[x][y] = 0^0, B[x][y+1] = 0^1, B[x+1][y] = 1^0, B[x+1][y+1] = 1^1
B[x:2][y:2] = __sec_implicit_index(0) ^ __sec_implicit_index(1);
```

**Reduction Operations**

A reduction combines array section elements to generate a scalar result. Intel® Cilk™ Plus supports reductions on array sections. It defines a generic reduction function that applies a user-defined dyadic function and a generic mutating reduction function that applies the result of the reduction function. Intel® Cilk™ Plus also has nine built-in common reduction functions. The built-in functions are polymorphic functions that accept int, float, and other C basic data type arguments. The names and descriptions of reduction functions are summarized in the table below followed by details and examples.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

<table>
<thead>
<tr>
<th>Function Prototypes</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>__sec_reduce(fun, identity, a[:])</td>
<td>Generic reduction function. Reduces <em>fun</em> across the array <em>a[:]</em> using <em>identity</em> as the initial value. Deprecated.</td>
</tr>
<tr>
<td>result __sec_reduce(initial, a[:], function-id)</td>
<td>Generic reduction function that supports scalar types as well as C++ arithmetic classes. Performs a reduction operation across array, <em>a[:]</em>, using the reduction function, <em>function-id</em>, with <em>initial</em> as the initial value. Returns the result of the reduction in <em>result</em>.</td>
</tr>
<tr>
<td>void __sec_reduce_mutating(reduction, a[:], function-id)</td>
<td>Generic mutating reduction function that supports scalar types as well as C++ arithmetic classes. Performs reduction operation across array, <em>a[:]</em>, using the mutating reduction function, <em>function-id</em>, with the result of the reducing operation, <em>reduction</em>, accumulated in the initial value. Returns nothing.</td>
</tr>
</tbody>
</table>

**Built-in Reduction Functions**

- __sec_reduce_add(a[:]) Adds values passed as arrays.
- __sec_reduce_mul(a[:]) Multiplies values passed as arrays.
- __sec_reduce_all_zero(a[:]) Tests that array elements are all zero.
- __sec_reduce_all_nonzero(a[:]) Tests that array elements are all non-zero.
- __sec_reduce_any_nonzero(a[:]) Tests for any array element that is non-zero.
- __sec_reduce_min(a[:]) Determines the minimum value of array elements.
 Built-in Reduction Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>__sec_reduce_max(a[:][])</td>
<td>Determines the maximum value of array elements.</td>
</tr>
<tr>
<td>__sec_reduce_min_ind(a[:])</td>
<td>Determines the index of minimum value of array elements.</td>
</tr>
<tr>
<td>__sec_reduce_max_ind(a[:])</td>
<td>Determines the index of maximum value of array elements.</td>
</tr>
<tr>
<td>__sec_reduce_and (a[:])</td>
<td>Performs bitwise AND operation of values passed as arrays.</td>
</tr>
<tr>
<td>__sec_reduce_or (a[:])</td>
<td>Performs bitwise OR operation of values passed as arrays.</td>
</tr>
<tr>
<td>__sec_reduce_xor (a[:])</td>
<td>Performs bitwise XOR operation of values passed as arrays.</td>
</tr>
</tbody>
</table>

**Generic reducing function:** the function denoted by *function-id* can be a user-defined function, operator, functor, or lambda expression that require assignment on top of the operation, for example, `operator+`. The reduction function must be commutative. The element type of the array section is used for:

- lookup and overload resolution of the reduction function
- the assignment operator needed to assign the return value to the result
- the copy constructor for the initial value to be assigned to the reduction variable used (if needed).

**NOTE** The implementation allows for non-constant function pointers as the reduction function. Also, The returning reduction function can replace the original defined `__sec_reduce(fun, identity, a[:]);` reduction function with your user-defined function. The original defined reduction function is deprecated.

**Example**

```cpp
...;
complex<double> a[N];
complex<double> result;
...;
result = __sec_reduce(complex<double>(0,0), a[:], operator+ );
...;
```

**Generic mutating reduction function:** the function denoted by *function-id* can be a user-defined function, operator, functor, or lambda expression that requires assignment on top of the operation, for example, compound assignment `operator+=`. The reduction function must be commutative. The element type of the array section is used for lookup and overload resolution for the compound reduction function.

**NOTE** An assignment operator is not needed for the mutating reduction case.

**Example**

```cpp
...;
complex<double> a[N];
complex<double> result;
...;
result = complex<double>(0,0);
__sec_reduce_mutating(result, a[:], operator+= );
...;
```

**Built-in reduction functions:** the reduction operation can reduce on multiple ranks. The number of ranks reduced depends on the execution context. For a given execution context of rank *m* and a reduction array section argument with rank *n*, where *n>* *m*, the last *n-* *m* ranks of the array section argument are reduced.
Example

```plaintext
sum = __sec_reduce_add(a[:][:]);  // sum across the whole array 'a'
sum_of_row[i] = __sec_reduce_add(a[i][:]); // sum elements in each row of 'a'
```

**Shift Operations**

A *shift* does a shift of the elements in the array section elements to generate a scalar result. Intel® Cilk™ Plus supports shift operations on array sections. The names and descriptions of shift functions are summarized in the table below. The shift and circular shift (rotate) functions are defined for rank one expressions.

<table>
<thead>
<tr>
<th>Function Prototypes</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>b[:]=__sec_shift(a[:], signed shift_val, fill_val)</code></td>
<td>Generic shift function. Performs a shift operation on the elements of the array <code>a[:</code> towards a higher/lower index value. A positive <code>shift_val</code> shifts towards lower index values while a negative <code>shift_val</code> shifts towards higher index values. The <code>fill_val</code> argument indicates the fill value of the array section element type that is used to fill the vacated elements. The result is assigned to the return value, <code>b[:</code>]. The array section argument <code>a[:</code> is not modified.</td>
</tr>
<tr>
<td><code>b[:]=__sec_rotate(a[:], signed shift_val)</code></td>
<td>Generic rotate function. Performs a circular shift (rotate) of the elements in the array section, <code>a[:</code> . A positive <code>shift_val</code> rotates towards lower index values while a negative <code>shift_val</code> rotates towards higher index values. The result is assigned to the return value, <code>b[:</code> . The array section argument <code>a[:</code> is not modified.</td>
</tr>
</tbody>
</table>

**Function Maps**

Maps are implicitly defined on scalar functions. All the array section arguments in a scalar function map call must have the same rank. Scalar arguments are automatically filled to match any rank.

Example

```plaintext
a[:]=sin(b[:]);
a[:]=pow(b[:], c);  // b[:]**c
a[:]=pow(c, b[:]);  // c**b[:]
a[:]=foo(b[:]);  // user defined function
a[:]=bar(b[:], c[:][i]);  // error, different ranks
```

Mapped function calls are executed in parallel for all the array elements, with no specific ordering. Vector functions may have side effects. When there are conflicts during parallel execution, the program semantics may be different from the serial program.

Function maps are powerful tools used to apply a set of operations in parallel to all elements of an array section.

Many routines in the `svml` library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

**Passing Array Section Arguments**

Intel® Cilk™ Plus supports a *vector kernel* style of programming, where vector code is encapsulated within a function by declaring array parameters of fixed or parameterized vector lengths.
The address of the first element of an array section can be passed as argument to an array parameter. The following example illustrates how to combine array notation to achieve vectorization inside a function body using Intel® Cilk™ Plus threading for parallel function calls.

**NOTE** The parameter `float x[m]` depending on an earlier parameter `int m` is only supported in C99 and not in C++.

### Example

```c
#include <cilk/cilk.h>

void saxpy_vec(int m, float a, float x[m], float y[m]){
    y[:]+=a*x[:];
}

void main(void){
    int a[2048], b[2048] ;
    cilk_for (int i = 0; i < 2048; i +=256){
        saxpy_vec(256, 2.0, &a[i], &b[i]);
    }
}
```

By writing the function explicitly with array arguments, you can write portable vector codes using any threading runtime and scheduler.

**Conditionals and if statements**

Array sections can be used with the C/C++ conditional operator, or in the conditional test of an `if` statement.

```c
Example

c[0:n] = (a[0:n] > b[0:n]) ? a[0:n] - b[0:n] : a[0:n];
// is equivalent to:
if (a[0:n] > b[0:n]) {
    c[0:n] = a[0:n] - b[0:n];
} else {
    c[0:n] = a[0:n];
}
```

In the above example, each element `c[i]` of the result array `c` will be assigned either `a[i]-b[i]` or `a[i]`, depending on whether `a[i] > b[i].`  

When array sections are used in conditional expressions (either an `if`-statement condition or a conditional operator), all array sections in every statement in the "true" and "false" clauses must have the same shape. Keep in mind that the hardware may need to compute both sides of the conditional and blend them together; the clauses should be kept short, if possible.

**Limitations**

There are two limitations on the usage of array sections:

- Functions cannot return array section values. To receive output values, two techniques can be used:
**Output array:**

```c
void addit(float out[N], float in[N]) {
    out[:] = in[:] + 4.5f;
}
float A[N], B[N];
addit(A, B);
```

**Function map:**

```c
float addit(float in) {
    return in + 4.5f;
}
float A[N], B[N];
A[:] = addit(B[:]);
```

When the function is not inlined, there are differences in the number of function calls between those two approaches. The function map approach calls `addit()` $N$-times more than the output array approach, so plan accordingly.

- The "true" and "false" clauses of conditional expressions with array sections must not contain the `return`, `break`, `while`, `for`, or `goto` statements. Nested if-statements are allowed.

### Programming Hints and Examples

There is no cost associated with writing an application that mixes scalar and data parallel operations on the same arrays. The Intel compiler uses the array operations in the program to guide vectorization. The following example implements an FIR filter. The scalar code consists of a doubly nested loop where both the inner and outer loop can be vectorized. By writing the program in different ways using array notation, you can direct the compiler to vectorize differently.

**Example: FIR Scalar Code**

```c
for (i=0; i<M-K; i++){
    s = 0
    for(j=0; j<K; j++){
        s+= x[i+j] * c[j];
    }
    y[i] = s;
}
```

**Example: FIR Inner Loop Vector**

```c
for (i=0; i<M-K; i++){
    y[i] = __sec_reduce_add(x[i:K] * c[0:K]);
}
```

**Example: FIR Outer Loop Vector**

```c
y[0:M-K] = 0;
for (j=0; j<K; j++){
    y[0:M-K] += x[j:M-K] * c[j];
}
```

The parallel array assignment semantics enable vectorization of computations on the right hand side (RHS) of the assignment even if the l-value of the assignment may alias with some operands on the RHS. Since the compiler does not automatically introduce temporary arrays when aliasing occurs one should add explicit temporary arrays to ensure the correct behavior, when in doubt. This may increase memory usage and incur extra overhead from writing and reading them, which needs to be amortized by the speed-up from vectorizing the code.
Example:

```c
void saxpy_vec (int m, float a, float *x, float y[m]){
    y[:] += a * x[0:m]; // Compiler assumes x and y are disjoint even if they are not
}

void saxpy_vec (int m, float a, float x[m], float y[m]){
    float z[m];
    z[:] = y[:]; // When in doubt, programmer has to introduce temporary array
    // It is best to confirm whether there are any possibilities of overlap.
    y[:] = z[:] + a * x[:];
}
```

To take full advantage of vector instruction set, it is often beneficial to use a fixed vector length supported by the processor, as illustrated in the next example. The example code computes an average over nine points in a two-dimensional grid (avoiding the 1-element boundary around the grid where the nine-point average is not defined). The core computation is written in vector form as in a function `nine_point_average`. The application is further parallelized using a `cilk_for` loop at the call site. The grain size of the computation is controlled by the two compile time constants, `VLEN` and `NROWS`, which designate the length of vector operations and the number of rows processed in each invocation. Because the loads of adjacent rows are reused across multiple rows, you gain on memory locality by processing multiple rows inside the function. Using compile time constant for vector length makes the vector code generation more efficient and predictable.

Example

```c
#include <malloc.h>
#include <cilk/cilk.h>
#define VLEN 4
#define NROWS 4

//-------------------------------------------------------------------
// Vector kernel
// for each grid
// o[x][y] = (i[x-1][y-1] + i[x-1][y] + i[x-1][y+1] +
// i[x][y-1] + i[x][y] + i[x][y+1] +
// i[x+1][y-1] + i[x+1][y] + i[x+1][y+1])/9;
// written with:
// 1) VLEN columns for vectorization
// 2) NROWS rows for the reuse of the adjacent row loads
//--------------------------------------------------------------------

void nine_point_average(int h, int w, int i, int j, float in[h][w], float out[h][w])
{
    float m[NROWS][VLEN];
    m[:,:,] = in[i:NROWS][j:VLEN];
    m[:,:,] += in[i+1:NROWS][j:VLEN];
    m[:,:,] += in[i+2:NROWS][j:VLEN];
    m[:,:,] += in[i:NROWS][j+1:VLEN];
    m[:,:,] += in[i+1:NROWS][j+1:VLEN];
    m[:,:,] += in[i+2:NROWS][j+1:VLEN];
    m[:,:,] += in[i:NROWS][j+2:VLEN];
    m[:,:,] += in[i+1:NROWS][j+2:VLEN];
    m[:,:,] += in[i+2:NROWS][j+2:VLEN];
    out[i:NROWS][j:VLEN] = 0.1111f * m[:,:,];
}
```
Example

```c
const int width = 512;
const int height = 512;
typedef float (*p2d)[];

int main() {
    p2d src = (p2d) malloc(width*height*sizeof(float));
    p2d dst = (p2d) malloc(width*height*sizeof(float));
    // …
    // perform average over 9 points
    cilk_for (int i = 0; i < height - NROWS - 3; i += NROWS) {
        for (int j = 0; j < width - VLEN - 3; j += VLEN) {
            nine_point_average(height, width, i, j, src, dst);
        }
    }
}
```

Command-line entry

```
icl /Qstd=c99 test.c   //on Windows*
icc -std=c99 test.c   //on Linux* and macOS*
```

Optimizing Data Layout for Array Notation Vectorization

Some applications may benefit from a data layout change that converts data structures written in an Array of Structures (AOS) representation to a Structure of Arrays (SOA) representation. This helps prevent gathers when accessing one field of the structure across the array elements, and helps the compiler vectorize loops that iterate over the array. Such data transformations should be done by you at the program level to avoid repeating costly transformations before and after each loop.

**AOS to SOA conversion:** The conversion of your data structures from an Array of Structures (AOS) to a Structure of Arrays (SOA) is a common optimization that helps prevent gathers and scatters in vectorized code. Maintaining separate arrays for each field of the structure keeps memory accesses contiguous and aids vectorization when operating over structure instances. The AOS representation requires gathers and scatters, which can impact both SIMD efficiency as well as introduce extra bandwidth and latency for memory accesses. The presence of a hardware gather-scatter mechanism does not eliminate the need for this transformation since gather-scatter accesses commonly need significantly higher bandwidth and latency than contiguous loads.

The SOA form does reduce the locality of multiple fields in a single instance of the original structure, which could increase Translation Look-aside Buffer (TLB) pressure. It may be preferable to use an **Array of Structures of Arrays (AOSOA)** data structure even if only traversing a subset of the structure’s instances. This provides the benefit of locality at the outer-level and unit-stride at the innermost-level. The length of the inner array can be a small multiple of vector length to take advantage of unit-stride full vectors. Each structure instance will have multiple fields laid out in small arrays. At the outer level, you will now have an array of larger structures. In such a layout, the field accesses will still be close enough to get the benefit of page locality for nearby structure-instance accesses in the original code.

Here is a simple example that shows the difference between these forms:
AOS Form (Array of Structures):

```c
struct node {
    float x, y, z;
};
struct node NODES[1024];

float dist[1024];
for(i=0;i<1024;i+=16){
    float x[16],y[16],z[16],d[16];
    x[:] = NODES[i:16].x;
    y[:] = NODES[i:16].y;
    z[:] = NODES[i:16].z;
    d[:] = sqrtf(x[:] * x[:] + y[:] * y[:] + z[:] * z[:]);
    dist[i:16] = d[:];
}
```

SOA Form (Structure of Arrays):

```c
struct node1 {
    float x[1024], y[1024], z[1024];
};
struct node1 NODES1;

float dist[1024];
for(i=0;i<1024;i+=16){
    float x[16],y[16],z[16],d[16];
    x[:] = NODES1.x[i:16];
    y[:] = NODES1.y[i:16];
    z[:] = NODES1.z[i:16];
    d[:] = sqrtf(x[:] * x[:] + y[:] * y[:] + z[:] * z[:]);
    dist[i:16] = d[:];
}
```

AOSOA Form (Array of Structures of Arrays OR Tiled Array of Structures):

```c
struct node2 {
    float x[16], y[16], z[16];
};
struct nodes2 NODES2[64];

float dist[1024];
for(i=0;i<64;i++){
    float x[16],y[16],z[16],d[16];
    x[:] = NODES2[i].x[:];
    y[:] = NODES2[i].y[:];
    z[:] = NODES2[i].z[:];
    d[:] = sqrtf(x[:] * x[:] + y[:] * y[:] + z[:] * z[:]);
    dist[i*16:16] = d[:];
}
Multi-Dimensional Casting Operations

For arrays of two or more dimensions the C language uses row-major ordering. When porting code to array notation format, it is not uncommon to encounter array access patterns that are impossible to express using array notations. However, you can often convert the array into a form that is suitable.

For instance, consider that you want to access the data in the center of a 4x4 array.

```
0 1 2 3
4 5 6 7
8 9 10 11
12 13 14 15
```

This 4x4 array can be represented as a two-dimensional array as follows:

```
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
```

If you are porting code in which this 2-dimensional data is represented as a 1-dimensional array there is no way to express this access pattern using array notation alone, unless you convert your array into a 2-dimensional one. You can do this as follows:

```
float (*array_2D)[4] = (float *)[4]array_1D;
```

Using this method, the above access pattern can be made accessible as array notations as follows:

```
array_2D[1:2][1:2];
```

You can extend this approach to any dimensionality, as the following example illustrates.

```
#define XRES 48
#define YRES 64
#define ZRES 48
float (*array_3D)[YRES][XRES] = (float *)[YRES][XRES]array_1D;
array_3D[1:ZRES-2][1:YRES-2][1:XRES-2];
```

Guided Auto Parallelism

NOTE This feature has been deprecated.

The Guided Auto Parallelism (GAP) feature of the Intel® C++ Compiler is a tool that offers selective advice to improve the performance of serially-coded applications by suggesting changes that take advantage of the compiler’s ability to automatically vectorize and parallelize code and improve the efficiency of data
operations. Despite having the words “auto parallelism” in the name, this tool does not require a threaded code implementation to improve the execution performance of the code, or require that the code is already threaded or parallel.

Advanced optimization techniques, such as inter-procedural analysis or profile-guided feedback, are not needed to use this feature. Using the [Q]guide set of options in addition to the compiler options normally used is sufficient to enable the GAP feature, with the requirement that you must compile with O2 or higher optimization levels. The compiler does not generate any object files or executables during the GAP run.

In debug mode (/zi on Windows*, -g on Linux*), the compiler’s optimization level defaults to /Od (on Windows*) or -O0 (on Linux* and macOS*); thus O2 (or a higher level optimization) must be specified explicitly on the command-line.

NOTE Use the [Q]diag-disable option along with the [Q]guide option to direct the compiler to suppress specific diagnostic messages. For example, the options: // (Windows*) /Qguide, /Qdiag-disable:30534 and // (Linux* and macOS*) -guide, -diag-disable:30534 tell the compiler not to emit the 30534 diagnostic. The [Q]diag-disable mechanism works the same way as it does for compiler-warnings.

If you decide to follow the advice offered by the GAP tool by making the suggested code changes and/or using the suggested compiler options, you must then recompile the program without the [Q]guide option.

Any advice generated by the compiler when using the GAP tool is optional; it can be implemented or rejected. The advice typically falls under three broad categories:

- **Advice for source modifications**: The compiler advises you to make source changes that are localized to a loop-nest or a routine. For example, the tool may recommend that you use a local-variable for the upper-bound of a loop, (instead of a class member) or that you should initialize a local variable unconditionally at the top of the loop-body, or you may be told to add the restrict keyword to pointer-arguments of a function definition (if appropriate).

- **Advice to apply pragmas**: The compiler advises you to apply a new pragma on a certain loop-level if the pragma semantics can be satisfied (you must verify this). In many cases, you may be able to apply the pragma (thus implicitly asserting new program/loop properties) that the compiler can take advantage of to perform enhanced optimizations.

- **Advice to add compiler options**: The compiler advises you to add command-line options that assert new properties; for example, you may be asked to use the [Q]ansi-alias option or /Qalias-args (Windows*) or -fargument-alias (on Linux*) compiler options.

NOTE These suggested compiler options apply to the entire file. It is your responsibility to check that the properties asserted by these options are valid for the entire file, and not just the loop in question.

If you use GAP options along with option [Q]parallel, the compiler may suggest options to further parallelize your application. The compiler may also offer advice on enabling other optimizations of your application, including vectorization.

If you use the GAP options without enabling auto parallelism (without using the [Q]parallel option), the compiler may only suggest enabling optimizations such as vectorization for your application. This approach is recommended when you wish to improve the performance of a single-threaded code without the use of parallelization or when you want to improve the performance of threaded applications that do not rely on the compiler for auto parallelism.

Using Guided Auto Parallelism

The Guided Auto Parallelism feature of the Intel® C++ Compiler is a tool offering selective advice to improve the performance of serially-coded applications. The tool suggests changes that take advantage of the compiler’s ability to automatically vectorize and parallelize code as well as improve the efficiency of data operations. The tool does not require that you implement threaded code to improve the execution performance of your code, nor does it require that your code is already threaded or parallel code.

To invoke this tool, use the compiler option [Q]guide[=n]. Using this option causes the compiler to generate messages suggesting ways to optimize the performance of your application. You can also use more specific compiler options such as [Q]guide-vec, [Q]guide-par, and [Q]guide-data-trans, to perform individual guided optimizations for vectorizing, parallelizing, and data transformation of your application.

When any guided auto parallelism option is used, the compiler provides only diagnostic advice. Object files or executables are not created in this mode. See the table below for descriptions of the options.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide</td>
<td>Allows you to set a level of guidance for auto-vectorization and data transformation analysis. To obtain guidance for auto parallelism, you must use the [Q]parallel option along with the [Q]guide option.</td>
</tr>
<tr>
<td>[Q]guide-par</td>
<td>Allows you to set a level of guidance only for auto parallelism analysis.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong> You must use the [Q]parallel option along with the [Q]guide-par option to get this advice.</td>
</tr>
<tr>
<td>[Q]guide-vec</td>
<td>Allows you to set a level of guidance for auto-vectorization analysis only.</td>
</tr>
<tr>
<td>[Q]guide-data-trans</td>
<td>Allows you to set a level of guidance for data transformation analysis only.</td>
</tr>
</tbody>
</table>

For all of the above options, the optional argument \( n \) specifies the level of guidance. The argument \( n \) takes the values 1-4. When \( n \) is not specified, the default is 4. If you specify \( n=1 \) or \( 2 \), a standard level of guidance is provided.

When you use \( n=3 \) or \( n=4 \), you may get advanced messages. For example, you may get messages about how to optimize a particular loop-nest or get a message on how exception-handling inside a loop-nest affects optimizations for that loop-nest. Or you may get a message on how to provide extra information to the compiler on cost-modeling (expected values of trip-counts, and so on).

If you simultaneously specify a level of guidance for the general [Q]guide option and also for one or more of the other specific guide options, the level of guidance (\( n \)) for the specific guide option overrides the general [Q]guide option setting.

If you do not specify a level of guidance for the general [Q]guide option, but do set a level of guidance for one or more of the specific guide options, the [Q]guide option is set equal to the greatest value passed to the specific guide options.
Capturing Guidance Messages

The guided auto parallelism tool analyzes all of your serial code or individual parts of your code and generates advisory messages. By default, messages that are generated by the guided auto parallelism tool are output to stderr.

To capture messages in a file, use the options listed in the following table.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide-file</td>
<td>Gathers all messages generated during a guided auto-parallelization run into the specified file.</td>
</tr>
<tr>
<td>[Q]guide-file-append</td>
<td>Allows you to specify the file into which all messages generated during a guided auto parallelism run should be appended.</td>
</tr>
</tbody>
</table>

For the above options, the file_name argument can also include a path. If a path is not specified, the file is created in the current working directory. If there is already a file named file_name, it is overwritten when you use the [Q]guide-file option. If you do not include an extension as part of the file_name, the extension .guide is appended.

Configuring Code Regions for GAP Messages

To limit guided auto parallelism analysis to specific regions (hotspots) in your application, use the options mentioned in the table below.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide-opts</td>
<td>Allows you to analyze specified code elements, identified by string.</td>
</tr>
<tr>
<td>[Q]guide-profile</td>
<td>Allows you to specify a loop profiler data file (or a set of files) when used with [Q]guide option.</td>
</tr>
</tbody>
</table>

You must use the [Q]guide-opts option along with one of the guided auto parallelism options, such as [Q]guide, [Q]guide-vec, [Q]guide-par, and [Q]guide-data-trans. Use the string parameter to provide information about known areas of interest (hotspots). The string parameter takes one or more of the following variables: filename, routine, range. The compiler parses the string parameter and generates syntax errors if there are any.

Windows* Syntax

/Qguide-opts:string

Linux* and macOS* Syntax

-guide-opts=string

Follow these guidelines when using the string parameter:

- Use only valid file names, routine names, and line numbers. The guided auto parallelism tool ignores invalid values and issues a diagnostic message stating what was ignored.
- Enclose routine names within single quotation marks. Specify original source names (demangled names) as routine names. A routine name alone may not always be sufficient to uniquely identify a routine. You may need to specify additional parameter information to uniquely identify the routine. For example:
For any specified routine name, the GAP tool first tries to uniquely identify the routine using specified
routine information. If that is not possible, then it selects all routines with the specified routine name. The
GAP tool uses the parameter information, if specified, to narrow the selection.

- When inlining is involved, use the callee line numbers. The generated messages also use the callee line
  numbers.

Alternatively, you can automate and narrow down the targeted regions to specific hotspots in your
application code by using the \[Q\]guide-profile option with the \[Q\]guide option.

Windows* Syntax

/\Qguide-profile:filename | dir [ , [filename|dir]...]

Linux* and macOS* Syntax

-\guide-profile=filename | dir [ , [ filename | dir ] ... ]

The region targeted by the \[Q\]guide option, when used along with the \[Q\]guide-profile option, is
configured by processing the XML data file(s) produced from a loop-profiler-instrumented run. The loop
profiler result files are specified as the actual loop profiler data file, or as the directory name where loop
profile data files are stored.

Guided Auto Parallelism Messages

The Guided Auto Parallelism (GAP) messages provide advice that should improve optimizations.
The messages provide suggestions for:

- Automatic parallelization of loop nests
- Automatic vectorization of inner loops
- Data transformation
You must decide whether to follow a particular suggestion. For example, if the advice is to apply a particular pragma, you must understand the semantics of the pragma and carefully consider whether it can be safely applied to the loop (or loop nest) in question.

If you apply the pragma improperly, the compiler may generate incorrect code, causing the application to execute incorrectly.

If you do not fully understand the suggested advice, please refer to the relevant topics in the compiler documentation before applying that advice.

Once you apply the suggested advice, the compiler assumes that it is correct and it does not perform any checks or issue any warnings.

In general, messages that relate to loops tend to target vectorization and/or parallelization of loops. If you are not familiar with loop optimizations, please refer to the compiler documentation on this kind of optimization.

Loop Constructs

GAP Message (Diagnostic ID 30506)

Message
If the following operations(s) can be safely performed unconditionally, the loop at line %d will be vectorized by adding a "%%s ivdep" statement right before the loop: %s.

Advice
Add "#pragma ivdep" before the specified loop.

This pragma enables the vectorization of the loop at the specified line. Insure that any conditional divide, sqrt, and inverse sqrt operations will not alter the exception semantics expected by the program when they are performed unconditionally.

Example
Consider the following:

```c
void foo(float *a, int n) {
    int i;
    for (i=0; i<n; i++) {
        if (a[i] > 0) {
            a[i] = 1 / a[i];
        }
    }
    return;
}
```

In this case, the compiler is unable to vectorize the loop if compiled with floating-point exception semantics (such as /fp:except option) because the condition "a[i] > 0" may be guarding floating-point exceptions for the divide.
If you determine it is safe to do so, you can add the pragma as follows:

```c
void foo(float *a, int n) {
    int i;
    #pragma ivdep
    for (i=0; i<n; i++) {
        if (a[i] > 0) {
            a[i] = 1 / a[i];
        }
    }
    return;
}
```

**Verify**

Confirm that the program operands have safe values for all iterations.

**GAP Message (Diagnostic ID 30513)**

**Message**

Insert a "%s ivdep" statement right before the loop at line %d to vectorize the loop.

**Advice**

Add "#pragma ivdep" before the specified loop. This pragma enables the vectorization of the loop at the specified line by ignoring some of the assumed cross-iteration data dependencies.

**Example**

Consider the following:

```c
void foo(float *a, int x, int n) {
    int i;
    for (i=0; i<n; i++) {
        a[i] = a[i+x]+1;
    }
    return;
}
```

In this case, the compiler is unable to vectorize the loop because x could be -1, where each iteration is dependent on the previous iteration. If x is known to be positive, you can vectorize this loop.

If you determine it is safe to do so, you can add the pragma as follows:

```c
void foo(float *a, int x, int n) {
    int i;
    #pragma ivdep
    for (i=0; i<n; i++) {
        a[i] = a[i+x]+1;
    }
    return;
}
```

**Verify**

Confirm that any arrays in the loop do not have unsafe cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a read or a write statement in another iteration of the loop. Make sure that there are no such dependencies, or that any cross-iteration dependencies can be safely ignored.
GAP Message (Diagnostic ID 30515)

Message
Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be vectorized.

Advice
You should unconditionally initialize the scalar variables at the beginning of the specified loop. This allows the vectorizer to privatize those variables for each iteration and vectorize the loop. You must ensure that all the uses of those variables see the same values before and after the source code change.

Example
Consider the following:

```c
void foo(float *a, int n) {
  int i;
  float b;
  for (i=0; i<n; i++) {
    if (a[i] > 0) {
      b = a[i];
      a[i] = 1 / a[i];
    }
    if (a[i] > 1) {
      a[i] += b;
    }
  }
  return;
}
```

In this case, the compiler is unable to vectorize the loop because it failed to privatize the variable \( b \). Vectorization is assisted when assignment to \( b \) occurs in each iteration where the value of \( b \) is used. One of the ways to do this is to assign the value in every iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```c
void foo(float *a, int n) {
  int i;
  float b;
  for (i=0; i<n; i++) {
    b = a[i];
    if (a[i] > 0) {
      a[i] = 1 / a[i];
    }
    if (a[i] > 1) {
      a[i] += b;
    }
  }
  return;
}
```

Verify
Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration.
GAP Message (Diagnostic ID 30519)

Message
Insert a "%s parallel" statement right before the loop at line %d to parallelize the loop.

Advice
Add "#pragma parallel" before the specified loop. This pragma enables the parallelization of the loop at the specified line by ignoring assumed cross-iteration data dependencies.

Example
Consider the following:

```c
void foo(float *a, int m, int n) {
    int i;
    for (i=0; i<n; i++) {
        a[i] = a[i+m]+1;
    }
    return;
}
```

In this case, the compiler is unable to parallelize the loop without further information about \( m \). For example, if \( m \) is negative, then each iteration will be dependent on the previous iteration. However, if \( m \) is known to be greater than \( n \), you can parallelize the loop.

If you determine it is safe to do so, you can add the pragma as follows:

```c
void foo(float *a, int m, int n) {
    int i;
    #pragma parallel
    for (i=0; i<n; i++) {
        a[i] = a[i+m]+1;
    }
    return;
}
```

Verify
Confirm that any arrays in the loop do not have cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a read or a write statement in another iteration of the loop.

GAP Message (Diagnostic ID 30521)

Message
Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

Advice
Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel pragma (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.
Example
Consider the following:

```c
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
    int i, t=7;
    for (i=0; i<N; i++){
        if (cond1) {
            t = i+1;
        }
        if (cond2) {
            t = i-1;
        }
        A[i] = t;
    }
}
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable `t` without further information. If you know that cond1 or cond2 is true, or both cond1 and cond2 are true, then you can assist the parallelizer by ensuring that any iteration that uses `t` also writes to `t` before its use in the same iteration. One of the ways to do this is to assign a value to `t` at the top of each iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```c
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
    int i, t=7;
    for (i=0; i<N; i++){
        t=0;
        if (cond1) {
            t = i+1;
        }
        if (cond2) {
            t = i-1;
        }
        A[i] = t;
    }
}
```

Verify
Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration.

See Also
GAP Message (Diagnostic ID 30523)

GAP Message (Diagnostic ID 30522)

Message
Insert a "%s parallel private(%s)" statement right before the loop at line %d to parallelize the loop.
Advice
Add "#pragma parallel private" before the specified loop. This pragma enables the parallelization of the loop at the specified line.

Example
Consider the following:

```c
float A[10][10000];
float B[10][10000];
float C[10][10000];
void foo(
    int n,
    int m1,
    int m2
){
    int i,j;
    float W[10000];
    for (i =0; i < n; i++) {
        for (j =0; j < m1; j++)
            W[j] = A[i][j] * B[i][j];
    for (j =0; j < m2; j++)
        C[i][j] += W[j] + 1.0;
    }
}
```

In this case, the compiler does not parallelize the loop since it cannot determine whether m1 >= m2. If you know that this property is true, and that no element of W is fetched before it is written to after the loop, then you can use the recommended pragma.

If you determine it is safe to do so, you can add the pragma as follows:

```c
float A[10][10000];
float B[10][10000];
float C[10][10000];
void foo(
    int n,
    int m1,
    int m2
){
    int i,j;
    float W[10000];
    #pragma parallel private (W)
    for (i =0; i < n; i++) {
        for (j =0; j < m1; j++)
            W[j] = A[i][j] * B[i][j];
    for (j =0; j < m2; j++)
        C[i][j] += W[j] + 1.0;
    }
}
```

Verify
Before an element of an array can be read in the loop, there must have been a previous write to it during the same loop iteration. In addition, if an element is read after the loop, there must have been a previous write to it before the read after the loop.
GAP Message (Diagnostic ID 30523)

Message
Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

Advice
Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel pragma (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

Example
Consider the following:

```c
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
    int i, t=7;
    for (i=0; i<N; i++){
        if (cond1) {
            t = i;
        }
        if (cond2) {
            A[i] = t;
        }
    }
}
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable \( t \) without further information. If you know that \( \text{cond2} \) always implies \( \text{cond1} \), then you can assist the parallelizer by ensuring that any iteration that uses \( t \) also writes to \( t \) before it is used in the same iteration. One of the ways to do this is to assign a value to \( t \) at the top of every iteration. Another way is to list the variables to be privatized in the private clause of a parallel pragma.

If you determine it is safe to do so, you can add the pragma as follows:

```c
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
    int i, t=7;
    #pragma private (t)
    for (i=0; i<N; i++){
        if (cond1) {
            t = i;
        }
        if (cond2) {
            A[i] = t;
        }
    }
}
```
Verify
Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration or have been privatized by means of the private clause of a parallel pragma.

See Also
GAP Message (Diagnostic ID 30521)

GAP Message (Diagnostic ID 30525)

Message
Insert a "%%s loop count min(%d)" statement right before the loop at line %d to parallelize the loop.

Advice
Add "#pragma loop count" before the specified loop. This pragma indicates the minimum trip count (number of iterations) of the loop that enables the parallelization of the loop.

The minimum trip count required to parallelize the loop may differ depending on the target architecture, and this will be reflected in the message generated.

Example
Consider the following:

```c
#define N 10000
float A[N], B[N];

void foo(int n) {
    int i;
    for (i =0; i < n; i++) {
    }
}
```

In this case, the compiler may not parallelize the loop because it is not sure that n is large enough for the parallelization to be beneficial.

If you determine it is safe to do so, you can add the pragma as follows:

```c
#define N 10000
float A[N], B[N];

void foo(int n) {
    int i;
    #pragma loop count min(128)
    for (i =0; i < n; i++) {
    }
}
```

Verify
Confirm that the loop has the minimum number of iterations, as specified in the diagnostic message.

See Also
Guided Auto Parallelism Messages provides advice for improving optimizations
**GAP Message (Diagnostic ID 30526)**

**Message**
To parallelize the loop at line %d, annotate the routine %s with %s.

**Advice**
If the loop contains a call to a function, the compiler cannot parallelize the loop without more information about the function being called.

However, if the function being called in the loop is a const function or a concurrency-safe function, then the call does not inhibit parallelization of the loop.

**Example**
Consider the following:

```c
#define N 10000
double A[N], B[N];
int bar(int);
void foo(){
    int i;
    for (i=0;i<N;i++){
        A[i] = B[i] * bar(i);
    }
}
```

In this case, the compiler does not parallelize the loop because it is not safe to do so without further information about routine `bar`, which is being called.

If you determine it is safe to do so, you can modify the program code as follows:

```c
#define N 10000
double A[N], B[N];
__declspec(const) int bar(int);
void foo(){
    int i;
    for (i=0;i<N;i++){
        A[i] = B[i] * bar(i);
    }
}
```

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```c
#define N 10000
double A[N], B[N];
__declspec(concurrency_safe(profitable)) int bar(int);
void foo(){
    int i;
    for (i=0;i<N;i++){
        A[i] = B[i] * bar(i);
    }
}
```

**Verify**
Confirm the routine satisfies the semantics of this annotation. A weaker annotation able to achieve a similar effect is `__declspec(concurrency_safe(profitable))`. 

2247
See Also
GAP Message (Diagnostic ID 30528)
__declspec(concurrency_safe) declaration
__declspec(const) declaration

GAP Message (Diagnostic ID 30528)

Message
Add "%s" to the declaration of routine "%s" in order to parallelize the loop at line %d. Adding "%s" achieves a similar effect.

Advice
Confirm that the routine specified is indeed a const function or a concurrency-safe function before following the advice to add the annotation.
If the routine is not one of these kinds of functions, try to inline it with #pragma forceinline recursive. This action may or may not be beneficial.

Example
Consider the following:

```c
#define N 10000
double A[N], B[N];
int bar(int);
void foo(){
    int i;
    for (i=0;i<N;i++){
        A[i] = B[i] * bar(i);
    }
}
```

In this case, the compiler does not parallelize the loop because it is not safe to do so without further information about routine `bar`, which is being called.
If you determine it is safe to do so, you can add the pragma as follows:

```c
#define N 10000
double A[N], B[N];
void foo(){
    int i;
    #pragma forceinline recursive
    for (i=0;i<N;i++){
        A[i] = B[i] * bar(i);
    }
}
```

Verify
Confirm that the routine satisfies the semantics of this declaration. Another way to help the loop being parallelized is to inline the routine with the forceinline recursive pragma, but this method does not guarantee parallelization.

**GAP Message (Diagnostic ID 30531)**

**Message**

Store the value of the upper-bound expression of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = upper-bound of loop" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

**Advice**

Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler cannot output the exact upper-bound variable to be replaced.

**Example**

Consider the following:

```cpp
class FooClass  {
public:
    const int getValue() { return m_numTimeSteps;}
    void Foo2(double* vec);
private:
    int m_numTimeSteps;
};
void FooClass::Foo2(double* vec) {
    // this will not vectorize
    for (int k=0; k < m_numTimeSteps; k++)
        vec[k] = 0.0;

    // this will not vectorize
    for (int k=0; k < getValue(); k++)
        vec[k] = 0.0;

    // this will vectorize
    int ub1 = m_numTimeSteps;
    for (int k=0; k < ub1; k++)
        vec[k] = 0.0;

    // this will vectorize
    int ub2 = getValue();
    for (int k=0; k < ub2; k++)
        vec[k] = 0.0;
}
```

**Verify**

Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

**See Also**

GAP Message (Diagnostic ID 30532)
**GAP Message (Diagnostic ID 30532)**

**Message**

Store the value of the upper-bound expression (%s) of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = %s" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

**Advice**

Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which in turn enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler can output the exact upper-bound variable to be replaced.

**Example**

Consider the following:

```c
typedef struct  {
    float*      data;
} Vector;

typedef struct {
    int         len;
} NetEnv;

// This one does not vectorize
void mul(
    NetEnv*     ne,
    Vector*     rslt,
    Vector*     den,
    Vector*     num)
{
    float*      r;
    float*      d;
    float*      n;
    int i;

    r = rslt->data;
    d = den->data;
    n = num->data;

    for (i = 0; i < ne->len; ++i) {
        r[i] = n[i] * d[i];
    }

    return;
}
```

In this case, the compiler is unable to vectorize the loop at setting O2, the default.
If you determine it is safe to do so, you can modify the program code as follows:

```c
typedef struct {
    float* data;
} Vector;

typedef struct {
    int len;
} NetEnv;

// This one vectorizes
void mul(
    NetEnv* ne,
    Vector* rslt,
    Vector* den,
    Vector* num)
{
    float* r;
    float* d;
    float* n;
    int i, local_len;

    r = rslt->data;
    d = den->data;
    n = num->data;

    local_len = ne->len;
    for (i = 0; i < local_len; ++i) {
        r[i] = n[i] * d[i];
    }
    return;
}
```

**Verify**

Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

**See Also**

GAP Message (Diagnostic ID 30531)

**GAP Message (Diagnostic ID 30533)**

**Message**

Compile with the `%s` option to vectorize and/or parallelize the loop at line `%d`.

**Advice**

Use the `[q or Q]opt-subscript-in-range` option for the specified file during compilation.

This option helps the compiler vectorize and parallelize the loop at the specified line. You must verify that the loops in the file do not contain very large integers and are not likely to generate very large integers in intermediate computations. A very large integer is loosely defined as follows: On an n-bit machine, a very large integer is typically $\geq 2^{n/2}$. For example, on a 32-bit machine, a very large integer would be $\geq 2^{15}$. 

2251
Example

Consider the following:

```c
int f(int* A, int upper1, int upper2){
    long extra = 100.0;
    int return_val = 0;
    int val;
    for(int j=0; j < upper1; j++){
        for(int i = 0; i < upper2; i++){
            val = A[i*extra];
            return_val += val;
        }
    }
    return return_val;
}
```

If you determine it is safe to do so, compiling this example with the \[q\ or \Q\opt-subscript-in-range\] option results in vectorization of the innermost loop.

Verify

Confirm that no loop in the program contains or generates very large integers (typically very large integers are \(\geq 2^{30}\)).

GAP Message (Diagnostic ID 30534)

Message

Add %s option for better type-based disambiguation analysis by the compiler if appropriate (the option will apply for the entire compilation). This will improve optimizations for the loop at line %d.

Advice

Use option \[Q\ansi-alias\] for the specified file. This option will help the compiler to optimize the loop at the specified line. You must verify that the ANSI rules are followed for the entire file. gcc assumes this property by default in default setting O2; the Intel compiler does not. This option is particularly useful for C++ programs since it enables type-based disambiguation between pointers and other elemental datatypes (that in turn enables optimizations such as vectorization and parallelization).

Option \[Q\ansi-alias\] enables or disables use of ANSI aliasing rules optimizations, and assert that the program adheres to these rules.

ANSI-aliasing rules are described in the Standards documentation:

- C: ISO/IEC 9899, chapter 6.5 paragraph 7
- C++: ISO/IEC 14882, chapter 3.10, paragraph 15

Example

Consider the following:

```c
#include <stddef.h>
template<typename T>
class blocked_range {
    T my_begin;
    T my_end;
public:
    blocked_range();
```
T begin() const {return my_begin;}
T end() const {return my_end;}
);

class ApplyMatAdd {
    double *const A, *const B, *const C;
    const size_t size;
public:
    ApplyMatAdd(double *A_, double *B_, double *C_, size_t size_) : A(A_), B(B_), C(C_),
        size(size_) {}
    void operator() (const blocked_range<size_t>& range) const;
};

void ApplyMatAdd::operator() (const blocked_range<size_t>& range) const {
    for (size_t i=range.begin(); i<range.end(); ++i) {
        for (size_t j=0; j<size; ++j) {
            C[i*size + j] = A[i*size + j] + B[i*size + j];
        }
    }
}

In this case, the compiler is unable to vectorize the innermost loop at setting O2, the default.
If you determine it is safe to do so, you can compile the above example with the [Q]ansi-alias option,
which enables vectorization of the innermost loop.

**Verify**

Make sure that the semantics of this option are obeyed for the entire compilation.

**GAP Message (Diagnostic ID 30535)**

**Message**

Removing Exception-Handling code associated with the loop-body may enable more optimizations for the loop at line %d.

**Advice**

Loop optimizations could not be performed because of exception-handling code inside the loop body. You can remove the exception-handling code or use different libraries, etc.

**Example**

Consider the following:

```cpp
#include <boost/numeric/ublas/vector.hpp>
#include <boost/numeric/ublas/io.hpp>

namespace ublas = boost::numeric::ublas;

int main () {
    unsigned size = 1000;
    ublas::vector<double> dest(size), src(size), arg(src);

    for (int i = 0; i < size; ++i) {
        src(i) = i * 1.2;
        arg(i) = i * 2.3;
    }
```
// Loop to be vectorized
dest = src + 1.5 * arg;
return 0;
};

In this case, the compiler is unable to vectorize the loop at setting `O2`, the default. Remove the exception-handling code or recode using different libraries.

**Verify**

Make sure that the restructured code without exception-handling code inside the loop-body follows original program semantics.

**GAP Message (Diagnostic ID 30536)**

**Message**

Add `%s` option for better type-based disambiguation analysis by the compiler, if appropriate (the option will apply for the entire compilation). This will improve optimizations such as vectorization for the loop at line `%d`.

**Advice**

Use option `-fnoargument-alias` (Linux* OS and macOS*) or `/Qno-alias-args` (Windows* OS) for the specified file. This option will help the compiler to optimize the loop at the specified line. The user has to verify that there is no argument-aliasing for routines in this file before applying this option for the current file. This option is particularly useful for C++ programs since it enables type-based disambiguation between pointers that are passed in as arguments, which in turn enables optimizations such as vectorization and parallelization.

Option `-fargument-alias` (Linux* OS and macOS*) and `/Qalias-args` (Windows* OS) enable or disable the C/C++ rule that function arguments may be aliased. When disabling the rule, you assert that this is safe.

**Example**

Consider the following example that demonstrates a violation of `-fnoargument-alias` or `/Qno-alias-args`:

```c
void f(double *p, double *q, double *r) {
  int i;
  for (i = 0; i < n; i++)
    p[i] = q[i] + r[i];
}

int n, m;
double A[100], B[100];
... f(&A[n], &A[m], &B[0]);
```

Since both pointers `p` and `q` will be pointing to the same array `A`, there may be overlap depending on the values of `n` and `m`.

Also, you cannot use the restrict keyword for parameters `p` and `q` in the function `f` for this test case.

You must analyze all the callers of function `f` in the current file and make sure that such overlap does not exist before applying `-fnoargument-alias` or `/Qno-alias-args` or the restrict qualifier. Note that such call sites may occur in other files as well.

Intel® C++ Compiler 19.0 Developer Guide and Reference
Verify

Make sure that the semantics of this option is obeyed for the entire compilation.

Another way to get the same effect is to add the "restrict" keyword to each pointer-typed formal parameter of the routine "%s". This allows optimizations such as vectorization to be applied to the loop at line %d.

Make sure that semantics of the "restrict" pointer qualifier is satisfied; in the routine, all data accessed through the pointer must not be accessed through any other pointer.

See Also

GAP Message (Diagnostic ID 30537)

GAP Message (Diagnostic ID 30537)

Message

Add the "restrict" keyword to each pointer-typed formal parameter of the routine "%s". This allows optimizations such as parallelization and vectorization to be applied to the loop at line %d.

Advice

Rather than using option -fnoargument-alias (Linux* OS and macOS*) or /Qno-alias-args (Windows* OS), which affects the entire file, you can add the restrict qualifier to the pointer arguments to this routine. This change is more localized since it affects only the routines where the keyword is applied.

The restrict qualifier is part of C standard C99. This qualifier can be applied to a data pointer to indicate that during the scope of that pointer declaration, all data accessed through it will be accessed only through that pointer but not through any other pointer. So, the restrict keyword enables the compiler to perform certain optimizations based on the premise that a given object cannot be changed through another pointer. You must ensure that restrict-qualified pointers are used as they are intended to be used. Otherwise, undefined behavior may result.

The Intel® Compiler requires that you also specify option [Q]restrict when compiling non-C99 programs.

Example

Consider the following:

```c
void matrix_mul_matrix(int N, float * C, float *A, float *B) {
  int i, j, k;
  for (i=0; i<N; i++) {
    for (j=0; j<N; j++) {
      C[i*N+j]=0;
      for (k=0; k<N; k++) {
        C[i*N+j]+=A[i*N+k] * B[k*N+j];
      }
    }
  }
}
```

In this case, the compiler is unable to apply loop optimizations such as loop-interchange and vectorization at default setting O2.

If you determine it is safe to do so, you can modify the program code as follows:

```c
void matrix_mul_matrix(int N, float * restrict C, float * restrict A, float * restrict B) {
  int i, j, k;
  for (i=0; i<N; i++) {
    for (j=0; j<N; j++) {
      C[i*N+j]=0;
      for (k=0; k<N; k++) {
        C[i*N+j]+=A[i*N+k] * B[k*N+j];
      }
    }
  }
}
```
for (j=0; j<N; j++) {
    C[i*N+j]=0;
    for(k=0;k<N;k++) {
        C[i*N+j]+=A[i*N+k] * B[k*N+j];
    }
}
}

Note that instead of using the restrict qualifier, you could have specified -fnoargument-alias or /Qno-alias-args before compiling the code.

Verify

Make sure that semantics of the "restrict" pointer qualifier is satisfied: in the routine, all data accessed through the pointer must not be accessed through any other pointer.

See Also
GAP Message (Diagnostic ID 30536)

GAP Message (Diagnostic ID 30538)

Message
Moving the block of code that consists of a function-call (line %d), if-condition (line %d), and an early return (line %d) to outside the loop may enable parallelization of the loop at line %d.

Advice
Move the function call and an associated return from inside the loop (perhaps by inserting them before the loop) to help parallelize the loop.

This kind of function-leading-to-return inside a loop usually handles some error-condition inside the loop. If this error check can be done before starting the execution of the loop without changing the program semantics, the compiler may be able to parallelize the loop thus improving performance.

Example
Consider the following:

extern int num_nodes;
typedef struct TEST_STRUCT {
    // Coordinates of city1
    float latitude1;
    float longitude1;

    // Coordinates of city2
    float latitude2;
    float longitude2;
} test_struct;

extern int *mark_larger;
extern float *distances, **matrix;
extern test_struct** nodes;
extern test_struct ***files;
extern void init_node(test_struct *node, int i);
extern void process_nodes(void);
float compute_max_distance(void);
extern int check_error_condition(int width);
#include <math.h>
#include <stdio.h>

void process_nodes(int width)
{
    float const R = 3964.0;
    float temp, lat1, lat2, long1, long2, result, pat2;
    int m, j, templ = num_nodes;
    nodes = files[0];
    m = 1;

#pragma loop count min(4)
#pragma parallel
    for (int k=0; k < templ; k++) {
        if (check_error_condition(width)) {
            return;
        }

        lat1 = nodes[k]->latitude1;
        lat2 = nodes[k]->latitude2;

        long1 = nodes[k]->longitude1;
        long2 = nodes[k]->longitude2;

        // Compute the distance between the two cities
        temp = sin(lat1) * sin(lat2) + cos(lat1) * cos(lat2) *
            cos(long1-long2);
        result = 2.0 * R * atan(sqrt((1.0-temp)/(1.0+temp)));

        pat2 = 0;
        for(j=0; j<width; j++) {
            pat2 += distances[j];
            matrix[k][j] = distances[k]+j;
        }
        // Store the distance computed in the distances array
        if (result > distances[k]) {
            distances[k] = result + pat2;
        }
    }
}

In this case, the compiler is unable to parallelize the loop at line 38.
If you determine it is safe to do so, you can modify the above code as follows:

extern int num_nodes;
typedef struct TEST_STRUCT {
    // Coordinates of city1
    float latitude1;
    float longitude1;

    // Coordinates of city2
    float latitude2;
    float longitude2;
} test_struct;

extern int *mark_larger;
extern float *distances, **matrix;
extern test_struct** nodes;
extern test_struct ***files;
extern void init_node(test_struct *node, int i);
extern void process_nodes(void);
float compute_max_distance(void);

extern int check_error_condition(int width);

#include <math.h>
#include <stdio.h>

void process_nodes(int width) {
    float const R = 3964.0;
    float temp, lat1, lat2, long1, long2, result, pat2;
    int m, j, templ = num_nodes;
    
    nodes = files[0];
    m = 1;
    
    if (check_error_condition(width)) {
        return;
    }
    
    #pragma loop count min(4)
    #pragma parallel
    for (int k=0; k < templ; k++) {
        lat1 = nodes[k]->latitude1;
        lat2 = nodes[k]->latitude2;
        
        long1 = nodes[k]->longitude1;
        long2 = nodes[k]->longitude2;
        
        // Compute the distance between the two cities
        temp = sin(lat1) * sin(lat2) + cos(lat1) * cos(lat2) * 
              cos(long1-long2);
        result = 2.0 * R * atan(sqrt((1.0-temp)/(1.0+temp)));
        pat2 = 0;
        for(j=0; j<width; j++) {
            pat2 += distances[j];
            matrix[k][j] = distances[k]+j;
        }
        // Store the distance computed in the distances array
        if (result > distances[k]) {
            distances[k] = result + pat2;
        }
    }
}

Verify

Confirm that the function call does not rely on any computation inside the loop and that restructuring the code as suggested above, retains the original program semantics.
GAP Message (Diagnostic ID 30753)

Message
Convert array of struct "%s" into a new struct whose fields are arrays of the corresponding fields in the original struct. This improves performance due to better data locality.

Advice
You should apply full peeling to a class or structure. This is done by splitting a class or structure into separate fields. This should improve performance by better utilizing the processor cache. This message is generated only when the entire application is built with Interprocedural Optimization (IPO). This transformation requires that you change all access to any peeled structure and its fields in the entire application. In some cases, it may not be easy to change source code to apply full peeling.

Example
Consider the following:

```c
// peel.c
#include <stdio.h>
#include <stdlib.h>
#define N 100000
int a[N];
double b[N];
struct S3 {
    int *pi;
    double d;
    int j;
};
struct S3 *sp;

void init_hot_s3_i() {
    int ii = 0;
    for (ii = 0; ii < N; ii++) {
        sp[ii].pi = &a[ii];
    }
}
void init_hot_s3_d() {
    int ii = 0;
    for (ii = 0; ii < N; ii++) {
        sp[ii].d = b[ii];
    }
}
void init_hot_s3_j() {
    int ii = 0;
    for (ii = 0; ii < N; ii++) {
        sp[ii].j = 0;
    }
}
void dump_s3() {
```

```c
```
int ii;

for (ii = 0; ii < N; ii++) {
    printf("i= %d ", *(sp[ii].pi));
    printf("d= %g \n", sp[ii].d);
    printf("j= %g \n", sp[ii].j);
}
}

main() {
    sp = (struct S3 *)calloc(N, sizeof(struct S3));
    init_hot_s3_i();
    init_hot_s3_d();
    init_hot_s3_j();
    dump_s3();
}

In this case, the compiler tells you to convert struct "S3".

If you determine it is safe to do so, you can modify the program code as follows:

#include <stdio.h>
#include <stdlib.h>

#define N 100000
int a[N];
double b[N];
struct S3 {
    int *pi;
};
struct new_d {
    double d;
};
struct new_j {
    int j;
};
struct S3 *sp;
struct new_d *sp_d;
struct new_j *sp_j;

void init_hot_s3_i() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].pi = &a[ii];
    }
}

void init_hot_s3_d() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].d = b[ii];
    }
}

void init_hot_s3_j() {
    int ii = 0;

for (ii = 0; ii < N; ii++) {
    sp[ii].j = 0;
}
}

void dump_s3() {
    int ii;
    for (ii = 0; ii < N; ii++) {
        printf("i= %d ", *(sp[ii].pi));
        printf("d= %g \n", sp[ii].d);
        printf("j= %g \n", sp[ii].j);
    }
}

main() {
    sp = (struct S3 *)calloc(N, sizeof(struct S3));
    init_hot_s3_i();
    init_hot_s3_d();
    init_hot_s3_j();
dump_s3();
}

Verify
Make sure that the restructured code satisfies the original program semantics.

GAP Message (Diagnostic ID 30754)

Message
Aligning the fields '%s' in the structure '%s' on an 8-byte boundary may improve performance. Default alignment of double precision floating point data is 4-byte on the Linux IA32 platform. [ALTERNATIVE] Reordering fields of the structure may help to align double precision floating point data on an 8-byte boundary. [ALTERNATIVE] Another way is to use __attribute__((aligned(8))) for the fields '%s' in the structure '%s' to allocate the fields on an 8-byte boundary.

This message is only available on Linux* systems.

Advice
You must reorder the fields of a class or structure type to make "double" fields 8-byte aligned. On Linux* systems on IA-32 architecture, "double" fields are not required to be 8-byte aligned. This should enable optimizations like vectorization to generate better code. You must verify that the application code does not rely on the structure fields to be laid out in a specific order.

Example
Consider the following:

//alignment.c
#include <stdlib.h>
#include <stdio.h>

#define N 1000

struct S {
int i;
  double d1;
  double d2;
  double d3;
};

struct S *sp;

static struct S*
alloc_s(int num) {
    struct S * temp;

    temp = calloc(num, sizeof(struct S));
    return temp;
}

struct S temp;

static void
swap_s(int i, int j) {
    memcpy(&temp, sp + i, sizeof(struct S));
    memcpy(sp + i, sp + j, sizeof(struct S));
    memcpy(sp + j, &temp, sizeof(struct S));
}

static void
init_s(int num) {
    int ii;

    for (ii = 0; ii < num; ii++) {
        sp[ii].i = ii;
        sp[ii].d1 = (double) ii + 1;
        sp[ii].d2 = (double) ii + 2;
        sp[ii].d3 = (double) ii + 3;
    }
}

main() {
    int ii;
    double d = 0.0;

    sp = alloc_s(N);

    for(ii = 0; ii < N -1; ii += 2) {
        swap_s(ii, ii+1);
    }

    for (ii = 0; ii < N ; ii++) {
        sp[ii].d1 = sp[ii].d1 * sp[ii].d2 * sp[ii].d3;
        d += sp[ii].d1;
    }

    for (ii = 0; ii < N ; ii++) {
        printf(" %d:  %g   %g  %g  \n", sp[ii].i, sp[ii].d1, sp[ii].d2, sp[ii].d3);
    }
}
In this case, when the program is compiled, the compiler generates a message saying that aligning the fields 'd1, d2, d3' in the structure 'S' on an 8-byte boundary may improve performance.

Alternatively, '__attribute__((aligned(8)))' can be used to align 'd1, d2, d3' on an 8-byte boundary. One possible way to do this is shown below:

```c
struct S {
    int i;
    __attribute__((aligned(8))) double d1;
    double d2;
    double d3;
};
```

**Verify**

Make sure that the restructured code satisfies the original program semantics. Note that size of the structure may change due to the alignment changes. Make sure that the change in the structure layout satisfies the original program semantics.

**GAP Message (Diagnostic ID 30755)**

**Message**

Reordering the fields of the structure '%s' will improve data locality. Suggested field order: '%s'.

**Advice**

You should reorder the fields of the class or structure type in the specified order. This should improve performance by better utilizing the processor cache.

You must verify that the application code does not rely on the structure fields to be laid out in a specific order. For example, if the application code uses the address of a field to access other fields, it may stop working once the field reordering is applied. Note also that such code is not considered valid.

**Example**

Consider the following:

```c
//field_reord.c
struct str {
    int a1, b1, carr[100], c1, d1, e1;
};
extern struct str sp[];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].e1;
    }
    return ret;
}
```
int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].carr[10];
    }
    return ret + sp[0].b1 + sp[0].d1;
}

In this case, when the program is compiled, the compiler generates a message saying that reordering the fields of the structure 'str' will improve data locality and that the suggested field order is 'a1, c1, e1, carr, b1, d1'.

For the above example, the only changes in field_reord.c to reorder fields of the structure 'str' as advised are the following:

```
//field_reord.c
struct str {
    int a1, c1, e1, carr[100], b1, d1;
};
```

Verify
The suggestion is based on the field references in the current compilation. Please make sure that the restructured code satisfies the original program semantics.

**GAP Message (Diagnostic ID 30756)**

**Message**
Split the structure '%s' into two parts to improve data locality. Frequently accessed fields are '%s'; performance may improve by putting these fields into one structure and the remaining fields into another structure. Alternatively, performance may also improve by reordering the fields of the structure. Suggested field order: '%s'.

**Advice**
This message is issued when both structure splitting and field reordering transformations are applicable. Structure splitting transformation is expected to lead to higher performance gains if the transformation can be successfully applied. However, field reordering transformation is usually simple enough to apply, but the downside is that the performance gain seen may be lower.

You must verify that the structure meets the requirements for applying the splitting or reordering transformation. Some of these requirements are described in the description of these individual transformations.

**Example**
Consider the following:

```
//str_split_reord.c
struct str {
    int a1, b1, carr[100], c1, e1;
};
```
#define N 1000000

struct str *sp;

void allocate_str_mem() {
    sp = malloc(N * sizeof(struct str));
}

int hot_func1() {
    int i, ret = 0;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    sp->carr[0] = ret;
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].e1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].b1;
    }
    return ret;
}

In this case, a message is displayed that is similar to the following:

drive: program-name: remark #30756: (DTRANS) Split the structure 'str' into two parts to improve data locality. Frequently accessed fields are 'a1, b1, c1'; performance may improve by putting these fields into one structure and the remaining fields into another structure. Alternatively, performance may also improve by reordering the fields of the structure. Suggested field order: 'a1, c1, e1, b1, carr'. ...(etc.)

If you determine it is safe to do so, you can modify the program code as shown below to split the structure 'str'. Other references to structure 'str' that are not in the current module should also be similarly modified.

struct str_cold {
    int carr[100], e1;
};

struct str {
    int a1, b1, c1; struct str_cold *cold_ptr;
};

#define N 1000000

struct str *sp;

void allocate_str_mem() {
}
struct str *temp;
struct str_cold *cold_begin;
int index;

temp = malloc(N * sizeof(struct str) + N * sizeof(struct str_cold));
sp = temp;
cold_begin = (struct str_cold *) (temp + N);
for(index = 0; index < N; index++) {
    temp[index].cold_ptr = cold_begin + index;
}
}

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    sp->cold_ptr->carr[0] = ret;
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].cold_ptr->e1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].b1;
    }
    return ret;
}

For the above example, the only source change required to reorder fields in structure 'str' as alternatively suggested are the following:

//str_split_reord.c
struct str {
    int a1, c1, e1, b1, carr[100];
};
...

Verify

The suggestion is based on the field references in the current compilation. Please make sure that the restructuring is applied to field references in all source files of the application, and that the restructured code satisfies the original program semantics.
GAP Message (Diagnostic ID 30757)

Message
Remove unused field(s) '%s' from the struct '%s'.
This message is emitted only with whole-program recognition.

Advice
Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

The advice is based on the analysis of the source code that is seen. You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. As an example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

Example
Consider the following:

```c
//unused_field_1.c
struct str {
    int a1, b1, c1, d1, e1;
};
struct str sp[1000000];
int hot_func1() {
    int i, ret = 0;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}
int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}
int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    return ret;
}
main() {
    hot_func1();
```
In this case, if the unused fields can be removed, the only source change needed would be the following:

```
//unused_field_1.c
struct str {
    int a1, b1, c1, d1;
};
...
```

**Verify**
Make sure that the restructured code satisfies the original program semantics.

**See Also**
GAP Message (Diagnostic ID 30758)

**GAP Message (Diagnostic ID 30758)**

**Message**
Remove unused field(s) "%s" from the struct "%s".

This message is emitted even without whole-program recognition in advanced mode.

**Advice**
Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

The advice is based on the analysis of the source code that is seen. You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. As an example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

**Example**
Consider the following:

```
//unused_field_2.c
struct str {
    int a1, b1, c1, d1, e1;
};
extern struct str sp[];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}
```
int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    return ret;
}

In this case, if the unused fields can be removed, the only source change needed would be the following:

//unused_field_2.c
struct str {
    int a1, b1, c1, d1;
};
...

**Verify**

The suggestion is based on the field references in the current compilation. Please make sure that there are no references to these fields across the entire application.

**See Also**

GAP Message (Diagnostic ID 30757)

**GAP Message (Diagnostic ID 30759)**

**Message**

Remove unused field(s) '%%s' from the struct '%%s'. The fields: '%%s' were conservatively assumed by the compiler as referenced since their address is taken.

This message is emitted only with whole-program recognition.

**Advice**

Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. For example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

The unused field analysis considers address taken fields as used. It will report address taken fields also when reporting any unused fields.
Example

Consider the following:

```c
//unused_field_3.c
struct str {
    int a1, b1, c1, d1, e1, f1;
};

struct str sp[1000000];

int hot_func1() {
int i, ret = 0;

for (i = 0; i < 1000000; i++) {
    ret += sp[i].a1;
    ret += sp[i].b1;
}
return ret;
}

int hot_func2() {
int ret = 0, i;
for (i = 0; i < 1000000; i++) {
    ret += sp[i].a1;
    ret -= sp[i].c1;
}
return ret;
}

int *gip;

int hot_func3() {
int ret = 0, i;
for (i = 0; i < 1000000; i++) {
    ret += sp[i].d1;
}
gip = &(sp->f1);
return ret;
}

int main() {
    hot_func1();
    hot_func2();
    hot_func3();
}
```

The above code will cause a message to be displayed that is similar to the following:

`program-name: remark #30759: (DTRANS) Remove unused field(s) 'e1' from the struct 'str'. The fields: 'f1'
were conservatively assumed by the compiler as referenced since their address is taken... (etc.)`

In this case, if the unused fields can be removed, the only source change needed would be the following:

```c
//unused_field_3.c
struct str {
    int a1, b1, c1, d1, f1;
};
```
**Verify**
Make sure that the restructured code satisfies the original program semantics.

**See Also**
GAP Message (Diagnostic ID 30760)

The unused field analysis considers address taken fields as used. It will report address taken fields also when reporting any unused fields.

**Example**
Consider the following:

```c
//unused_field_4.c
struct str {
    int a1, b1, c1, d1, e1, f1;
};
extern struct str sp[];
int hot_func1() {
    int i, ret = 0;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}
```
int *gip;

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    gip = &sp->f1;
    return ret;
}

The above code will cause a message to be displayed that is similar to the following:

drive: program-name: remark #30760: (DTRANS) Remove unused field(s) 'e1' from the struct 'str'. The fields: 'f1' were conservatively assumed by the compiler as referenced since their address is taken. ...(etc.)

GAP Message (Diagnostic ID 30759)

Intel® Many Integrated Core Architecture (Intel® MIC Architecture)

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture). The Intel® Xeon Phi™ processors are based on the Intel® Many Integrated Core architecture (Intel® MIC architecture).

The Intel® C++ Compiler provides several elements to enable programming for and building binaries to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture), including:

• language extensions
• compiler options
• environment variables
• attributes
• keywords
• intrinsics
• class libraries
• OpenMP® considerations

Code that is defined for offloading runs on an Intel® Xeon® processor-based host, running Linux* or Windows*, and on targets supporting Intel® MIC Architecture.
Programming for Intel® MIC Architecture

You can write parallel programs that offload sections of code to run on the Intel® MIC Architecture, or alternatively, that run natively on Intel® MIC Architecture. Compiling a source file that contains extensions to facilitate programming for the Intel MIC Architecture creates what is called a fat binary which contains both the host binary and an offload binary. Fat binaries can be objects, archives, or executables depending on the options used at compilation. Refer to the documentation on the Offload Extract Tool \((\text{offload\_extract})\) for information on how to extract the offload binary from the fat binary.

The compiler provides the following language extensions to facilitate programming for Intel® MIC Architecture:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>offload pragma</td>
<td><strong>NOTE</strong> These pragmas are deprecated.</td>
</tr>
<tr>
<td>offload_attribute pragma</td>
<td>Pragmas to control the data transfer between the CPU and the coprocessor.</td>
</tr>
<tr>
<td>offload_transfer pragma</td>
<td><strong>NOTE</strong> These keywords are deprecated.</td>
</tr>
<tr>
<td>offload_wait pragma</td>
<td>Keywords to control the data transfer between the CPU and the coprocessor. The data to be exchanged between the CPU and the coprocessor can be arbitrarily complex.</td>
</tr>
<tr>
<td>_Cilk_offload keyword</td>
<td><strong>Intel® Cilk™ Plus is a deprecated feature.</strong></td>
</tr>
<tr>
<td>_Cilk_shared keyword</td>
<td></td>
</tr>
<tr>
<td>target attribute</td>
<td><strong>NOTE</strong> This attribute is deprecated.</td>
</tr>
<tr>
<td>__INTEL_OFFLOAD macro</td>
<td>An attribute to place variables and functions on the target.</td>
</tr>
<tr>
<td>__TARGET_ARCH_MIC macro</td>
<td><strong>NOTE</strong> The __INTEL_OFFLOAD macro is deprecated.</td>
</tr>
<tr>
<td><strong>AVX512F</strong> macro</td>
<td>Predefined macros for use with the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing).</td>
</tr>
<tr>
<td><strong>AVX512CD</strong> macro</td>
<td></td>
</tr>
<tr>
<td><strong>AVX512ER</strong> macro</td>
<td></td>
</tr>
<tr>
<td><strong>AVX512PF</strong> macro</td>
<td></td>
</tr>
<tr>
<td>Intrinsics</td>

<td>A set of functions for:</td>
</tr>
<tr>
<td></td>
<td>• dealing with multiple coprocessors</td>
</tr>
</tbody>
</table>
### Calling Functions

- calling functions on the CPU to modify the coprocessor’s execution environment
- writing code that should not be built for CPU-only execution

### Building for Intel® MIC Architecture

The compiler provides the following compiler options and environment variables that you can use when building a binary for Intel® MIC Architecture:

<table>
<thead>
<tr>
<th>Compiler Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qoffload- (Windows*)</td>
<td>Ignores language constructs for offloading.</td>
</tr>
<tr>
<td>qno-offload (Linux*)</td>
<td>Ignores language constructs for offloading. <strong>NOTE</strong> This option is deprecated.</td>
</tr>

Programming for Intel® MIC Architecture

Overview: Heterogeneous Programming
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

About Heterogeneous Programming
The compiler includes language extensions that simplify writing parallel programs that can offload sections to
Execution begins on the host CPU and, based on user-defined code, some sections are offloaded to the
coprocessor.
Heterogeneous programming must deal with two differences from traditional CPU programming:
• The instruction sets on the CPU and the coprocessor are similar, but not identical.
• The host CPU and the coprocessor do not share common system memory.

Programming Models
The compiler supports the following programming models, which differ in their approach to dealing with the
lack of shared system memory:
• A non-shared memory model.

This model uses the pragma offload, and other pragmas with the prefix offload_.

This model is appropriate for dealing with flat data structures such as scalars, arrays and structs that are
bit-wise copyable.
Data in this model is copied back and forth between the CPU and the coprocessor around regions of offloaded code. The data selected for transfer is a combination of variables implicitly transferred because they are lexically referenced within offload constructs, and variables explicitly listed in clauses in the pragma.

- A virtual-shared memory model.

  This model uses _Cilk_shared and _Cilk_offload keywords. Intel® Cilk™ Plus is a deprecated feature.

  This model is appropriate for dealing with complex pointer-based data structures, such as linked lists, trees and the like.

  This model uses a software implementation of virtual memory that is shared between the CPU and the coprocessor. You either declare data to be exchanged during offloads as shared, or if the data is dynamic, it is allocated using special alloc and free calls.

You can use both models of offloading in a single program. However, the data manipulated by the two models should be distinct.

In both models, specifying that a construct should run on the coprocessor does not guarantee that it will. The presence of an Intel® MIC Architecture-based subsystem and its availability at the offload point determines if the offload succeeds. When an offload fails, the program exits with an error message.

### Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Dealing with Multiple Coprocessors in a System

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Use the functions described in this section to determine:

- the number of coprocessors in a system
- the coprocessor on which a program is running

Use the header file offload.h to define the interfaces for these functions and their usage. Include it with #include offload.h.
NOTE
In a system with multiple coprocessors, you need to specify the target-number argument when using the offload pragma to reliably use data persistence. When you use alloc_if or free_if to implement data persistence on the coprocessor, but do not specify target-number, the compiler runtime randomly chooses a coprocessor, so the chosen coprocessor could be one on which the data is not available.

Determining the Number of Coprocessors in a System
To determine the number of coprocessors in the system, use the function int _Offload_number_of_devices().
The function returns an integer equal to the number of coprocessors installed and working in the system. If none are installed and working, the return value is 0.

Determining the Coprocessor on Which a Program is Running
To determine the coprocessor that is executing the program, use the function int _Offload_get_device_number().
The function returns an integer equal to the number of the coprocessor executing the program, where 0 is the first card. If the program is executing on the CPU, the return value is -1.

Determining if Code has Completed Running on a Coprocessor
To determine if a section of offloaded code has completed running on a given coprocessor, you can use the API _Offload_signaled().
The syntax for this API is:
extern int _Offload_signaled(int target_number, void *signal);

offload pragma
_Cilk_offload keyword

Offload Using a Pragma
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
This programming model is suitable when the data exchanged between the CPU and the coprocessor consists of scalars, arrays, and structs that can be copied from one variable to another using a simple memcpy.
Data that flows between the CPU and the coprocessor must have a flat structure.
Data that is created and used entirely on the CPU, or used entirely within the offloaded regions, can be arbitrarily complex, including multi-dimensional arrays, C++ classes of any types, and any composition of data structures using pointers, arrays and structs.
In this model, you control the data transfer between the CPU and the coprocessor. The data transfer consists of densely packed data structures. You can select the data to be transferred at the point of offload, without needing to declare or allocate it in any special way.

Initiating an Offload

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture). This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

You can place the offload pragma before any statement, including a compound statement. The statement prefixed with the offload pragma can also be an OpenMP* parallel pragma.

For example:

```c
#pragma offload target(mic : target_id) \
   in(all_Vals : length(MAXSZ)) \
   inout(numEs) out(E_vals : length(MAXSZ))

for (k=0; k < MAXSZ; k++) {
   if ( all_Vals[k] % 2 == 0 ) {
      E_vals[numEs] = all_Vals[k];
      numEs++;
   }
}
```

This code excerpt finds the even numbers and then puts those numbers into an array. The code excerpt begins with #pragma offload. The compiler builds the code block to run on both the host and target.

While the instruction sets for the host and targets are similar, they do not share the same system memory. This means that the variables used by the code block must exist on both the host and the target. To ensure that they do, the pragmas use specifiers to define the variables to copy between the host and target.

- The in specifier defines a variable as strictly an input to the target. The value is not copied back to the host.
- The out specifier defines a variable as strictly an output of the target. The host does not copy the variable to the target.
- The inout specifier defines a variable that is both copied from the host to the target and back from the target to the host.

The pragma also has the target (mic:target_number) specifier to direct the code to a specific target in a system with multiple targets.

When the main program has offload constructs, by default the compiler builds an application that runs on both the host and target. However, you can also build the same source code to run on just the CPU, using the negative form of the [Q]offload compiler option.

Placing Variables and Functions on the Coprocessor

These attributes ensure that variables and functions are available on the coprocessor.

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture). This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
The statement following the offload pragma is converted into an outlined function that runs on the coprocessor. This code is permitted to call other functions. To ensure that these called functions are also available on the coprocessor, you must specify one of the following special function attributes:

\[
\begin{align*}
&\ _\text{declspec}(\ \text{target (mic)}) \ \text{function-declaration} \\
&\ _\text{declspec}(\ \text{target (mic)}) \text{variable-declaration} \\
&\ _\text{attribute} \ (((\ \text{target (mic)})) \ \text{function-declaration} \\
&\ _\text{attribute} \ (((\ \text{target (mic)})) \ \text{variable-declaration}
\end{align*}
\]

All functions in the program are always compiled for the CPU and are available to be called on the CPU. However, only functions marked with the special attribute are available to be called by offloaded code, and only these functions can be called on the coprocessor.

Global variables are treated in a similar fashion. All global variables are always present in the CPU code. But only global variables with the target attribute are compiled into the binary offloaded to the coprocessor.

Compiling only functions and data explicitly marked with the target attribute into the Intel® MIC Architecture binary ensures that the code on the coprocessor is as small as possible.

The compiler issues warnings for functions and data referenced within offloaded code that do not have the target attribute.

**Example**

\[
\begin{align*}
&\ _\text{declspec(target(mic))} \\
&\ \text{int global} = 55; \\
&\ _\text{declspec(target(mic))} \\
&\ \text{int foo()}
\{
&\quad \text{return ++global;}
\}
&\ \text{main()}
\{
&\quad \text{int i;}
&\quad \#pragma offload target(mic) in(global) out(i, global)
\{
&\quad \quad i = \text{foo();}
\}
&\quad \text{printf("global = %d, i = %d (should be the same)\n",}
&\quad \quad \quad \text{global, i);}
\}
\end{align*}
\]

**NOTE**
The presence of a function call within an offloaded construct with a target attribute does not automatically declare that function as available on that target. The function definition must include the appropriate target attribute to ensure that the function is available on the target.

**NOTE**
The definition and all declarations of a variable or function with a target attribute must be consistent with each other across all compilation units.

Managing Memory Allocation for Pointer Variables

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Memory management on the CPU for pointer variables used in offloaded programs is the same as non-offload programs. That is, the offload pragmas do not affect memory allocation and freeing on the CPU. As usual, you, the programmer, must do this.

Memory management on the coprocessor for pointer variables named in in and out clauses of #pragma offload is done automatically by the compiler and runtime system.

Target Memory Management for Input Pointer Variables

For in variables of a #pragma offload the default behavior is to do a fresh memory allocation for each pointer variable. On return from the construct the memory is de-allocated. In order to retain data between offloads, you can use the alloc_if and free_if qualifiers to modify the memory allocation defaults on the coprocessor.

The alloc_if qualifier specifies a boolean condition that controls whether the pointer variables in the in clause are allocated a fresh block of memory on the target when the construct is executed on the target. If the expression evaluates to TRUE, a fresh memory allocation is performed for each variable listed in the clause. If the condition evaluates to FALSE, the existing pointer values on the target are reused. You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a free_if(FALSE) clause on an earlier offload.

The free_if qualifier specifies a boolean condition which controls whether to free the memory allocated for the pointer variables in an in clause. If the expression evaluates to TRUE, the memory pointed to by each variable listed in the clause is freed. If the condition evaluates to FALSE, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory.

The alloc_if and free_if boolean expressions are evaluated on the CPU at the point the construct is offloaded to the target.

Target Memory Management for Output Pointer Variables

By default an out variable is allocated fresh memory on the target at the start of an offload and the memory is freed at the end of the offload. The alloc_if and free_if modifiers change the defaults. The expressions are evaluated on the host and used to control coprocessor memory allocation.

When the output value is received on the host, no memory allocation is done. The variables listed in out clauses must point to allocated memory of sufficient size to receive the results on the host.

Transferring Data into Pre-allocated Memory on the Target

As described in the previous section a pointer variable in an in, out, inout, or nocopy clause can retain the target memory allocation when you set the free_if modifier to false. You can reuse that memory in subsequent offloads by using in, out, inout, or nocopy and specifying alloc_if(0). When target memory is allocated it is associated with the value of the CPU pointer variable used as the destination in the in, out, inout, or nocopy clause. When target memory is to be reused, it is located using the value of the CPU pointer variable that is the destination of that transfer. The associations between the CPU address used when target memory is allocated and the target memory are automatically maintained by the offload runtime library. The associations are created or dropped along with target memory allocation or deallocation. Create the association at allocation time using alloc_if(1) free_if(0) and delete the association at de-allocation time using free_if(1).
Pointers to static data on the CPU are special-cased. The `alloc_if` and `free_if` modifiers are ignored when the following are both true:

- The CPU address used during creation of a target memory association points to statically allocated data.
- The variable is also available in the target binary because it has `__declspec(target(mic))`.

The target's statically allocated memory is used as the destination of the transfer. This target memory is not dynamically allocated and never freed.

There is only one block of target memory associated with a CPU address. It is an error to call `alloc_if(1)` to create a second association for a CPU address before freeing the existing one. The new association overwrites the earlier one, which has the potential for causing memory leaks on the target.

It is an error to call `free_if(1)` for a transferred pointer if a matching association is not found. The attempted removal of an association is silently ignored. An association can be made with a CPU address, and a certain length, and another association made with a different CPU address within that range. Since origin addresses are different, you can use `alloc_if` and `free_if` to create distinct target allocations.

### Alignment of Pointer Variables

When memory is allocated for a pointer variable on the target, it is aligned at the natural boundary for the type of the data pointed to by the pointer. Sometimes it may be necessary to request that the data be aligned on larger boundaries, for example, when the program expects to use assembly code or intrinsic functions or array notation, that operate on data with more stringent alignment requirements. In these cases, the `align` modifier may be used to specify an alignment. The operand of the `align` modifier must be an integral expression which evaluates to a power of two. The expression is evaluated on the host and the region of memory allocated for the pointer on the target is aligned at a boundary that is greater than or equal to the value of the expression. When the output value is received on the host, no memory allocation is done. The variables listed in `out` clauses must point to allocated memory of sufficient size to receive the results.

**NOTE**

For optimal data transfer performance, by default, the target memory address for a transfer through a pointer is made to match the offset within 64 bytes of the CPU data. That is, if the CPU source address is 16 bytes past a 64 byte boundary, the target data address will also be 16 bytes past a 64 byte boundary.

The `align` modifier overrides this default and aligns the target memory at the requested alignment. To get the benefits of fast data transfer and the necessary alignment on the target, ensure that the CPU data is aligned on the same boundary as the alignment needed on the target. Doing so meets the requirements for fast data transfer and the requirements for target data alignment.

### Examples

Consider the following macros, presented here to make the modifiers in the offload clauses more understandable:

```c
#define ALLOC   alloc_if(1)
#define FREE    free_if(1)
#define RETAIN  free_if(0)
#define REUSE   alloc_if(0)
```

The following example illustrates the default behavior, which is no data persistence on the coprocessor.
The compiler allocates and frees data around the offload. No alloc or free modifiers are necessary.

```c
#pragma offload target(mic) in( p:length(l) )
...
```

The following examples illustrate keeping data on the coprocessor between offloads.

The following code allocates memory for \( p \) as part of this offload, and keeps the memory allocated for \( p \) after the offload.

Notice that alloc is the default, and you do not need to explicitly specify it.

```c
#pragma offload target(mic) in (p:length(l) ALLOC RETAIN)
...
```

The following code reuses the memory allocated for \( p \) previously. It only transfers fresh data into that memory, and after the offload completes, it continues to retain the memory.

```c
#pragma offload target(mic) in (p:length(l) REUSE RETAIN)
...
```

The following code reuses the memory allocated for \( p \) previously. However, it frees the memory for \( p \) after this offload.

Notice that free is the default, and you do not need to explicitly specify it.

```c
#pragma offload target(mic) in (p:length(l) REUSE FREE)
```

The following code uses a pointer to create a memory allocation on the target. Then the pointer value is passed to another function. Through the pointer value, the target memory can be reused. Notice that the \#pragma offload_transfer statement uses array notation. The length modifier is not required when a variable is specified in array notation.

```c
// Transfer through a function parameter
int *p = malloc(...);
int count;
void bar()
{
    ...
    // Allocate memory on the coprocessor, and transfer data
    #pragma offload_transfer ... in( p[0:count] : RETAIN )
    foo(p, l);
}
foo(int *arg_p, int count)
{
    // Transfer will succeed
    #pragma offload ... in( arg_p[0:count] : REUSE )
    ...
}
```

The following transfers static data to the target. The target static data allocation for the matching CPU variable is automatically used.

```c
// When bar is called with array_cpu_only, dynamic memory is used on target
// When bar is called with array_both, the target array_both is used
__declspec(target(mic)) int array_both[1000];
int array_cpu_only[1000];
void foo()
{
    bar(&array_cpu_only[0]);
    bar(&array_both[0]);
}
```
The following code shows mixing of pointers to statics and pointers to dynamically allocated memory between the CPU and the target.

```c
// Associations created by offloading named variables and pointers
// to dynamically allocated variables are treated the same way
__declspec(target(mic)) float array[1000];
main()
{
   // copies array to target
   #pragma offload target(mic) in(array)
   {   ...  }

   // bar1 will use dynamically allocated memory on the target
   printf("%e\n", bar2());

   // bar1 will use statically allocated "array"
   printf("%e\n", bar1(&array[0], 100));
}
float bar2()
{
   float * my_p = malloc(100 * sizeof(float));
   #pragma offload target(mic) in(my_p[0:100] : RETAIN )
   {  ...  }
   return bar1(my_p, 100);
}
float bar1(float *p, int n)
{
   #pragma offload target(mic) IN(p : length(0) REUSE RETAIN)
   {  sum = ... <sum of elements in p>  }
   return sum;
}
```

**Device-Only Memory Allocation**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

When using Intel's language extensions for offload to Intel® MIC Architecture, the values of pointer variables used in #pragma offload are never modified on the CPU by the process of offloading. The CPU addresses in the pointer variables are used to keep track of dynamic memory allocation on Intel® MIC Architecture. The offload library manages the association between CPU addresses that have associated memory on Intel® MIC Architecture and uses the mapping during data transfer operations.

However, this requires that memory allocated on Intel® MIC Architecture have a matching memory range allocated on the CPU. Sometimes this may lead to CPU memory being allocated unnecessarily.

The `targetptr` and `preallocated` modifiers allow dynamic memory allocation on Intel® MIC Architecture without matching memory allocation on the CPU.

**targetptr**

The `targetptr` modifier permits allocating memory for Intel® MIC Architecture only.
If the `targetptr` modifier is used when memory is allocated using `alloc_if(1)`, then the CPU variable is updated with the address of the memory allocated on Intel® MIC Architecture. Since this value is not meaningful on the CPU, such a variable can only be used as a source or destination of data transfer in offload pragmas until a valid CPU address is assigned to it.

You can only use the `targetptr` modifier with mandatory offloads. Other modifiers you can use with `targetptr` are the offload modifiers `align` and `alloc`.

The `alloc_if` and `free_if` modifiers control both memory allocation on Intel® MIC Architecture and also adding or removing the allocated memory ranges from the runtime tables maintained by the offload runtime.

The following example shows how to allocate memory using `#pragma offload_transfer`, `#pragma offload`, and modifier `targetptr`:

```cpp
01 #define ALLOC  alloc_if(1) free_if(0)
02 #define REUSE  alloc_if(0) free_if(0)
03 #define FREE   alloc_if(0) free_if(1)
10 int* cpu_p = (int*)malloc(1000*sizeof(int));
11 __declspec(target(mic)) int* mic_p;
20 // Allocate memory on Intel(R) MIC Architecture using targetptr
21 // mic_p is undefined before, has MIC memory address after
22 #pragma offload_transfer target(mic) \
23   nocopy(mic_p[0:1000] : ALLOC targetptr)
30 // Transfer data from CPU and Intel(R) MIC Architecture and do some work
31 #pragma offload target(mic) \
32   in(cpu_p[0:1000] : into(mic_p[0:1000]) REUSE targetptr)
33 {
34   ... = *mic_p; // Use data pointed to by mic_p
35   *mic_p = ...  // Update values pointed to by mic_p
36 }
40 // Return data from Intel(R) MIC Architecture to CPU and free the memory
41 #pragma offload_transfer target(mic) \
42   out(mic_p[0:1000] : into(cpu_p[0:1000]) FREE targetptr)
```

**preallocated targetptr**

You can use the `preallocated` modifier with modifier `targetptr` to do memory allocation on Intel® MIC Architecture yourself. It specifies that the memory in Intel® MIC Architecture is already allocated by the user and has to be made available for data transfer.

Modifiers `alloc_if` and `free_if` affect entry or removal from the offload library tables only, and do not control memory allocation. The programmer manages the allocation.

The combination `preallocated targetptr alloc_if(1)` cannot be used with an `in` clause because although the memory may already be allocated on Intel® MIC Architecture, the memory address is not yet available on the CPU for data transfer. The modifiers `preallocated targetptr alloc_if(1)` are permissible with clause `out` or `nocopy`. At the end of the offload, the memory address on Intel® MIC Architecture is brought to the CPU. Once on the CPU, the variable can be used in future offloads to access that memory.

The following table explains the actions taken for `preallocated targetptr` with various combinations of clauses `in`, `out`, `inout`, and `nocopy`, and modifiers `alloc_if` and `free_if`.

The `preallocated` modifier is useful only with mandatory offloads. With optional offloads, if the offload that allocates memory does not occur then subsequent offloads that attempt to use preallocated memory will fail.

The `align` modifier cannot be used with preallocated because the memory allocation is done by the programmer.

You can use the `alloc` modifier with `preallocated`.

The following example shows how to allocate memory using `#pragma offload` and modifiers `preallocated` targetptr:

```c
01 // Allocate memory on Intel(R) MIC Architecture using malloc and register it
02 #pragma offload target(mic) \n03   nocopy(mic_p[0:1000] ALLOC preallocated targetptr ) \n04 { \n05    mic_p = user_malloc(1000*sizeof(int)); \n06 }
```

```c
10 // Transfer data from CPU and Intel(R) MIC Architecture and do some work
11 #pragma offload target(mic) \n12   in(cpu_p[0:1000] : into(mic_p[0:1000]) REUSE targetptr ) \n13 { \n14   *mic_p = ... \n15  }
```

```c
20 // Remove MIC memory registration and free Intel(R) MIC Architecture memory
21 #pragma offload target(mic) \n22   nocopy(mic_p : FREE preallocated targetptr ) \n23 { \n24    free(mic_p); \n25 }
```

Writing Target-Specific Code Using a Pragma

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. The topic will be removed in a future release.

You can write functions that you intend to run on a target, and sections of offloaded code, to take advantage of target-specific intrinsic functions.
When the compiler generates code for the coprocessor, it defines a macro specific to the coprocessor architecture, for example __TARGET_ARCH_MIC. You can then write target-specific code within an #ifdef __TARGET_ARCH_MIC section.

NOTE
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Writing Code that Should Not Be Built for CPU-Only Execution
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
You can write code that should not be built when the target is a CPU-only executable.
By default, the compiler defines the macro __INTEL_OFFLOAD. You can write code within an #ifdef __INTEL_OFFLOAD section when the source code is customized for running on the coprocessor heterogeneously.
For example, you can use this macro to protect code on the host that should only be executed for an offload build, such as calls to theomp_set_num_threads_target family of APIs in offload.h.

Example
The section for the host compiler works only when you compile with the [Q]offload compiler option with the keyword optional.

```c
#include <stdio.h>
__declspec(target(mic)) void print()
{
  #ifdef __INTEL_OFFLOAD
  #ifdef __MIC__
      printf("Using offload compiler : Hello from the coprocessor\n");
      fflush(0);
  #elif __TARGET_ARCH_MIC
      printf("Using offload compiler : Hello from the coprocessor\n");
      fflush(0);
  #else /* !__MIC__ and !__TARGET_ARCH_MIC */
      printf("Using offload compiler : Hello from the CPU\n");
  #endif /* __MIC__ */
  #else /* !__INTEL_OFFLOAD */
    printf("Using host compiler : Hello from the CPU\n");
  #endif /* !__INTEL_OFFLOAD */

  }
int main()
{
  #pragma offload target(mic)
      print();
}
```

Allocating Memory for Parts of Arrays
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
This topic discusses using the alloc modifier with the offload set of pragmas
The alloc modifier contains an array section reference. When you specify it, then the allocation on the coprocessor is limited to that shape of array. Only unit stride is allowed in the section. When a section has a rank greater than one, the second and subsequent index expressions must specify all elements at that dimension. The array section must be contiguous.
Data is transferred into that portion of the array specified by the in or out expression. Thus memory allocation and the data transfer can use separate array slice references.
When the lower bound of the first dimension of a section used in the alloc modifier is non-zero, then the memory allocation begins with that element. The memory preceding the lower bound is unallocated and should not be referenced by your program. By not referencing it, you enable a smaller section of the array to be transferred to the coprocessor without requiring that the entire array be allocated.

Example
In the following example,

- The alloc(p[5:1000]) modifier allocates 1000 elements on the coprocessor.
- The first usable element has index 5 and the last has index 1004. Thus only elements 5 through 1004 are accessible on the coprocessor.
- Data transfer is specified by the in(p[10:100]) clause.

100 elements are transferred into the allocated memory in the range p[10] through p[109].

```c
int *p;
// 1000 elements allocated. Data transferred into p[10:100]
#pragma offload … in ( p[10:100] : alloc(p[5:1000]) )
{ … }
```

typedef int ARRAY[4][4];
ARRAY *p;
p = malloc(...);

// On the coprocessor, 16 elements are allocated for an array of shape 5x4.
// The first row is unallocated.
// Data is transferred into row 2 only
#pragma offload … in ( (*p)[2][:] : alloc([1:4][:]) )
{ … }
Moving Data from One Variable to Another

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This topic discusses using the into modifier with the offload set of pragmas.

The into modifier enables you to transfer data from a variable on the CPU to another on the coprocessor, and the reverse, from a variable on the coprocessor to another on the CPU. Only one item is allowed in the variable-ref list when using the into modifier. Thus a one to one correspondence is established between a single source and destination.

When you use into with the in clause, data is copied from the CPU object to the coprocessor object. The alloc_if, free_if, and alloc modifiers apply to the into expression.

When you use into with the out clause, data is copied from the coprocessor object to the CPU object. The alloc_if, free_if, and alloc modifiers apply to the out expression.

The into modifier is not allowed with inout and nocopy clauses.

When you use the into modifier, the source expression generates a stream of elements to be copied into the memory ranges specified by the into expression. Overlap between the source and destination memory ranges leads to undefined behavior. No ordering can be assumed between transfers from different in and out clauses.

Example

```c
int p[1000], p1[2000];
int rank1[1000], rank2[10][100];

// Partial copy
#pragma offload … in( p[0:500] : into (p1[500:500]) )

// Overlapping copy; result undefined
#pragma offload … in( p[0:600] : into (p1[0:600]) ) \
    in( p[601:400] : into (p1[100:400]) )
```

Restrictions on Offloaded Code Using a Ppragma

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Offloaded code has the following restrictions:

- Exception handling may be done as usual within code running on the CPU and within code running on the coprocessor. So exceptions can be raised, caught and handled on the CPU, or raised, caught and handled on the coprocessor. However it is not possible to propagate an exception from the coprocessor to the CPU.
- This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Do not use coprocessor-specific macros inside the statement following a #pragma offload statement. You can, however, use them in a subprogram called from the pragma.

- The compiler does not inline functions inside statements following an offload pragma statement, including functions marked with the forceinline pragma. However, inline function expansion might occur at the compiler’s discretion inside a subprogram called from the offload pragma.
- Multiple host CPU threads can execute concurrently while one host CPU thread offloads a section of code. In this case synchronization mechanisms such as locks, atomic, mutexes, OpenMP atomic operations, OpenMP critical, OpenMP taskwait, OpenMP barriers, etc. do not work between host CPU code and code offloaded to the target. However, if parallelism on the host CPU is enabled using OpenMP, then OpenMP synchronization at the end of a parallel region is guaranteed to work even if some part of the OpenMP parallel region has been offloaded to the target.
- Global variables referenced by functions called from within offloaded code must be declared with matching target attributes to ensure that the variables are available on the target. You must also explicitly send and receive the value of these variables with explicit in/out/inout clauses to sync their values between the host and target. Global variables visible within the lexical scope of the offload pragma do not require declaration with matching target attributes, and their associated values are sent and received by default. Global pointer variables used in lexical scope of the offload pragma do require being specified within in/out/inout clauses and this is enforced by the compiler.

By default, pointer variables are assumed to point to a single element of the corresponding type. The offloaded code may dereference the pointer and access a single element. The data element pointed to is automatically copied into target memory and the pointer value adjusted accordingly. The element-count-expr expression available with in / out / inout parameters enable variable-length data to be copied back and forth.

- Only pointers to non-pointer types are supported. Pointers to pointer variables are not supported. The compiler enforces this restriction.
- Arrays are supported provided the array element type is a scalar or bitwise copyable struct or class. So arrays of pointers are not supported.
- Because pointers are not copied across the host-target interface, but instead the data they point to is copied, do not assume that the relative distance between pointers that point to distinct variables remains the same between the host and target. Pointers within the same data structure still have the same distance between them after offload. Thus, some pointer comparisons and arithmetic that were meaningful on the host CPU can no longer be used reliably on the target.
- Similarly, although the data pointed to is available after an offload, the program cannot assume that the same user variable is pointed to after offload. For example, consider the following line of code:

```c
{int a = 55; int *p = &a; #pragma offload ( q = p; ... )
```

Although q on the target will point to the value 55, the value of q will not be &a on the target.
• Unions containing a combination of pointer and non-pointer members are treated as holding the non-pointer value type. Thus, no special treatment is given to the pointer, and the data pointed to is not copied to the target.

• Unions consisting entirely of pointer members are not allowed to be copied between the host and the target.

• If an offload region calls a function defined in a separate file and that function references global variables, care must be taken to ensure that those global variables are copied in and/or out as needed.

  If the global variables are referenced only in the external function and not directly within the offloaded region, then they will not be copied because the references outside the current compilation unit are not known to the compiler.

  If the variables referenced from the external function are also referenced in the offloaded region, then they will be copied.

  When global variables are file-scope static variables, then they cannot be named in the in or out clauses.

  You need to access their values using one of the following methods:

  • Make them external and add them to the in or out clauses in the offload specification.

  • Fetch the variable values into local variables using functions designed specifically for that purpose, and then add the local variables to the in or out clauses.

• You cannot use objects that are not bitwise copyable, such as the ostream object std::cout, inside a #pragma offload region. The compiler enforces this restriction and issues an error such as: error: variable "std::cout" is not bitwise copyable.

• There are three Intel® Cilk™ Plus constructs: _Cilk_spawn, _Cilk_sync, and _Cilk_for (Intel® Cilk™ Plus is a deprecated feature.). You can use all of these in functions called from a #pragma offload construct, but you can only use _Cilk_for directly within the offloaded construct. You cannot use _Cilk_spawn and _Cilk_sync within a #pragma offload construct, because it is illegal to offload only a portion of an Intel® Cilk™ Plus spawning routine. The whole spawning routine must be offloaded.

  For example, the following code is illegal:

```
#pragma offload target(mic)
{
  _Cilk_spawn f();     // _Cilk_spawn used within
  }                        // offloaded construct
```

  The following code is legal:

```
#pragma offload target(mic)
{
  g();
}
...

void g()
{
  _Cilk_spawn f(); // _Cilk_spawn used within
  } // offloaded function
```

  The following code is illegal:

```
Void foo()
{
  #pragma offload target(mic) {
    _Cilk_spawn test()  // cannot use inside offload
    test();
    _Cilk_sync;         // cannot use inside offload
  }
}
```
The following code is legal:

```c
__declspec(target(mic))
void foo() {
    #pragma offload target(mic) {
        _Cilk_spawn test()
        test();
        _Cilk_sync;
    }
}

void bar() {
    #pragma offload target(mic) {
        foo();
    }
}
```

The following code is legal:

```c
void foo() {
    #pragma offload target(mic)
    {
        _Cilk_for (int i = 0; i < 10; i++) {  // Can use directly within an offload region
            // ...
        }
    }
}
```

Offload Using Shared Virtual Memory
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This programming model is suitable when the data exchanged between the CPU and the coprocessor is more complex than scalars, arrays, and structs that can be copied from one variable to another using a simple memcpy. The data to be exchanged between the CPU and the coprocessor can be arbitrarily complex. It can use pointers, and any composition of structs and pointers.

Data exchanged in this model is unrestricted in data structural complexity. However, at the point of offload, the data must already be in the shared memory region, either as a result of its being declared _Cilk_shared (Intel® Cilk™ Plus is a deprecated feature.), or because it was allocated using _Offload_shared_malloc() or _Offload_shared_aligned_malloc().

Using Shared Memory
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
About Using Shared Memory
The offload runtime system maintains a section of memory at the same virtual address on the CPU and the coprocessor. The keyword _Cilk_shared enables you to use this shared memory as follows:

- It places variables in this shared memory address range.
- It specifies that a function is defined on both the CPU and the coprocessor.

About Shared Variables
The compiler allocates shared variables such that:

- their virtual addresses are the same on the CPU and the coprocessor
- their values are synchronized between the CPU and the coprocessor at a predefined point

Pointers to shared variables have the same value on the CPU and the coprocessor, because shared variables have the same addresses. So offloaded code can easily operate on linked data structures. Memory is synchronized between the CPU and the coprocessor only at offload call sites.

Conditional Control with Shared Variables
You cannot conditionally control shared variables when you compile them to run on Intel® MIC Architecture.

When a variable is marked _Cilk_shared, the memory allocation for the variable is dynamic instead of static, and only the host allocates the memory, within the memory space that the host and the coprocessor share. When the program is compiled, the host generates code to create the shared memory dynamically, so if the host does not see the shared variable, it doesn't allocate any memory for the variable. Since the memory is not allocated in the shared space, when the coprocessor tries to access this memory an illegal access occurs.

Because the host allocates memory for the shared variable, the variable must be visible on the host even if the host does not use the variable.

For example, the following code is incorrect because the variable is only conditionally compiled for the coprocessor. Therefore, no code is generated on the host to allocate memory for the variable.

```c
#ifdef __MIC__
    _Cilk_shared int res;
#endif
```

If you compile the variable conditionally for the coprocessor, the _Cilk_shared keyword is not necessary because the host does not access the variable. Use _Cilk_shared only when sharing data between the host and the coprocessor.

About Shared Functions
By default, the compiler builds two binary files:

- A CPU version: Includes all functions in the source code, whether marked _Cilk_shared or not.
- A target version: Includes only functions marked _Cilk_shared in the source code.

Use the negative form of the [Q]offload compiler option to build only the CPU version.

Shared Memory Management Functions
The functions described below are available for allocating and freeing shared memory to work with the _Cilk_shared and _Cilk_offload keywords. These functions revert to the standard malloc or free versions if Intel® MIC Architecture-based hardware is not installed in the system, or if the Intel® Manycore Platform Software Stack (Intel® MPSS) is not loaded.

- `void * _Offload_shared_malloc(size_t size);`
- `void * _Offload_shared_aligned_malloc(size_t size, size_t alignment);`
Shared Memory Allocator

By default, containers provided in the standard C++ library allocate non-shared memory. When an object of such a container is marked `_Cilk_shared`, its data members are allocated in shared memory. However, any memory that its data accesses is not shared. To enable sharing of this memory, use the `shared_allocator<T>` class template. The `shared_allocator<T>` class template is defined in `offload.h`.

Example: Shared Memory Allocator

```cpp
#pragma offload_attribute (push, _Cilk_shared)
#include <vector>
#include <offload.h>
#pragma offload_attribute (pop)
#include <stdio.h>
using namespace std;

// typedef vector to use the offload shared allocator
typedef vector<int, __offload::shared_allocator<int> > shared_vec_int;

_Cilk_shared shared_vec_int * _Cilk_shared v;

_Cilk_shared int test_result() {
    int result = 1;
    for (int i = 0; i < 5; i++) {
        if (*(v)[i] != i) {
            result = 0;
        }
    }
    return result;
}

int main()
{
    int result;

    // Use placement new to construct an object in the shared memory space.
    v = new (_Offload_shared_malloc(sizeof(vector<int>))) _Cilk_shared vector<int,
    __offload::shared_allocator<int> >(5);

    for (int i = 0; i < 5; i++) {
        *(v)[i] = i;
    }
    result = _Cilk_offload test_result();

    if (result != 1)
        printf("Failed\n");
    else
        printf("Passed\n");
    return 0;
}
```
See Also
_Cilk_shared Keyword
_Cilk_offload Keyword
offload, Qoffload

_Cilk_offload
Controls synchronous and asynchronous execution of functions on the CPU and coprocessor. This keyword only applies to Intel® MIC Architecture.

Syntax
lvalue = _Cilk_offload func_name ( rvalue )
lvalue = _Cilk_offload_to ( target-number ) func_name ( rvalue )
lvalue = _Cilk_spawn _Cilk_offload func_name ( rvalue )
lvalue = _Cilk_spawn _Cilk_offload_to ( target-number ) func_name ( rvalue )
_Cilk_offload_Cilk_for ( init-expr; test-expr; incr-expr)
_Cilk_offload_to ( target-number ) _Cilk_for ( init-expr; test-expr; incr-expr)

Arguments
lvalue
An expression that designates an object.

rvalue
An expression that represents a value.

func_name
A function name.

target-number
An expression whose value is interpreted as follows:

>=0
Executes the statement on a specified target according to the following formula:

\[ target = target-number \mod \text{number\_of\_targets} \]

For example, in a system with four targets:

- Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 \( \mod 4 \) and 6 \( \mod 4 \) is 2.
- Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 \( \mod 4 \) is 0.

-1 or no value
Executes the statements on a target selected by the runtime system.

<-1
Reserved.

init-expr
An initialization expression for a _Cilk_for loop.

test-expr
A test expression for a _Cilk_for loop.

incr-expr
An increment expression for a _Cilk_for loop.
Description

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

_Cilk_offload before a function call indicates that the runtime system chooses to execute the function being called either on the host, or on the coprocessor synchronously, and if multiple coprocessors are available, on which coprocessor.

Placing the keyword _Cilk_offload between a _Cilk_spawn keyword and a call results in asynchronous execution on the CPU using the normal Intel® Cilk™ Plus rules, and a synchronous offload of the function by an Intel® Cilk™ Plus task, effectively doing an asynchronous offload. Just as in normal Intel® Cilk™ Plus usage, you need a _Cilk_sync keyword before the CPU can use the results of the offloaded function.

_Cilk_offload before a _Cilk_for loop specifies that the entire loop be executed on the coprocessor.

_Cilk_offload_to (target-number) specifies mandatory offload to a coprocessor. target-number determines the specific coprocessor.

Example

Offload function calls:

```
z = _Cilk_offload func(a);
z = _Cilk_spawn _Cilk_offload func(a);
```

Offload _Cilk_for loop:

```
_Cilk_offload _Cilk_for ( init-expr; test-expr; incr-expr ) {
...
}
```

Using Shared Memory

_Cilk_shared

Shares a variable or function. This keyword only applies to Intel® MIC Architecture.

Syntax

_Cilk_shared type variable(s)

_Cilk_shared type func_def

Arguments

- **type**: The type of the variable or variables being declared.
- **variable(s)**: One or more variables.
- **func_def**: A function definition or declaration.

Description

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
Using **_Cilk_shared** with a variable allocates the variable to shared memory.

Using **_Cilk_shared** with a function definition or declaration makes the function available to the CPU and the coprocessor.

**Examples: Variables**

A shared declaration:

```c
_Cilk_shared int x, y, z;
```

A shared typedef:

```c
typedef _Cilk_shared str_type shr_str_type;
shr_str_type a;
```

**Examples: Pointers**

`p` is a pointer to a shared int, but the pointer itself is not shared:

```c
int _Cilk_shared *p;
```

`p` is itself in shared memory:

```c
int * _Cilk_shared p;
```

**Examples: Functions**

A shared function definition:

```c
_Cilk_shared void func() {
    x = y + z;
}
```

A shared function declaration:

```c
_Cilk_shared int bar();
```

**Examples: Functions**

Using **pragma offload-attribute** to apply this attribute to multiple declarations:

```c
#pragma offload_attribute(push, _Cilk_shared)
#include <math.h>
void function_1();
void function_2();
#pragma offload_attribute(pop)
void function_3();

int main(){
    _Cilk_offload function_1();

    function_3();
    _Cilk_offload function_2();
}
_Cilk_shared int bar();
```

**See Also**

Using Shared Memory

**Rules for Using **_Cilk_shared** and **_Cilk_offload****

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
Follow these rules for using _Cilk_shared and _Cilk_offload for correct execution. In most cases the compiler issues diagnostics for incorrect usage.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

---

**Correct and Permitted Usage**
- When applied to a C++ class, all member functions are shared and all objects of that class type are shared.
- On static fields of a class.
- Assigning pointer-to-shared to pointer-to-non-shared.
- Assigning the address of a shared variable to a shared pointer.
- The named function called by _Cilk_offload func must be marked _Cilk_shared and must have external linkage.
- The function in _Cilk_offload indirect-call must be of the type pointer-to-shared.
- Shared functions whose address is taken must have external linkage.
- Pointer arguments passed to an offloaded function call must be pointer-to-shared.
- Global variables referenced within _Cilk_offload _Cilk_for must have the attribute _Cilk_shared.
- Functions called from _Cilk_offload _Cilk_for must be shared.
- Pointers referenced within _Cilk_offload _Cilk_for must be pointers to shared variables.
- Global variables referenced inside functions marked _Cilk_shared must have the attribute _Cilk_shared.

**Incorrect and Non-permitted Usage**
- _Cilk_shared on a field of a structure is not allowed.
- _Cilk_shared on static variables is not allowed.
- _Cilk_shared on variables local to a function is not allowed.
- Assigning pointer-to-non-shared to pointer-to-shared is not allowed.

**Example**
This example demonstrates incorrect usage of _Cilk_shared. The code attempts to declare a _Cilk_shared object, mark, local to a function.

```cpp
#include <vector>
#include "tbb/concurrent_vector.h"
#pragma offload_attribute(push, _Cilk_shared)

class _Cilk_shared Thing
{
public:
  Thing(void) { m_size = 100; }
  void work();
  int m_size;
};

void Thing::work()
{
  _Cilk_shared std::vector<bool> mark(m_size); // Error
  tbb::concurrent_vector< std::pair<unsigned int, unsigned int> > m_hits(m_size);
}
```
In this example of correct usage, the object `mark` has been allocated statically, and its usage modified slightly.

```cpp
#include <vector>
#include "tbb/concurrent_vector.h"
_Cilk_shared std::vector<bool> mark;
_Cilk_shared tbb::concurrent_vector< std::pair<unsigned int, unsigned int> > m_hits;

class _Cilk_shared Thing
{
  public:
    Thing(void) { m_size = 100; }
    void work();
    int m_size;
};

void Thing::work()
{
    mark.resize(m_size);
    m_hits.resize(m_size);
}
```

### Synchronization Between the CPU and the Target

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Memory synchronization between the CPU and the target occurs at the following predefined points:

- when an offloaded function is called by the CPU, and upon entering the offloaded function on the target
- when an offloaded function on the target returns, and upon the return of the function to the CPU

Currently no other synchronization points exist, so any simultaneous access to the shared memory location between the predefined points is treated as a race condition, and the behavior is undefined.

### Writing Target-Specific Code with `_Cilk_offload`

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can write offloaded sections of code to take advantage of target-specific intrinsic functions. When the compiler generates code for the coprocessor, it defines the macro `__MIC__`. You can write target-specific code within an `#ifdef __MIC__` section.

**NOTE** Intel® Cilk™ Plus is adeprecated feature.

### Example

This example shows how target-specific code may be written within an `#ifdef __MIC__` section.

The implementation of the class `F32vec` is specialized for the CPU and the coprocessor. The offloaded code can use the specialized version if it runs on the coprocessor. If `function_1` is executed on the CPU, it uses the CPU version of the class `F32vec`. If it runs on the coprocessor, it uses the definition from `micvec.h`.

```cpp
// The class F32vec will be used in offloaded code
// It needs the target(mic) attribute
```

```cpp
// The class F32vec will be used in offloaded code
// It needs the target(mic) attribute
```

Special Cases

Restrictions on Offloaded Code Using Shared Virtual Memory

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Offloaded code using virtual shared memory has the following restrictions:

- Multiple host CPU threads can execute concurrently while one host CPU thread offloads a section of code. In this case, synchronization mechanisms such as locks, atomics, mutexes, OpenMP* atomic operations, OpenMP critical, OpenMP taskwait, OpenMP barriers, etc. do not work between the host CPU code and code that is offloaded to the coprocessor. However, if parallelism on the host CPU is enabled using OpenMP, then OpenMP synchronization at the end of a parallel region is guaranteed to work even if some part of the OpenMP parallel region has been offloaded to the coprocessor.

- Exception handling may be done as usual within code running on the CPU and within code running on the coprocessor. So exceptions can be raised, caught and handled on the CPU, or raised, caught and handled on the coprocessor. However it is not possible to propagate an exception from the coprocessor to the CPU.

- Virtual shared memory classes that allocate and free memory must use either the _Offload_shared_malloc() and _Offload_shared_free() or _Offload_shared_aligned_malloc() and _Offload_shared_aligned_free() APIs instead of standard allocate and free APIs.

For an example, see install-dir/Samples/en_US/C++/mic_samples/LEO_tutorial.

Standard Template libraries which provide classes that allocate and free their own memory are not usable currently with _Cilk_shared (unless they are modified to use the _Offload_shared_* specific APIs mentioned above.)
NOTE Intel® Cilk™ Plus is a deprecated feature.

- Runtime Type Information (RTTI) is not supported under the Shared Virtual memory programming method. Specifically, use of `dynamic_cast<>` and `typeid()` is not supported.

Writing Target-Specific Code

Restrictions When Programming on Windows* for Intel® MIC Architecture

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Several programming features that are specific to Windows* might result in errors when you use them in an offload compilation for Intel® MIC Architecture, even if you do not use these features in the code or data that is actually offloaded. When you use code with these features in your application, you must correctly structure the code so that it is not visible in a target compilation.

These features include, but are not limited to:

- Windows calling conventions. For example:
  ```c
  extern void __cdecl foo(void);
  ```
- Windows structured exception handling. For example:
  ```c
  void foo() {
    __try {
      1/0;
    } __finally {
      printf("In finally\n");
    }
  }
  ```
- The storage-class attributes `declspec(dllexport)` and `declspec(dllimport)`. For example:
  ```c
  __declspec(dllexport) void foo(void);
  ```
- Header files or libraries that are specific to Windows. For example:
  ```c
  #include <Windows.h>
  ```

In addition, you must take care to ensure that code does not depend on specific data size or order of allocation of classes, as these can vary between the host and the target.

About Asynchronous Computation (Intel® MIC Architecture)

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

By default, the `offload` pragma causes the CPU thread that encounters the pragma to wait for completion of the offload before continuing to the next statement. You can execute an asynchronous offload computation, which enables the CPU to initiate the offload and immediately continue to the next statement.

To specify an asynchronous offloaded computation, specify a `signal` clause in the `offload` pragma to initiate the computation, and subsequently use the `offload_wait` pragma to wait for completion of the offloaded computation.

Alternatively, on Intel® MIC Architecture, you can use the non-blocking API `_Offload_signaled()` to also determine if a section of offloaded code has completed running on a specific target device.
NOTE
On Intel® MIC Architecture, the signal and wait clauses, the offload_wait construct and the 
_Offload_signaled() API refer to a specific target device, so you must specify target-number in 
the target() clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime 
abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where 
the signal was actually initiated for target device 1. The signal was initiated for target device 1, so 
there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

Example: Asynchronous Computation

The following example enables the CPU to issue offloaded computations and continue concurrent activity 
without using any additional CPU threads:

```c
//Intel(R) MIC Architecture Example
char signal_var;
do {
  #pragma offload target (mic:0) signal(&signal_var)
  {
    long_running_mic_compute();
  }
  concurrent_cpu_activity();
  #pragma offload_wait target (mic:0) (&signal_var)
} while (1);
```

About Asynchronous Data Transfer (Intel® MIC Architecture)

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

To transfer data between the CPU and the target device, use the offload_transfer pragma with either all 
in clauses or all out clauses. Without a signal clause the data transfer is synchronous: The next statement 
is executed only after the data transfer is complete.

offload_transfer with a signal makes the data transfer asynchronous. The tag specified in the signal 
clause is an address expression associated with that dataset. The data transfer is initiated and the CPU can 
continue past the pragma statement.

A later pragma written with a wait clause causes the activity specified in the pragma to begin only after all 
the data associated with the tag has been received or shared with the target device. The data is placed into 
the variables specified when the data transfer was initiated. These variables must still be accessible.

Alternatively, on Intel® MIC Architecture, you can use the non-blocking API _Offload_signaled() to also 
determine if a section of offloaded code has completed running on a specific target device.
**NOTE**

On Intel® MIC Architecture, the `signal` and `wait` clauses, the `offload_wait` construct and the `_Offload_signaled()` API refer to a specific target device, so you must specify `target-number` in the `target()` clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where the signal was actually initiated for target device 1. The signal was initiated for target device 1, so there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

If, during an asynchronous offload, a signal is created in one thread, Thread A, and waited for in a different thread, Thread B, you are responsible for ensuring that Thread B does not query the signal before Thread A has initiated the asynchronous offload to set up the signal. Thread B querying the signal before Thread A has initiated the asynchronous offload to set up the signal, results in a runtime abort of the application.

If `if-specifier` evaluates to false and you use a `signal (tag)` clause, then the signal is undefined and any wait on this signal has undefined behavior.

### Asynchronous Data Transfer From the CPU to the Target

To transfer data asynchronously from the CPU to the target, use a `signal` clause in an `offload_transfer` pragma with `in` clauses. The variables listed in the `in` clauses form a data set. The pragma initiates the data transfer of those variables from the CPU to the target. A subsequent `offload` pragma with a `wait` clause that uses the same value for `tag` as that used in the `signal` clause causes the statement controlled by the pragma to begin execution on the target only after the data transfer is complete.

### Asynchronous Data Transfer from the Target to the CPU

To transfer data asynchronously from the target to the CPU, use the `signal` and `wait` clauses in two different pragmas. The first `offload` pragma performs the computation, but only initiates the data transfer. The second pragma causes a wait for the data transfer to complete.

### Examples for Intel® MIC Architecture: Target to CPU and CPU to Target

The example below demonstrates various asynchronous data transfers between the CPU and target.

```c
#include <stdio.h>
__attribute__((target(mic)))
void add_inputs(int N, float *f1, float*f2);

void display_vals(int id, int N, float*f2);

int main()
{
    const int N = 5;
    float *f1, *f2;
    int i, j;
    f1 = (float *)_mm_malloc(N*sizeof(float),4096);
    f2 = (float *)_mm_malloc(N*sizeof(float),4096);
    for (i=0;i<N;i++){
        f1[i]=i+1;
        f2[i]=0.0;
    }
    add_inputs(N, f1, f2);
    display_vals(0, N, f2);
}
```
Section 1 below (lines 22-56) demonstrates asynchronous data transfers, using IN and OUT, between the CPU and target with asynchronous computation. The data transfer of the arrays \( f_1 \) and \( f_2 \) is initiated at lines 28-30. The `offload_transfer` does not initiate a computation. Its only purpose is to start transferring data for \( f_1 \) and \( f_2 \) to the target. At lines 40-44 the CPU initiates the computation, with the function `add_inputs`, on the target and continues execution to the `offload_wait` at line 51. The offloaded function uses the data \( f_1 \) and \( f_2 \), whose transfer was initiated earlier on the CPU. The execution of the offloaded region on the target begins only after the transfers of \( f_1 \) and \( f_2 \) are complete and the signal tag, \( (f_1) \) is set accordingly. While the offloaded region executes on the target, the CPU waits at line 51 pending completion of the computation and data transfer of the results in \( f_2 \) to the CPU. Execution on the CPU only continues beyond line 50 after the data for \( f_2 \) is transferred to the CPU and the signal tag \( (f_2) \) is set accordingly.

```c
22     //-----------  Section 1   --------------------------------------
23     24     // Asynchronous transfer IN (to target) of f1 and f2
25     // CPU issues send and then continues
26     #pragma offload_transfer target(mic:0)  signal (f1) \ 
27         in( f1 : length(N) alloc_if(1) free_if(0) ) \ 
28             in( f2 : length(N) alloc_if(1) free_if(0) )
29
30     // Asynchronous compute and transfer OUT (to CPU) of f2
31     // CPU issues request to perform computation and continues
32     // target receives offload request, waits for pre-sent
33     // data. After receiving data, performs computation and
34     // transfers (asynchronous) data OUT (to CPU)
35     #pragma offload target(mic:0) wait(f1) signal (f2) \ 
36         in( N ) \ 
37             nocopy( f1 : alloc_if(0) free_if(1) ) \ 
38                 out( f2 : length(N) alloc_if(0) free_if(1) )
39         add_inputs(N, f1, f2);
40
41     // Wait for offload completion
42     // CPU waits for completion of previous offload and
43     // data transfer out (to CPU) of f2
44     #pragma offload_wait target(mic:0)  wait(f2)
45
46     // Show current values
47     display_vals(1, N, f2);
48
49   50     51   52
```

In the same example, section 2 (lines 57-90) demonstrates multiple asynchronous data transfers, using IN, from the CPU to the target with synchronous computation and synchronous data transfer, using OUT, from the target to the CPU. Multiple independent asynchronous data transfers can occur at any time. The `offload_transfer` sends \( f_1 \) and \( f_2 \) to the target at different times, first \( f_1 \) in lines 63-64, and then \( f_2 \) in lines 68-69. The transfers are independent. At lines 81-85 the execution of the offloaded region and the function `add_inputs` on the target begins only after the transfers of \( f_1 \) and \( f_2 \) are complete and the signal
tags ($f_1$ and $f_2$) are both set accordingly. Execution on the CPU waits for the completion of the offloaded computation and data transfer of the results in $f_2$ to the CPU. The data transfer of $f_2$ to the CPU occurs synchronous with the execution of the offloaded region.

Section 3 (lines 91-132) in the example demonstrates an independent asynchronous data transfer (IN) from the CPU to the target with synchronous data transfer (IN) from the CPU to the target and computation, followed by an independent asynchronous data transfer (OUT) from the target to the CPU. The offloaded function uses the data $f_1$ and $f_2$. The transfer of $f_2$ was initiated earlier on the CPU at lines 97-98. The execution of the offloaded region on lines 111-115 on the target begins only after the transfers of $f_1$ and $f_2$ are complete and the signal tag ($f_2$) is set accordingly for the transfer of $f_2$. After the offloaded region executes on the target, the computed results of $f_2$ remain on the target and execution on the CPU continues beyond line 115. At lines 122-123, the CPU initiates an asynchronous data transfer (OUT) from the target to the CPU for the computed results for $f_2$ and continues execution to line 128 where the CPU waits for the completion of the transfer of $f_2$. Execution on the CPU continues beyond line 128 only after the data for $f_2$ is transferred to the CPU and the signal tag ($f_2$) is set accordingly.
in( f2 : length(N) alloc_if(1) free_if(0) )

// Synchronous transfer IN (to target) of f1 with
// synchronous compute of f2 where new computed values
// of f2 remain on target

#pragma offload target(mic:0) wait(f2) \
    in( N ) \
        in( f1 : length(N) alloc_if(1) free_if(0) ) \ 
        nocopy( f2 )
add_inputs(N, f1, f2);

// CPU transfers values IN (to target) of f1, then issues
// request to perform computation and waits for completion
// target receives offload request, waits for pre-sent
// data for f2. After receiving data, performs the
// computation and holds the results in f2 on target

// CPU waits for completion of previous offload, then
// initiates asynchronous transfer OUT (to CPU) of f2
// and continues

#pragma offload_transfer target(mic:0)  signal (f2) \
    out( f2 : length(N) alloc_if(0) free_if(1) )

// CPU waits for completion of transfer of f2 to the CPU

#pragma offload_wait target(mic:0)  wait(f2)

// Show current values
display_vals(3, N, f2);

}

void add_inputs (int N, float *f1, float*f2)
{
    int i;
    for (i=0; i<N; i++)
    f2[i] = f2[i] + f1[i];
}

void display_vals (int id, int N, float *f2)
{
    int i;
    printf("\nResults after Offload #%d:\n",id);
    for (i=0; i<N; i++)
    printf("    f2[%d]= %f\n",i,f2[i]);
}
The following example double buffers inputs to an offload.

```c
#include <offload.h>

int count = 25000000;
int iter = 10;
float *in1, *out1;
float *in2, *out2;

#pragma offload_attribute(push, target(mic))
void do_async_in()
{
    int i;
    #pragma offload_transfer target(mic:0) in(in1 : length(count) alloc_if(0) free_if(0) ) signal(in1)
    for (i=0; i<iter; i++)
    {
        if (i%2 == 0) {
            #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in2 : length(count) alloc_if(0) free_if(0) ) signal(in2)
            #pragma offload target(mic:0) nocopy(in1) wait(in1) out(out1 : length(count) alloc_if(0) free_if(0) )
            compute(in1, out1);
        } else {
            #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in1 : length(count) alloc_if(0) free_if(0) ) signal(in1)
            #pragma offload target(mic:0) nocopy(in2) wait(in2) out(out2 : length(count) alloc_if(0) free_if(0) )
            compute(in2, out2);
        }
    }
}
#pragma offload_attribute(pop)
```

Offload Using Streams

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Streams can be used to offload multiple concurrent computations to a device on Intel® MIC Architecture from a single CPU thread.

A stream is a logical queue of offloads. Offloads in any one stream complete in the order in which they were issued to the stream.

To use this feature, specify the **stream clause** in `#pragma offload` or `#pragma offload_transfer`. To specify a wait for all offloads to the stream, specify the **stream clause** in `#pragma offload_wait`.

---

2307
Defining Streams
The following API creates a stream and specify the number of threads allocated to it:

```c
OFFLOAD_STREAM* handle =
    _Offload_stream_create(
        int device, // Intel(R) MIC Architecture device number
        int number_of_threads); // Threads allocated to the stream
```

After a stream has been created, it is tied to a target device. So, there is no need to specify a device whenever offloading to a stream; this is in contrast to non-stream offloads, which always require a target device specification.

Destroying Streams
The following API destroys a stream and returns the device threads to the pool for future streams:

```c
int _Offload_stream_destroy(
    _Offload_stream stream); // The stream
```

This API returns true if the stream was successfully destroyed.

Offloading to a Stream
Offloads can be issued to a stream using the following syntax:

```c
// Issue an offload to a stream
#pragma offload … stream(handle)
```

You can use a signal clause to identify a particular offload issued to a stream. The signal identifier can later be used to wait for completion of that specific offload; for example

```c
// Issue offload to a stream and identify with a signal
#pragma offload … stream(handle) signal(s)
```

Waiting for Offload Completion
A wait can be specified for all offloads in a stream or for a particular offload issued to a stream.

The following example shows how to specify a wait for completion of all offloads in a stream:

```c
// Issue offload to a stream
#pragma offload … stream(handle)
{ … }

// Issue another offload to that stream
#pragma offload … stream(handle)
{ … }

// Wait for all offloads in that stream to complete
#pragma offload_wait stream(handle)
```

The following example shows how to specify a wait for completion of a particular offload in a stream:

```c
// Issue offload to a stream and identify with signal value s1
#pragma offload … stream(handle) signal(s1)
{ … }

// Issue offload to a stream and identify with signal value s2
#pragma offload … stream(handle) signal(s2)
{ … }
```
// Wait for offload with signal value s1 to complete
#pragma offload_wait stream(handle) wait(s1)

The following example shows how to specify a wait for completion of all offloads in all streams:

// Issue offload to a stream 1
#pragma offload … stream(handle1)
{ … }
…
// Issue offload to a stream 2
#pragma offload … stream(handle2)
{ … }
…
// Wait for completion of all offloads in all streams using handle 0
#pragma offload_wait stream(0)

Testing for Offload Completion

This feature includes non-blocking APIs that return a Boolean value to test whether:

- All stream offloads to a specific device have completed
- All stream offloads on all devices have completed
- A particular stream offload has completed

The following function tests whether all offloads to the specified stream have completed. Specifying a 0 for stream will test whether offloads to all streams have completed.

```c
int _Offload_stream_completed(
    _Offload_stream stream);           // The stream
```

The following function tests whether all offloads to the specified device have completed. Specifying -1 for the device will test whether all stream offloads on all devices have completed.

```c
int _Offload_device_streams_completed(
    int device);                 // Intel(R) MIC Architecture device number
```

The following example shows how to check for completion of all offloads in a stream:

```c
// Issue offload to a stream
#pragma offload … stream(handle)
{ … }
…
// Issue another offload to that stream
#pragma offload … stream(handle)
{ … }
…
// Check if all offloads in that stream have completed
if (_ Offload_stream_completed(handle)) ...
```

The following example shows how to check for a particular offload in a stream:

```c
// Issue offload to a stream and identify with signal value s1
#pragma offload … stream(handle) signal(s1)
{ … }
…
// Issue offload to a stream and identify with signal value s2
#pragma offload … stream(handle) signal(s2)
{ … }
```
...  
// Check if offload with signal value s1 has completed  
if (_Offload_signaled(s1)) ...

The following example shows how to check for completion of all offload in all streams:

// Issue offload to a stream 1  
#pragma offload ... stream(handle1)  
{ ... }

// Issue offload to a stream 2  
#pragma offload ... stream(handle2)  
{ ... }

// Check for completion of all offloads in all streams using handle 0  
if (_Offload_stream_completed(0)) ...

The following example shows how to check for completion of all offloads on a device:

// Issue offload to a stream 1  
#pragma offload ... stream(handle1)  
{ ... }

// Issue offload to a stream 2  
#pragma offload ... stream(handle2)  
{ ... }

// Check for completion of all stream offloads on device 2  
if (_Offload_device_streams_completed(2) ...

The following example shows how to check for completion of all offloads on all devices:

// Issue offload to a stream 1  
#pragma offload ... stream(handle1)  
{ ... }

// Issue offload to a stream 2  
#pragma offload ... stream(handle2)  
{ ... }

// Check for completion of all stream offloads on device 2  
if (_Offload_device_streams_completed(-1) ...  
OR  
if (_Offload_stream_completed(0) ...

Applying the target Attribute to Multiple Declarations

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

When you have several data and function declarations, rather than specifying each declaration with its own target attribute, you can enclose a group of data and function declarations between the push and pop variants of the offload_attribute pragma.
When offloaded code makes use of declarations from C standard headers, Intel® Threading Building Blocks (Intel® TBB), Intel® Cilk™ Plus, or user-written #include declarations, you must enclose those declarations within the `offload_attribute` pragma, with a specified target-name corresponding to the offload model under which the declarations are used.

**NOTE** Intel® Cilk™ Plus is a deprecated feature.

**NOTE**
The code represented by the external routine in the header files must exist on the coprocessor either as a system library or as a user library that can run on Intel® MIC Architecture.

Enclose the calls to the include files when offloading using a pragma as follows:

```c
#pragma offload_attribute(push, target(mic))
...
#pragma offload_attribute(pop)
```

Enclose the calls to the include files when offloading using shared virtual memory as follows:

```c
#pragma offload_attribute(push, _Cilk_shared)
...
#pragma offload_attribute(pop)
```

You can only use functions and data under a single offload model within your program, so any include file you call can only be marked for use under a single offload model. Consequently, you cannot use the keyword `_Cilk_offload` with any include file enclosed between `#pragma offload_attribute(push, target(mic))` and `#pragma offload_attribute(pop)`.

Conversely, you cannot use the the `#pragma offload` statement with any include file enclosed between `#pragma offload_attribute(push, _Cilk_shared)` and `#pragma offload_attribute(pop)`.

**NOTE**
There is one important exception for the virtual shared memory model: Do not enclose C standard headers within `#pragma offload_attribute(push, _Cilk_shared)` and `#pragma offload_attribute(pop)`. Such decoration is unnecessary and may lead to undefined symbols at run-time.

**Example**
The functions `function_1` and `function_2` each need the `target` attribute, as do all the declarations within some include files. It is convenient to put the `offload_attribute` pragma around all those declarations.

```c
#pragma offload_attribute(push,target(mic))
#include <stdio.h>
#include <math.h>

void function_1();
void function_2();
#pragma offload_attribute(pop)

int main()
{
    #pragma offload target(mic)
```
{  
    function_1();  
    printf("...");  
}  
...  
#pragma offload target(mic)  
function_2();  
...  }

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**Controlling the Coprocessor's Execution Environment**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can modify the coprocessor's execution environment using the following mechanisms:

- Setting environment variables for the coprocessor on the CPU, and passing them to the coprocessor
- Calling functions from the CPU

In general, function calls override environment variables.

**See Also**

Setting Environment Variables on the CPU to Modify the Coprocessor...

Calling Functions on the CPU to Modify the Coprocessor's Execution Environment

**Environment Variable for I/O Proxy Control for Offloaded Code**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

---

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

---

The MIC_PROXY_IO=0|1 environment variable controls the proxy of stderr and stdout. It specifies whether the process wants I/O proxy support between the host and coprocessor.

The default is 1 (enable proxy of I/O from coprocessor to host).

### Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Some CPU APIs have offload equivalents, each of which take two additional arguments to specify the target type and target number, defined by the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target_type</td>
<td>target_type is static. It is recommended to use the following pre-defined default: DEFAULT_TARGET_TYPE</td>
</tr>
</tbody>
</table>
| target_number| The specific coprocessor to target. An expression whose value is interpreted as follows:  
|            | >=0  
|            | Executes the statement on a specified target according to the following formula:  
|            | target = target-number % number_of_targets  
|            | For example, in a system with four targets:  
|            | • Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 % 4 and 6 % 4 is 2.  
|            | • Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 % 4 is 0. |
|            | -1 or no value  
|            | Executes the statements on a target selected by the runtime system. |
|            | <-1  
|            | Reserved. |

The offload.h header file defines all the function calls that can be made from the CPU to affect the coprocessor’s environment.

This topic uses the CPU API `omp_set_num_threads` and its offload variations as an example. See also the topics listed below for more CPU APIs.

### Example

**CPU API**

```c
void omp_set_num_threads (int num_threads);
```

**Offload API**

```c
void omp_set_num_threads_target (TARGET_TYPE target_type, int target_number, int num_threads);
```

```c
#include "offload.h"
#include "omp.h"
#include <stdio.h>

int main()
{
    int value, result;
```
value = 66;
omp_set_num_threads_target(TARGET_MIC, 0, value);
#pragma offload target(mic) out(result)
#pragma omp parallel
#pragma omp master
result = omp_get_num_threads();

printf("Number of threads on target %d\n", result);
if (result != value) {
    printf("failed1 result=%d, value=%d\n", result, value);
    return 1;
}
return 0;

Using Libraries With Offloaded Code
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
The heterogeneous compilation environment consists of a host CPU compilation environment and a target compilation environment. Each environment consists of the compiler, linker and standard libraries. Code for the host CPU is compiled within the host environment and offloaded code within the target environment. The target environment may supply its own sets of standard libraries and these would be available to be called from offloaded code with no need to use special syntax or runtime features.
Some common libraries, such as the Intel® Math Kernel Library (Intel® MKL) and Intel® Performance Primitives (Intel® IPP) will be available in CPU versions as well as target versions.
When the target is available, the target executable is loaded when the CPU version of the executable is loaded, or when the first offload is attempted. At this time the libraries linked with the target code are initialized. The loaded target executable remains in the target memory until the host program terminates. Thus, any global state maintained by the library is maintained across offload instances.
When you offload code only within shared libraries, you must link the main program with the [Q]offload compiler option.

NOTE
Separate copies of libraries are linked or loaded with the host program and the offloaded target code. So there are two sets of global state: One on the host CPU and one on the target. The host CPU code only sees the host CPU state and the offloaded code only sees the state of the library on the target.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
Special Cases
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

**setjmp and longjmp**
setjmp saves function state and longjmp resumes execution from a saved state. Saved state cannot be transported between the CPU and the target.

If you use setjmp in the offloaded code, the corresponding longjmp must also happen on the target within the same offload.

**Thread-private variables**
Thread-private variables are supported only with the pragma-based programming model, using copyin and copyout. They are not supported with the shared virtual memory model.

When a statement is offloaded, thread-private variable values from the CPU thread that does the offload are copied to the target, and then copied back when default in and out are in effect. Copies of thread-private variables in other CPU threads are not modified.

Writing Target-Specific Code

OpenMP* Considerations

OpenMP* Defaults
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The OpenMP* runtime has the following default on Intel® MIC Architecture:

- The OpenMP* runtime creates four threads per core by default under the coprocessor OS.
- If you do not specify the number of threads, the OpenMP* runtime uses the number of logical processors available in the affinity mask of the thread that initially goes parallel.

See Also
Thread Affinity Interface
Supported Environment Variables

OpenMP* Affinity Specifications
The coprocessor OS kernel on the coprocessor uses the logical processor number in /proc/cpuinfo, the calls to sched_{get,set}affinity() and sched_getcpu(), and the taskset command. The OpenMP* runtime library uses the logical processor number if you explicitly specify affinity using a proclist.

The logical processor number used by the coprocessor OS on Intel® MIC Architecture is different from that on the host, and probably not what you expect. There is one logical processor for each hardware thread context. Logical processor 0 is placed on the first hardware context of the highest numbered core. Logical processors
from 1 up to the highest, minus three, are placed consecutively on core 0 context 0, core 0 context 1, core 0 context 2, core 0 context 3, core 1, context 0 and so on, with the last three logical processors being on the highest numbered core, with hardware thread contexts 1, 2, and 3.

The simple way to think of this is that you should start enumerating the logical processors to use at logical processor 1, not logical processor 0.

**Balanced Affinity Type**

The affinity type balanced is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.

**NOTE**
The OpenMP* environment variable OMP_PROC_BIND=spread is similar to KMP_AFFINITY=balanced and is available on all platforms, including multi-socket CPU systems.

Under this setting, the OpenMP* runtime places threads on separate cores until all cores have at least one thread, similar to the scatter type. However, when the runtime must use multiple hardware thread contexts on the same core, the balanced type ensures that the OpenMP* thread numbers are close to each other, which scatter does not do.

The following diagrams illustrate the allocation of six OpenMP* threads across a 3-core system with the compact, scatter, and balanced affinity types.

**Allocation with the compact affinity type**
On the Intel® MIC Architecture, it is normally beneficial to use cores before threads, so the compact affinity type is unlikely to yield the best results, because it leaves cores unused.

**Allocation with the scatter affinity type**

The thread allocation under scatter is likely to be better than compact, because it uses cores before threads. However, scatter allocates thread IDs such that threads with IDs in close numerical proximity are on different cores, and therefore do not share caches. Because threads with neighboring IDs often operate on closely related data, placing them on different cores is unlikely to be the best way to allocate them.

**Allocation with balanced affinity type**
The thread allocation under balanced is balanced over the cores and the threads allocated to a core are neighbors of each other. Therefore, cache utilization should be efficient if the threads access data that is near in store.

Allocation with balanced affinity type for 9 OpenMP* threads

Tuning affinity is a complicated and machine specific process. Using the balanced affinity type is a reasonable starting point on Intel® MIC Architecture.

The balanced affinity type is also recognized and supported by the OpenMP* runtime on the CPU, but only for single socket systems.

Using the balanced type with the environment variable KMP_AFFINITY propagates to the coprocessor when MIC_ENV_PREFIX is not set. However, this may generate the following runtime warning on a multi-socket CPU:

```
OMP: Warning #230: KMP_AFFINITY: Affinity balanced is not available.
```

To set the balanced affinity type for only the Intel® MIC Architecture environment, assign a specific prefix using the MIC_ENV_PREFIX=prefix and then set prefix_KMP_AFFINITY with balanced.

Supported Environment Variables
Setting Environment Variables on the CPU to Modify the Coprocessors Execution Environment

Setting the Number of OpenMP* Threads on the Coprocessor
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Several methods exist to override the default number of threads per core on the coprocessor.

Using the OpenMP* API
The OpenMP* API specification provides the following standard ways to change the desired number of threads on the coprocessor:

- Calling the function `omp_set_num_threads(n)` before the `omp parallel region`
- Using the clause `num_threads with #pragma omp parallel`
- Setting the environment variable `OMP_NUM_THREADS=n`

For more information, refer to the OpenMP* API Specification at http://www.openmp.org.
Using the Intel® Compiler

In addition to the standard methods that the OpenMP® API specification provides, listed below, you can use the environment variable MIC_ENV_PREFIX to define a custom-prefixed environment variable to control the number of OpenMP® threads on the coprocessor separately from the host CPU. For example, the following environment variable definitions set OMP_NUM_THREADS on both the CPU and the coprocessor, but with different values.

```
OMP_NUM_THREADS=8
MIC_ENV_PREFIX=ABC
ABC_OMP_NUM_THREADS=124
```

Direct calls on the coprocessor to APIs in libiomp5.so to establish a specific runtime setting override any setting previously set by a CPU environment variable that is replicated on the coprocessor.

Setting Environment Variables on the CPU to Modify the Coprocessor's Execution Environment

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture). By default, all environment variables defined in the environment of an executing CPU program are replicated to the coprocessor’s execution environment when an offload occurs. You can modify this behavior by defining the environment variable MIC_ENV_PREFIX. When you set MIC_ENV_PREFIX to a specific prefix, then not all CPU environment variables are replicated to the coprocessor, but only those environment variables that begin with the value of the MIC_ENV_PREFIX environment variable. The environment variables set on the coprocessor have the prefix value removed. You thus have independent control of OpenMP®, Intel® Cilk™ Plus, and other execution environments that use common environment variable names.

**NOTE**

Intel® Cilk™ Plus is a deprecated feature.

Setting Multiple Environment Variables on All Coprocessors

You can send multiple variables, each with its own value to all coprocessors.

To do so, use the following form:

```
mic_prefix_VAR=variable1=value1|variable2=value2|variable3=value3|...
```

Where variableN is the variable, and valueN is its value.

Specifying a Particular Coprocessor

You can specify a particular coprocessor, which is useful when you have multiple coprocessors installed.

To do so, use the following form:

```
mic_prefix_card_number_VAR=value
```

Where the value of card_number is 0 for the first device, 1 for the second, and so on.

Similarly, when setting multiple environment variables, specify a particular coprocessor, using card_number.

**Example: Setting a Single Environment Variables on All Coprocessors**

The following environment variable definitions set OMP_NUM_THREADS on both the CPU and all installed coprocessors, but with different values.

```
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_OMP_NUM_THREADS=124
```
Example: Setting Multiple Environment Variables on All Coprocessors

The following environment variable definition sets \( X=x \) and \( Y=y \) on all coprocessors.

```plaintext
MIC_ENV_PREFIX=ABC
ABC_VAR=X=x|Y=y
```

Example: Setting a Single Environment Variables on a Particular Coprocessor

The following environment variable definitions set \( OMP\_NUM\_THREADS \) on both the CPU and the fifth coprocessor installed, but with different values.

```plaintext
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_4_OMP_NUM_THREADS=124
```

Example: Setting Multiple Environment Variables on a Particular Coprocessor

The following environment variable definition sets \( X=x \) and \( Y=y \) on the fifth coprocessor installed.

```plaintext
MIC_ENV_PREFIX=ABC
ABC_4_VAR=X=x|Y=y
```

Calling Functions on the CPU to Modify the Coprocessor's Execution Environment

Data Alignment for Intel® MIC Architecture

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Unlike the IA-32 and Intel® 64 architectures, the Intel® MIC Architecture requires all data accesses to be properly aligned according to their size, otherwise the program may behave unpredictably.

For example, an integer variable, which requires four bytes of storage, has to be allocated on an address that is a multiple of four. Likewise, a double-precision floating point variable, which requires eight bytes of storage, has to be allocated on an address that is a multiple of eight.

Generating an Offload Report

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can measure the amount of time it takes to execute an offload region of code, as well as the amount of data transferred during the execution of the offload region.

You can print an offload report, which contains information about an offload as the execution proceeds on the host and on the target. An offload report includes the following information:

- the amount of time it takes to execute an offload region of code
- the amount of data transferred between the host and the target
- additional details, including device initialization, and individual variable transfers

The following mechanisms enable and disable offload reporting:

- the `OFFLOAD_REPORT` environment variable.
- the `_Offload_report` API.

A compiler offload report line starts with `[Offload]` to clearly mark prints from compiler offloads, as opposed to other offloads, such as those from the Intel® Math Kernel Library.

Activities on the host are marked with `[HOST]`, while activities on the target are marked with `[MIC n]` where \( n \) is the logical number of the coprocessor to which the offload is sent. The top of the report shows the mapping of logical devices to physical devices. (Note that
An offloaded program can use a subset of physical devices when you specify the OFFLOAD_DEVICES environment variable.

Because multiple offloads may be in progress concurrently, either when multiple host threads initiate offloads or when asynchronous offloads are used, it is necessary to tag all the output associated with a specific offload pragma. Otherwise the reports from several concurrent offloads would be interleaved, making it impossible to determine to which offload a particular line of output belongs. A tag of the form [Tag n] uniquely identify lines in the offload report that belong to a particular offload.

For each offload, the first two report lines are the source file name and the line number of the offload pragma. After that, a line that assigns a Tag to that offload is printed. Subsequent report lines printed for that offload each use the tag [Tag n] to associate that line with that offload.

The rest of the report contains a line for each major activity. These lines contain an annotation of the activity after the tag that identifies which offload the activity belongs to. The annotations are as follows:

<table>
<thead>
<tr>
<th>Line Marker</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[State]</td>
<td>Activity being performed as part of the offload.</td>
</tr>
<tr>
<td>[Var]</td>
<td>The name of a variable transferred and the direction(s) of transfer.</td>
</tr>
<tr>
<td>[CPU Time]</td>
<td>The total time measured for that offload pragma on the host.</td>
</tr>
<tr>
<td>[MIC Time]</td>
<td>The total time measured for executing the offload on the target.</td>
</tr>
<tr>
<td></td>
<td>This excludes the data transfer time between the host and the target, and</td>
</tr>
<tr>
<td></td>
<td>counts only the execution time on the target.</td>
</tr>
<tr>
<td>[CPU-&gt;MIC Data]</td>
<td>The number of bytes of data transferred from the host to the target.</td>
</tr>
<tr>
<td>[MIC-&gt;CPU Data]</td>
<td>The number of bytes of data transferred from the target to the host.</td>
</tr>
</tbody>
</table>

The various activities printed after [State] describe the internal operation of the Offload Library and are helpful in diagnosing the point at which a runtime failure may occur. In most cases the description is self-explanatory.

Example

For this example, example.c, the offload report output is explained below.
The compiler option opt-report-phase with the offload keyword provides summary information about data transfers between the host and the target. There are two reports for each offload code section defined in the source code. The first report beginning with Offload to target MIC is from the host compilation. The second report beginning with Outlined offload region is from the target compilation. The information in this report option reflects similar information in the output when the OFFLOAD_REPORT environment variable is set to 3.

```c
int main()
{
    for (k=0; k < (siz/2); k++)
    {
        efg[k] = abc[k] + abc[k + (siz/2)];
        sumT += efg[k];
    }
    return sumT;
}
```
The rest of this example explains the offload report for the source program shown above.

NOTE
The host and the target execute independently, so once an offload has been initiated the sequence between host prints and target prints is unpredictable, and can vary from run to run. However, all the host prints will be in the same sequence, as well as all the target prints.

Here, the target device is initialized, and the report shows the mapping between logical and physical devices:

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>State</th>
<th>Initialize logical card 0 = physical card 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>State</td>
<td>Initialize logical card 1 = physical card 1</td>
</tr>
</tbody>
</table>

Offload code in example.c at line number 6 has started executing on the target.

<table>
<thead>
<tr>
<th>Offload</th>
<th>MIC 0</th>
<th>File</th>
<th>example.c</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>MIC 0</td>
<td>Line</td>
<td>6</td>
</tr>
</tbody>
</table>

Tag value Tag0 is assigned to this offload to enable identifying reports printed for this offload.

<table>
<thead>
<tr>
<th>Offload</th>
<th>MIC 0</th>
<th>Tag</th>
<th>Tag0</th>
</tr>
</thead>
</table>

The offload is initiated on the host.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Start Offload</th>
</tr>
</thead>
</table>

The target function corresponding to this offload.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Initialize function __offload_entry_example_c_6Hysum</th>
</tr>
</thead>
</table>

Create data transfer buffers for pointer data.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Create buffer from Host memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>Create buffer from MIC memory</td>
</tr>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>Create buffer from Host memory</td>
</tr>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>Create buffer from MIC memory</td>
</tr>
</tbody>
</table>

Pointer data sent from the host to the target using DMA, for the variable abc.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Send pointer data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>CPU-&gt;MIC pointer data 40</td>
</tr>
</tbody>
</table>

Non-pointer data from the variable siz is collected together and sent from host to target.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Gather copyin data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>CPU-&gt;MIC copyin data 4</td>
</tr>
</tbody>
</table>

The offloaded code (line 6) on the target is started.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Compute task on MIC</th>
</tr>
</thead>
</table>

The offload has completed. Start receiving data from target.

<table>
<thead>
<tr>
<th>Offload</th>
<th>HOST</th>
<th>Tag 0</th>
<th>State</th>
<th>Receive pointer data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>HOST</td>
<td>Tag 0</td>
<td>State</td>
<td>MIC-&gt;CPU pointer data 20</td>
</tr>
</tbody>
</table>
This is output from the target. The offload code is invoked on the target.

```
[Offload] [MIC 0] [Tag 0] [State] Start target function __offload_entry_example_c_6Hysum
```

The variable *abc* is an **IN** for this offload.

```
[Offload] [MIC 0] [Tag 0] [Var] abc_2_V$0 IN
```

The variable *efg* is an **OUT** for this offload.

```
[Offload] [MIC 0] [Tag 0] [Var] efg_2_V$1 OUT
```

The variable *sumT* is an **OUT** for this offload.

```
[Offload] [MIC 0] [Tag 0] [Var] sumT OUT
```

The variable *siz* is an **IN** for this offload.

```
[Offload] [MIC 0] [Tag 0] [Var] siz_2_V$2 IN
```

On the target, non-pointer data is copied into target memory.

```
[Offload] [MIC 0] [Tag 0] [State] Scatter copyin data
```

User program output:

```
On device : 0
```

On the target, non-pointer data, the variable *sumT*, is gathered and sent from the target to the host.

```
[Offload] [MIC 0] [Tag 0] [State] Gather copyout data
```

```
[Offload] [MIC 0] [Tag 0] [State] MIC->CPU copyout data 4
```

Non-pointer data is copied into target memory.

```
[Offload] [HOST] [Tag 0] [State] Scatter copyout data
```

Host time on the target.

```
[Offload] [HOST] [Tag 0] [CPU Time] 0.832872 (seconds)
```

The total amount of pointer and non-pointer data, the variables *abc* and *siz*, transferred from host to target.

```
[Offload] [MIC 0] [CPU->MIC Data] 44 (bytes)
```

Computation time on the target.

```
[Offload] [MIC 0] [MIC Time] 0.000298 (seconds)
```

The total amount of pointer and non-pointer data, the variables *efg* and *sumT*, transferred from target to host.

```
[Offload] [MIC 0] [MIC->CPU Data] 24 (bytes)
```

User Program output:

```
sum total=45
```

Cleanup at end of program:

```
[Offload] [MIC 1] [State] Unregister data tables
[Offload] [MIC 0] [State] Unregister data tables
[Offload] [HOST] [State] Unregister data tables
```

---

<tr>
<td></td>
<td></td>
<td>details on offload activity, including device initialization, and individual</td>
</tr>
<tr>
<td></td>
<td></td>
<td>variable transfers.</td>
</tr>
</tbody>
</table>

Description

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This API enables you to time offload regions and measure the amount of data transferred during their execution.

Using this API is equivalent to setting the environment variable OFFLOAD_REPORT.

Example

In the following example if the OFFLOAD_REPORT environment variable is set, the report is produced for offloads before line 20 but suppressed from line 20 to line 30.

Reporting is turned back on at line 30, and subsequent offloads have reporting enabled.

```c
01 int main()
02 {
   // By default reporting is on and level is controlled by OFFLOAD_REPORT value
   ...
10    #pragma offload target(mic) ...
   ...
20    _Offload_report(0);       // Turns off offload report
21    #pragma offload target(mic) ...
   ...
30    _Offload_report(1);      // Turns offload report back on
   ...
90 }
```
The following examples of output are just to give you an idea of the type of output you can expect for each setting. These output examples are not connected to the code examples above.

Here is an example of output for `_Offload_report(1)`:

```
[Offload] [MIC 0] [File]            test.f90
[Offload] [MIC 0] [Line]            5
[Offload] [MIC 0] [Tag]             Tag0
sub #1, initial pc: 12345678910
[Offload] [MIC 0] [CPU Time]        0.000000 (seconds)
[Offload] [MIC 0] [MIC Time]        0.000876 (seconds)
```

Here is an example of output for `_Offload_report(2)`:

```
[Offload] [MIC 0] [File]            test.f90
[Offload] [MIC 0] [Line]            5
[Offload] [MIC 0] [Tag]             Tag0
sub #1, initial pc: 12345678910
[Offload] [MIC 0] [CPU Time]        0.000000 (seconds)
[Offload] [MIC 0] [CPU->MIC Data]   44 (bytes)
[Offload] [MIC 0] [MIC Time]        0.001131 (seconds)
[Offload] [MIC 0] [MIC->CPU Data]   4 (bytes)
```

Here is an example of output for `_Offload_report(3)`:

```
[Offload] [MIC 0] [File]            sampleC14.c
[Offload] [MIC 0] [Line]            104
[Offload] [MIC 0] [Tag]             Tag626
[Offload] [HOST]  [Tag 626] [State]  Start Offload
[Offload] [HOST]  [Tag 626] [State]  Initialize function __offload_entry_sampleC14_c_104sample14
[Offload] [HOST]  [Tag 626] [State]  Send pointer data
[Offload] [HOST]  [Tag 626] [State]  CPU->MIC pointer data 100
[Offload] [HOST]  [Tag 626] [State]  Gather copyin data
[Offload] [HOST]  [Tag 626] [State]  CPU->MIC copyin data 0
[Offload] [HOST]  [Tag 626] [State]  Compute task on MIC
[Offload] [HOST]  [Tag 626] [State]  Receive pointer data
[Offload] [HOST]  [Tag 626] [State]  MIC->CPU pointer data 100
[Offload] [MIC 0]  [Tag 626] [State]  Start target function __offload_entry_sampleC14_c_104sample14
  __offload_entry_sampleC14_c_104sample14
[Offload] [MIC 0]  [Tag 626] [Var]    inp_14_V$1  IN
[Offload] [MIC 0]  [Tag 626] [Var]    micp_14_V$2  OUT
[Offload] [MIC 0]  [Tag 626] [Var]    i  OUT
[Offload] [MIC 0]  [Tag 626] [State]  Scatter copyin data

Calling exit() From an Offload Region

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

When calling exit() from within an offload region, the application reports an offload error stating the process on the device exited unexpectedly.

Building for Intel® MIC Architecture

Setting Stack Size on Coprocessors

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Each CPU thread that offloads code executes the offloaded code in a coprocessor thread dedicated to that CPU thread. The default stack size for that coprocessor thread is fairly small, 2 MB.

To increase the stack size allocated to offloaded code, set the environment variable MIC_STACKSIZE to a size sufficient for the offloaded code. MIC_STACKSIZE is always honored. It does not require the variable MIC_ENV_PREFIX to be set.

Specify the value for MIC_STACKSIZE as follows:

<table>
<thead>
<tr>
<th>integerB</th>
<th>A value, in bytes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>integerK</td>
<td>A value, in kilobytes.</td>
</tr>
<tr>
<td>integerM</td>
<td>A value, in megabytes.</td>
</tr>
<tr>
<td>integerG</td>
<td>A value, in gigabytes.</td>
</tr>
<tr>
<td>integerT</td>
<td>A value, in terabytes.</td>
</tr>
</tbody>
</table>

For example, the following Bash, Dash and C shell commands set the maximum stacksize for the main coprocessor thread to 50MB:

- `export MIC_STACKSIZE=50M` #(Bash or Dash shell)
- `setenv MIC_STACKSIZE 50M` # (C shell)

NOTE OpenMP* and Intel® Cilk™ Plus runtime libraries have their own environment variables for adjusting the sizes of the stacks used by additional OpenMP or Intel® Cilk™ Plus threads (Intel® Cilk™ Plus is a deprecated feature.). MIC_STACKSIZE does not apply to such threads. For example, to increase the available stack size for every OpenMP thread except the main thread to 3 MB using Bash or Dash, enter: `export OMP_STACKSIZE=3M` (affects OpenMP threads on both host and coprocessor) or `export MIC_ENV_PREFIX=ABC export ABC_OMP_STACKSIZE=3M` (affects coprocessor OpenMP threads only).
If you use pthreads, you can set the pthreads stack size by using `posix_memalign()` to allocate a page-aligned stack (4096 byte page) with one extra guard page at the bottom, and then passing that stack to `pthread_attr_setstack()`. Then, use `pthread_attr_setstack()` for `pthread_create()`. The following code demonstrates this method.

```c
#define PAGESIZE 4096

void *makestack(int size) {
    int ret;
    void *space;
    char *stack;

    /* size in pages */
    ret = posix_memalign(&space, PAGESIZE, (size+1) * PAGESIZE);
    if (ret != 0) {
        printf(stderr, "posix_memalign returns %d\n", ret);
        return 0;
    }

    mprotect(space, PAGESIZE, PROT_NONE);
    stack = (char *)space + PAGESIZE;
    printf("makestack: size %d stack %p space %p\n", size, stack, space);
    return stack;
}

void setstack(int argc, char **argv) {
    void *i;
    pthread_t t;
    int ret;
    const int stacksize = (12 * 1024 * 1024) / PAGESIZE;

    pthread_attr_init(&thread_attrs);
    pthread_attr_setstack(&thread_attrs,
        makestack(stacksize), stacksize * PAGESIZE);
    pthread_create(&t, &thread_attrs, chkstack, (void *)stacksize);
}
```

Appending Archiver Options for Creating Libraries

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You may find it useful to customize the target code generation when creating libraries. You can do so by appending additional archiver options to the built-in options.

To append additional archiver options:

- Use Eclipse* (C/C++ applications only):
  1. Open your project's property pages and select C/C++ Build > Settings > Intel(R) 64 Archiver.
  2. Select Archiver Command Line.
  3. Enter the options in the Archiver Options field.
- Use the \{Q\}offload-option command line option.

See Also
offload-option, Qoffload-option
Appending Linker Options

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You may find it useful to customize the target code generation with the linker. You can do so by appending additional linker options to the built-in options.

To append additional linker options:

- Use Eclipse* (C/C++ applications only):
  1. Open your project’s property pages and select C/C++ Build > Settings > Intel(R) 64 C Linker.
  2. Select Miscellaneous.
  3. Enter the options in the Additional Options field.
- Use [Q]offload-option.

See Also
offload-option, Qoffload-option

Logging Stdout and Stderr from Offloaded Code

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Capturing C/C++ program output to stdout and stderr from writes performed inside offloaded code may require calling fflush(). This function is under the control of the coprocessor offload interface (COI) layer, not the compiler or compiler run-time libraries.

Writes performed in offloaded code may be buffered, while writes on the non-offloaded code happen immediately. If the application exits prior to the buffer threshold being reached then the output data may be lost. Therefore, I/O requires an additional explicit fflush() on the coprocessor to capture this output data, as shown in the sample.c example below.

Example

/* sample.c: */

#pragma omp declare target
#include <stdio.h>

void sub()
{
    printf("hello from MIC
");
    fflush(0);
}

#pragma omp end declare target

int main(int argc, char* argv[])
{
    printf("hello from main
");
    #pragma omp target
    sub();
}

Compile and execute the above example as follows:

$ icc -qopenmp -o sample sample.c
$ ./sample > log.txt
$ cat log.txt hello from MIC hello from main

When calling fflush(), you can control directing stdout and stderr to the same or separate output files.
For example, to send the stdout (1) and stderr (2) to log.txt, enter:

```
$ ./sample > log.txt 2>&1
```

To redirect stdout to one file and stderr to another, use:

```
$ ./sample > log.txt 2> log_err.txt
```

### About Building Native Intel® MIC Architecture Applications

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can build a binary to run natively on Intel® MIC Architecture, without building one to run on the CPU at all. To do this, include the `mmic` (Linux*) or `Qmic` (Windows*) compiler option when you invoke the compiler. You can use the `MIC_LIBRARY_PATH` environment variable to add additional paths to search for libraries needed to build the native binary.

**NOTE**

When you specify Windows* option `/Qmic`, you must specify any other options on the command line in the Linux* form. This is because all other options are passed directly to the native compiler for Intel® 64 architecture targeting the Intel® MIC architecture, which is a Windows*-hosted Linux* compiler.

When debugging applications for Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) on Windows*, you should use:

```
icl /Qmic-avx512 -g
```

See the related links below for information on setting the compiler environment and the class libraries for Intel® Many Integrated Core (Intel® MIC) Architecture. For information on debugging native Intel® MIC Architecture applications, see the debugger documentation.

### Profile-Guided Optimization (PGO)

Profile-guided Optimization (PGO) improves application performance by shrinking code size, reducing branch mispredictions, and reorganizing code layout to reduce instruction-cache problems. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. **Instrument the program.** The compiler creates and links an instrumented program from your source code and special code from the compiler.
2. **Run the instrumented executable.** Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.
3. **Final compilation.** When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.
See Profile-guided Optimization Options for information about the supported options and Profile an Application for specific details about using PGO from the command line.

PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.
- Detect and do not vectorize loops that execute only a small number of iterations, reducing the run time overhead that vectorization might otherwise add.

Interprocedural optimization (IPO) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about inline function expansion, which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. If you modify your program, the compiler can issue a warning that the dynamic information does not correspond to a modified function when PGO remarks are enabled or found in the optimization report.
Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.

Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.

Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance, execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile-Guided Optimization via HW counters

A lightweight profiling mechanism is available that can be used to achieve many of the benefits of instrumentation based profiling, but without the overhead of inserting instrumentation into the application binary. This mode of operation can be beneficial in cases where increase in code/data size or changes in run time due to instrumentation may make regular Performance-Guided Optimization (PGO) infeasible. This approach requires the use of Intel® VTune™ Amplifier to collect information from the hardware counters. The information is collected with minimal overhead, and combined with debug information produced by the compiler to identify the primary code path for optimizations.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Follow these steps to use this method:

Phase 1: Compile the application with the option `prof-gen-sampling`.

This option will instruct the compiler to generate additional debug information for the application, which is used to map the information collect by the hardware counters to specific source code. However, use of the option does not affect the generated instruction sequence in the way instrumented PGO would. Optimizations may be enabled during this build, however it is recommended to disable function inlining during this build.

Phase 2: Run the generated executable on one or more representative workloads with the Intel VTune Amplifier tool:

```bash
<installation-root>/bin64/amplxe-pgo-report.sh <your application and command line>
```

Additional information regarding options for data collection can be found in the Intel VTune Amplifier documentation. This step will generate files of the form `rNNNpgo_icc.pgo` (where `NNN` is a 3 digit number) which will be used as input to the following phases.

Phase 3: (optional) Merge the report files produced during phase 2.

The tool `profmergesampling` can be used to produce an indexed file of results that will speed up the processing of the data during the next phase.

```bash
profmergesampling -file <input-file[:input_file]*> -out <output_name>
```

Phase 4: Compile the application with the option `prof-use-sampling:input-file[:input_file]*`

In phase 4, one or more result files produced during phase 2 (or an indexed file from phase 3) can be fed into the compiler to direct the optimizations.

- `prof-gen-sampling` compiler option
- `prof-use-sampling` compiler option
Profile an Application with Instrumentation

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking

   Use 
   \[Q\]prof-gen to produce an executable with instrumented information included. Use /Qcov-gen (Windows) option to obtain minimum instrumentation only for code coverage.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>icpc -prof-gen -prof-dir/usr/profiled a1.cpp a2.cpp a3.cpp icpc a1.o a2.o a3.o</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Qprof-gen /Qprof-dir:\profiled a1.cpp a2.cpp a3.cpp icl a1.obj a2.obj a3.obj</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Qcov-gen /Qcov-dir:/cov_data a1.cpp a2.cpp a3.cpp icl a1.obj a2.obj a3.obj</td>
</tr>
</tbody>
</table>

Use the [Q]prof-dir or /Qcov-dir (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

The compiler gathers extra information when you use the -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows) option; however, the extra information is collected to provide support for specific Intel tools, including the code coverage Tool. If you do not expect to use such tools, do not specify -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows); the extended option does not provide better optimization and could slow parallel compile times. If you are interested in using the instrumentation only for code coverage, use the /Qcov-gen (Windows) option, instead of the /Qprof-gen:srcpos (Windows) option, to minimize instrumentation overhead.

PGO data collection is optimized for collecting data on serial applications at the expense of some loss of precision on areas of high parallelism. However, you can specify the threadsafe keyword with the -prof-gen (Linux* and macOS*) or the /Qprof-gen (Windows) compiler option for files or applications that contain parallel constructs using OpenMP* features, for example. Using the threadsafe keyword produces instrumented object files that support the collection of PGO data on applications that use a high level of parallelism but may increase the overhead for data collection. On applications specific to Intel® 64 architecture targeting Intel® MIC Architecture, the only valid mode for using the PGO -prof-gen (Linux and macOS*) or /Qprof-gen (Windows) compiler option is to use the keyword threadsafe.

**NOTE**

Unlike serial programs, parallel programs using OpenMP* may involve dynamic scheduling of code paths, and counts collected may not be perfectly reproducible for the same training data set.

2. Instrumented execution
Run your instrumented program with a representative set of data to create one or more dynamic information files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>./a1.out</td>
</tr>
<tr>
<td>Windows</td>
<td>a1.exe</td>
</tr>
</tbody>
</table>

Executing the instrumented applications generates a dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

By default, the .dyn filename follows this naming convention: `<timestamp>_<pid>.dyn`. The .dyn file is either placed into a directory specified by an environment variable, a compile-time specified directory, or the current directory.

To make it easy to distinguish files from different runs, you can specify a prefix for the .dyn filename in the environment variable, INTEL_PROF_DYN_PREFIX. In such a case, executing the instrumented application generates a .dyn filename as follows: `<prefix>_<timestamp>_<pid>.dyn`, where `<prefix>` is the identifier that you have specified. Be sure to set the INTEL_PROF_DYN_PREFIX environment variable prior to starting your instrumented application.

**NOTE**
The value specified in INTEL_PROF_DYN_PREFIX environment variable must not contain < > : " / \ | ? * characters. The default naming scheme will be used if an invalid prefix is specified.

### 3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with [Q]prof-use; the option instructs the compiler to use the generated dynamic information to guide the optimization:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>icpc -prof-use -ipo -prof-dir/usr/</td>
</tr>
<tr>
<td></td>
<td>profiled a1.cpp a2.cpp a3.cpp</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Qprof-use /Qipo /Qprof-dir:/c:</td>
</tr>
<tr>
<td></td>
<td>\profiled a1.cpp a2.cpp a3.cpp</td>
</tr>
</tbody>
</table>

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations, `O2`, for phase 1, and specify more advanced optimizations, `[Q]ipo`, during the phase 3 (final) compilation. The example shown above used `O2` in step 1 and `[Q]ipo` in step 3.

**NOTE**
The compiler ignores the `[Q]ipo` or `[Q]ip option during phase 1 with `[Q]prof-gen.
Profile Function or Loop Execution Time

This topic describes how to profile an application for function or loop execution time. Using the instrumentation method to profile function or loop execution time provides an easy means of getting a view of where cycles are being spent in your application. The Intel® compiler inserts instrumentation code into your application to collect the time spent in various locations. Such data helps you to identify hotspots that may be candidates for optimization tuning or targeting parallelization.

Different levels of instrumentation are available because of the difference in the overhead associated with the inserted probe points that read the CPU cycle counter. The instrumentation levels, in increasing amount of collected data, are grouped as follows:

- Function level
- Function and loop level

You do not need to profile the entire application but it is recommended that the same level of instrumentation is used for all instrumented files. Compile your application with the command line options described below for all the files that require profile information.

After the instrumented application is run, data files containing a summary of the collected data are created in the working directory. View these data files to identify the time proportions of the different parts of your application.

Compiler Options to Obtain Instrumented Program

Use the following command-line compiler options to instrument your application code to profile execution times for functions/loops. When you compile your application using any one of these options, you get an instrumented program.

<table>
<thead>
<tr>
<th>Instrumentation Level</th>
<th>Linux* or macOS* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function level</td>
<td>-profile-functions</td>
<td>/Qprofile-functions</td>
<td>Instruments function entry/exit points only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Inserts instrumentation calls on the function entry and exit points to collect the cycles spent within the function.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Data collection is supported for single-threaded applications only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- The collected data from execution of the instrumented application is placed in the file, loop_prof_funcs_&lt;timestamp&gt;.dump in the current working directory.</td>
</tr>
<tr>
<td>Function and loop level</td>
<td>-profile-loops=&lt;arg&gt;</td>
<td>/Qprofile-loops</td>
<td>Instruments function and loop entry/exit points:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;arg&gt;</td>
<td>- The &lt;arg&gt; argument allows you to specify the types of the loops to be instrumented. The &lt;arg&gt; value must be one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Inner: Instrument inner loops.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Outer: Instrument outer loops.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- All: Instrument both inner and outer loops.</td>
</tr>
<tr>
<td>Instrumentation Level</td>
<td>Linux* or macOS* Operating System</td>
<td>Windows* Operating System</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------</td>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Inserts instrumentation calls for function entry and exit points, and before and after instrumentable loops as listed in the <code>&lt;arg&gt;</code> argument.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>NOTE</strong> The compiler may be unable to instrument some loops.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Data collection is supported for single-threaded applications only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The collected data from execution of the instrumented application is placed in the files, <code>loop_prof_funcs_&lt;timestamp&gt;.dump</code> and <code>loop_prof_loops_&lt;timestamp&gt;.dump</code> in the current working directory for the function data and loop data, respectively.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>NOTE</strong> Because the instrumentation takes place after many compiler transformations have taken place, loops that have been restructured or replicated by the compiler may result in multiple entries in the generated reports. Additionally, functions may have been inlined into other functions, which may cause the same loop to be listed in multiple functions.</td>
</tr>
</tbody>
</table>

**Loop body level**

- `profile-loops-report= profile-loops-report=[n]`

  Controls level of instrumentation for loop bodies where:
  
  • Specifying `n=1` collects the cycle counts on entry and exits of loops. This is the default value if no value is specified for `n`.
  
  • Specifying `n=2` inserts additional instrumentation for collecting loop iteration counts to compute loop min/max and average iteration counts. Such instrumentation increases overhead in the instrumented application.
**Instrumentation Level**

<table>
<thead>
<tr>
<th>Linux* or macOS* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
</table>

**NOTE**
- Because instrumentation takes place after compiler transformations have taken place, the loop trip count is based on the generated form of the loop, which may be unrolled, and may be different from the original source form.
- This option is effective only when used with the `[Q]profile-loops` option enabled; it acts as a modifier of the `[Q]profile-loops` option.

**NOTE**
Because this instrumentation relies on the CPU time stamp counter for collecting timing information, only single threaded applications should be profiled with these options. Using these options with other compiler options that enable parallel code generation is not supported.

**Output Formats Obtained on Running Instrumented Program**

After compiling your application using the options, you obtain an instrumented program. Run this instrumented program with a representative set of data to create one or more data files.

The output files are produced by a routine that is registered with the `atexit()` routine, and are created only when the program exits via a standard exit procedure. Two formats of the output files are created:
- A plain text file using ‘tab’ delimiters, which can be viewed within a text editor or a spreadsheet.
- An XML data file that can be loaded into the data viewer application.

**Text Output Format**

The text output is written into separate files in the current directory. The filenames are `loop_prof_funcs_<timestamp>.dump` and `loop_prof_loops_<timestamp>.dump` for functions and loops respectively. The `<timestamp>` value is the same for both files to indicate they are from the same instrumentation run.

You can load the text files into a spreadsheet by specifying that the data is delimited with ‘tab’ delimiters.

The function report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (abs)</td>
<td>Total accumulated cycles spent between function entry and exit.</td>
</tr>
<tr>
<td>Time %</td>
<td>Percentage of total application time for cycles between function entry and exit.</td>
</tr>
<tr>
<td>Self (abs)</td>
<td>Accumulated cycles spent between function entry and exit less the cycles spent within calls to other instrumented functions.</td>
</tr>
<tr>
<td>Column Heading</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Self %</strong></td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td><strong>Call count</strong></td>
<td>Number of times the function was entered.</td>
</tr>
<tr>
<td><strong>Exit count</strong></td>
<td>Number of times the function exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a function without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
</tbody>
</table>
| **Loop ticks (%)** | The percentage of total application time for the self-time cycles of loops within the function. This field is relevant only when you use 
[Q]profile-loops compiler option. |
| **Function**   | Demangled function name |
| **File:line**  | Source file containing the code for the function, and the line number the function begins on. |

The loop report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Time (abs)</strong></td>
<td>Total accumulated cycles spent between loop entry and exit.</td>
</tr>
<tr>
<td><strong>Time %</strong></td>
<td>Percentage of total application time for cycles between loop entry and exit.</td>
</tr>
<tr>
<td><strong>Self (abs)</strong></td>
<td>Accumulated cycles spent between loop entry and exit less the cycles spent within calls to other instrumented functions/loops.</td>
</tr>
<tr>
<td><strong>Self %</strong></td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td><strong>Loop entries</strong></td>
<td>Number of times the loop was entered.</td>
</tr>
<tr>
<td><strong>Loop exits</strong></td>
<td>Number of times the loop exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a loop without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
<tr>
<td><strong>Min iteration counts</strong></td>
<td>The smallest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the [Q]profile-loops-report=2 compiler option.</td>
</tr>
<tr>
<td><strong>Avg iteration counts</strong></td>
<td>The average iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the [Q]profile-loops-report=2 compiler option.</td>
</tr>
<tr>
<td><strong>Max iteration counts</strong></td>
<td>The largest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the [Q]profile-loops-report=2 compiler option.</td>
</tr>
<tr>
<td><strong>Function</strong></td>
<td>Demangled function name that executed the loop; this may be different from the function that contained the loop source code, if that function was inlined into another function.</td>
</tr>
<tr>
<td><strong>Function file:line</strong></td>
<td>The name of the source file containing the function that executed the loop, and the line number the function begins on.</td>
</tr>
<tr>
<td>Column Heading</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Loop file:line</td>
<td>The name of the source file containing the loop body, and the line number the loop body begins on.</td>
</tr>
</tbody>
</table>

**XML Output Format**

The **INTEL_LOOP_PROF_XML_DUMP** environment variable is used to control the creation of the XML output format. When **INTEL_LOOP_PROF_XML_DUMP = 0**, no XML file is created.

The XML output file, named `loop_prof_<timestamp>.xml`, is written into the current directory. This file is viewed with the data viewer utility. The XML data file contains both the function and loop level data.

Remember, using the environment variable with a value of 0 implies that the data viewer utility is not going to be used since no XML data files are created.

**Data Viewer Utility**

You must have the Java Runtime Environment, version 1.6 or later installed on your system to use the data viewer utility. The JRE is not included with the Intel® Compiler package.

The Data Viewer displays the data collected for the functions and loops in a sequence of columns that allows for sorting of individual columns. The Data Viewer also provides the ability to filter the function or loops to only display items that meet some threshold amount (total time % or self-time %) of the total application time, or to only show loops that are associated with a particular function.

To launch the Data Viewer utility, or use the following commands from the command line:

**On Windows® operating system:**

```
loopprofileviewer[.bat] <datafile>
```

**On Linux® and macOS® operating systems:**

```
loopprofileviewer.sh <datafile>
```

or

```
loopprofileviewer.csh <datafile>
```
The main user interface displays an upper pane, **Function Profile**, containing function level data, and a lower pane, **Loop Profile**, containing loop level data. If the XML data file is created using only function level instrumentation, the lower pane is not displayed. Drag the separator between individual panes to resize them or click the up/down arrows available on the separator line.

The **Function Profile** pane and **Loop Profile** pane contain the set of columns described in the section, **Text Output Format**. Click on any of these columns to sort the data based on that column.

The Data Viewer utility has two specific menus - the **View** menu and the **Filter** menu - in the menu bar besides the generic **File** and **Help** menus.

**View Menu**

The **View** menu allows you to open a window that shows the source code for the line you have selected in the table (these menus are grayed out if no line is selected). To use the **View** menu:

1. Select a line in the **Function Profile** pane.
2. Go to **View > Function source for selected function** to see the source code for the selected function.
3. Select a line in the **Loop Profile** pane.
4. Go to **View > Function source for selected loop** to see the source code for the selected loop.
5. Go to **View > Loop source for selected loop** to see the source code for the selected loop.
NOTE The source code displayed is the current version of the file, in the directory the file was compiled from when the instrumentation compilation was performed.

When the cursor is within the Function Profile pane or the Loop Profile pane, right-click on any line to display a popup menu that gives access to these View menu options.

By default, the Data Viewer utility displays the most relevant columns based on the data file loaded. Go to View > Select Columns to display or hide the columns. In the dialog box that opens, columns not available for the currently loaded data file are grayed out.

Filter Menu

The Filter menu allows you to limit the data displayed in the tables to items that meet some criteria. As an example, you can use the Filter menu as follows:

1. Go to Filter > Function Profile > “Self time > 1.00%” to list only the functions in the Function Profile pane that represented more than 1.0 % of the application time.
2. Go to Filter > Set thresholds to modify the default thresholds used when enabling the filters for total time % or self-time %.

To display only the loops of a particular function, do the following:

1. Select a function in the Function column of the Function Profile pane.
2. Go to Filter > Loop Profile > Show loops for selected function to display the loops for the selected function.

When the cursor is within the Function Profile pane or the Loop Profile pane, you can right-click any function to display a popup menu that gives access to these Filter menu options.

Profile-Guided Optimization Report

The PGO report can help identify where and how the compiler used profile information to optimize the source code. The PGO report can also identify where profile information was discarded due to source code changes made between the time of instrumentation and feedback steps. The PGO report is most useful when combined with the PGO compilation steps outlined in the topic, Profile an Application with Instrumentation. Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including -prof-use (Linux* and macOS*) or /Qprof-use (Windows*). The following syntax examples demonstrate how to run the report using the combined options.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>macOS*</td>
<td>icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /Qprof-use /Qopt-report-phase:pgo pgotools_sample.c</td>
</tr>
</tbody>
</table>

By default the PGO report generates a medium level of detail (where the [Q]opt-report argument \( n=2 \)). You can use the -qopt-report=\( n \) (Linux and macOS*) or /Qopt-report:\( n \) option along with the [Q]opt-report-phase option if you want a greater or lesser level of diagnostic detail.
The output, by default, comes out to a file with the same name as the object file but with an .optrpt extension and is written into the same directory as the object file. Using the entries in the example above, the output file will be pgotools_sample.optrpt. Use the -qopt-report-file (Linux and macOS*) or the /Qopt-report-file (Windows) option to specify any other name for the output file that captures the report results, or to specify that the output should go to stdout or stderr.

Profile an Application

PGO API Support

The Profile-Guided Optimizations (PGO) API lets you control the generation of profile information during the instrumented execution phase of profile-guided optimizations.

A set of functions and an environment variable comprise the PGO API. The remaining topics in this section describe the associated functions and environment variables.

The compiler sets a define for the _PGO_INSTRUMENT pre-processor macro when you compile with [Q]prof-gen options, to instrument your code. Without instrumentation, the PGO API functions cannot provide PGO API support.

Normally, profile information is generated by an instrumented application when it terminates by calling the standard exit() function.

To ensure that profile information is generated, the functions described in this section may be necessary or useful in the following situations:

- The instrumented application exits using a non-standard exit routine.
- The instrumented application is a non-terminating application: exit() is never called.
- The application requires control of when the profile information is generated.

You can use the PGO API functions in your application by including the pgouser.h header file at the top of any source file where the functions may be used.

Example

```c
#include <pgouser.h>
```

NOTE
You do not need to remove the PGO API functions from your code when you have completed the instrumentation step. Changes to the source code at this stage could inhibit obtaining profile data feedback on the routines that were modified. For the instrumentation step (using -[Q]prof-gen or -[Q]prof-gen:<aug> option, where <aug> can be srcpos, globdata, or default), the definition for the _PGO_INSTRUMENT macro is automatically set, allowing instrumentation library routines to be used. For the production step (using -[Q]prof-use option), the definition for the _PGO_INSTRUMENT macro is removed, allowing profile data to be fed back.
The Profile IGS Environment Variables

The environment variable for PGO API is `INTEL_PROF_DUMP_INTERVAL`. This environment variable may be used to initiate Interval Profile Dumping in an instrumented user application.

The environment variable `INTEL_PROF_DUMP_CUMULATIVE` can be used to provide additional control over the internal profiling dumping behavior.

The environment variable, `INTEL_PROF_DYN_PREFIX`, allows specifying a prefix string that is used for naming the `.dyn` files. If this variable is defined then the `.dyn` files will be named as 

```
<prefix>_<timestamp>_<pid>.dyn
```

instead of the default naming convention of

```
<timestamp>_<pid>.dyn
```

This can be useful for identifying `.dyn` files produced by specific training sets.

[Q]prof-gen

Resetting Profile Information

The `_PGOPTI_Prof_Reset_All()` function clears the profile information collected by the instrumented application. The prototype of the function call is listed below.

During a run of an instrumented executable, a segment is maintained for each routine executed during that run, storing the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the `_PGOPTI_Prof_Reset()` function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

### Syntax

```
void _PGOPTI_Prof_Reset_All(void);
```

The older version of this function, `_PGOPTI_Prof_Reset()`, is deprecated.

When `_PGOPTI_Prof_Reset_All()` function is called, it insures that all the counters within the main application and all the instrumented shared libraries are cleared. All the counters for block execution counts and value profiling information is reset to 0.

**NOTE**

For routines that were in progress when the reset call was made, the counts for portions of the routine that executed following the call to the reset function may have higher counts than portions of the routine that executed prior to the reset call.

Dumping Profile Information

The `_PGOPTI_Prof_Dump_All()` function dumps the profile information collected by the instrumented application. The prototype of the function call is listed below.

### Syntax

```
void _PGOPTI_Prof_Dump_All(void);
```

An older version of this function, `_PGOPTI_Prof_Dump()`, is deprecated and no longer used.
The new function, `_PGOPTI_Prof_Dump_All()`, operates much like the deprecated function, except on Linux* operating systems, when it is used in connection with shared libraries (.so). When `_PGOPTI_Prof_Dump_All()` is called, it insures that a .dyn file is created for all shared libraries needing to create a .dyn file. Use `_PGOPTI_Prof_Dump_All()` on Linux OS to insure portability and correct functionality.

The profile information is generated in a .dyn file (generated in phase 2 of PGO).

The environment variables that affect the `_PGOPTI_Prof_Dump_All()` function are PROF_DIR, COV_DIR, PROF_DPI, and COV_DPI. Set the PROF_DIR or COV_DIR environment variable to specify the directory to which the .dyn file must be stored. Alternately, you can use the -[Q]prof_dir compiler option, when building with -[Q]prof-gen, to specify this directory without setting the PROF_DIR or COV_DIR variable. Set the PROF_DPI or COV_DPI environment variables to specify an alternative .dpi filename. The default filename is pgopti.dpi. You can also use the -prof_dpi profmerge tool option, when merging the .dyn files, to specify the filename for the summary .dpi file.

**Recommended Usage**

If your application does not use a standard exit() call, insert a single call to this function in the body of the function that terminates the user application. Normally, `_PGOPTI_Prof_Dump_All()` should be called just once. It is also possible to use this function in conjunction with `_PGOPTI_Prof_Reset_All()` function to generate multiple .dyn files (presumably from multiple sets of input data).

**NOTE**

If the data is not reset between the dumps with a call to the `_PGOPTI_Prof_Reset_All()` function, the counters will continue accumulating data, resulting in the subsequent .dyn file containing data that was previously dumped.

### Example

```c
#include <pgouser.h>
void process_data(int foo) {}
int get_input_data() { return 1; }
int main(void)
{
    // Selectively collect profile information for the portion
    // of the application involved in processing input data.
    int input_data = get_input_data();
    while (input_data) {
        _PGOPTI_Prof_Reset_All();
        process_data(input_data);
        _PGOPTI_Prof_Dump_All();
        input_data = get_input_data();
    }
    return 0;
}
```

### Interval Profile Dumping

The `_PGOPTI_Set_Interval_Prof_Dump()` function activates Interval Profile Dumping and sets the approximate frequency at which dumps occur. This function is used in non-terminating applications.

The prototype of the function call is listed below.

**Syntax**

```c
void _PGOPTI_Set_Interval_Prof_Dump(int interval);
```
This function is used in non-terminating applications.

The `interval` parameter specifies the time interval at which profile dumping occurs and is measured in milliseconds. For example, if interval is set to 5000, then a profile dump and reset will occur approximately every 5 seconds. The interval is approximate because the time-check controlling the dump and reset is only performed upon entry to any instrumented function in your application.

Setting the interval to zero or a negative number will disable interval profile dumping, and setting a very small value for the interval may cause the instrumented application to spend nearly all of its time dumping profile information. Be sure to set interval to a large enough value so that the application can perform actual work and substantial profile information is collected.

The following example demonstrates one way of using interval profile dumping in non-terminating code.

```
#include <stdio.h>
// The next include is to access
// _PGOPTI_Set_Interval_Prof_Dump_All
#include <pgouser.h>

int returnValue() { return 100; }

int main() {
    int ans;
    printf("CTRL-C to quit.\n");
    _PGOPTI_Set_Interval_Prof_Dump(5000);
    while (1)
        ans = returnValue();
}
```

You can compile the code shown above by entering commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>icc -prof-gen -o intrumented_number number.c</td>
</tr>
<tr>
<td>macOS*</td>
<td>icc -prof-gen -o intrumented_number number.c</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /Qprof-gen /Finstrumented_number number.c</td>
</tr>
</tbody>
</table>

When compiled, the code shown above will dump profile information a `.dyn` file about every five seconds until the program is ended.

You can use the `profmerge` and `proforder` Tools tool to merge the `.dyn` files.

**Recommended usage**

Call this function at the start of a non-terminating user application to initiate interval profile dumping. Note that an alternative method of initiating interval profile dumping is by setting the environment variable `INTEL_PROF_DUMP_INTERVAL` to the desired interval value prior to starting the application.

Using interval profile dumping, you should be able to profile a non-terminating application with minimal changes to the application source code.

To control the behavior during dumping, you may use the environment variable `INTEL_PROF_DUMP_CUMULATIVE`. When `INTEL_PROF_DUMP_INTERVAL` or the API routine `_PGOPTI_SET_INTERVAL_PROF_DUMP` are used without `INTEL_PROF_DUMP_CUMULATIVE`, the counters are reset after each dump, and a new `.dyn` file will be created containing the data collected during each interval. This may result in a potentially large number of `.dyn` files that need to be stored and merged together by profmerge.
When INTEL_PROF_DUMP_CUMULATIVE is set (to any value), the .dyn file dump will be created at a specified interval as before, but the data will not be reset following the dump, and only the most recent .dyn file will be kept on the file system. This allows for the ability to create a .dyn file for a non-terminating application that contains all the accumulated counts to that point, but without the need for storage and merging of a large set of .dyn files.

**Resetting the Dynamic Profile Counters**

The _PGOPTI_Prof_Reset() function resets the dynamic profile counters. The prototype of the function call is listed below.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>void _PGOPTI_Prof_Reset(void);</td>
</tr>
</tbody>
</table>

This function is now deprecated. See _PGOPTI_Prof_Reset_All() function, which can be used instead.

One of the activities performed under profile-guided optimization is value-profiling. With value-profiling, the compiler inserts instrumentation to obtain a sample of the variable values in the program. Based upon this sampling, the compiler optimizes the user's code using frequently observed values.

In effect, during a run of an instrumented executable, the segment maintained for each routine executed during that run stores the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the _PGOPTI_Prof_Reset() function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

**Recommended Usage**

Use this function to clear the profile counters prior to collecting profile information on a section of the instrumented application. See the example under Dumping Profile Information.

**Dumping and Resetting Profile Information**

The _PGOPTI_Prof_Dump_And_Reset() function dumps the profile information to a new .dyn file and then resets the dynamic profile counters. Then the execution of the instrumented application continues.

The prototype of the function call is listed below.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>void _PGOPTI_Prof_Dump_And_Reset(void);</td>
</tr>
</tbody>
</table>

This function is used in non-terminating applications and may be called more than once. Each call will dump the profile information to a new .dyn file.

**Recommended Usage**

Periodic calls to this function enables a non-terminating application to generate one or more profile information files (.dyn files). These files are merged during the feedback phase of profile-guided optimizations. The direct use of this function enables your application to control precisely when the profile information is generated.
Getting Coverage Summary Information on Demand

This API is supported only on Linux* OS for C/C++ applications. The _PGOPTI_Get_Coverage_Info() function gets the basic-block and line coverage percentage for each instrumented file while the application is running.

The prototype of the function call is given below.

**Syntax**

```c
int _PGOPTI_Get_Coverage_Info(PGOPTI_COVERAGE_SUMMARY *coverage_array);
```

This API provides on-demand coverage information for all the files that get profiled. The coverage information is stored in a dynamically allocated array of structures, a pointer to which is returned in the argument `coverage_array`. The return value of the call is the number of elements in this array.

You can use the coverage information as needed but you are responsible for freeing up the dynamically allocated coverage array.

You can also choose to print the on-demand coverage information onto the terminal screen as shown in the example below.

```c
#include <pgouser.h>
void Coverage_Summary(void)
{
    int index, num_files;
    PGOPTI_COVERAGE_SUMMARY coverage_array, curp;
    // Get coverage summary information and print it out
    num_files = _PGOPTI_Get_Coverage_Info(&coverage_array);
    for (index = 0; index < num_files; index++) {
        curp = &coverage_array[index];
        printf( "%s ", curp->file_name);
        printf( "Block coverage percent: %u, ", curp->coverage_percent);
        printf( "Line coverage percent: %u\n", curp->line_coverage_percent);
        free(curp->file_name);
    }
    if (num_files > 0) {
        free(coverage_array);
    }
}
```

---

**High-Level Optimization (HLO)**

High-level Optimizations (HLO) exploit the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. While the default optimization level, option `O2`, performs some high-level optimizations, specifying the `O3` option provides the best chance for performing loop transformations to optimize memory accesses.

**NOTE**

Loop optimizations may result in calls to library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The optimizations performed can also be affected by certain options, such as `/arch (Windows*)`, `-m (Linux* and macOS*)`, or `[Q]x options. Additional HLO transformations may be performed for Intel® microprocessors than for non-Intel microprocessors.
Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Predicate Optimization
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Malloc Combining and Memset Combining, Memory Layout Change
- Loop Rerolling
- Memset and Memcpy Recognition
- Statement Sinking for Creating Perfect Loopnests
- Multiversioning: Checks include Dependency of Memory References, and Trip Counts
- Loop Collapsing

**Interprocedural Optimization (IPO)**

Interprocedural Optimization (IPO) is an automatic, multi-step process that allows the compiler to analyze your code to determine where you can benefit from specific optimizations.

The compiler may apply the following optimizations:

- Address-taken analysis
- Array dimension padding
- Alias analysis
- Automatic array transposition
- Automatic memory pool formation
- C++ class hierarchy analysis
- Common block variable coalescing
- Common block splitting
- Constant propagation
- Dead call deletion
- Dead formal argument elimination
- Dead function elimination
- Formal parameter alignment analysis
- Forward substitution
- Indirect call conversion
- Inlining
- Mod/ref analysis
- Partial dead call elimination
- Passing arguments in registers to optimize calls and register usage
- Points-to analysis
- Routine key-attribute propagation
- Specialization
- Stack frame alignment
- Structure splitting and field reordering
- Symbol table data promotion
- Un-referenced variable removal
- Whole program analysis
IPO Compilation Models

IPO supports two compilation models - single-file compilation and multi-file compilation.

Single-file compilation uses the [Q]ip compiler option, and results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the O2 default optimization level; additionally the compiler may perform some inlining for the O1 optimization level, such as inlining functions marked with inlining pragmas or attributes (GNU C and C++) and C++ class member functions with bodies included in the class declaration.

Multi-file compilation uses the [Q]ipo option, and results in one or more mock object files rather than normal object files. (See the Compilation section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files.

NOTE
Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see Profile an Application.

Compiling with IPO

As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file. The mock object files contain the IR instead of the normal object code. Mock object files can be ten times or more larger than the size of normal object files.

During the IPO compilation phase only the mock object files are visible.

Linking with IPO

When you link with the [Q]ipo compiler option the compiler is invoked a final time. The compiler performs IPO across all mock object files. The mock objects must be linked with the Intel compiler or by using the Intel linking tools. While linking with IPO, the Intel compilers and other linking tools compile mock object files as well as invoke the real/true object files linkers provided on the user’s platform.

Link-time optimization using the -ffat-lto-objects compiler option is provided for GCC compatibility. During IPO compilation, you can specify -ffat-lto-objects option, for the compiler to generate a fat link-time optimization (LTO) object that has both a real/true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.

You can specify the -fno-fat-lto-objects option for the compiler to generate a link-time optimization (LTO) object that only has a discardable intermediate language section; no real/true object is generated. These files are inserted into archives in the form in which they were created. Using this option may improve compilation time and save space for objects.

If you use ld rather than xild to link objects or ar instead of xiar to create an archive, the real/true object, generated during fat link-time optimization guarantees that there will be no impediment to linking/building the archive. However, cross-file optimizations are lost in this case. The extra true object also takes additional space and takes compile time to generate it, so using -fno-fat-lto-objects compiler option is an advantage provided that you link the IPO mock object files with xild and archive them with xiar.

Whole Program Analysis

The compiler supports a large number of IPO optimizations that can be applied or have its effectiveness greatly increased when the whole program condition is satisfied.
During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis - object reader method and table method. Most optimizations can be applied if either type of whole program analysis determines that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

**Object reader method**

In the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

**Table method**

In the table method the compiler analyzes the mock object files and generates a call-graph.

The compiler contains detailed tables about all of the functions for all important language-specific libraries, like *libc*. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls by finding an entry for each unresolved function in the compiler tables. If the compiler can resolve the functions call, the whole program condition exists.

Using IPO

**Using IPO**

This topic discusses how to use IPO from the command line.

**Compiling and Linking Using IPO**

To enable IPO, you first compile each source file, then link the resulting source files. First, compile your source files with [Q]ipo compiler as shown below:
### Operating System Example Command

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>icpc -ipo -c a.cpp b.cpp c.cpp</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /Qipo /c a.cpp b.cpp c.cpp</td>
</tr>
</tbody>
</table>

The output of the above example command differs according to operating system:

- **Linux and macOS***: The commands produce a.o, b.o, and c.o object files.
- **Windows**: The commands produce a.obj, b.obj, and c.obj object files.

Use the c compiler option to stop compilation after generating .o or .obj files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.

Second, link the resulting files. The following example command will produce an executable named app:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>icpc -o app a.o b.o c.o</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Feapp a.obj b.obj c.obj</td>
</tr>
</tbody>
</table>

The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the xild (Linux and macOS*) or xilink (Windows) tool, with the appropriate linking options.

### Combining the Steps

The separate compile and link commands demonstrated above can be combined into a single command, as shown in the following examples:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>icpc -ipo -o app a.cpp b.cpp c.cpp</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Qipo /Feapp a.cpp b.cpp c.cpp</td>
</tr>
</tbody>
</table>

The icl/icpc command, shown in the examples above, calls GCC ld (Linux and macOS*) or link.exe (Windows only) to link the specified object files and produce the executable application, which is specified by the -o (Linux and macOS*) or /Fe (Windows) option.

**NOTE**

- **Linux**: Using icpc allows the compiler to use standard C++ libraries automatically; icc will not use the standard C++ libraries automatically.
- **macOS***: Using icc/icpc commands allows the compiler to use libc++ libraries, by default. You can switch to using the GNU implementation of the standard C++ library using the -stdlib=libstdc++ compiler option.
- The Intel linking tools emulate the behavior of compiling at -O0 (Linux and macOS*) and /Od (Windows) option.
- If multiple file IPO is applied to a series of object files, no one which are mock object files, no multi-file IPO is performed. The object files are simply linked with the linker.

### Capturing Intermediate IPO Output

The [Q]ipo-c and [Q]ipo-S compiler options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.
• Use the `ipo-c` compiler option to optimize across files and produce an object file. The option performs optimizations as described for the `ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.o` (Linux and macOS*) or `ipo_out.obj` (Windows).

• Use the `ipo-S` compiler option to optimize across files and produce an assembly file. The option performs optimizations as described for `ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and macOS*) or `/Fe` (Windows) option to specify a different name.

These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and macOS*) or `/Fe` (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and macOS*) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `ipo-c` option, but you will not get the full benefit of whole program optimizations if you use this option.

The object file created using the `ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. Whole program optimizations, which require a knowledge of how the real object file will be linked in with other files to produce and object, are not applied.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

**Using -auto-ilp32 (Linux* OS) or /Qauto-ilp32 (Windows* OS) Option**

On Linux systems based on Intel® 64 architecture, the `auto-ilp32` option has no effect unless you specify SSE3 or a higher suffix for the `x` option.

**See Also**

**IPO-Related Performance Issues**

There are some general optimization guidelines for using IPO that you should keep in mind:
• Using IPO on very large programs might trigger internal limits of other compiler optimization phases.
• Combining IPO and PGO can be a key technique for optimizing C++ applications. The O3, [Q]ipo, and [Q]prof-use compiler options may result in performance gains.
• Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to these general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

• Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. The Intel® Compiler cannot inspect mock object files generated by other compilers for optimization opportunities.
• Do not link mock files with the [Q]prof-use compiler option unless the mock files were also compiled with the [Q]prof-use compiler option.
• Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and macOS*, replace all instances of ld with xild; for Windows, replace all instances of link with xilink.

prof-use, Qprof-use

IPO for Large Programs

In most cases, IPO generates a single true object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use [Q]ipo compiler option on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple true object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

• Use the [Q]ipoN compiler option and pass an integer value in the place of N.
• Use the [Q]ipo-separate compiler option.

The number of true object files generated by the link-time compilation is invisible to you unless the [Q]ipo-c or [Q]ipo-S compiler option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the desired results then experiment with generating a different number of object files.

You can use the [Q]ipo-jobs compiler option to control the number of processes, or jobs, executed during parallel IPO builds.

Using [Q]ipoN to Create Multiple Object Files

If you specify [Q]ipo0, which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications. If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass a value that exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files.

The following example commands demonstrate how to use [Q]ipo2 option to compile large programs.
<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td><code>icl /Qipo2 /c a.cpp b.cpp</code></td>
</tr>
<tr>
<td>Linux*</td>
<td><code>icpc -ipo2 -c a.cpp b.cpp</code></td>
</tr>
<tr>
<td>macOS*</td>
<td><code>icpc -ipo2 -c a.cpp b.cpp</code></td>
</tr>
</tbody>
</table>

In executing the above commands, the compiler generates object files using an OS-dependent naming convention. On Linux* and macOS*, the example command results in object files named `ipo_out.o`, `ipo_out1.o`, and `ipo_out2.o`. On Windows*, the file names follow the same convention; however, the file extensions will be `.obj`.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

**Creating the Maximum Number of Object Files**

Using `[Q]ipo-separate` allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation. The maximum number of true object files is equal to the number of mock object files passed on the link line.

For example, you can pass example commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td><code>Icl -Qipo-separate -Qipo-c a.obj b.obj c.obj</code></td>
</tr>
<tr>
<td>Linux*</td>
<td><code>icpc -ipo-separate -ipo-c a.o b.o c.o</code></td>
</tr>
<tr>
<td>macOS*</td>
<td><code>icpc -ipo-separate -ipo-c a.o b.o c.o</code></td>
</tr>
</tbody>
</table>

The compiler generates multiple object files that use the same naming convention discussed above.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

**Understanding Code Layout and Multi-Object IPO**

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system:

Windows:
• The first routine is placed in `.text$00001`, the second is placed in `.text$00002`, and so on.

Linux:
• The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on.

Creating a Library from IPO Objects

Linux* and macOS*
Libraries are often created using a library manager such as `xiar` for Linux*/macOS* or `xilib` for Windows. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xiar cru user.a a.o b.o</code></td>
</tr>
</tbody>
</table>

The above command creates a library named `user.a` containing the `a.o` and `b.o` objects.

If the objects have been created using `[Q]ipo -c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icc -ipo -c a.cpp b.cpp</code></td>
</tr>
</tbody>
</table>

The commands generate mock objects files, which when placed in archive will also be accompanied by a true object file.

Using `xiar` is the same as specifying `xild -lib`.

macOS* Only
When using `xilibtool`, specify `-static` to generate static libraries, or specify `dynamic` to create dynamic libraries. For example, the following command will create a static library named `mylib.a` that includes the `a.o`, `b.o`, and `c.o` objects.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xilibtool -static -o mylib.a a.o b.o c.o</code></td>
</tr>
</tbody>
</table>

Alternately, the following example command will create a dynamic library named `mylib.dylib` that includes the `a.o`, `b.o`, and `c.o` objects.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xilibtool -dynamic -o mylib.dylib a.o b.o c.o</code></td>
</tr>
</tbody>
</table>

Specifying `xilibtool` is the same as specifying `xild -libtool`.
Windows* Only
Create libraries using xilib or xilink -lib to create libraries of IPO mock object files and link them on the command line.

For example, assume that you create three mock object files by using a command similar to the following:

```
Example
icl /c /Qipo a.cpp b.cpp c.cpp
```

Further assume a.obj contains the main subprogram. You can enter commands similar to the following to create a library.

```
Example
xilib -out:main.lib b.obj c.obj
or
xilink -lib -out:main.lib b.obj c.obj
```

You can link the library and the main program object file by entering a command similar to the following:

```
Example
xilink -out:result.exe a.obj main.lib
```

Requesting Compiler Reports with the xi* Tools
The compiler options qopt-report (Linux* and macOS*) and [Q]opt-report (Windows*) generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a file (instead of stderr), and request reports from all routines with names containing a specific string as part of their name.

The xi* tools are used with inter-procedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported xi* tools are:

- Linker tools: xilink (Windows*) and xild (Linux* and macOS*)
- Library tools: xilib (Windows*), xiar (Linux* and macOS*), xilibtool (macOS*)

The following tables lists the compiler report options that can be used with the xi* tools during the final IPO compilation.

<table>
<thead>
<tr>
<th>Optimization Report Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-qopt-report[=n] (Linux* and macOS*)</td>
<td>Enables optimization report generation with different levels of detail. Valid values for ( n ) are 0 through 5. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail. Higher numbers give greater levels of detail.</td>
</tr>
<tr>
<td>/Qopt-report[:n] (Windows*)</td>
<td></td>
</tr>
</tbody>
</table>

### Optimization Report Option

<table>
<thead>
<tr>
<th>Optimization Report Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-qopt-report-file=filename</code> (Linux* and macOS*)</td>
<td>Generates an optimization report and directs the report output to the specified file name. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.</td>
</tr>
<tr>
<td><code>/Qopt-report-file:filename</code> (Windows*)</td>
<td></td>
</tr>
<tr>
<td><code>-qopt-report-phase=[list]</code> (Linux* and macOS*)</td>
<td>Specifies a comma separated list of optimization phases to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phases by using the <code>/Qopt-report-help</code> option.</td>
</tr>
<tr>
<td><code>/Qopt-report-phase:[list]</code> (Windows*)</td>
<td></td>
</tr>
<tr>
<td><code>-qopt-report-routine=substring</code> (Linux* and macOS*)</td>
<td>Generates reports for all routines with names containing substring as part of their name. You can also specify a sequence of substrings separated by commas. If you do this, the compiler generates an optimization report for each of the routines whose name contains one or more of these substrings. If substring is not specified, the compiler generates reports on all routines.</td>
</tr>
<tr>
<td><code>/Qopt-report-routine:substring</code> (Windows*)</td>
<td></td>
</tr>
<tr>
<td><code>-qopt-report-filter=string</code> (Linux* and macOS*)</td>
<td>Tells the compiler to find the indicated parts of your application specified by string, and generate optimization reports for them. If both <code>-qopt-report-routines=string1</code> and <code>-qopt-report-filter=string2</code> are specified, it is treated as <code>-qopt-report-filter=string1;string2</code>.</td>
</tr>
<tr>
<td><code>/Qopt-report-filter:string</code> (Windows*)</td>
<td></td>
</tr>
<tr>
<td><code>-qopt-report-help</code> (Linux* and macOS*)</td>
<td>Displays the optimization phases available to use when using the <code>-qopt-report-phase</code> (Linux* and macOS*) or <code>/Qopt-report-phase</code> (Windows*) or option.</td>
</tr>
<tr>
<td><code>/Qopt-report-help</code> (Windows*)</td>
<td></td>
</tr>
<tr>
<td><code>-qopt-report-names</code> (Linux* and macOS*)</td>
<td>Specifies whether mangled or unmangled names appear in the optimization report. If this option is not specified, unmangled names are used by default. If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing. If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing. If you use this option, you do not have to specify option <code>-qopt-report</code> (Linux* OS and macOS*) or <code>/Qopt-report</code> (Windows* OS).</td>
</tr>
<tr>
<td><code>/Qopt-report-names</code> (Windows*)</td>
<td></td>
</tr>
</tbody>
</table>

Inline Expansion of Functions

Inline function expansion does not require that the applications meet the criteria for whole program analysis normally required by IPO; so this optimization is one of the most important optimizations done in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the Intel® compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion is performed on relatively small user functions more often than on functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying the [Q]ip compiler option, single-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying the [Q]ipo compiler option, multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

Caution
Using the [Q]ip and [Q]ipo (Windows*) options can, in some cases, significantly increase compile time and code size.

The Intel compiler does a certain amount of inlining at the default level. Although such inlining is similar to what is done when you use the [Q]ip option, the amount of inlining done is generally less than when you use the option.

Selecting Routines for Inlining

The compiler attempts to select the routines whose inline expansions provide the greatest benefit to program performance. The selection is done using default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use options for Profile-Guided Optimizations (PGO): [Q]prof-use compiler option.

When you use PGO with [Q]ip or [Q]ipo (Windows), the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

Using IPO with PGO

Combining IPO and PGO typically produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.
**Inline Expansion of Library Functions**

By default, the compiler automatically inlines (expands) a number of standard and math library functions at the point of the call to that function, which usually results in faster computation.

Many routines in the libirc, libm, or the svml library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.

The `-fno-builtin` (Linux* and macOS*) or the `/Qno-builtin-<name>` and `/Oi-` (Windows) options disable inlining for intrinsic functions and disable the by-name recognition support of intrinsic functions and the resulting optimizations. The `/Qno-builtin-<name>` option provides the ability to disable inlining for intrinsic functions, fine-tuning the functionality of the `/Oi-` option, which disables almost all intrinsic functions when used. Use these options if you redefine standard library routines with your own version and your version of the routine has the same name as the standard library routine.

**Inlining and Function Preemption (Linux)**

You must specify `fpic` to use function preemption. By default the compiler does not generate the position-independent code needed for preemption.

---

**Compiler Directed Inline Expansion of Functions**

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance. See Inline Expansion of Functions for more information.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits.

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inline-level</code> (Linux* and macOS*) or <code>Ob</code> (Windows*)</td>
<td>Specifies the level of inline function expansion.</td>
</tr>
<tr>
<td></td>
<td>Note that the option <code>/Ob2</code> on Windows* is equivalent to <code>-inline-level=2</code> on Linux* and macOS*. Allowed values are 0, 1, and 2.</td>
</tr>
<tr>
<td><code>[Q]ip-no-inlining</code></td>
<td>Disables only inlining enabled by the <code>[Q]ip</code>, <code>[Q]ipo</code>, or <code>Ob2</code> options.</td>
</tr>
<tr>
<td><code>[Q]ip-no-pinlining</code></td>
<td>Disables partial inlining enabled by the <code>[Q]ip</code> or <code>[Q]ipo</code> options.</td>
</tr>
<tr>
<td></td>
<td>No other IPO optimizations are disabled.</td>
</tr>
<tr>
<td><code>fno-builtin</code> (Linux* and macOS*) or <code>Oi-</code> (Windows)</td>
<td>Disables inlining for intrinsic functions. Disables the by-name recognition support of intrinsic functions and the resulting optimizations. Use this option if</td>
</tr>
</tbody>
</table>
Option | Effect
---|---
you redefine standard library routines with your own version and your version of the routine has the same name as the standard library routine.
By default, the compiler automatically inlines (expands) a number of standard and math library functions at the point of the call to that function, which usually results in faster computation.
Many routines in the libirc, libm, or svml library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.
Indicates that the source position information for an inlined function should be retained, rather than replaced, by that of the call which is being inlined.

### Developer Directed Inline Expansion of User Functions
In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options and pragmas that allow you to more precisely direct when and if inline function expansion should occur.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

Typically, the compiler targets functions that have been marked for inlining based on the following:

- **Inlining keywords**: indicates to the compiler to inline the specified function. For example, __inline, __forceinline.
- **Procedure-specific inlining pragmas**: indicates to the compiler to inline calls within the targeted procedure if it is legal to do so. For example, #pragma inline or #pragma forceinline.
- **GCC function attributes for inlining**: indicates to the compiler to inline the function even when no optimization level is specified. For example, __attribute__((always_inline)).

The following developer directed inlining options and pragmas provide the ability to change the boundaries used by the inliner to distinguish between small and large functions.
In general, you should use the \texttt{[Q]inline-factor} option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

If your code hits an inlining limit, the compiler issues a warning at the highest warning level. The warning specifies which of the inlining limits have been hit, and the compiler option and/or pragmas needed to get a full report. For example, you could get a message as follows:

\texttt{Inlining inhibited by limit max-total-size. Use -qopt-report -qopt-report-phase=ipo for full report.}

Messages in the report refer directly to the command line options or pragmas that can be used to overcome the limits.

The following table lists the options you can use to fine-tune inline expansion of functions. The pragmas associated with the options are documented in the \texttt{Effect} column.

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{[Q]inline-factor}</td>
<td>Controls the multiplier applied to all inlining options that define upper limits: inline-max-size, inline-max-total-size, inline-max-per-routine, and inline-max-per-compile. While you can specify an individual increase in any of the upper-limit options, this single option provides an efficient means of controlling all of the upper-limit options with a single command. By default, this option uses a multiplier of 100, which corresponds to a factor of 1. Specifying 200 implies a factor of 2, and so on. Experiment with the multiplier carefully. You could increase the upper limits to allow too much inlining, which might result in your system running out of memory.</td>
</tr>
<tr>
<td>\texttt{[Q]inline-forceinline}</td>
<td>Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so. Without this option, the compiler treats functions declared with the \texttt{__inline} keyword as merely being recommended for inlining. When this option is used, it is as if they were declared with the \texttt{__forceinline} keyword.</td>
</tr>
<tr>
<td>\texttt{[Q]inline-min-size}</td>
<td>Redefines the maximum size of small routines; routines that are equal to or smaller than the value specified are more likely to be inlined.</td>
</tr>
<tr>
<td>\texttt{[Q]inline-max-size}</td>
<td>Redefines the minimum size of large routines; routines that are equal to or larger than the value specified are less likely to be inlined.</td>
</tr>
<tr>
<td>\texttt{[Q]inline-max-total-size}</td>
<td>Limits the expanded size of inlined functions. You can also use \texttt{#pragma optimization_parameter inline-max-total-size=N} to control the size an individual routine can grow through inlining.</td>
</tr>
<tr>
<td>\texttt{[Q]inline-max-per-routine}</td>
<td>Limits the number of times inlining can be applied within a routine. You can also use \texttt{#pragma optimization_parameter inline-max-per-routine} to control the number of times inlining may be applied to a routine.</td>
</tr>
<tr>
<td>Option</td>
<td>Effect</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>[Q]inline-max-per-compile</td>
<td>Limits the number of times inlining can be applied within a compilation unit. The compilation unit limit depends on whether or not you specify the [Q]ipo compiler option. If you enable IPO, all source files that are part of the compilation are considered one compilation unit. For compilations not involving IPO each source file is considered an individual compilation unit.</td>
</tr>

**Inlining Report**

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler examines the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

The Inlining Report is part of the Opt Report. The compiler options -qopt-report [Linux* and macOS*] and -Qopt-report [Windows*] generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a specific file, stdout or stderr, and request reports from all routines with names containing a specific string as part of their name.

The inlining report is a description of the inlining choices that were made for each routine that is compiled in the program. It is produced as part of the opt report. To restrict the opt report to contain ONLY the inlining report, use the option -qopt-report-phase=ipo [Linux* and macOS*] or -Qopt-report-phase:ipo [Windows*].

The user can control the amount of information by specifying a level for the inlining report. The level is shown by a number from 1 to 5. Level 1 contains the smallest amount of information, and each level adds information to the report. Level 2 is the default report.

<table>
<thead>
<tr>
<th>Level</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1</td>
<td>Shows each call that was inlined</td>
</tr>
<tr>
<td>Level 2 (default report)</td>
<td>Shows the values of the key inlining options</td>

<tr>
<td>Level 3</td>
<td>Shows the calls to routines with external linkage</td>
</tr>
<tr>
<td>Level 4</td>
<td>Shows:</td>
</tr>
<tr>
<td></td>
<td>• Whole program information</td>
</tr>
<tr>
<td></td>
<td>• Size (sz) of the each routine inlined and the increase in application size (isz) due to each instance of inlining</td>
</tr>
<tr>
<td></td>
<td>• Routine percentages</td>
</tr>
<tr>
<td></td>
<td>• Calls that are not inlined</td>
</tr>
<tr>
<td>Level 5</td>
<td>Shows inlining footnotes, which contain advice on how to change the inlining to potentially improve application performance</td>
</tr>
</tbody>
</table>
The inlining report gives you an in-depth overview of the compiler's inlining decisions, which occur within five levels of granularity. You can specify levels with `-qopt-report=1`, `-qopt-report=2`, etc., [Linux* and macOS*] or `-Qopt-report=1`, `-Qopt-report=2`, etc. [Windows*]. See below for specific level details.

**Level 1**
The Inlining Report is activated when you run the Opt Report, using `-qopt-report.`

For each routine you compile, you get one report with the title INLINE REPORT that shows the calls inlined into that routine.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The report gives the name of the compiled routine (APPLU), and contains one line for each call that the compiler decided to inline or not inline. In the above report, the compiler made 15 inlining decisions for calls in the routine APPLU. It decided to inline 12 of the calls. These decisions are indicated by the lines which start with `-> INLINE.` It decided not to inline three of the calls. These decisions are indicated by the lines without the word INLINE.

On each line, the position of the call in the source code is given in parentheses, followed by the name of the routine being called. For example:

| -> INLINE: (398,18) EXACT |

This refers to a call at line 398 column 18 to a routine called EXACT.

**Level 2**
Level 2 includes the values of important compiler options related to inlining. Unless the user specifies one of these values by using the option on the command line, the default value of the option in shown. You can read more about the meaning of the individual inlining options in the Inlining Options section.

<table>
<thead>
<tr>
<th>Example: Inlining Report Level 2 - Values of Inlining Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>INLINING OPTION VALUES:</td>
</tr>
<tr>
<td>-inline-factor: 100</td>
</tr>
<tr>
<td>-inline-min-size: 30</td>
</tr>
<tr>
<td>-inline-max-size: 230</td>
</tr>
<tr>
<td>-inline-max-total-size: 2000</td>
</tr>
<tr>
<td>-inline-max-per-routine: 10000</td>
</tr>
<tr>
<td>-inline-max-per-compile: 500000</td>
</tr>
</tbody>
</table>
Level 3

Level 3 contains one additional line for each call to an external routine made in the application. Such calls are not candidates for inlining, because the code for these routines is not present in the file or files being compiled.

**Example: Inlining Report Level 3 - External Linkage**

Begin optimization report for: APPLU
- Report from: Interprocedural optimizations [ipo]
- INLINE REPORT: (APPLU) [1] applu.f (1,16)
  -> EXTERN: (1,16) for_set_reentrancy
  -> EXTERN: (80,7) for_read_seq_lis

Level 4

Level 4 adds four additional pieces of information. The specifics are shown below:

- **Whole Program values:**

  **Example: Whole Program**

  WHOLE PROGRAM [SAFE] [EITHER METHOD]: false
  WHOLE PROGRAM [SEEN] [TABLE METHOD]: true
  WHOLE PROGRAM [READ] [OBJECT READER METHOD]: false

  An application for which whole program is determined is subject to a higher degree of optimization than one which is not. The Intel compiler uses two methods of determining whole program, a TABLE METHOD and an OBJECT READER METHOD.

- **The size of the routine [sz] and the inlined size of the routine [isz]. Usually isz is less than sz:**

  **Example: Size of the Routine (sz) vs. Inlined Size of the Routine (isz)**

  -> INLINE: (295,12) SETBV (isz = 752) (sz = 755)
  -> INLINE: (398,18) EXACT (isz = 98) (sz = 109)

  In the above example, the routine SETBV was inlined into the routine that called it. The size of SETBV, before inlining, was 755 units. After inlining, the calling routine was increased by 752 units. The increase in the size of the calling routine is slightly less than the size of SETBV, because some of the overhead of calling SETBV was removed when SETBV was inlined.

- **The percentage of time that has passed in the process of compiling the file:**

  **Example: Percentage of Time Passed During Compilation**

  INLINE REPORT: (APPLU) [1/16=6.2%] applu.f (1,16)

  For example, on the line above, [1/16 = 6.2%] indicates that APPLU is the first routine out of 16 to be compiled, and when this routine is done being compiled, 6.2% of the compilation is finished. You can use these numbers to estimate how long the compilation is going to take.

- **The calls that did not get inlined and the reason why they did not get inlined. The reason is shown in double brackets [][]:**

  **Example: Calls That Are Not Inlined**

  -> (303,12) ERHS (isz = 2125) (sz = 2128)
  [[[ Inlining would exceed -inline-max-size value (2128>253)]]]
In the above example, the routine ERHS is not inlined, because the size of the routine (2128 units) is larger than the allowable size (253 units). If you wish to inline routines that are this large, you can use the option `-inline-max-size=2128` (or larger).

**Level 5**

Level 5 adds the inlining footnotes.

---

**Example: Use of Footnote**

```
-> (303,12) ERHS (isz = 2058) (sz = 2061)
    [[ Inlining would exceed -inline-max-size-value (2061>230) <1>]]
```

The inlining footnotes explain the text found in the double brackets `[[ ]]`. They include a description for why an inlining call did not happen, and what you can do to make the inlining of this call happen.

The footnote annotation `<1>` refers to the first footnote in the INLINING FOOTNOTES section at the bottom of the inlining report, which is produced when the user selects Level 5. For example, the footnote produced for annotation `<1>` above is:

---

**Example: Footnote Text**

```
<1> The subprogram is larger than the inliner would normally inline. Use the option `-inline-max-size` to increase the size of any subprogram that would normally be inlined, add `"!DIR$ATTRIBUTES FORCELINE"` to the declaration of the called function, or add `"!DIR$ FORCELIN"` before the call site.
```

---

**Processor Targeting**

The manual processor dispatch feature allows you to target processors manually. There are several ways to control processor dispatching:

- **Use the `cpu_specific` and `cpu_dispatch` keywords**—attributes in Linux* or `__declspecs` in Windows*—to write one or more versions of a function that executes only on specified types of Intel® processors as well as a generic version that executes on other Intel or non-Intel processors. The Intel processor type is detected at run-time, and the corresponding function version is executed. This feature is available only for Intel processors based on IA-32 or Intel® 64 architecture. It is not available for non-Intel processors. Applications built using the manual processor dispatch feature may be more highly optimized for Intel processors than for non-Intel processors.

  For more information see below.

- **Use the `optimization_parameter` pragma.**

  For more information see below.

- **On Linux*, in addition to the Intel-defined attributes `cpu_specific` and `cpu_dispatch`, C++ compilations with GNU Compiler Collection (GCC*) compatibility 4.8 or higher support creation of multiple function versions using the `target` attribute.**

  For more information see the GCC documentation on "Function Multiversioning".

**Using `cpu_dispatch` for Manual Processor Dispatch Programming**

Use the `__declspec(cpu_dispatch(cpuid, cpuid, ...))` syntax in your code to provide a list of targeted processors along with an empty function body/function stub. Use the `__declspec(cpu_specific(cpuid))` in your code to declare each function version targeted at particular type[s] of processors.

For a list of the values for `cpuid`, see the list on `cpu_specific`.  

---

2365
NOTE
If no other matching Intel processor type is detected, the generic version of the function is executed.
If you want the program to execute on non-Intel processors, a generic function version must be provided. You can control the degree of optimization of the generic function version and the processor features that it assumes.

The cpuid attributes are not case sensitive. The body of a function declared with __declspec(cpu_dispatch) must be empty, and is referred to as a stub (an empty-bodied function).

The following example illustrates how the cpu_dispatch and cpu_specific keywords can be used to create function versions for the 2nd generation Intel® Core™ processor family with support of Intel® Advanced Vector Extensions (Intel® AVX), for the Intel® Core™ processor family, for the Intel® Core™2 Duo processor family, and for other Intel and compatible, non-Intel processors. Each processor-specific function body might contain processor-specific intrinsic functions, or it might be placed in a separate source file and compiled with a processor-specific compiler option.

Example

```c
#include <stdio.h>
// need to create specific function versions for the following processors:
__declspec(cpu_dispatch(core_2nd_gen_avx, core_i7_sse4_2, core_2_duo_ssse3, generic ))
void dispatch_func() {};      // stub that will call the appropriate specific function version
__declspec(cpu_specific(core_2nd_gen_avx))
void dispatch_func() {
    printf("Code for 2nd generation Intel Core processors with support for Intel AVX goes here\n");
}
__declspec(cpu_specific(core_i7_sse4_2))
void dispatch_func() {
    printf("Code for Intel Core processors with support for SSE4.2 goes here\n");
}
__declspec(cpu_specific(core_2_duo_ssse3))
void dispatch_func() {
    printf("Code for Intel Core 2 Duo processors with support for SSSE3 goes here\n");
}
__declspec(cpu_specific(generic))
void dispatch_func() {
    printf("Code for non-Intel processors and generic Intel processors goes here\n");
}
int main() {
    dispatch_func();
    printf("Return from dispatch_func\n");
    return 0;
}
```

Considerations
Before using manual dispatch, consider whether the benefits outweigh the additional effort and possible performance issues. You may encounter any one or all of the following issues when using manual processor dispatch in your code:
- code and executable sizes increase considerably
- additional performance overhead may be introduced because of additional function calls

Test your application on all targeted platforms before release.

**Using Pragmas to Target Processors Manually**

You can use `#pragma intel optimization_parameter target_arch` to flag those routines in your code that you want to execute on specified types of processors. This pragma controls the `-m` or `/arch` option at a routine level, overriding the option values specified at the command-line, using the same values as the `-m` or `/arch` option to target processors. The following example illustrates how to use the pragma to target a routine `bar()` to execute only on Intel® AVX supported processors regardless of what the command-line has specified.

**Example**

```c
#include <immintrin.h>
#define N 1024

double x[N], y[N], z[N];

void VectorMultiply(int allow_avx)
{
    int i;
    if (allow_avx) {
        _allow_cpu_features(_FEATURE_AVX);
        for (i = 0; i < N; i++) {
            z[i] = x[i] * y[i];
        }
    }
    else {
        for (i = 0; i < N; i++) {
            z[i] = x[i] * y[i];
        }
    }
}
```

You can also use the `_allow_cpu_features` intrinsic to tell the compiler that the code region may be targeted for processors with specified features, and the `_may_i_use_cpu_feature` to query the processor dynamically at the source level to determine if processor-specific features are available.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Methods to Optimize Code Size

This section provides some guidance on how to achieve smaller object and smaller executable size when using the optimizing features of Intel compilers.

To begin, there are two compiler options that are designed to prioritize code size over performance:

<table>
<thead>
<tr>
<th>Favors size over speed</th>
<th>Linux* and macOS*: -Os</th>
<th>Windows*: /Os</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This option enables optimizations that do not increase code size; it produces smaller code size than option O2.</td>
<td>Option Os disables some optimizations that may increase code size for a small speed benefit.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Minimizes code size</th>
<th>Linux* and macOS*: -O1</th>
<th>Windows*: /O1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Compared to option Os, option O1 disables even more optimizations that are generally known to increase code size. Specifying option O1 implies option Os.</td>
<td>As an intermediate step in reducing code size, you can replace option O3 with option O2 before specifying option O1.</td>
</tr>
<tr>
<td></td>
<td>Option O1 may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.</td>
<td></td>
</tr>
</tbody>
</table>

For more information about the above options, see their full descriptions in the Compiler Reference.

The rest of this section briefly discusses methods that may help you further improve code size even when compared to the default behaviors of options Os and O1.

The following table summarizes the topics in this section.

**Most Common Methods to Reduce Code Size:**
- Disable or Decrease the Amount of Inlining
- Strip Symbols from Your Binaries
- Dynamically Link Intel-Provided Libraries
- Exclude Unused Code and Data from the Executable
- Disable Recognition and Expansion of Intrinsic Functions
- Optimize Exception Handling Data on Linux and macOS* Systems

**Methods to Use Only When Code Size is Very Important:**
- Disable Passing Arguments in Registers Instead of On the Stack
- Disable Loop Unrolling
- Disable Automatic Vectorization
Methods to Use Under Special Circumstances:

Avoid References to Compiler-Specific Libraries

Avoid Unnecessary 16-Byte Alignment

The following are important considerations:

- Some of these methods may already be applied by default when options Os and O1 are specified. All the methods mentioned in subsequent topics can be applied at higher optimization levels.
- Some of the options referred to in these topics will not necessarily cause code size reduction, and they may provide varying results (good, bad, or neutral) based on the characteristics of the target code. Still, these are the recommended things to try to see if they cause your binaries to become smaller while maintaining acceptable performance.
- You should read the full description of compiler options that are mentioned in these topics to get complete information about their behavior, syntax, and target platforms.

See Also
- Os compiler option
- O compiler option

Disable or Decrease the Amount of Inlining

Inlining replaces a call to a function with the body of the function. This lets the compiler optimize the code for the inlined function in the context of its caller, usually yielding more specialized and better performing code. This also removes the overhead of calling the function at run-time.

However, replacing a call to a function by the code for that function usually increases code size. The code size increase can be substantial. To eliminate this code size increase, at the cost of the potential performance improvement, inlining can be disabled.

As an alternative to completely disabling inlining, the default amount of inlining can be decreased by using an inline factor less than the default value of 100. It corresponds to scaling the default values of the main inlining parameters by $n\%$.

Options to specify:

To disable inlining:

- **Linux* and macOS***: -fno-inline
- **Windows***: /Ob0

To reduce inlining and factor the main inlining parameters:

- **Linux* and macOS***: -inline-factor=$n$
- **Windows***: /Qinline-factor:$n$

To fine tune the main inlining parameters:

- **Linux* and macOS***:
  - -inline-factor
  - -inline-max-per-compile
  - -inline-max-per-routine
  - -inline-max-size
  - -inline-max-total-size
  - -inline-min-size

- **Windows***:
  - /Qinline-factor
  - /Qinline-max-per-compile
  - /Qinline-max-per-routine
  - /Qinline-max-size
  - /Qinline-max-total-size
  - /Qinline-min-size
For further details about the compiler options, see the compiler option descriptions.

| Advantages of this method: | Disabling or reducing this optimization can reduce code size. |
| Disadvantages of this method: | Performance is likely to be sacrificed by disabling or reducing inlining especially for applications with many small functions. |

### Strip Symbols from Your Binaries

You can specify a compiler option to omit debugging and symbol information from the executable without sacrificing its operability.

**Options to specify:**

| Linux* and macOS*: | -Wl,--strip-all |
| Windows*: | None |

| Advantages of this method: | This method noticeably reduces the size of the binary. |
| Disadvantages of this method: | It may be very difficult to debug a stripped application. |

### Dynamically Link Intel-Provided Libraries

By default, some of the Intel support and performance libraries are linked statically into an executable. As a result, the library codes are linked into every executable being built. This means that codes are duplicated. It may be more profitable to link them dynamically.

**Options to specify:**

| Linux* and macOS*: | -shared-intel |
| Windows*: | /MD |

| Advantages of this method: | • Performance of the resulting executable is normally not significantly affected.  
• Library codes that are otherwise linked in statically into every executable will not contribute to the code size of each executable with this option. These codes will be shared between all executables using them, and will be available independent of those executables. |
| Disadvantages of this method: | • The libraries on which the resulting executable depends must be re-distributed with the executable in order for it to work properly.  
• When libraries are linked statically, only library content that is actually used is linked into the executable. Dynamic libraries, on the other hand, contain all the library content. Therefore, it may not be beneficial to use this option if you only need to build and/or distribute a single executable.  
• The executable itself may be much smaller when linked dynamically, compared to a statically linked executable. However, the total size of the |
executable plus shared libraries or DLLs may be much larger than the size of the statically linked executable.

**Exclude Unused Code and Data from the Executable**

Programs often contain dead code or data that is not used during their execution. Even if no expensive whole-program inter-procedural analysis is made at compile time to identify dead code, there are compiler options you can specify to eliminate unused functions and data at link time.

This method is often referred to as function-level linking.

**Options to specify:**

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>-fdata-sections -ffunction-sections -Wl,--gc-sections</td>
</tr>
<tr>
<td>Windows*</td>
<td>/Gy /Qoption,link,/OPT:REF</td>
</tr>
</tbody>
</table>

Some of the options in the above specifications are passed to the linker.

Advantages of this method: Only the code that is referenced remains in an executable. Dead functions and data are stripped from the executable.

Disadvantages of this method:

- The object codes may become slightly larger because each function or datum is put into a separate section. The overhead is eliminated at the linking stage.
- This method requires linker support to strip unused sections.
- This method can slightly increase linking time.

**Disable Recognition and Expansion of Intrinsic Functions**

When recognized, intrinsic functions can get expanded inline or their faster implementation in a library may be assumed and linked in. By default, Inline expansion of intrinsic functions is enabled.

In some cases, disabling this behavior may noticeably improve the size of the produced object or binary.

**Options to specify:**

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>-fno-builtin</td>
</tr>
<tr>
<td>Windows*</td>
<td>/Oi-</td>
</tr>
</tbody>
</table>

Advantages of this method: Both the size of the object files and the size of library codes brought into an executable can be reduced.

Disadvantages of this method:

- This method can prevent various performance optimizations from happening. Slower standard library implementation will be used.
- The size of the final executable can be increased in cases when code pulled in statically from a library for an otherwise inlined intrinsic is large.

Notes:

- This option is already the default if you specify option O1.
- You can specify option -nolib-inline to disable inline expansion of standard library or intrinsic functions.
- Depending on code characteristics, this option can sometimes increase binary size.
Optimize Exception Handling Data on Linux and macOS* Systems

If a program requires support for exception handling, the compiler creates a special section containing DWARF directives that are used by the Linux* and macOS* run-time to unwind and catch an exception. This information is located in the .eh_frame section and may be shrunk using the compiler options listed below.

Options to specify:

<table>
<thead>
<tr>
<th></th>
<th>Linux* and macOS*:</th>
<th>Windows*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-fno-exceptions</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>-fno-asynchronous-unwind-tables</td>
<td>None</td>
</tr>
</tbody>
</table>

Advantages of this method:
- These options may shrink the size of the object or binary file by up to 15%, though the amount of the reduction depends on the target platform.
- These options control whether unwind information is precise at an instruction boundary or at a call boundary. For example, option -fno-asynchronous-unwind-tables can be used for programs that may only throw or catch exceptions.

Disadvantages of this method:
Both options may change the program's behavior:
- Do not use option -fno-exceptions for programs that require standard C++ handling for objects of classes with destructors.
- Do not use option -fno-asynchronous-unwind-tables for functions compiled with option -fexceptions or option -traceback that contain calls to other functions that might throw exceptions or for C++ functions that declare objects with destructors.

Please read the compiler option descriptions, which explain what the defaults and behavior are for each target platform.

Disable Passing Arguments in Registers Instead of On the Stack

You can specify an option that causes the compiler to pass arguments in registers rather than on the stack. This can yield faster code.

However, doing this may require the compiler to create an additional entry point for any function that can be called outside the code being compiled.

In many cases, this will lead to an increase in code size. To prevent this increase in code size, you can disable this optimization.

Options to specify:

<table>
<thead>
<tr>
<th></th>
<th>Linux* and macOS*:</th>
<th>Windows*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-qopt-args-in-regs=none</td>
<td>/Qopt-args-in-regs:none</td>
</tr>
</tbody>
</table>

Advantages of this method: Disabling this optimization can reduce code size.
Disadvantages of this method: The amount of code size saved may be small when compared to the corresponding performance loss of disabling the optimization.

Notes:
If you do not specify "none" for option [q or Q]opt-args-in-regs, the default behavior for the option is that parameters are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.
Depending on code characteristics, this option can sometimes increase binary size.

**Disable Loop Unrolling**

Unrolling a loop increases the size of the loop proportionally to the unroll factor.
Disabling (or limiting) this optimization may help reduce code size at the expense of performance.

**Options to specify:**

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>-unroll=0</td>
</tr>
<tr>
<td>Windows*</td>
<td>/Qunroll:0</td>
</tr>
</tbody>
</table>

Advantages of this method: Code size is reduced.
Disadvantages of this method: Performance of otherwise unrolled loops may noticeably degrade because this limits other possible loop optimizations.

Notes:
This option is already the default if you specify option Os or option O1.

**Disable Automatic Vectorization**

The compiler finds possibilities to use SIMD (SSE/AVX) instructions to improve performance of applications. This optimization is called automatic vectorization.

In most cases, this optimization involves transformation of loops and increases code size, in some cases significantly.
Disabling this optimization may help reduce code size at the expense of performance.

**Options to specify:**

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>-no-vec</td>
</tr>
<tr>
<td>Windows*</td>
<td>/Qvec-</td>
</tr>
</tbody>
</table>

Advantages of this method: Compile-time is also improved significantly.
Disadvantages of this method: Performance of otherwise vectorized loops may suffer significantly. If you care about the performance of your application, you should use this option selectively to suppress vectorization on everything except performance-critical parts.

Notes:
Depending on code characteristics, this option can sometimes increase binary size.

**Avoid References to Compiler-Specific Libraries**

While Intel compiler-specific libraries are intended to improve the performance of your application, they increase the size of your binaries.
Certain compiler options may improve the code size.

**Options to specify:**

<table>
<thead>
<tr>
<th></th>
<th>Linux* and macOS*:</th>
<th>Windows*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-ffreestanding</td>
<td>/Qfreestanding</td>
</tr>
</tbody>
</table>

**Advantages of this method:**
The compiler will not assume the presence of compiler-specific libraries. It will only generate calls that appear in the source code.

**Disadvantages of this method:**
This method may sacrifice performance if the library codes were in hotspots. Also, since we cannot assume any libraries, some compiler optimizations will be suppressed.

**Notes:**
- This option implies option `-fno-built-in`; you can override that default by explicitly specifying option `-fbuiltin`.
- Depending on code characteristics, this option can sometimes increase binary size.

## Avoid Unnecessary 16-Byte Alignment

This method should only be used in certain situations that are well understood. It can potentially cause correctness issues when linking with other objects or libraries that aren’t built with this option. This topic only applies to Linux systems on IA-32 architecture.

The 32-bit Linux ABI states that stacks need only maintain 4-byte alignment. However, for performance reasons in modern architectures, GCC and ICC maintain an alignment of 16-bytes on the stack. Maintaining 16-byte alignment may require additional instructions to adjust the stack on function entries where no stack adjustment would otherwise be needed. This can impact code size, especially in code that consists of many small routines.

You can specify a compiler option that will revert ICC back to maintaining 4-byte alignment, which can eliminate the need for extra stack adjust instructions in some cases.

Use this option *only* if one of the following is true:
- Your code does not call any other object or library that can be built without this option and, therefore, may rely on the stack being aligned to 16-bytes when called.
- Your code is targeted for architectures that do not have or support SSE instructions; therefore, it would never need 16-byte alignment for correctness reasons.

**Options to specify:**

<table>
<thead>
<tr>
<th></th>
<th>Linux*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-falign-stack=assume-4-byte</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>macOS*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Windows*:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

**Advantages of this method:**
- Code size can be smaller because you do not need extra instructions to maintain 16-byte alignment when not needed.
- This method can improve performance in some cases because of this reduction of instructions.

**Disadvantages of this method:**
This method can cause incompatibility when linked with other objects or libraries that rely on the stack being 16-byte aligned across the calls.

**Notes:**
Depending on code characteristics, this option can sometimes increase binary size.
Overview: Intel® Math Library

The Intel® C++ Compiler includes a mathematical software library containing highly optimized and very accurate mathematical functions. These functions are commonly used in scientific or graphic applications, as well as other programs that rely heavily on floating-point computations. To include support for C99 _Complex data types, use the [Q]std=c99 compiler option.

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

---

**NOTE**

Intel's math.h header file is compatible with the gcc math library libm, but it does not cause the gcc* math library to be linked. The source can be built with either gcc, icc, or icl. When built with icc or icl, the Intel® Math Library will be linked. The header file for the Intel® Math Library mathimf.h contains additional functions that are found only in the Intel® Math Library. The source can only be built using the Intel® C++ Compilers and libraries.

---

**NOTE**

The long double functions, such as expl or logl, in the Intel® Math Library are ABI incompatible with the Microsoft* libraries. This is because Intel's compiler and libraries support the 80-bit long double data type (see the description of the Qlong-double option). For maximum compatibility we recommend use of Intel's math.h or mathimf.h header files along with the Intel Math Library.

---

**Intel® Math Libraries for Linux* and macOS***

- std, Qstd compiler option

Using the Intel® Math Library

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

To use the Intel® Math Library, include the header file, mathimf.h, in your program. If the Intel® C++ Compiler is used for linking, then the Intel® Math Library is used by default.

**Example: Using Real Functions**

The following examples demonstrate how to use the Intel® Math Library with the Intel® C++ Compiler. After you compile this example and run the program, the program will display the sine value of \( x \).

**Linux* and macOS***

```c
// real_math.c
#include <stdio.h>
#include <mathimf.h>

int main() {
    float fp32bits;
    double fp64bits;
    long double fp80bits;
    long double pi_by_four = 3.141592653589793238/4.0;

    // pi/4 radians is about 45 degrees
    fp32bits = (float) pi_by_four; // float approximation to pi/4
    fp64bits = (double) pi_by_four; // double approximation to pi/4
    fp80bits = pi_by_four; // long double (extended) approximation to pi/4

    // The sin(pi/4) is known to be 1/sqrt(2) or approximately .7071067
    printf("When x = %8.8f, sinf(x) = %8.8f \n", fp32bits, sinf(fp32bits));
    printf("When x = %16.16f, sin(x) = %16.16f \n", fp64bits, sin(fp64bits));
    printf("When x = %20.20Lf, sinl(x) = %20.20Lf \n", fp80bits, sinl(fp80bits));

    return 0;
}
```

Use the following command to compile the example code on Linux* platforms:

```bash
icc real_math.c
```
Windows*

```c
// real_math.c
#include <stdio.h>
#include <mathimf.h>

int main() {
    float fp32bits;
    double fp64bits;

    // /Qlong-double compiler option required because, without it,
    // long double types are mapped to doubles.
    long double fp80bits;
    long double pi_by_four = 3.141592653589793238/4.0;

    // pi/4 radians is about 45 degrees
    fp32bits = (float) pi_by_four;
    // float approximation to pi/4
    fp64bits = (double) pi_by_four;
    // double approximation to pi/4
    fp80bits = pi_by_four;
    // long double (extended) approximation to pi/4

    // The sin(pi/4) is known to be 1/sqrt(2) or approximately .7071067
    printf("When x = %8.8f, sinf(x) = %8.8f \n", fp32bits, sinf(fp32bits));

    printf("When x = %16.16f, sin(x) = %16.16f \n", fp64bits, sin(fp64bits));

    printf("When x = %20.20f, sinl(x) = %20.20f \n", (double) fp80bits, (double) sinl(fp80bits));

    // printf() does not support the printing of long doubles
    // on Microsoft* Windows*, so fp80bits is cast to double in this example.
    return 0;
}
```

Since the `real_math.c` program includes the `long double` data type, use the `/Qlong-double` and `/Qpc80` compiler options in the command line:

`icl/Qlong-double/Qpc80real_math.c`

**Example Using Complex Functions**

After you compile this example and run the program, you should get the following results:

When \( z = 1.0000000 + 0.7853982 \ i \), \( \textrm{cexpf}(z) = 1.9221154 + 1.9221156 \ i \)

When \( z = 1.000000000000 + 0.785398163397 \ i \), \( \textrm{cexp}(z) = 1.922115514080 + 1.922115514080 \ i \)

**Linux*, **macOS**, and **Windows**

```c
// complex_math.c
#include <stdio.h>
#include <complex.h>

int main() {
    float _Complex c32in,c32out;
```
double _Complex c64in,c64out;
double pi_by_four= 3.141592653589793238/4.0;
c64in = 1.0 + I* pi_by_four;

// Create the double precision complex number 1 + (pi/4) * i
where I is the imaginary unit.
c32in = (float _Complex) c64in;

// Create the float complex value from the double complex value.
c64out = cexp(c64in);
c32out = cexpf(c32in);

// Call the complex exponential,
// cexp(z) = cexp(x+iy) = e^ (x + i y) = e^x * (cos(y) + i sin(y))
printf("When z = %7.7f + %7.7f i, cexpf(z) = %7.7f + %7.7f i \n",
crealf(c32in),cimagf(c32in),crealf(c32out),cimagf(c32out));
printf("When z = %12.12f + %12.12f i, cexp(z) = %12.12f + %12.12f i \n",
creal(c64in),cimag(c64in),creal(c64out),cimagf(c64out));

return 0;
}

Since this example program includes the _Complex data type, be sure to include the [Q]std=c99 compiler option in the command line.

To compile this example code in Linux* or macOS*, use the following command:

    icc -std=c99 complex_math.c

To compile this example code in Windows*, use the following command:

    icl /Qstd=c99 complex_math.c

NOTE
Complex data types are supported in C but not in C++ programs.

**Exception Conditions**

If you call a math function using argument(s) that may produce undefined results, an error number is assigned to the system variable errno. Math function errors are usually domain errors or range errors.

**Domain errors** result from arguments that are outside the domain of the function. For example, acos is defined only for arguments between -1 and +1 inclusive. Attempting to evaluate acos(-2) or acos(3) results in a domain error, where the return value is QNaN.

**Range errors** occur when a mathematically valid argument results in a function value that exceeds the range of representable values for the floating-point data type. Attempting to evaluate exp(1000) results in a range error, where the return value is INF.

When domain or range error occurs, the following values are assigned to errno:

- domain error (EDOM): errno = 33
- range error (ERANGE): errno = 34

The following example shows how to read the errno value for an EDOM and ERANGE error.

    // errno.c
    #include <errno.h>
    #include <mathimf.h>
```c
#include <stdio.h>

int main(void) {
    double neg_one=-1.0;
    double zero=0.0;

    // The natural log of a negative number is considered a domain error - EDOM
    printf("log(%e) = %e and errno(EDOM) = %d \n",neg_one,log(neg_one),errno);

    // The natural log of zero is considered a range error - ERANGE
    printf("log(%e) = %e and errno(ERANGE) = %d \n",zero,log(zero),errno);
}
```

The output of `errno.c` will look like this:

```
log(-1.000000e+00) = nan and errno(EDOM) = 33
log(0.000000e+00) = -inf and errno(ERANGE) = 34
```

For the math functions in this section, a corresponding value for `errno` is listed when applicable.

**Other Considerations**

Some math functions are inlined automatically by the compiler. The functions actually inlined may vary and may depend on any vectorization or processor-specific compilation options used. You can disable automatic inline expansion of all functions by compiling your program with the `-fno-builtin` option (Linux* and macOS*) or the `/Oi-` option (Windows*).

It is strongly recommended to use the default rounding mode (round-to-nearest-even) when calling math library transcendental functions and compiling with default optimization or higher. Faster implementations—in terms of latency and/or throughput—of these functions are validated under the default round-to-nearest-even mode. Using other rounding modes may make results generated by these faster implementations less accurate, or set unexpected floating-point status flags. This behavior may be avoided by using the `-no-fast-transcendentals` option (Linux* and macOS*) or `/Qfast-transcendentals` option (Windows*), which disables calls to the faster implementations of math functions, or by using the `-fp-model strict` option (Linux* and macOS*) or `/fp: strict` option (Windows*). This option warns the compiler not to assume default settings for the floating-point environment.

**NOTE**

64-bit decimal transcendental functions rely on binary double extended precision arithmetic.

To obtain accurate results, user applications that call 64-bit decimal transcendentals should ensure that the x87 unit is operating in 80-bit precision (64-bit binary significands). In an environment where the default x87 precision is not 80 bits, such as Windows*, it can be set to 80 bits by compiling the application source files with the `/Qpc80` option.

A change of the default precision control or rounding mode may affect the results returned by some of the mathematical functions.

The following are important compiler options when using certain data types in IA-32 and Intel® 64 architectures running Windows* operating systems:

- `/Qlong-double`: Use this option when compiling programs that require support for the `long double` data type (80-bit floating-point). Without this option, compilation will be successful, but `long double` data types will be mapped to `double` data types.
- `/Qstd=c99`: Use this option when compiling programs that require support for `_Complex` data types.

**Trigonometric Functions**

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

The Intel® Math Library supports the following trigonometric functions:

**acos**

**Description:** The acos function returns the principal value of the inverse cosine of x in the range [0, pi] radians for x in the interval [-1,1].

**errno:** EDOM, for |x| > 1

**Calling interface:**

double acos(double x);
long double acosl(long double x);
float acosf(float x);

**acosd**

**Description:** The `acosd` function returns the principal value of the inverse cosine of `x` in the range \([0,180]\) degrees for `x` in the interval \([-1,1]\).

*errno:* EDOM, for \(|x| > 1\)

**Calling interface:**
double acosd(double x);
long double acosdl(long double x);
float acosdf(float x);

**acospi**

**Description:** The `acospi` function returns the principal value of the inverse cosine of `x`, divided by pi, in the range \([0,1]\) for `x` in the interval \([-1,1]\).

*errno:* EDOM, for \(|x| > 1\)

**Calling interface:**
double acospi(double x);
float acospif(float x);

**asin**

**Description:** The `asin` function returns the principal value of the inverse sine of `x` in the range \([-\pi/2, +\pi/2]\) radians for `x` in the interval \([-1,1]\).

*errno:* EDOM, for \(|x| > 1\)

**Calling interface:**
double asin(double x);
long double asinl(long double x);
float asinf(float x);

**asind**

**Description:** The `asind` function returns the principal value of the inverse sine of `x` in the range \([-90,90]\) degrees for `x` in the interval \([-1,1]\).

*errno:* EDOM, for \(|x| > 1\)

**Calling interface:**
double asind(double x);
long double asindl(long double x);
float asindf(float x);

**asinpi**

**Description:** The `asinpi` function returns the principal value of the inverse sine of `x`, divided by pi, in the range \([-1/2,1/2]\) degrees for `x` in the interval \([-1,1]\).

*errno:* EDOM, for \(|x| > 1\) divided by pi

**Calling interface:**
double asinpi(double x);
float asinpif(float x);
atan
**Description:** The *atan* function returns the principal value of the inverse tangent of *x* in the range [-pi/2, +pi/2] radians.

**Calling interface:**
```c
double atan(double x);
long double atanl(long double x);
float atanf(float x);
```

atan2
**Description:** The *atan2* function returns the principal value of the inverse tangent of *y/x* in the range [-pi, +pi] radians.

**errno:** EDOM, for *x* = 0 and *y* = 0

**Calling interface:**
```c
double atan2(double y, double x);
long double atan2l(long double y, long double x);
float atan2f(float y, float x);
```

atan2pi
**Description:** The *atan2pi* function returns the principal value of the inverse tangent of *y/x*, divided by pi, in the range [-1, +1].

**errno:** EDOM, for *x* = 0 and *y* = 0

**Calling interface:**
```c
double atan2pi(double y, double x);
floating atan2pif(float y, float x);
```

atand
**Description:** The *atand* function returns the principal value of the inverse tangent of *x* in the range [-90,90] degrees.

**Calling interface:**
```c
double atand(double x);
long double atandl(long double x);
float atandf(float x);
```

atan2d
**Description:** The *atan2d* function returns the principal value of the inverse tangent of *y/x* in the range [-180, +180] degrees.

**errno:** EDOM, for *x* = 0 and *y* = 0.

**Calling interface:**
```c
double atan2d(double x, double y);
long double atan2dl(long double x, long double y);
float atan2df(float x, float y);
```

atanpi
**Description:** The *atanpi* function returns the principal value of the inverse tangent of *x*, divided by pi, in the range [-1/2, +1/2].

**Calling interface:**
double atanpi(double x);
float atanpif(float x);

cos
Description: The cos function returns the cosine of \( x \) measured in radians.

Calling interface:
double cos(double x);
long double cosl(long double x);
float cosf(float x);

cosd
Description: The cosd function returns the cosine of \( x \) measured in degrees.

Calling interface:
double cosd(double x);
long double cosdl(long double x);
float cosdf(float x);

cospi
Description: The cospi function returns the cosine of \( x \) multiplied by \( \pi \), \( \cos(x \pi) \).

Calling interface:
double cospi(double x);
float cospf(float x);

cot
Description: The cot function returns the cotangent of \( x \) measured in radians.
errno: ERANGE, for overflow conditions at \( x = 0 \).

Calling interface:
double cot(double x);
long double cotl(long double x);
float cotf(float x);

cotd
Description: The cotd function returns the cotangent of \( x \) measured in degrees.
errno: ERANGE, for overflow conditions at \( x = 0 \).

Calling interface:
double cotd(double x);
long double cotdl(long double x);
float cotdf(float x);

sin
Description: The sin function returns the sine of \( x \) measured in radians.

Calling interface:
double sin(double x);
long double sinl(long double x);
float sinf(float x);
**sincos**

**Description:** The *sincos* function returns both the sine and cosine of \( x \) measured in radians.

**Calling interface:**

```c
void sincos(double x, double *sinval, double *cosval);
void sincosl(long double x, long double *sinval, long double *cosval);
void sincosf(float x, float *sinval, float *cosval);
```

**sincosd**

**Description:** The *sincosd* function returns both the sine and cosine of \( x \) measured in degrees.

**Calling interface:**

```c
void sincosd(double x, double *sinval, double *cosval);
void sincosdl(long double x, long double *sinval, long double *cosval);
void sincosdf(float x, float *sinval, float *cosval);
```

**sind**

**Description:** The *sind* function computes the sine of \( x \) measured in degrees.

**Calling interface:**

```c
double sind(double x);
long double sindl(long double x);
float sindf(float x);
```

**sinpi**

**Description:** The *sinpi* function returns the sine of \( x \) multiplied by \( \pi \), \( \sin(x\pi) \).

**Calling interface:**

```c
double sinpi(double x);
float sinpif(float x);
```

**tan**

**Description:** The *tan* function returns the tangent of \( x \) measured in radians.

**Calling interface:**

```c
double tan(double x);
long double tanl(long double x);
float tanf(float x);
```

**tand**

**Description:** The *tand* function returns the tangent of \( x \) measured in degrees.

**errno**: ERANGE, for overflow conditions

**Calling interface:**

```c
double tand(double x);
long double tandl(long double x);
float tandf(float x);
```

**tanpi**

**Description:** The *tanpi* function returns the tangent of \( x \) multiplied by \( \pi \), \( \tan(x\pi) \).

**Calling interface:**
double tanpi(double x);
float tanpif(float x);

**Hyperbolic Functions**
Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
The `mathimf.h` header file includes prototypes for Intel® Math Library functions.
The Intel® Math Library supports the following hyperbolic functions:

**acosh**
**Description:** The acosh function returns the inverse hyperbolic cosine of x.
**errno:** EDOM, for x < 1
**Calling interface:**
double acosh(double x);
long double acoshl(long double x);
float acoshf(float x);

**asinh**
**Description:** The asinh function returns the inverse hyperbolic sine of x.
**Calling interface:**
double asinh(double x);
long double asinhl(long double x);
float asinhf(float x);

**atanh**
**Description:** The atanh function returns the inverse hyperbolic tangent of x.
**errno:** EDOM, for x > 1
**errno:** ERANGE, for x = 1
**Calling interface:**
double atanh(double x);
long double atanh1(long double x);
float atanhf(float x);

**cosh**
**Description:** The cosh function returns the hyperbolic cosine of x, \((e^x + e^{-x})/2\).
**errno:** ERANGE, for overflow conditions
**Calling interface:**
double cosh(double x);
long double coshl(long double x);
float coshf(float x);

**sinh**
**Description:** The sinh function returns the hyperbolic sine of x, \((e^x - e^{-x})/2\).
**errno:** ERANGE, for overflow conditions
Calling interface:
double sinh(double x);
long double sinhl(long double x);
float sinhf(float x);

sinhcosh
Description: The sinhcosh function returns both the hyperbolic sine and hyperbolic cosine of x.
errno: ERANGE, for overflow conditions
Calling interface:
void sinhcosh(double x, double *sinval, double *cosval);
void sinhcoshl(long double x, long double *sinval, long double *cosval);
void sinhcoshf(float x, float *sinval, float *cosval);

tanh
Description: The tanh function returns the hyperbolic tangent of x, \((e^x - e^{-x}) / (e^x + e^{-x})\).
Calling interface:
double tanh(double x);
long double tanhl(long double x);
float tanhf(float x);

Exponential Functions
Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
The mathimf.h header file includes prototypes for Intel® Math Library functions.
The Intel® Math Library supports the following exponential functions:

cbrt
Description: The cbrt function returns the cube root of x.
Calling interface:
double cbrt(double x);
long double cbrtl(long double x);
float cbrtf(float x);

exp
Description: The exp function returns \(e\) raised to the \(x\) power, \(e^x\).
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double exp(double x);
long double expl(long double x);
float expf(float x);

exp10
Description: The exp10 function returns 10 raised to the \(x\) power, \(10^x\).
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double exp10(double x);
long double exp10l(long double x);
float exp10f(float x);

**exp2**

**Description:** The `exp2` function returns 2 raised to the \(x\) power, \(2^x\).

**errno:** `ERANGE`, for underflow and overflow conditions

**Calling interface:**
double exp2(double x);
long double exp2l(long double x);
float exp2f(float x);

**expm1**

**Description:** The `expm1` function returns \(e\) raised to the \(x\) power, minus 1, \(e^x - 1\).

**errno:** `ERANGE`, for overflow conditions

**Calling interface:**
double expm1(double x);
long double expm1l(long double x);
float expm1f(float x);

**frexp**

**Description:** The `frexp` function converts a floating-point number \(x\) into signed normalized fraction in \([1/2, 1)\) multiplied by an integral power of two. The signed normalized fraction is returned, and the integer exponent stored at location `exp`.

**Calling interface:**
double frexp(double x, int *exp);
long double frexpl(long double x, int *exp);
float frexpf(float x, int *exp);

**hypot**

**Description:** The `hypot` function returns the square root of \((x^2 + y^2)\).

**errno:** `ERANGE`, for overflow conditions

**Calling interface:**
double hypot(double x, double y);
long double hypotl(long double x, long double y);
float hypotf(float x, float y);

**ilogb**

**Description:** The `ilogb` function returns the exponent of \(x\) base two as a signed int value.

**errno:** `ERANGE`, for \(x = 0\)

**Calling interface:**
int ilogb(double x);
int ilogbl(long double x);
int ilogbf(float x);
**invsqrt**

**Description:** The `invsqrt` function returns the inverse square root.

**Calling interface:**
```c
double invsqrt(double x);
long double invsqrtrl(long double x);
float invsqrtf(float x);
```

**ldexp**

**Description:** The `ldexp` function returns \( x \times 2^{\text{exp}} \), where `exp` is an integer value.

**errno:** `ERANGE`, for underflow and overflow conditions

**Calling interface:**
```c
double ldexp(double x, int exp);
long double ldexpl(long double x, int exp);
float ldexpf(float x, int exp);
```

**log**

**Description:** The `log` function returns the natural log of \( x \), \( \ln(x) \).

**errno:**
- `EDOM`, for \( x < 0 \)
- `ERANGE`, for \( x = 0 \)

**Calling interface:**
```c
double log(double x);
long double logl(long double x);
float logf(float x);
```

**log10**

**Description:** The `log10` function returns the base-10 log of \( x \), \( \log_{10}(x) \).

**errno:**
- `EDOM`, for \( x < 0 \)
- `ERANGE`, for \( x = 0 \)

**Calling interface:**
```c
double log10(double x);
long double log10l(long double x);
float log10f(float x);
```

**log1p**

**Description:** The `log1p` function returns the natural log of \((x+1)\), \( \ln(x + 1) \).

**errno:**
- `EDOM`, for \( x < -1 \)
- `ERANGE`, for \( x = -1 \)

**Calling interface:**
```c
double log1p(double x);
long double log1pl(long double x);
float log1pf(float x);
```

**log2**

**Description:** The `log2` function returns the base-2 log of \( x \), \( \log_{2}(x) \).

**errno:** `EDOM`, for \( x < 0 \)
errno: ERANGE, for \( x = 0 \)

**Calling interface:**

```c
double log2(double x);
long double log2l(long double x);
float log2f(float x);
```

---

**logb**

**Description:** The \( \text{logb} \) function returns the signed exponent of \( x \).

errno: EDOM, for \( x = 0 \)

**Calling interface:**

```c
double logb(double x);
long double logbl(long double x);
float logbf(float x);
```

---

**pow**

**Description:** The \( \text{pow} \) function returns \( x \) raised to the power of \( y \), \( x^y \).

errno: EDOM, for \( x = 0 \) and \( y < 0 \)
errno: EDOM, for \( x < 0 \) and \( y \) is a non-integer
errno: ERANGE, for overflow and underflow conditions

**Calling interface:**

```c
double pow(double x, double y);
long double powl(double x, double y);
float powf(float x, float y);
```

---

**pow2o3**

**Description:** The \( \text{pow2o3} \) function returns the cube root of \( x \) squared, \( \text{cbrt}(x^2) \).

**Calling interface:**

```c
double pow2o3(double x);
float pow2o3f(float x);
```

---

**pow3o2**

**Description:** The \( \text{pow3o2} \) function returns the square root of the cube of \( x \), \( \text{sqrt}(x^3) \).

errno: EDOM, for \( x < 0 \)
errno: ERANGE, for overflow and underflow conditions

**Calling interface:**

```c
double pow3o2(double x);
float pow3o2f(float x);
```

---

**powr**

**Description:** The \( \text{powr} \) function returns \( x \) raised to the power of \( y \), \( x^y \), where \( x \geq 0 \).

errno: EDOM, for \( x < 0 \)
errno: ERANGE, for overflow and underflow conditions

**Calling interface:**

```c
double powr(double x, double y);
float powrf(float x, float y);
```
scalb
Description: The scalb function returns \( x \times 2^y \), where \( y \) is a floating-point value.
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double scalb(double x, double y);
long double scalbl(long double x, long double y);
float scalbf(float x, float y);

scalbn
Description: The scalbn function returns \( x \times 2^n \), where \( n \) is an integer value.
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double scalbn(double x, int n);
long double scalbln (long double x, int n);
float scalblnf(float x, int n);

scalbln
Description: The scalbln function returns \( x \times 2^n \), where \( n \) is a long integer value.
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double scalbln(double x, long int n);
long double scalblnl (long double x, long int n);
float scalblnf(float x, long int n);

sqrt
Description: The sqrt function returns the correctly rounded square root.
errno: EDOM, for \( x < 0 \)
Calling interface:
double sqrt(double x);
long double sqrtl(long double x);
float sqrtf(float x);

Special Functions
Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
The mathimf.h header file includes prototypes for Intel® Math Library functions.
The Intel® Math Library supports the following special functions:

annuity
Description: The annuity function computes the present value factor for an annuity, \( \frac{(1 - (1+x)^{-y})}{x} \), where \( x \) is a rate and \( y \) is a period.
errno: ERANGE, for underflow and overflow conditions
Calling interface:
double annuity(double x, double y);
long double annuityl(long double x, long double y);
float annuityf(float x, float y);

**acdfnorminv**

*Description*: The `acdfnorminv` function returns the inverse cumulative normal distribution function value.

*errno*: 
- EDOM, for finite or infinite \((x > 1) \text{ || } (x < 0)\)
- ERANGE, for \(x = 0\) or \(x = 1\)

*Calling interface:*
- `double acdfnorminv(double x)`
- `float acdfnorminvf(float x)`

**compound**

*Description*: The `compound` function computes the compound interest factor, \((1+x)^y\), where \(x\) is a rate and \(y\) is a period.

*errno*: ERANGE, for underflow and overflow conditions

*Calling interface:*
- `double compound(double x, double y)`
- `long double compoundl(long double x, long double y)`
- `float compoundf(float x, float y)`

**erf**

*Description*: The `erf` function returns the error function value.

*Calling interface:*
- `double erf(double x)`
- `long double erfl(long double x)`
- `float erf(float x)`

**erfc**

*Description*: The `erfc` function returns the complementary error function value.

*errno*: EDOM, for finite or infinite \(|x| > 1\)

*Calling interface:*
- `double erfc(double x)`
- `long double erfcl(long double x)`
- `float erfcf(float x)`

**erfinv**

*Description*: The `erfinv` function returns the value of the inverse error function of \(x\).

*errno*: EDOM, for finite or infinite \(|x| > 1\)

*Calling interface:*
- `double erfinv(double x)`
- `long double erfinvl(long double x)`
- `float erfinvf(float x)`
**gamma**

**Description:** The `gamma` function returns the value of the logarithm of the absolute value of gamma.

**errno:** `ERANGE`, for overflow conditions when `x` is a negative integer.

**Calling interface:**
```c
double gamma(double x);
long double gammal(long double x);
float gammaf(float x);
```

**gamma_r**

**Description:** The `gamma_r` function returns the value of the logarithm of the absolute value of gamma. The sign of the gamma function is returned in the integer `signgam`.

**Calling interface:**
```c
double gamma_r(double x, int *signgam);
long double gammal_r(long double x, int *signgam);
float gammaf_r(float x, int *signgam);
```

**j0**

**Description:** Computes the Bessel function (of the first kind) of `x` with order 0.

**Calling interface:**
```c
double j0(double x);
long double j0l(long double x);
float j0f(float x);
```

**j1**

**Description:** Computes the Bessel function (of the first kind) of `x` with order 1.

**Calling interface:**
```c
double j1(double x);
long double j1l(long double x);
float j1f(float x);
```

**jn**

**Description:** Computes the Bessel function (of the first kind) of `x` with order `n`.

**Calling interface:**
```c
double jn(int n, double x);
long double jnl(int n, long double x);
float jnf(int n, float x);
```

**lgamma**

**Description:** The `lgamma` function returns the value of the logarithm of the absolute value of gamma.

**errno:** `ERANGE`, for overflow conditions, `x=0` or negative integers.

**Calling interface:**
```c
double lgamma(double x);
long double lgammal(long double x);
float lgammaf(float x);
```
**lgamma_r**

**Description:** The `lgamma_r` function returns the value of the logarithm of the absolute value of gamma. The sign of the gamma function is returned in the integer `signgam`.

**errno:** `ERANGE`, for overflow conditions, x=0 or negative integers.

**Calling interface:**

```c
double lgamma_r(double x, int *signgam);
long double lgammal_r(long double x, int *signgam);
float lgammaf_r(float x, int *signgam);
```

**tgamma**

**Description:** The `tgamma` function computes the gamma function of `x`.

**errno:** `EDOM`, for x=0 or negative integers.

**Calling interface:**

```c
double tgamma(double x);
long double tgammal(long double x);
float tgammaf(float x);
```

**y0**

**Description:** Computes the Bessel function (of the second kind) of `x` with order 0.

**errno:** `EDOM`, for x <= 0

**Calling interface:**

```c
double y0(double x);
long double y0l(long double x);
float y0f(float x);
```

**y1**

**Description:** Computes the Bessel function (of the second kind) of `x` with order 1.

**errno:** `EDOM`, for x <= 0

**Calling interface:**

```c
double y1(double x);
long double y1l(long double x);
float y1f(float x);
```

**yn**

**Description:** Computes the Bessel function (of the second kind) of `x` with order `n`.

**errno:** `EDOM`, for x <= 0

**Calling interface:**

```c
double yn(int n, double x);
long double ynl(int n, long double x);
float ynf(int n, float x);
```

**Nearest Integer Functions**

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
The `mathimf.h` header file includes prototypes for Intel® Math Library functions.

The Intel® Math Library supports the following nearest integer functions:

**ceil**

**Description:** The `ceil` function returns the smallest integral value not less than \( x \) as a floating-point number.

**Calling interface:**
```c
double ceil(double x);
long double ceill(long double x);
float ceill(float x);
```

**floor**

**Description:** The `floor` function returns the largest integral value not greater than \( x \) as a floating-point value.

**Calling interface:**
```c
double floor(double x);
long double floorl(long double x);
float floorf(float x);
```

**llrint**

**Description:** The `llrint` function returns the rounded integer value (according to the current rounding direction) as a `long long int`.

**errno:** `ERANGE`, for values too large

**Calling interface:**
```c
long long int llrint(double x);
long long int llrintl(long double x);
long long int llrintf(float x);
```

**llround**

**Description:** The `llround` function returns the rounded integer value as a `long long int`.

**errno:** `ERANGE`, for values too large

**Calling interface:**
```c
long long int llround(double x);
long long int llroundl(long double x);
long long int llroundf(float x);
```

**lrint**

**Description:** The `lrint` function returns the rounded integer value (according to the current rounding direction) as a `long int`.

**errno:** `ERANGE`, for values too large

**Calling interface:**
```c
long int lrint(double x);
long int lrintl(long double x);
long int lrintf(float x);
```
**lround**

**Description:** The `lround` function returns the rounded integer value as a `long int`. Halfway cases are rounded away from zero.

**errno:** `ERANGE`, for values too large

**Calling interface:**
```
long int lround(double x);
long int lroundl(long double x);
long int lroundf(float x);
```

**modf**

**Description:** The `modf` function returns the value of the signed fractional part of `x` and stores the integral part at `*iptr` as a floating-point number.

**Calling interface:**
```
double modf(double x, double *iptr);
long double modfl(long double x, long double *iptr);
float modff(float x, float *iptr);
```

**nearbyint**

**Description:** The `nearbyint` function returns the rounded integral value as a floating-point number, using the current rounding direction.

**Calling interface:**
```
double nearbyint(double x);
long double nearbyintl(long double x);
float nearbyintf(float x);
```

**rint**

**Description:** The `rint` function returns the rounded integral value as a floating-point number, using the current rounding direction.

**Calling interface:**
```
double rint(double x);
long double rintl(long double x);
float rintf(float x);
```

**round**

**Description:** The `round` function returns the nearest integral value as a floating-point number. Halfway cases are rounded away from zero.

**Calling interface:**
```
double round(double x);
long double roundl(long double x);
float roundf(float x);
```

**trunc**

**Description:** The `trunc` function returns the truncated integral value as a floating-point number.

**Calling interface:**
```
double trunc(double x);
long double truncl(long double x);
```
float truncf(float x);

**Remainder Functions**

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

The Intel® Math Library supports the following remainder functions:

**fmod**

**Description:** The `fmod` function returns the value $x-n*y$ for integer $n$ such that if $y$ is nonzero, the result has the same sign as $x$ and magnitude less than the magnitude of $y$.

**errno:** EDOM, for $y = 0$

**Calling interface:**

double fmod(double x, double y);
long double fmodl(long double x, long double y);
float fmodf(float x, float y);

**remainder**

**Description:** The `remainder` function returns the value of $x \text{ REM } y$ as required by the IEEE standard.

**Calling interface:**

double remainder(double x, double y);
long double remainderl(long double x, long double y);
float remainderf(float x, float y);

**remquo**

**Description:** The `remquo` function returns the value of $x \text{ REM } y$. In the object pointed to by `quo` the function stores a value whose sign is the sign of $x/y$ and whose magnitude is congruent modulo $2^n$ of the integral quotient of $x/y$. $N$ is an implementation-defined integer. For all systems, $N$ is equal to 31.

**Calling interface:**

double remquo(double x, double y, int *quo);
long double remquol(long double x, long double y, int *quo);
float remquof(float x, float y, int *quo);

**Miscellaneous Functions**

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

The Intel® Math Library supports the following miscellaneous functions:

**copysign**

**Description:** The `copysign` function returns the value with the magnitude of $x$ and the sign of $y$.

**Calling interface:**

double copysign(double x, double y);
long double copysignl(long double x, long double y);
float copysignf(float x, float y);

**fabs**

**Description:** The `fabs` function returns the absolute value of `x`.

**Calling interface:**
- `double fabs(double x);`
- `long double fabsl(long double x);`
- `float fabsf(float x);`

**fdim**

**Description:** The `fdim` function returns the positive difference value, `x-y` (for `x > y`) or `+0` (for `x <= y`).

**errno:** `ERANGE`, for values too large

**Calling interface:**
- `double fdim(double x, double y);`
- `long double fdiml(long double x, long double y);`
- `float fdimf(float x, float y);`

**finite**

**Description:** The `finite` function returns 1 if `x` is not a NaN or +/- infinity. Otherwise 0 is returned.

**Calling interface:**
- `int finite(double x);`
- `int finitel(long double x);`
- `int finitef(float x);`

**fma**

**Description:** The `fma` functions return `(x*y)+z`.

**Calling interface:**
- `double fma(double x, double y, double z);`
- `long double fmal(long double x, long double y, long double z);`
- `float fmaf(float x, float y, float double z);`

**fmax**

**Description:** The `fmax` function returns the maximum numeric value of its arguments.

**Calling interface:**
- `double fmax(double x, double y);`
- `long double fmaxl(long double x, long double y);`
- `float fmaxf(float x, float y);`

**fmin**

**Description:** The `fmin` function returns the minimum numeric value of its arguments.

**Calling interface:**
- `double fmin(double x, double y);`
- `long double fminl(long double x, long double y);`
- `float fminf(float x, float y);`
**fpclassify**

**Description:** The `fpclassify` function returns the value of the number classification macro appropriate to the value of its argument.

<table>
<thead>
<tr>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (NaN)</td>
</tr>
<tr>
<td>1 (Infinity)</td>
</tr>
<tr>
<td>2 (Zero)</td>
</tr>
<tr>
<td>3 (Subnormal)</td>
</tr>
<tr>
<td>4 (Finite)</td>
</tr>
</tbody>
</table>

**Calling interface:**
- `double fpclassify(double x);`
- `long double fpclassifyl(long double x);`
- `float fpclassifyf(float x);`

**isfinite**

**Description:** The `isfinite` function returns 1 if `x` is not a NaN or +/- infinity. Otherwise 0 is returned.

**Calling interface:**
- `int isfinite(double x);`
- `int isfinite6l(long double x);`
- `int isfinite6f(float x);`

**isgreater**

**Description:** The `isgreater` function returns 1 if `x` is greater than `y`. This function does not raise the invalid floating-point exception.

**Calling interface:**
- `int isgreater(double x, double y);`
- `int isgreater6l(long double x, long double y);`
- `int isgreater6f(float x, float y);`

**isgreaterequal**

**Description:** The `isgreaterequal` function returns 1 if `x` is greater than or equal to `y`. This function does not raise the invalid floating-point exception.

**Calling interface:**
- `int isgreaterequal(double x, double y);`
- `int isgreaterequal6l(long double x, long double y);`
- `int isgreaterequal6f(float x, float y);`

**isinf**

**Description:** The `isinf` function returns a non-zero value if and only if its argument has an infinite value.

**Calling interface:**
- `int isinf(double x);`
- `int isinf6l(long double x);`
- `int isinf6f(float x);`
isless
**Description:** The `isless` function returns 1 if `x` is less than `y`. This function does not raise the invalid floating-point exception.

**Calling interface:**
```c
int isless(double x, double y);
int islesssl(long double x, long double y);
int islessf(float x, float y);
```

islessequal
**Description:** The `islessequal` function returns 1 if `x` is less than or equal to `y`. This function does not raise the invalid floating-point exception.

**Calling interface:**
```c
int islessequal(double x, double y);
int islessequall(long double x, long double y);
int islessequalf(float x, float y);
```

islessgreater
**Description:** The `islessgreater` function returns 1 if `x` is less than or greater than `y`. This function does not raise the invalid floating-point exception.

**Calling interface:**
```c
int islessgreater(double x, double y);
int islessgreaterl(long double x, long double y);
int islessgreaterf(float x, float y);
```

isnan
**Description:** The `isnan` function returns a non-zero value, if and only if `x` has a NaN value.

**Calling interface:**
```c
int isnan(double x);
int isnanl(long double x);
int isnanf(float x);
```

isnormal
**Description:** The `isnormal` function returns a non-zero value, if and only if `x` is normal.

**Calling interface:**
```c
int isnormal(double x);
int isnormall(long double x);
int isnormalf(float x);
```

isunordered
**Description:** The `isunordered` function returns 1 if either `x` or `y` is a NaN. This function does not raise the invalid floating-point exception.

**Calling interface:**
```c
int isunordered(double x, double y);
int isunorderedl(long double x, long double y);
int isunorderedf(float x, float y);
```
maxmag

**Description:** The `maxmag` function returns the value of larger magnitude from among its two arguments, \( x \) and \( y \). If \( |x| > |y| \) it returns \( x \); if \( |y| > |x| \) it returns \( y \); otherwise it behaves like \( \text{fmax}(x, y) \).

**Calling interface:**

```c
double maxmag(double x, double y);
float maxmagf(float x, float y);
```

minmag

**Description:** The `minmag` function returns the value of smaller magnitude from among its two arguments, \( x \) and \( y \). If \( |x| < |y| \) it returns \( x \); if \( |y| < |x| \) it returns \( y \); otherwise it behaves like \( \text{fmin}(x, y) \).

**Calling interface:**

```c
double minmag(double x, double y);
float minmagf(float x, float y);
```

nextafter

**Description:** The `nextafter` function returns the next representable value in the specified format after \( x \) in the direction of \( y \).

**errno:** `ERANGE`, for overflow and underflow conditions

**Calling interface:**

```c
double nextafter(double x, double y);
long double nextafterl(long double x, long double y);
float nextafterf(float x, float y);
```

nexttoward

**Description:** The `nexttoward` function returns the next representable value in the specified format after \( x \) in the direction of \( y \). If \( x \) equals \( y \), then the function returns \( y \) converted to the type of the function. Use the `Qlong-double` option on Windows* operating systems for accurate results.

**errno:** `ERANGE`, for overflow and underflow conditions

**Calling interface:**

```c
double nexttoward(double x, long double y);
long double nexttowardl(long double x, long double y);
float nexttowardf(float x, long double y);
```

signbit

**Description:** The `signbit` function returns a non-zero value, if and only if the sign of \( x \) is negative.

**Calling interface:**

```c
int signbit(double x);
int signbitl(long double x);
int signbitf(float x);
```

significand

**Description:** The `significand` function returns the significand of \( x \) in the interval \([1,2)\). For \( x \) equal to zero, \( \text{NaN} \), or +/- infinity, the original \( x \) is returned.

**Calling interface:**

```c
double significand(double x);
long double significandl(long double x);
```
float significandf(float x);

**Complex Functions**

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The mathimf.h header file includes prototypes for Intel® Math Library functions.

The Intel® Math Library supports the following complex functions:

**cabs**

**Description:** The `cabs` function returns the complex absolute value of `z`.

**Calling interface:**

```c
double cabs(double _Complex z);
long double cabsl(long double _Complex z);
float cabsf(float _Complex z);
```

**cacos**

**Description:** The `cacos` function returns the complex inverse cosine of `z`.

**Calling interface:**

```c
double _Complex cacos(double _Complex z);
long double _Complex cacosl(long double _Complex z);
float _Complex cacosf(float _Complex z);
```

**cacosh**

**Description:** The `cacosh` function returns the complex inverse hyperbolic cosine of `z`.

**Calling interface:**

```c
double _Complex cacosh(double _Complex z);
long double _Complex cacoshl(long double _Complex z);
float _Complex cacoshf(float _Complex z);
```

**carg**

**Description:** The `carg` function returns the value of the argument in the interval \([-\pi, +\pi]\).

**Calling interface:**

```c
double carg(double _Complex z);
long double cargl(long double _Complex z);
float cargf(float _Complex z);
```

**casin**

**Description:** The `casin` function returns the complex inverse sine of `z`.

**Calling interface:**

```c
double _Complex casin(double _Complex z);
long double _Complex casinl(long double _Complex z);
float _Complex casinf(float _Complex z);
```

**casinh**

**Description:** The `casinh` function returns the complex inverse hyperbolic sine of `z`.
Calling interface:
\begin{verbatim}
double _Complex casinh(double _Complex z);
long double _Complex casinhl(long double _Complex z);
float _Complex casinhf(float _Complex z);
\end{verbatim}

catan

Description: The `catan` function returns the complex inverse tangent of \( z \).

Calling interface:
\begin{verbatim}
double _Complex catan(double _Complex z);
long double _Complex catanl(long double _Complex z);
float _Complex catanf(float _Complex z);
\end{verbatim}

catanh

Description: The `catanh` function returns the complex inverse hyperbolic tangent of \( z \).

Calling interface:
\begin{verbatim}
double _Complex catanh(double _Complex z);
long double _Complex catanhl(long double _Complex z);
float _Complex catanhf(float _Complex z);
\end{verbatim}

ccos

Description: The `ccos` function returns the complex cosine of \( z \).

Calling interface:
\begin{verbatim}
double _Complex ccos(double _Complex z);
long double _Complex ccosl(long double _Complex z);
float _Complex ccosf(float _Complex z);
\end{verbatim}

ccosh

Description: The `ccosh` function returns the complex hyperbolic cosine of \( z \).

Calling interface:
\begin{verbatim}
double _Complex ccosh(double _Complex z);
long double _Complex ccoshl(long double _Complex z);
float _Complex ccoshf(float _Complex z);
\end{verbatim}

cexp

Description: The `cexp` function returns \( e^z \) (\( e \) raised to the power \( z \)).

Calling interface:
\begin{verbatim}
double _Complex cexp(double _Complex z);
long double _Complex cexpl(long double _Complex z);
float _Complex cexpf(float _Complex z);
\end{verbatim}

cexp2

Description: The `cexp` function returns \( 2^z \) (2 raised to the power \( z \)).

Calling interface:
\begin{verbatim}
double _Complex cexp2(double _Complex z);
long double _Complex cexp2l(long double _Complex z);
float _Complex cexp2f(float _Complex z);
\end{verbatim}
**cexp10**

**Description:** The `cexp10` function returns \(10^z\) (10 raised to the power of \(z\)).

**Calling interface:**
```c
double _Complex cexp10(double _Complex z);
long double _Complex cexp10l(long double _Complex z);
float _Complex cexp10f(float _Complex z);
```

**cimag**

**Description:** The `cimag` function returns the imaginary part value of \(z\).

**Calling interface:**
```c
double cimag(double _Complex z);
long double cimagl(long double _Complex z);
float cimagf(float _Complex z);
```

**cis**

**Description:** The `cis` function returns the cosine and sine (as a complex value) of \(z\) measured in radians.

**Calling interface:**
```c
double _Complex cis(double x);
long double _Complex cisl(long double z);
float _Complex cisf(float z);
```

**cisd**

**Description:** The `cisd` function returns the cosine and sine (as a complex value) of \(z\) measured in degrees.

**Calling interface:**
```c
double _Complex cisd(double x);
long double _Complex cisdl(long double z);
float _Complex cisdf(float z);
```

**clog**

**Description:** The `clog` function returns the complex natural logarithm of \(z\).

**Calling interface:**
```c
double _Complex clog(double _Complex z);
long double _Complex clogl(long double _Complex z);
float _Complex clogf(float _Complex z);
```

**clog2**

**Description:** The `clog2` function returns the complex logarithm base 2 of \(z\).

**Calling interface:**
```c
double _Complex clog2(double _Complex z);
long double _Complex clog2l(long double _Complex z);
float _Complex clog2f(float _Complex z);
```

**clog10**

**Description:** The `clog10` function returns the complex logarithm base 10 of \(z\).

**Calling interface:**
```c
double _Complex clog10(double _Complex z);
```
long double _Complex clog10l(long double _Complex z);
float _Complex clog10f(float _Complex z);

**conj**

**Description:** The `conj` function returns the complex conjugate of `z` by reversing the sign of its imaginary part.

**Calling interface:**

double _Complex conj(double _Complex z);
long double _Complex conjl(long double _Complex z);
float _Complex conjf(float _Complex z);

**cpow**

**Description:** The `cpow` function returns the complex power function, $x^y$.

**Calling interface:**

double _Complex cpow(double _Complex x, double _Complex y);
long double _Complex cpowl(long double _Complex x, long double _Complex y);
float _Complex cpowf(float _Complex x, float _Complex y);

**cproj**

**Description:** The `cproj` function returns a projection of `z` onto the Riemann sphere.

**Calling interface:**

double _Complex cproj(double _Complex z);
long double _Complex cprojl(long double _Complex z);
float _Complex cprojf(float _Complex z);

**creal**

**Description:** The `creal` function returns the real part of `z`.

**Calling interface:**

double creal(double _Complex z);
long double creall(long double _Complex z);
float crealf(float _Complex z);

**csin**

**Description:** The `csin` function returns the complex sine of `z`.

**Calling interface:**

double _Complex csin(double _Complex z);
long double _Complex csinl(long double _Complex z);
float _Complex csinf(float _Complex z);

**csinh**

**Description:** The `csinh` function returns the complex hyperbolic sine of `z`.

**Calling interface:**

double _Complex csinh(double _Complex z);
long double _Complex csinhl(long double _Complex z);
float _Complex csinhf(float _Complex z);
\textbf{csqrt}

\textbf{Description:} The \texttt{csqrt} function returns the complex square root of \texttt{z}.

\textbf{Calling interface:}
\begin{verbatim}
double _Complex csqrt(double _Complex z);
long double _Complex csqrtl(long double _Complex z);
float _Complex csqrtf(float _Complex z);
\end{verbatim}

\textbf{ctan}

\textbf{Description:} The \texttt{ctan} function returns the complex tangent of \texttt{z}.

\textbf{Calling interface:}
\begin{verbatim}
double _Complex ctan(double _Complex z);
long double _Complex ctanl(long double _Complex z);
float _Complex ctanf(float _Complex z);
\end{verbatim}

\textbf{ctanh}

\textbf{Description:} The \texttt{ctanh} function returns the complex hyperbolic tangent of \texttt{z}.

\textbf{Calling interface:}
\begin{verbatim}
double _Complex ctanh(double _Complex z);
long double _Complex ctanhl(long double _Complex z);
float _Complex ctanhf(float _Complex z);
\end{verbatim}

\textbf{C99 Macros}

Many routines in the Intel\textsuperscript{\textregistered} Math Library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

The \texttt{mathimf.h} header file includes prototypes for Intel\textsuperscript{\textregistered} Math Library functions.

The Intel\textsuperscript{\textregistered} Math Library and \texttt{mathimf.h} header file support the following C99 macros:

\begin{verbatim}
int fpclassify(x); int isfinite(x); int isgreater(x, y); int isgreaterequal(x, y); int isinf(x); int isless(x, y); int islessequal(x, y); int islessgreater(x, y); int isnan(x); int isnormal(x); int isunordered(x, y); int signbit(x);
\end{verbatim}

Miscellaneous Functions

\textbf{Automatically-Aligned Dynamic Allocation}

\textbf{Automatically-Aligned Dynamic Allocation}

\textbf{Background}

It is possible to tell the compiler that a data structure has a greater alignment requirement than its individual elements require. For example:
**C++ standard syntax**

```cpp
class alignas(64) X {
  double elem[8];
};
```

**GNU-compatible syntax**

```cpp
class __attribute__((aligned(64))) X {
  double elem[8];
};
```

**Microsoft-compatible syntax**

```cpp
class __declspec(align(64)) X {
  double elem[8];
};
```

This is especially important for a structure that will be used with SIMD instructions, which typically require greater alignment than the individual data elements. The compiler will ensure that variables declared with such a type, either statically or on the stack, will be allocated with the appropriate alignment.

However, if an object of such a type is allocated dynamically, with a `new`-expression, the compiler was not previously able to do anything to ensure the appropriate alignment. That is because the C++ language requires that only very specific allocation methods be used, over which the programmer can take control if necessary, and none of those allocation methods are able to support specific alignment. They all assume that some alignment value is enough for everything, and guarantee that (and nothing more).

In the past, to ensure a greater alignment for a given type, a programmer had to take control of its allocation. One way to do that is by always allocating the memory separately with the appropriate alignment, and using a non-allocating placement `new`-expression. For example:

**Incorrect alignment**

```cpp
new X
```

**Correct alignment**

```cpp
new (_mm_malloc(sizeof(X), alignof(X))) X
```

However, this method is verbose, tedious, and error-prone.

Another way is to write class-specific allocation and deallocation functions—`operator new` and `operator delete`. For example:

```cpp
class alignas(64) X {
  double elem[8];

public:
  void *operator new(size_t size){
    return _mm_malloc(size, alignof(X));
  }

  void operator delete(void *p){
    return _mm_free(p);
  }
};
```

This method is easier, because the changes are centralized in the class, instead of being distributed over the uses of the class. But to get it right in general is still fairly involved, because it requires defining several more functions, in case arrays of the class are dynamically allocated or `nothrow` allocation is used.
Automatically-Aligned Dynamic Allocation

In this release of the compiler, all that is necessary in order to get correct dynamic allocation for aligned data is to include a new header:

```cpp
#include <aligned_new>
```

After this header is included, a `new`-expression for any aligned type will automatically allocate memory with the alignment of that type.

On Windows*, it is possible to direct the compiler to include a file at the beginning of the primary source file, without modifying the source, using the `/FI` command-line option.

Implementation Details

This section explains the language rules for the new feature. If a program needs to take control of dynamic allocation and deallocation of aligned data for some reason other than alignment, this section explains how it can be done.

Header `<aligned_new>` defines several new alignment-aware allocation and deallocation functions, each of which takes an alignment argument:

```cpp
void *operator new (size_t, align_val_t);
void *operator new (size_t, align_val_t, nothrow_t const &);
void operator delete  (void *, align_val_t);
void operator delete  (void *, align_val_t, nothrow_t const &);
void *operator new[] (size_t, align_val_t);
void *operator new[] (size_t, align_val_t, nothrow_t const &);
void operator delete[] (void *, align_val_t);
void operator delete[] (void *, align_val_t, nothrow_t const &);
```

The type `align_val_t` is declared internally by the compiler as if by a declaration like this:

```cpp
namespace std {
  enum class align_val_t: size_t;
};
```

In other words, `std::align_val_t` is a scoped enumeration type, which can not be implicitly converted to an integer type, but has the same range and representation as `std::size_t`.

When the compiler processes a `new`-expression for a type whose alignment is greater than `(2 * sizeof(void *))`, it builds an argument list according to the normal C++ rules, but with an additional alignment argument of type `align_val_t` following the size argument (followed by the placement arguments from the `new`-expression, if any). It then uses overload resolution to try to find an alignment-aware `operator new` or `operator new[]` function that can be called with those arguments. If no alignment-aware function is found, the alignment argument is removed from the argument list, and overload resolution is attempted again. An error is reported if this second attempt fails.

Class-specific Allocation and Deallocation Functions

If a program already provides class-specific allocation and deallocation functions for an aligned class, including `<aligned_new>` will not change the behavior, because class-specific functions take precedence over global functions, and `<aligned_new>` defines only global functions.

Unless class-specific allocation and deallocation functions are written for a base class of a class hierarchy containing classes with different alignments, it is probably not necessary to write alignment-aware allocation and deallocation functions that take an alignment argument; the appropriate alignment can instead be built into the class-specific allocation and deallocation functions.
Replacing Global Allocation and Deallocation Functions

**NOTE** If a program defines its own global allocation and deallocation functions, replacing the ones from the standard library, and uses a non-placement new-expression to allocate aligned data, and `<aligned_new>` is included before the point of such a new-expression, the behavior of the program will change. The allocation will no longer use the program's replacement allocation functions, but instead Intel's provided alignment-aware allocation functions. In a program that replaces the global allocation and deallocation functions, care must be used to decide whether to include `<aligned_new>`.

If a program wants to replace the global allocation and deallocation functions, and also wants to take advantage of the compiler’s ability to provide an alignment argument to such functions, `<aligned_new>` should not be included, because it provides inline definitions of the alignment-aware functions, which will conflict with or take precedence over the program’s definitions. Instead, `<aligned_new>` should be used as a guide to write program-specific declarations and definitions of the alignment-aware functions that need to be replaced.

**Pointer Checker**

**Pointer Checker Overview**

The pointer checker is not supported on macOS* systems.

This feature requires installation of another product. For more information, see Feature Requirements.

The pointer checker is a debugging feature that helps you find buffer overruns in applications. The feature performs bounds checking for memory accesses through pointers and identifies any out-of-bounds access in pointer-checker enabled code. The pointer checker can also detect dangling pointers, that is, pointers that point to memory that has been freed. When this detection is enabled, using a dangling pointer in an indirect access will also cause an out-of-bounds error.

The C and C++ languages define semantics for memory access for pointers. However, many applications still make out-of-bounds memory accesses and these accesses can go undetected, risking data corruption and increasing vulnerability to malicious attacks. The pointer checker provides full checking of all memory accesses through pointers and catches out-of-bounds memory accesses before memory corruption occurs. When you compile your code with the pointer checker enabled, it identifies and reports out-of-bounds memory accesses.

The pointer checker is designed for use during application testing and debugging. Because it adds overhead in terms of the size and execution time of a program, you will want to deploy programs with the pointer checker disabled.

Your application can contain both pointer checker enabled code as well as code that is not enabled. The pointer checker allows this co-existence because it does not change the data structure layout of functions during its checking.

Pointer Checker Feature Summary

Feature Requirements

**Pointer Checker Feature Summary**

The pointer checker is not supported on macOS* systems.

The pointer checker provides a number of related elements, summarized in the following table.
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Compiler Options:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| [Q]check-pointers | Enables the pointer checker and adds the associated libraries. This compiler option enables checking of all indirect accesses through pointers and accesses to arrays.  
  The possible option keywords are [ none | write | rw ], where:  
  - **none**: Disables the pointer checker (default).  
  - **write**: Checks bounds for only writes through pointers.  
  - **rw**: Checks bounds for reads and writes through pointers.  
  If the compiler determines that an access is safe during optimization, then the compiler removes the pointer checking code.  
  See Checking Bounds. |
| [Q]check-pointers-dangling | Enables checking for dangling pointer references.  
  The possible option keywords are [ none | heap | stack | all ], where:  
  - **none**: Disables checking for dangling pointer references (default).  
  - **heap**: Checks for dangling pointer references on the heap.  
  - **stack**: Checks for dangling pointer references on the stack.  
  - **all**: Checks for dangling pointer references on both the heap and the stack.  
  **NOTE**  
  To use this option, you must also use the [Q]check-pointers compiler option.  
  This option cannot be used with [Q]check-pointers-mpx.  
  See Checking for Dangling Pointers. |
| [Q]check-pointers-undimensioned | Enables the checking of bounds for arrays without dimensions.  
  **NOTE**  
  To use this option, you must also use the [Q]check-pointers compiler option.  
  See Checking Arrays. |
| [Q]check-pointers-narrowing | Determines whether the compiler enables or disables the narrowing of pointers to structure fields. Narrowing restricts a field pointer so that it can only legally point to that field.  
  Enables or disables the compiler narrowing of pointers to structure fields.  
  The default is enabled for narrowing pointer references. Disabling this feature can improve Pointer Checker compatibility with non-ANSI compliant code. To disable the narrowing of pointers to structure fields, specify the negative form of the option. |
To use this option, you must also use the `[Q]check-pointers` compiler option.

Determines whether the compiler checks bounds for memory access through pointers on processors supporting Intel® Memory Protection Extensions (Intel® MPX). It enables checking of all indirect accesses through pointers, and all array accesses.

Specifies what type of bounds checking occurs. The possible option keywords are `[ none | write | rw ]`, where:

- **none**: Disables the pointer checker (default).
- **write**: Checks bounds for only writes through pointers.
- **rw**: Checks bounds for reads and writes through pointers.

The compiler may optimize these checks away when it can determine that an access is safe.

This option cannot be used with `[Q]check-pointers-dangling`.

If you specify option `[Q]check-pointers` along with option `[Q]check-pointers-mpx`, `[Q]check-pointers-mpx` takes precedence.

**Intrinsics:**

- `void * __chkp_lower_bound(void **)`
  - Returns the lower bound associated with the pointer.
  - See Writing a Wrapper.

- `void * __chkp_upper_bound(void **)`
  - Returns the upper bound associated with the pointer.
  - See Writing a Wrapper.

- `void * __chkp_kill_bounds(void *p)`
  - Removes the bounds information to allow the pointer specified in the argument to access all memory. Use this function for a pointer from a non-enabled module that will be used in an enabled module where you cannot determine the bounds of the pointer.
  - The function ensures that the pointer created from a non-enabled module does not inherit the bounds from another pointer that was in the same memory address.
  - The return value is a pointer without bounds information.
  - See Working with Enabled and Non-Enabled Modules.

- `void * __chkp_make_bounds(void *p, size_t size)`
  - Creates new bounds information within the allocated memory address for the pointer in the argument, replacing any previously associated bounds information. The new bounds are:

    ```cpp
    p = __chkp_make_bounds(q, size)
    // lower_bound(p) = (char *)q
    // upper_bound(p) = lower_bound(p) + size
    ```
### Reporting Function:

```c
void __chkp_report_control(__chkp_report_option_t option, __chkp_callback_t callback)
```

Determines how errors are reported. See Finding and Reporting Out-of-Bounds Errors.

### Enumeration:

```c
__chkp_report_option_t
```

Controls how out-of-bounds error are reported. This enumeration is declared in the header file `chkp.h`.

### Environment Variable:

`INTEL_CHKP_REPORT_MODE`

Changes the pointer checker reporting mode at runtime.

### Header file:

`chkp.h`

Defines intrinsic and reporting functions. The header file is located in the `<install-dir>/include` directory.

---

**Using the Pointer Checker**

---

**Checking Bounds**

The pointer checker is not supported on macOS* systems.

The pointer checker checks indirect accesses through pointers for accesses that are out of bounds.

**Checking Bounds on Read/Write Operations**

To check the bounds of pointers, compile your module with `Q|check-pointers` compiler option, specifying the `rw` argument.

You can also check bounds by specifying the `write` argument. This also checks the bounds of pointers, but only for pointer write operations.
Consider the case where you create an array with ten elements using the `malloc()` function and then you write a character to each array element:

**Example: Writing to Each Array Element**

```c
char *buf = malloc(10);
for (int i=0; i<=10; i++) { buf[i] = 'A' + i; }
```

The array has ten elements, but the loop iterates eleven times. On the eleventh iteration, the function writes a character to the eleventh element of the array, which is outside of the allocated memory. Regardless of whether you specify bounds checking for read and write operations or only write operations, the pointer checker will report an out-of-bounds error. Even in the case of a statically allocated buffer, the pointer checker will still report an error. Consider this case:

**Example: Out-of-bounds Error with a Statically Allocated Buffer**

```c
fprintf(stderr, "buf[%d]=%d\n",i,buf[i]);
```

Here, the reference to `buf[i]` is a read (or load) operation. Therefore, an out-of-bounds error will not be reported if you specified pointer checking only for write operations.

### Pointer Arithmetic and Pointer Checking

Pointer arithmetic does not affect the pointer checker. A pointer can go out of range as long as the pointer does not make an indirect reference to an out of range address.

In the case where you create an array with 100 elements, the following applies:

**Example: Pointer Arithmetic with Pointer Checking**

```c
char *p = malloc(100);
p += 200;       // pointer is out of range, but no error
p[-101] = 0;   // access is still in range, it is the original p[99]
p[0] = 0;      // out-of-bounds error occurs here, because it is original p[200]
```

### See Also

`check-pointers`, `Qcheck-pointers` compiler option

### Checking for Dangling Pointers

The pointer checker is not supported on macOS* systems.

When dangling pointer checking or heap is enabled, the compiler uses a wrapper for the C runtime function `free()` and the C++ `delete` operator. These wrappers find all pointers that point to the block being freed, and change their bounds so that any access through the pointer will cause a bound violation. The bounds of these dangling pointers are actually set to:

- `lower_bound(p) = 2;`
- `upper_bound(p) = 0;`

If your program gets a bound violation with these bounds, it is the result of a reference through a dangling pointer.

When dangling pointer checking is enabled for stack, the compiler finds all pointers that point to the locals of the function and changes their bounds in the same way as heap pointers above, just before the function exits.

If you have a custom memory allocator, you can enable it to do dangling pointer checking. The `free()` function of your custom memory allocator should call this function in the pointer checker runtime code:

```c
void __chkp_invalidate_dangling(void *ptr, size_t size);
```
This function is declared in the `chkp.h` file. You must include that header file to use this function because it uses a custom call interface.

```c
#include <chkp.h>
void my_free(void *ptr) {
    size_t size = my_get_size(ptr);
    // do the free
    __chkp_invalidate_dangling(ptr, size);
}
```

You can also enabled dangling pointer checking in any function you use to override the C++ `delete` operator.

**See Also**

`check-pointers-dangling`, `Qcheck-pointers-dangling` compiler option

### Checking Arrays

The pointer checker is not supported on macOS* systems.

The C and C++ language allows you to define arrays in another module with the `extern` keyword. These arrays can be defined without specifying the dimensions.

**Example: Creating an Undimensioned Array**

```c
extern char an_undimensioned_array[];
```

The compiler allows more than one definition for externally defined arrays. During link time, the compiler uses the array definition with the largest bounds.

To check these arrays, the compiler defines a global symbol that marks the end of the array. However, checking undimensioned arrays can lead to a multiple defined linker error. To fix this linker error, do one of the following:

- Use only one array definition.
- Use the negative form of the `[Q]check-pointers-undimensioned` compiler option to disable checking arrays without bounds.

**NOTE**

This compiler option suppresses checking in the module that declares an array without bounds. The pointer checker will still check the arrays in modules that actually define the arrays with bounds.

**See Also**

`check-pointers-undimensioned`, `Qcheck-pointers-undimensioned` compiler option

### Working with Enabled and Non-Enabled Modules

The pointer checker is not supported on macOS* systems.

An enabled module is a module compiled with the pointer checker option enabled, while a non-enabled module is a module compiled with this compiler option disabled.

If you write a pointer to memory or return a pointer from a non-enabled module, the pointer may get incorrect bounds information. If you use this pointer with the incorrect bounds information in an enabled module, the pointer checker will report an incorrect out-of-bounds error because the bounds do not correspond to the pointer.
To minimize this issue, the pointer checker stores a copy of the pointer along with the bounds information. When the pointer is loaded into memory, the value of the pointer is compared with the value of the pointer copy. If these two values match, the bounds information is assumed to be correct and is then used. However, if the two values do not match, the bounds are set to allow access to any memory.

The pointer checker can still report an out-of-bounds error if a pointer from a non-enabled module matches the pointer copy stored with the bounds information.

For example, consider the case where you create the following pointer by using a run-time library function from a non-enabled module:

```
Example: Pointer Created with RTL Function

p = my_realloc(p, old_size + 100);
```

If the memory allocator can simply extend the memory allocated to \texttt{p}, and then returns the same pointer, an enabled module could use this pointer with the old bounds information. The pointer checker then reports an out-of-bounds error because this feature does not know about the extension created by the \texttt{realloc()} function.

To prevent incorrect out-of-bounds errors when you have both enabled and non-enabled modules, do one of the following:

- Remove the bounds information from the pointer by using the \texttt{__chkp_kill_bounds()} intrinsic function
- Set the correct bounds information by using the \texttt{__chkp_make_bounds()} intrinsic function in an enabled module.

### Removing the Bounds Information

When you remove the bounds information, you disable pointer checking on this pointer. You can remove the bounds information by using the \texttt{__chkp_kill_bounds()} intrinsic function.

```
Example: Removing Bounds Information with __chkp_kill_bounds()

void * unknown_pointer_returning_function() {
    ...
    // Use the intrinsic function in the return pointer
    return __chkp_kill_bounds(the_ptr);
}
```

### Setting the correct bounds information

You can use the \texttt{__chkp_make_bounds()} intrinsic function to set the correct bounds information for a pointer.

For example, you use the Windows* \texttt{HeapAlloc()} function to create a pointer. Since this operating system function is from a non-enabled module, the pointer from this function will not have the correct bounds information.

To get a pointer with the correct bounds information, use the \texttt{__chkp_make_bounds()} intrinsic function in the return value:

```
Example: Obtaining a Pointer with __chkp_make_bounds()

void * myalloc(size_t size){ return __chkp_make_bounds(HeapAlloc(MyHeap, flags, size), size); }
```

### Storing Bounds Information

The pointer checker is not supported on macOS* systems.
The pointer checker stores bounds information in a bounds table located in a memory address that is not adjacent to the memory address of the pointer. The pointer checker calculates this address by using the address of the pointer.

Because the bounds information is being stored in a separate memory address, use of the pointer checker in this module does not affect the data structure layouts and stack frames. You can check the bounds of pointers in enabled modules. Non-enabled modules will still work properly although this feature will not check the pointers in these modules.

When a pointer is loaded in a register, the compiler also loads the bounds from the bounds table. When a pointer is stored from a register, the compiler stores the bounds information in the bounds table.

**Passing and Returning Bounds**

The pointer checker is not supported on macOS* systems.

When you pass a pointer to a function, the pointer checker also passes the bounds information associated with the pointer. The feature uses the following methods to pass and return arguments:

- If you pass a pointer on the stack, the pointer is in a memory location, so the pointer checker stores the bounds information when you compile your enabled module. The bounds information is stored in the bounds table entry associated with the address of the pointer.
- If you pass a pointer on a register, the compiler uses a location in thread local storage to pass the bounds. There is one such location associated with each register in which a pointer can be passed. This same location is used to return the bounds when a pointer is returned by a function.

**Checking Run-Time Library Functions**

The pointer checker is not supported on macOS* systems.

The pointer checker provides checking on C run-time library functions that manipulate memory through pointers. It uses a library of functions that either replace the run-time library function, or wrap them with the appropriate pointer checking mechanisms.

For functions that allocate memory, such as the `malloc()` function or various C++ new functions, the wrapper function create bounds information for the pointers returned by the memory allocator.

For functions that copy memory, such as the `memcpy()` function, the memory address may contain the pointers along with their associated bounds information. The wrapper functions check for out-of-bounds accesses and ensure that any bounds associated with the copied memory are also copied.

The pointer checker C run-time function wrappers are located in the `libchkpwrap` library. To determine which C run-time routines are wrapped, you can examine the entry points in the library. For example, the following will yield a list of entry points:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| // Linux*
  % nm libchkpwrap.a | egrep 'T __chkp_' |
| // Windows* (x86) dumpbin /symbols libchkpwrap.lib | egrep 'SECT.*External.*' 
  ['_']*__chkp_ ' |

The returned list will include entry points that signify wrappers. For example, `__chkp_strdup` is the wrapper for `strdup`.

**Writing a Wrapper**

The pointer checker is not supported on macOS* systems.
You can write your own wrappers for run-time library functions. Typically, you would use one or more of the pointer checker intrinsics.

**Example: Allocation Wrapping with __chkp_make_bounds**

```c
extern void *wrap_malloc(size_t bytes) {
  void* ppp;
  ppp = malloc(bytes);
  if (ppp) { ppp = (void*)__chkp_make_bounds(ppp, bytes);
  } else { ppp = (void*)0;}
  return ppp;
}
```

The next example shows a wrapper that checks the validity of the pointer passed by performing writes to the first and last addresses that the C run-time routine will write. This will cause out of bounds events if necessary, while still allowing optimized handling of the C run-time library call.

**Example: Checking without using Pointer Checker Intrinsics**

```c
extern void *wrap_memset(void *dst, int c, size_t size) {
  if (size > 0) {
    *(char *)dst = c;          // write to first address
    *((char*)dst+size-1) = c;  // write to last address
    (void)memset(dst, c, size);
  }
  return dst;
}
```

Alternatively, you can perform the checking directly by comparing to the bounds associated with the pointer. In this case, you must first make sure that the bounds are meaningful. You can use the __chkp_upper_bound and __chkp_lower_bound intrinsics for this purpose.

**Example: Upper and Lower Bound Intrinsics**

```c
extern void *wrap_memset(void *dst, int c, size_t size) {
  if (size > 0) {
    char *ub = __chkp_upper_bound(&dst);
    if ((intptr_t)ub != (intptr_t)-1) {
      char *lb = __chkp_lower_bound(&dst);
      char *max = (char*)dst+size-1;
      if (dst < lb)
        *(char*)dst = c;  // cause bounds violation
      if (max > ub)
        *(char*)max = c;  // cause bounds violation
    }
    (void)memset(dst, c, size);
  }
  return dst;
}
```

**Checking Custom Memory Allocators**

The pointer checker is not supported on macOS* systems.

Many C and C++ applications use standard memory allocation functions to allocate large chunks of memory and then define their own custom memory allocation functions to allocate these large chunks of memory into smaller chunks. If you use the pointer checker on a module that contains custom memory allocation functions, every memory allocation from these custom functions will have the bounds information from the large chunk of memory.
To create the correct bounds information for a pointers in a custom memory allocator function, use the __chkp_make_bounds() intrinsic function.

For example, consider the case where you create a custom memory allocator function that returns a pointer. To add the exact bounds information to the return pointer, use the __chkp_make_bounds() intrinsic function in the return value:

```
Adding exact bounds information to a return pointer

void *myalloc(size_t size) {
    // Code to do allocate the large chunk of memory into small chunks.
    // Add bounds information to the pointer
    return __chkp_make_bounds(p, size);
}
```

**NOTE**
If you override the new operator in C++, you can use the same technique to give bounds information to the return pointer.

### Checking Multi-Threaded Code

The pointer checker is not supported on macOS* systems.

A common assumption is that reading or writing a pointer is an atomic operation that cannot be interrupted by starting another thread. This is not the case with using the pointer checker to check pointers in multi-threaded modules.

When you read or write a pointer from memory, the bounds information associated with the pointer must also be read or written. Reading and writing bounds information takes multiple instructions. While a thread is in the process of writing a pointer and its bounds, it could be swapped out for another thread. If that thread then writes to the same pointer, you can end up with a pointer and bounds information that are not synchronized—the pointer is from one thread and the bounds information is from another thread.

To synchronize the pointer and bounds information in multi-threaded code, use a locking mechanism, such as a mutex or critical section when reading or writing a pointer in memory locations shared by more than one thread. Typically, accesses to shared memory are already protected this way.

If your application relies on a pointer read or a pointer write that is atomic and performs reads or writes to shared pointers without such locking, you can get extraneous bounds violations unless you protect these accesses.

### How the Compiler Defines Bounds Information for Pointers

The pointer checker is not supported on macOS* systems.

The following defines how the compiler determines the bound information for pointers.

**NOTE**
In each section, lower_bound(p) refers to the lower bound associated with p and upper_bound(p) refers to the upper bound associated with p.
Pointers created by the `alloca()` function

```c
p = alloca(size);
// lower_bound(p) is (char *)p
// upper_bound(p) is lower_bound(p) + size - 1
```

Pointers created by the `calloc()` function

```c
p = calloc(num, size);
// lower_bound(p) is (char *)p
// upper_bound(p) is lower_bound(p) + size * num - 1
```

Pointers created by the `malloc()` function

```c
p = malloc(size);
// lower_bound(p) is (char *)p
// upper_bound(p) is lower_bound(p) + size - 1
```

Pointers created by casting

```c
p = (T *)q;
// lower_bound(p) is lower_bound(q)
// upper_bound(p) is upper_bound(q)
```

Casting a pointer does not affect the bounds of a pointer. If you cast a pointer to a new type that is larger than the bounds associated with the original pointer, you will get an out-of-bounds error when you try to access any member or element outside the original bounds. If you cast a pointer to a smaller type than the original pointer, you can still access the original data.

Pointers created for a variable length array in a structure

```c
typedef struct {
    int num;
    int a[];
} T;

q = malloc(sizeof(T) + sizeof(int) * num);
p = &q->a;
// lower_bound(p) is (char *)&q->a
// upper_bound(p) is upper_bound(q)
```

When you define an array as the last member of a structure, the upper bound is not narrowed and is allowed to access all of the array elements allocated by the `malloc()` function.

Pointers defined by the address (`&`) operator

```c
p = &v;
// lower_bound(p) is (char *)&v
// upper_bound(p) is (char *)&v + sizeof(v) - 1
```

```c
p = &v.m;
// lower_bound(p) is (char *)&v + offsetof(typeof(v), m)
```
### Pointers defined by the address (&) operator

```c
p = &q->m;
// lower_bound(p) is (char *)q + offsetof(typeof(*q), m)
// upper_bound(p) is lower_bound(p) + sizeof(q->m) - 1
```

**NOTE**
The bounds information is narrowed to the size of the member when you point to a member of a structure, union, or class.

### Pointers defined by the new operator

```c
p = new T;
// lower_bound(p) is (char *)p
// upper_bound(p) is lower_bound(p) + sizeof(T) - 1
```

### Pointers defined by the addresses in an array

```c
T a[X][Y];
```

```c
p = a;
p = &a[x];
p = &a[x][y];
// lower_bound(p) is (char *)a
// upper_bound(p) is lower_bound(p) + sizeof(a) - 1
```

When you take the address of an element of an array or the address of a single row of a multi-dimensioned array, the bounds are not narrowed to the size of the element. You can increment or decrement the pointer throughout the array.

### Incrementing and Decrementing Pointers

```c
p = &a[x][y].m;
// lower_bound(p) is (char *)&a[n][m] + offsetof(T, m)
// upper_bound(p) is lower_bound(p) + sizeof(T.m) - 1
```

When you take the address of a member of an element, the bounds are narrowed to the size of the member.

### Pointers defined by pointer copies

```c
p = q;
p = q + expr;
p = q - expr;
// lower_bound(p) is lower_bound(q)
// upper_bound(p) is upper_bound(q)
```

The bounds are copied from `q`. Offsetting the pointer on the right does not affect the bounds.
### Pointers defined by incrementing or decrementing a pointer

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p++;</code></td>
<td>Increment pointer <code>p</code>.</td>
</tr>
<tr>
<td><code>p--;</code></td>
<td>Decrement pointer <code>p</code>.</td>
</tr>
<tr>
<td><code>++p;</code></td>
<td>Increment pointer <code>p</code> and then assign to <code>p</code>.</td>
</tr>
<tr>
<td><code>--p;</code></td>
<td>Decrement pointer <code>p</code> and then assign to <code>p</code>.</td>
</tr>
<tr>
<td><code>p += expr;</code></td>
<td>Add <code>expr</code> to <code>p</code> and then assign to <code>p</code>.</td>
</tr>
<tr>
<td><code>p -= expr;</code></td>
<td>Subtract <code>expr</code> from <code>p</code> and then assign to <code>p</code>.</td>
</tr>
</tbody>
</table>

The bounds do not change when you increment or decrement a pointer.

### Finding and Reporting Out-of-Bounds Errors

The pointer checker is not supported on macOS* systems.

The pointer checker includes the `__chkp_report_control()` library function and the `__chkp_report_option_t` enumeration to allow you to control how errors are reported. The function and enumeration are declared in the header file `chkp.h`.

The report control enumeration has one of the following values:

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__CHKP_REPORT_NONE</code></td>
<td>Do nothing.</td>
</tr>
<tr>
<td><code>__CHKP_REPORT_BPT</code></td>
<td>Execute a breakpoint interrupt. If you specify this value, the pointer checker will issue a breakpoint for any out-of-bounds error that it finds. If you are using a debugger, the breakpoint will trap into the debugger so that you can determine where the error occurred. You can then use the features of the debugger to determine the cause of the error.</td>
</tr>
<tr>
<td><code>__CHKP_REPORT_LOG</code></td>
<td>Log the error and continue; the compiler will report each out-of-bounds pointer it finds.</td>
</tr>
<tr>
<td><code>__CHKP_REPORT_TERM</code></td>
<td>Log the error and exit the program; the compiler will only report the first bounds violation and then terminate.</td>
</tr>
<tr>
<td><code>__CHKP_REPORT_CALLBACK</code></td>
<td>Call a user defined function; the compiler will invoke a user-defined function to deal with a bounds error.</td>
</tr>
<tr>
<td><code>__CHKP_REPORT_TRACEBACK_K_BPT</code></td>
<td>Print a traceback including source file and line number for the instruction where the out-of-bounds error occurred, then execute a breakpoint interrupt.</td>
</tr>
</tbody>
</table>

**NOTE**
Specify the `traceback` compiler option to obtain better traceback information, including routine names.

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__CHKP_REPORT_TRACE_LOG</code></td>
<td>Log the error and continue; the log will include traceback information for each out-of-bounds error. This is the default reporting mode.</td>
</tr>
</tbody>
</table>

**NOTE**
Specify the `traceback` compiler option to obtain better traceback information, including routine names.

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__CHKP_REPORT_TRACE_TERM</code></td>
<td>Log the error and terminate; the log will include traceback information for each out-of-bounds error. Only the first bounds error will be reported.</td>
</tr>
<tr>
<td>Enum Value</td>
<td>Action</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>__CHKP_REPORT_TRACE_CALLBACK</td>
<td>Log the error and call a user-defined routine; the log will include traceback information for each out-of-bounds error.</td>
</tr>
<tr>
<td>__CHKP_REPORT_OOB_STATS</td>
<td>Emit statistics for the bounds violation; Currently, this is a count of the out-of-bounds errors.</td>
</tr>
<tr>
<td>__CHKP_REPORT_USE_ENV_VAR</td>
<td>Use the environment variable INTEL_CHKP_REPORT_MODE to specify the reporting mode. If the environment variable is not set, the default reporting mode is used.</td>
</tr>
</tbody>
</table>

### Changing the Reporting Mode

To change the reporting mode from the default `__CHKP_REPORT_TRACE_LOG`:

1. Include `chkp.h` in your program source.
2. Add a call to the report control routine `__chkp_report_control()` (before any pointer references are made), specifying one of the enum values.

   For example, to report all bounds errors, specify the following:
   ```c
   __chkp_report_control(__CHKP_REPORT_LOG, 0);
   ```

   In the above, the first parameter to the routine is the enum value and the second parameter is 0, except in the case of the `__CHKP_REPORT_CALLBACK` enum value, which requires the name of a user-defined callback routine as the second parameter.

   You can also change the reporting mode using the environment variable `INTEL_CHKP_REPORT_MODE`. This allows you to change the reporting mode without recompiling your code. To use the environment variable, do the following:

   1. Add an include of `chkp.h` in your program source.
   2. Add a call to the report control routine `__chkp_report_control()` (before any pointer references are made), specifying `__CHKP_REPORT_USE_ENV_VAR`.
   3. Set the `INTEL_CHKP_REPORT_MODE` environment variable to the desired report mode. For example:
      ```bash
      export INTEL_CHKP_REPORT_MODE=__CHKP_REPORT_OOB_STATS
      ```

   **NOTE**
   The `INTEL_CHKP_REPORT_MODE` environment variable is valid only if a call to `__chkp_report_control` has been made with the report mode set to `__CHKP_REPORT_USE_ENV_VAR`. Otherwise, it is ignored.

   If you specify the report mode to be `__CHKP_REPORT_USE_ENV_VAR` and the `INTEL_CHKP_REPORT_MODE` environment variable is not set, the default report mode (`__CHKP_REPORT_TRACE_LOG`) is used.

Tools

PGO Tools

PGO Tools Overview
This section describes the tools that take advantage of or support the Profile-guided Optimizations (PGO) available in the compiler.

- Code coverage Tool
- Test prioritization Tool
- Profmerge and proforder Tools

Code Coverage Tool
The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are listed below:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- Code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate an HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on all supported Intel architectures on Linux*, Windows*, and macOS* operating systems.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.
Code Coverage Tool Requirements

To run the code coverage tool on an application, you must have following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows) option.

NOTE

Use the -[Q]prof-gen:srcpos option if you intend to use the collected data for code coverage and profile feedback. If you are only interested in using the instrumentation for code coverage, use the /Qcov-gen option. Using the /Qcov-gen option saves time and improves performance. This option can be used only on Windows platform for all architectures.

- A pgopti.dpi file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge tool. This file is also generated implicitly by the Intel® compilers when compiling an application with [Q]prof-use options with available .dyn and .dpi files.

Using the Tool

The tool uses the following syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov [-codecov_option]</td>
</tr>
</tbody>
</table>

where -codecov_option is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in the code coverage tools Options section. If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows), and/or /Qcov-gen (Windows) option.

   This step generates an instrumented executable and a corresponding static profile information (pgopti.spi) file when the [Q]prof-gen=srcpos option is used. When the /Qcov-gen option is used, minimum instrumentation only for code coverage and generation of .spi file is enabled.

   NOTE

   You can specify both the /Qprof-gen=srcpos and /Qcov-gen options on the command line. The higher level of instrumentation needed for profile feedback is enabled along with the profile option for generating the .spi file, regardless of the order the options are specified on the command line.

2. Run the instrumented application.

   This step creates the dynamic profile information (.dyn) file. Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by the -prof-dir (Linux or macOS*) or /Qprof-dir (Windows) option, or PROF_DIR environment variable. On Windows, you can use the /Qcov-dir or COV_DIR environment variable. These have the same meaning as /Qprof-dir and PROF_DIR.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (pgopti.dpi) file.

   This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.
You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the `profmerge -a` option. Select an alternate name for the output .dpi file using the `profmerge -prof_dpi` option.

**Caution**
The profmerge tool merges all .dyn files that exist in the given directory. Confirm that unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. The valid syntax and tool options are shown below.

This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.

**NOTE**
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-.").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

**Example: specify .dpi and .spi files**

```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

**Example: add contact information**

```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

**Example: export data to text**

```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

### Code Coverage Tool Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-bcolor color</code></td>
<td><code>#FFFF99</code></td>
<td>Specifies the HTML color name for code in the uncovered blocks.</td>
</tr>
<tr>
<td><code>-beginblkdsbl string</code></td>
<td></td>
<td>Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td><code>-ccolor color</code></td>
<td><code>#FFFFFF</code></td>
<td>Specifies the HTML color name or code of the covered code.</td>
</tr>
<tr>
<td><code>-comp file</code></td>
<td></td>
<td>Specifies the file name that contains the list of files being (or not) displayed.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-counts</td>
<td></td>
<td>Generates dynamic execution counts.</td>
</tr>
<tr>
<td>-demang</td>
<td></td>
<td>Demangles both function names and their arguments.</td>
</tr>
<tr>
<td>-dpifile</td>
<td>pgopti.dpi</td>
<td>Specifies the file name of the dynamic profile information file (.dpi).</td>
</tr>
<tr>
<td>-endblkdsblstring</td>
<td></td>
<td>Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-fcolorcolor</td>
<td>#FFCCCC</td>
<td>Specifies the HTML color name for code of the uncovered functions.</td>
</tr>
<tr>
<td>-help, -h</td>
<td></td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-icolorcolor</td>
<td>#FFFFFFFF</td>
<td>Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.</td>
</tr>
<tr>
<td>-include-nonexec</td>
<td></td>
<td>Block details will also be listed for functions that did not execute, when used with -xmlbcvrg[full] or -txtbcvrg[full] options.</td>
</tr>
<tr>
<td>-maddrstring</td>
<td>Nobody</td>
<td>Sets the email address of the web-page owner</td>
</tr>
<tr>
<td>-mnamestring</td>
<td>Nobody</td>
<td>Sets the name of the web-page owner.</td>
</tr>
<tr>
<td>-nopartial</td>
<td></td>
<td>Treats partially covered code as fully covered code.</td>
</tr>
<tr>
<td>-nopmeter</td>
<td></td>
<td>Turns off the progress meter. The meter is enabled by default.</td>
</tr>
<tr>
<td>-nounwind</td>
<td></td>
<td>Ignores compiler-generated unwind handlers for exception handling cleanup when computing and displaying basic block coverage.</td>
</tr>
<tr>
<td>-onelinedsblstring</td>
<td></td>
<td>Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-pcolorcolor</td>
<td>#FAFAD2</td>
<td>Specifies the HTML color name or code of the partially covered code.</td>
</tr>
<tr>
<td>-prjstring</td>
<td></td>
<td>Sets the project name.</td>
</tr>
<tr>
<td>-ref</td>
<td></td>
<td>Finds the differential coverage with respect to ref_dpi_file.</td>
</tr>
<tr>
<td>-showdirnames</td>
<td></td>
<td>Displays the full path name for source files in the HTML report, instead of just the base filename.</td>
</tr>
<tr>
<td>-spifile</td>
<td>pgopti.spi</td>
<td>Specifies the file name of the static profile information file (.spi).</td>
</tr>
<tr>
<td>-srcrootdir</td>
<td></td>
<td>Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.</td>
</tr>
</tbody>
</table>
## Option

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-txtbcvrgfile</td>
<td></td>
<td>Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtbcvrgfullfile</td>
<td></td>
<td>Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtdcgfile</td>
<td></td>
<td>Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtfcvrgfile</td>
<td></td>
<td>Export function coverage for covered function in text format. The file parameter must by in the form of a valid file name.</td>
</tr>
<tr>
<td>-ucolorcolor</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the unknown code.</td>
</tr>
<tr>
<td>-xcolorcolor</td>
<td>#90EE90</td>
<td>Specifies the HTML color of the code ignored.</td>
</tr>
<tr>
<td>-xmlbcvrgfile</td>
<td></td>
<td>Export the block-coverage for the covered function in XML format. The file parameter must by in the form of a valid file name.</td>
</tr>
<tr>
<td>-xmlbcvrgfullfile</td>
<td></td>
<td>Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-xmlfcvrgfile</td>
<td></td>
<td>Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.</td>
</tr>
</tbody>
</table>

### NOTE

In order for the substitution to take place, the sources need to be compiled with one of the following options: 

\[Q\profsrcret, [Q]prof-src-root-cwd. This option specifies the base directory that is to be treated as the project root directory.

An example of use is:

```plaintext
C:> ifort -Qprof-gen:srcpos -Qprof-src-root c:\workspaces\orig_project_dir test1.f90 test2.f90
C:> test1.exe
C:> profmerge
C:> cd \workspaces\
C:> mv orig_project_dir new_project_dir
C:> cd new_project_dir\src
C:> codecov -srcroot C:\workspaces\new_project_dir
```

Now, "C:\workspaces\new_project_dir" will be substituted for "c:\workspaces\orig_project_dir" when looking for the source files.

Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application’s critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

Top-Level Coverage

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest.
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.
- By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  - Basic-block coverage
  - Function coverage
  - Function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.
The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. With one click you can see the least-covered function in the list, and with another click you can see the body of the function. You can scroll down in the source view and browse through the function body.

**Individual Module Source View**

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

**Setting the Coloring Scheme for the Code Coverage**

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covered code</td>
<td>#FFFFFF</td>
<td>Indicates code was exercised by the tests. You can override the default color with the -ccolor tool option.</td>
</tr>
<tr>
<td>Uncovered basic block</td>
<td>#FFFF99</td>
<td>Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed during the tests. You can override the default color with the -bcolor tool option.</td>
</tr>
<tr>
<td>Uncovered function</td>
<td>#FFCCCC</td>
<td>Indicates functions that were never called during the tests. You can override the default color with the -fcolor tool option.</td>
</tr>
<tr>
<td>Partially covered code</td>
<td>#FAFAD2</td>
<td>Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the -pcolor tool option.</td>
</tr>
<tr>
<td>Ignored code</td>
<td>#90EE90</td>
<td>Indicates code that was specifically marked to be ignored. You can override this default color using the -xcolor tool option.</td>
</tr>
<tr>
<td>Information lines</td>
<td>#FFFFFF</td>
<td>Indicates basic-block markers and dynamic counts. You can override the default color with the -icolor tool option.</td>
</tr>
<tr>
<td>Unknown</td>
<td>#FFFFFF</td>
<td>Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the -ucolor tool option.</td>
</tr>
</tbody>
</table>
The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

**NOTE**
You need to interpret the colors in the context of the code. For example, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks. Another example is the closing brackets in C/C++ applications.

**Dynamic Counters**
The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the code is an `if` statement:

```
11  if ((N == 1).OR. (N == 0))
   ^ 10 (1/2)
12      printf("%d\n", N)
   ^
```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.
- Only one of the two blocks was executed, resulting in the partial coverage color.
- Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

**Differential Coverage**
Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run, and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

**Generating Reference Data**
Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the -ref option. The following command demonstrate a typical command for generating the reference data:

### Example: generating reference data

```
codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code with the same coverage property (covered or not covered) on both runs is considered covered code. Otherwise, if the new run indicates that the code was executed, while in the reference run the code was not executed, then the code is treated as uncovered. Alternately, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

### Running Differential Coverage

To run the code coverage tool for differential coverage, you must have the application sources, the .spi file, and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of differential coverage analysis:

### Example

```
codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi
```

Specify the .dpi and .spi files using the -spi and -dpi options.

### Excluding Code from Coverage Analysis

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will be unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, lack of a test case is preferred. You may want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking portions of the code infeasible and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

#### Including and Excluding Coverage at the File Level

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the -comp option. The following example shows the general command:

### Example: specifying a component file

```
codecov -comp file
```

where `file` is the name of a text file containing strings that act as file/directory name masks for including and excluding file-level analysis. For example, assume the following:

- You want to include all files with the string "source" in the file name or directory name.
- You create a component text file named `myComp.txt` with the selective inclusion string "source".
Once you have a component file, enter a command similar to the following:

```bash
codecov -comp myComp.txt
```

In this example, filenames with string "source" (like source1.c and source2.c) and all files within directories where the directory name contains the string "source" (like source/file1.c and source2/file2.c) are included in the analysis.

To exclude files or directories, add the tilde (~) prefix to the string. You can specify inclusion and exclusion in the same component file. For example, assume you want to analyze all individual files or files in a directory where the file/directory name includes the string "source", and you want to exclude all individual files and files in directories where the file/directory name includes the string "skip". You add content similar to the following to the component file (myComp.txt) and pass it to the -comp option:

```
source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file, myComp.txt, instructs the tool to:

- Include files with filename containing "source" (like source1.c and source2.c)
- Include all files in directories with the directory name containing "source" (like source/file1.c and source2/file2.c)
- Exclude all files with filename containing "skip" (like skipthis1.c and skipthis2.c)
- Exclude all files in directories with the directory name containing "skip" (like skipthese1/debug1.c and skipthese2/debug2.c)

### Excluding Coverage at the Line and Function Level

You can mark individual lines for exclusion my passing string values to the -onelinedsbl option. For example, assume that you have some code similar to the following:

```
Sample code

printf ("internal error 123 - please report!\n"); // NO_COVER
printf ("internal error 456 - please report!\n"); /* INF IA-32 architecture */
```

If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following.

```bash
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.
Sample code
void dumpInfo (int n) {
    // NO_COVER
    ...
}

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the -onelinedsbl and -xcolor options. The following example commands demonstrate the combination:

Example: combining tool options
```
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

Excluding Code by Defining Arbitrary Boundaries
The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the -beginblkdsbl and -endblkdsbl options to mark the beginning and end (respectively) of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

Sample code
void div (int m, int n) {
    if (n == 0)
    /* BEGIN_INF */
    { printf (internal error 314 please report\n);
        recover (); }
    /* END_INF */
    else { ... }
}
...
// BINF
Void recover () { ... }
// EINF

The following example commands demonstrate how to use the -beginblkdsbl option to mark the beginning and the -endblkdsbl option to mark the end of code to exclude from the sample shown above.

Example: arbitrary code marker commands
```
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF
codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the -xcolor option.
Exporting Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool.

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The -xmlfcvrg, -txtfcvrg, -xmlbcvrg and -txtbcvrg options support the first method.

- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The -xmlbcvrgfull and -txtbcvrgfull options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

**Quick Export**

The profile of covered functions of an application can be exported quickly using the -xmlfcvrg, -txtfcvrg, -xmlbcvrg, and -txtbcvrg options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

```
Example: quick export of function data
codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function, together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report.

**XML-formatted report example**

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.C">
    <FUNCTION name="f0" freq="2">
      <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
    </FUNCTION>
    ...
  </MODULE>
  <MODULE name = "D:\SAMPLE2.C">
    ...
  </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.c, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.
You can also export the data in text format using the `-txtfcvrg` option. The generated text report, using this option, for the above example would be similar to the following example:

<table>
<thead>
<tr>
<th>Function name</th>
<th>Execution frequency</th>
<th>Line number of the start of the function definition</th>
<th>Column number of the start of the function definition</th>
<th>Percentage of basic-block coverage of the function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;f0&quot;</td>
<td>2</td>
<td>6</td>
<td>5</td>
<td>83.33</td>
</tr>
<tr>
<td>&quot;f1&quot;</td>
<td>1</td>
<td>6</td>
<td>4</td>
<td>66.67</td>
</tr>
<tr>
<td>&quot;f2&quot;</td>
<td>1</td>
<td>6</td>
<td>3</td>
<td>50.00</td>
</tr>
</tbody>
</table>

In the text formatted version of the report, the each line of the report should be read in the following manner:

Additionally, the tool supports exporting the block level coverage data using the `-xmlbcvrg` option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

```
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cpp">
    <FUNCTION name="f0" freq="2">
      ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1" />
      </INSTANCE>
    </BLOCK>
    <BLOCK line="12" col="3">
      <INSTANCE id="1" freq="2" />
      <INSTANCE id="2" freq="1" />
    </BLOCK>
  </FUNCTION>
</MODULE>
</PROJECT>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.cpp. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column 3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

**Combined Exports**

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.
Use the -xmlbcvrgfull and -txtbcvrgfull options to generate reports in all supported formats in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

**Dynamic Call Graphs**

Using the -txtdcg option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

**Test Prioritization Tool**

The test prioritization tool, also known as the tselect tool, enables the profile-guided optimizations on all supported Intel® architectures, on Linux*, Windows*, and macOS* operating systems, to select and prioritize tests for an application based on prior execution profiles.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool

**Features and Benefits**

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application. The tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing. Instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests’ execution time.

See Understanding Profile-guided Optimization and Profile an Application topics for general information on creating the files needed to run this tool.

**Test Prioritization Tool Requirements**

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the -prof-gen=srcpos (Linux* and macOS*) or /Qprof-gen:srcpos (Windows*) option.
- The .dpi files generated by the profmerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. Run the profmerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.
- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
- Name each test .dpi file so the file names uniquely identify each test.
- Create a .dpi list file, which is a text file that contains the names of all .dpi test files.
  Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.
  For example: Test1.dpi 00:00:60:35 states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.
  The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

**Caution**
The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code. The tool uses the following general syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>tselect -dpi_listfile</td>
</tr>
</tbody>
</table>

-dpi_list is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.

**NOTE**
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

**Usage Model**
The following figure illustrates a typical test prioritization tool usage model.
Test Prioritization Tool Options

The tool uses the options that are listed in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-dpi_listfile</td>
<td>Required. Specifies the name of the file that contains the names of the dynamic profile information (.dpi) files. Each line of the file must contain only one .dpi file name, which can be followed by its execution time (optional). The name must uniquely identify the test.</td>
</tr>
<tr>
<td>-spifile</td>
<td>Specifies the file name of the static profile information file (.SPI). Default is pgopti.spi</td>
</tr>
<tr>
<td>-ofile</td>
<td>Specifies the file name of the output report file.</td>
</tr>
<tr>
<td>-compfile</td>
<td>Specifies the file name that contains the list of files of interest.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-cutoff value</td>
<td>Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by <code>value</code>, of pre-computed total coverage. <code>value</code> must be greater than 0.0 (for example, 99.00) but not greater than 100. <code>value</code> can be set to 100.</td>
</tr>
<tr>
<td>-nototal</td>
<td>Instructs the tool to ignore the pre-compute total coverage process.</td>
</tr>
<tr>
<td>-mintime</td>
<td>Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the same line of <code>dpi_list</code> file, after the test name in <code>dd:hh:mm:ss</code> format.</td>
</tr>
<tr>
<td>-srcbasedir dir</td>
<td>Specifies a different top-level project directory than was used during compiler instrumentation run with the <code>prof-src-root</code> compiler option to support relative paths to source files in place of absolute paths.</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to generate more logging information about program progress.</td>
</tr>
</tbody>
</table>

**Running the Tool**

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

   **Example**

   ```
   set PROF_DIR=c:\myApp\prof-dir
   ```

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

   **Operating System** | **Command**                                                                                           |
                        |                                                                                                        |
                        | Linux and macOS*                                          | `icpc -prof-gen=srcpos myApp.cpp`                        |
                        | Windows                                                  | `icl /Qprof-gen=srcpos myApp.cpp`                        |

   The commands shown above compile the program and generate instrumented binary `myApp`, as well as the corresponding static profile information `pgopti.spi`.

3. Confirm that unrelated `.dyn` files are not present by issuing a command similar to the following:

   **Example**

   ```
   rm prof-dir \*.*.dyn
   ```

4. Run the instrumented files by issuing a command similar to the following:

   **Example**

   ```
   myApp < data1
   ```
The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by the -prof-dir step above.

5. Merge all .dyn file into a single file by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test1.dpi
```

The profmerge tool merges all the .dyn files into one file (Test1.dpi) that represents the total profile information of the application on Test1.

6. Confirm again there are no unrelated .dyn files present a second time by issuing a command similar to the following:

Example

```
rm prof-dir \*.dyn
```

7. Run the instrumented application, and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified in the prof-dir step above by issuing a command similar to the following:

Example

```
myApp < data2
```

8. Merge all .dyn files into a single file by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test2.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test2.dpi) that represents the total profile information of the application on Test2.

9. Confirm that there are no unrelated .dyn files present for the final time by issuing a command similar to the following:

Example

```
rm prof-dir \*.dyn
```

10. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified by -prof-dir by issuing a command similar to the following:

Example

```
myApp < data3
```

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test3.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test3.dpi) that represents the total profile information of the application on Test3.

12. Create a file named tests_list with three lines. The first line contains Test1.dpi, the second line contains Test2.dpi, and the third line contains Test3.dpi.

Tool Usage Examples
When these items are available, the test prioritization tool may be launched from the command line in the prof-dir directory as described in the following examples.

**Example 1: Minimizing the Number of Tests**
The following example describes how minimize the number of test runs.

**Example Syntax**

```
tselect -dpi_list tests_list -spi pgopti.spi
```

where the `--spi` option specifies the path to the `.spi` file.

The following sample output shows typical results.

**Sample Output**

```
Total number of tests  =  3
Total block coverage   ~  52.17
Total function coverage ~  50.00

num  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
    ----------  --------  ----------  -------------------
    1   87.50     45.65     37.50    Test3.dpi
    2   100.50    52.17     50.00    Test2.dpi
```

In this example, the results provide the following information:
- By running all three tests, you achieve 52.17% block coverage and 50.00% function coverage.
- Test3 alone covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, you achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

**Example 2: Minimizing Execution Time**
Assume you have the following execution time of each test in the `tests_list` file:

**Sample Output**

```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `--mintime` option:

**Sample Syntax**

```
tselect -dpi_list tests_list -spi pgopti.spi --mintime
```

The following sample output shows possible results:
In this case, the results indicate that running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests when based on minimizing time (first Test2, then Test3) may be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

**Using Other Options**

The `-cutoff` enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to use the option:

```
Example

tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-cutoff` enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

**Profmerge and Proforder Tools**

**Profmerge Tool**

Use the profmerge tool to merge dynamic profile information (.dyn) files and any specified summary files (.dpi). The compiler executes profmerge automatically during the feedback compilation phase when you specify the `[Q]prof-use` option.

The command-line usage for profmerge is as follows:

```
Syntax

profmerge [-prof_dir dir_name]
```

The tool merges all .dyn files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: pgopti.dpi.
NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example [Q]prof-dir) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen (“-”) unlike Windows* compiler options, which are preceded by a forward slash (“/”).

You can use profmerge tool to merge .dyn files into a .dpi file without recompiling the application. You can run the instrumented executable file on multiple systems to generate .dyn files, and optionally use profmerge with the -prof_dpi option to name each summary .dpi file created from the multiple .dyn files.

Because the profmerge tool merges all the .dyn files that exist in the given directory, confirm that unrelated .dyn files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

Profmerge Options
The profmerge tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dump</td>
<td>Displays profile information.</td>
</tr>
<tr>
<td>-help</td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-exclude_files files</td>
<td>Excludes functions from the profile if the function comes from one of the listed files. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot;) as a wild card character in function names.</td>
</tr>
<tr>
<td>-exclude_funcs functions</td>
<td>Excludes functions from the profile. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot;) as a wild card character in function names.</td>
</tr>
<tr>
<td>-prof_dir dir</td>
<td>Specifies the directory from which to read .dyn and .dpi files, and write the .dpi file. Alternatively, you can set the environment variable PROF_DIR.</td>
</tr>
<tr>
<td>-prof_dpifile</td>
<td>Specifies the name of the .dpi file being generated.</td>
</tr>
<tr>
<td>-src_old dir-src_new dir</td>
<td>Changes the directory path stored within the .dpi file.</td>
</tr>
<tr>
<td>-no_src_dir</td>
<td>Uses only the file name and not the directory name when reading dyn/dpi records. If you specify -no_src_dir, the directory name of the source file is ignored.</td>
</tr>
</tbody>
</table>
### Tool Option Description

- **-src-rootdir**: Specifies a directory path prefix for the root directory where the user's application files are stored. This option is ignored if you specify `-no_src_dir`.

- **-a file1.dpi...fileN.dpi**: Specifies and merges available `.dpi` files.

- **-verbose**: Instructs the tool to display full information during merge.

- **-weighted**: Instructs the tool to apply an equal weighting (regardless of execution times) to the `.dyn` file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.

- **-gen_weight_spec file**: Instructs the tool to generate a text file containing a list of the `.dyn` and `.dpi` file that were merged with default weight=1/run_count.

  The text file is created in the directory specified by the `prof_dir` option.

- **-weight_spec weight_spec.txt**: Instructs the profmerge tool to generate and use the text file, `weight_spec.txt`, listing individual `.dyn`/.`dpi` files or directory names along with weight values for them.

  When the `-weight_spec` option is used:
  - A new `.dpi` file is always created
  - Only files called out by the specification file are merged
  - `.dyn` timestamps are ignored and merge always takes place

  The `prof_dir` option controls where the input/output `weight_spec.txt` is located, and the destination of the `.dpi` file.

  The `-weight_spec` option overrides:
  - Any values of `-a` option
  - Any computation from using `-weighted` option

---

**Weighting the Runs**

Using the `-weight_spec` option results in a new `.dpi` file. Only the files listed in the text file are merged. No files in the current directory are used unless they are included in the text file.

**Relocating source files using profmerge**
The Intel® C++ Compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (.dpi) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading .dyn/.dpi file records by specifying the profmerge option -no_scr_dir. This profmerge option is the same as the compiler option -no-prof-src-dir (Linux* and macOS*) and /Qprof-src-dir- (Windows*).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the profmerge option -src-root to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair -src_old-src_new to modify the data in an existing summary dpi file. For example:

### Example: relocation command syntax

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where `<dir1>` is the full path to dynamic information file (.dpi), `<dir2>` is the old full path to source files, and `<dir3>` is the new full path to source files. The example command (above) reads the pgopti.dpi file, in the location specified in `<dir1>`. For each function represented in the pgopti.dpi file, whose source path begins with the `<dir2>` prefix, profmerge replaces that prefix with `<dir3>`. The pgopti.dpi file is updated with the new source path information.

You can run profmerge more than once on a given pgopti.dpi file. For example, you may need to do this if the source files are located in multiple directories:

### Operating System | Command Examples
--- | ---
Linux* and macOS* | profmerge -prof_dir /src/prog_1 -src_old /src/prog_1 -src_new /src/prog_2  
 | profmerge -prof_dir /src/prog_1 -src_old /proj_1 -src_new /proj_2
Windows* | profmerge -src_old "c:/program files" -src_new "e:/program files"  
 | profmerge -src_old c:/proj/application -src_new d:/app

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical in Windows. Likewise, forward slash (`/`) and backward slash (`\`) characters are treated as identical.

**NOTE**  
Because the source relocation feature of profmerge modifies the pgopti.dpi file, consider making a backup copy of the file before performing the source relocation.

### Proforder Tool

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the /ORDER linker option in Windows. The tool uses the following syntax:

### Syntax

```
proforder [-prof_dir dir] [-o file]
```

where `dir` is the directory containing the profile files (.dpi and .spi), and `file` is the optional name of the function order list file. The default name is proford.txt.
NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example [Q]prof-dir) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-"), unlike Windows* compiler options, which are preceded by a forward slash ("/").

Proforder Options

The proforder tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td></td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td></td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-omit_static</td>
<td></td>
<td>Instructs the tool to omit static functions from function ordering.</td>
</tr>
<tr>
<td>-prof_dir dir</td>
<td></td>
<td>Specifies the directory where the .spi and .dpi file reside.</td>
</tr>
<tr>
<td>-prof_dpi file</td>
<td></td>
<td>Specifies the name of the .dpi file.</td>
</tr>
<tr>
<td>-prof_file string</td>
<td></td>
<td>Selects the .dpi and .spi files that include the substring value in the file name matching the values passed as string.</td>
</tr>
<tr>
<td>-prof_spi file</td>
<td></td>
<td>Specifies the name of the .spi file.</td>
</tr>
<tr>
<td>-o file</td>
<td>proford.txt</td>
<td>Specifies an alternate name for the output file.</td>
</tr>
</tbody>
</table>

Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option [Q]ipo, you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the functions and data in your application. These optimizations are not supported on macOS* systems.

The following table lists each optimization, the type of functions or global data it applies to, and the operating systems and architectures that it is supported on.

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type of Function or Data</th>
<th>Supported OS and Architectures</th>
</tr>
</thead>
</table>
| Function Order Lists: Specifies the order in which the linker should link the non-static routines (functions) of your program. This optimization can improve application performance | extern functions procedures and library functions only (not static functions). | Windows: all Intel architectures  
Linux: not supported |
Optimization | Type of Function or Data | Supported OS and Architectures
--- | --- | ---
by improving code locality and reduce paging. Also see Comparison of Function Order Lists and IPO Code Layout. | extern functions and static functions only (not library functions). | Linux: IA-32 and Intel 64 architectures
Function Grouping: Specifies that the linker should place the extern and static routines (functions) of your program into hot or cold program sections. This optimization can improve application performance by improving code locality and reduce paging. | extern functions and static functions only (not library functions). | Windows: not supported
Function Ordering: Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (functions) of your program. This optimization can improve application performance by improving code locality and reduce paging. | extern functions and static functions only (not library functions) | Linux and Windows: all Intel architectures
Data Ordering: Enables ordering of static global data items based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use. | Static global data only | Linux and Windows: all Intel architectures

You can only use one of the function-related ordering optimizations listed above on each application. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the prof-gen option keyword globdata (needed for Data Ordering) instead of srcpos (needed for function-related ordering).
The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the [Q]ipo or equivalent compiler option.

Generating a Function Order List (Windows)

This section provides an example of the process for generating a function order list. Assume you have a C++ program that consists of the following files: file1.cpp and file2.cpp. Additionally, assume you have created a directory for the profile data files called c:\profdata. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the /Qprof-gen:srcpos option. Use the /Qprof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

```
Example commands
icl /Femyprog /Qprof-gen=srcpos /Qprof-dir c:\profdata file1.cpp file2.cpp
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

```
Example commands
myprog.exe
```

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the pgopti.dpi file. Use the /prof_dir option to specify the directory location of the .dyn files.

```
Example commands
profmerge /prof_dir c:\profdata
```

4. Generate the function order list using the proforder tool. By default, the function order list is produced in the file proford.txt.

```
Example commands
proforder /prof_dir c:\profdata /o myprog.txt
```

5. Compile the application with the generated profile feedback by specifying the ORDER option to the linker. Use the /Qprof-dir option to specify the directory location of the profile files.

```
Example commands
icl /Femyprog /Qprof-use /Qprof-dir c:\profdata file1.cpp file2.cpp /link - ORDER:@myprog.txt
```

Using Function Grouping (Linux)

This section provides a general example of the process for using the function grouping optimization. Assume you have a C++ program that consists of the following files: file1.cpp and file2.cpp. Additionally, assume you have created a directory for the profile data files called profdata. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the -prof-gen option. Use the -prof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

```
Example commands
icl /Femyprog /Qprof-use /Qprof-dir c:\profdata file1.cpp file2.cpp /link - ORDER:@myprog.txt
```
Example commands

```
icc -o myprog -prof-gen -prof-dir ./profdata file1.cpp file2.cpp
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

Example commands

```
./myprog
```

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the -prof-func-group option to request the function grouping as well as the -prof-use option to request feedback compilation. Again, use the -prof-dir option to specify the location of the profile files.

Example commands

```
icl /Femyprog file1.cpp file2.cpp -prof-func-group -prof-use -prof-dir ./profdata
```

NOTE On Linux, the -prof-func-group option is on by default when -prof-use is selected.

Finer grain control over the number of functions placed into the hot region can be controlled with the -prof-hotness-threshold compiler option, see the command line reference for more details.

Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a C++ program that consists of the following files: file1.cpp and file2.cpp, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the -prof-gen=srcpos (Linux) or /Qprof-gen:srcpos (Windows) option. Use the [Q]prof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>icc -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.cpp file2.cpp</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Femyprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.cpp file2.cpp</td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
</tbody>
</table>
3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the [Q]prof-func-order option to request the function ordering, as well as the [Q]prof-use option to request feedback compilation. Again, use the [Q]prof-dir option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>icpc -o myprog -prof-dir ./profdata file1.cpp file2.cpp -prof-func-order-prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Fmyprog /Qprof-dir c:\profdata file1.cpp file2.cpp /Qprof-func-order /Qprof-use</td>
</tr>
</tbody>
</table>

### Using Data Ordering

This section provides an example of the process for using the data order optimization. Assume you have a C++ program that consists of the following files: file1.cpp and file2.cpp, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the -prof-gen=globdata (Linux) or /Qprof-gen=globdata (Windows) option. Use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>icc -o myprog -prof-gen=globdata -prof-dir ./profdata file1.cpp file2.cpp</td>
</tr>
<tr>
<td>Windows</td>
<td>icl /Fmyprog /Qprof-gen=globdata /Qprof-dir c:\profdata file1.cpp file2.cpp</td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
</tbody>
</table>

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the [Q]prof-data-order option to request the data ordering as well as the [Q]prof-use option to request feedback compilation. Again, use the [Q]prof-dir option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>icpc -o myprog -prof-dir ./profdata file1.cpp file2.cpp -prof-data-order-prof-use</td>
</tr>
</tbody>
</table>
Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the /Qipo (Windows) compiler option

Each method has advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions (external and library functions whose names are exposed to the linker).

The linker cannot directly affect the layout order for static functions because the names of these functions are not available in the object files.

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Alternately, using the /Qipo (Windows) option allows you to optimize the layout of all static or extern functions compiled with the Intel® C++ Compiler. The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

**Function Order List Effects**

<table>
<thead>
<tr>
<th>Function Type</th>
<th>IPO Code Layout</th>
<th>Function Ordering with proforder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static</td>
<td>X</td>
<td>No effect</td>
</tr>
<tr>
<td>Extern</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Library</td>
<td>No effect</td>
<td>X</td>
</tr>
</tbody>
</table>

**Function Order List Usage Guidelines (Windows*)**

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
- You must compile with /Gy to enable function-level linking. (This option is active if you specify either option /O1 or /O2.)

**Compiler Option Mapping Tool**

The Intel compiler's Option Mapping Tool provides an easy method to derive equivalent options between Windows* and Linux*. If you are a Windows-based application developer who is developing an application for Linux, you may want to know, for example, the Linux equivalent for the /Oy- option. Likewise, the Option Mapping Tool provides Windows equivalents for Intel compiler options supported on Linux.

**NOTE**

The Option Mapping Tool is not supported on macOS*.

**Using the Compiler Option Mapping Tool**

You can start the Option Mapping Tool from the command line by:
• invoking the compiler and using the [Q]map-opts option
• executing the tool directly

NOTE
Compiler options are mapped to their equivalent on the architecture you are using.

Calling the Option Mapping Tool with the Compiler
If you use the compiler to execute the Option Mapping Tool, the following syntax applies:

```<compiler command> <map-opts option> <compiler option(s)>```

Example: Finding the Linux equivalent for /Oy-

```icl /Qmap-opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for C++
'Qmap-opts' Windows option maps to
--> '-map-opts' option on Linux
--> '-map_opts' option on Linux
'Oy-' Windows option maps to
--> '-fomit-frame-pointer-' option on Linux
--> '-fno-omit-frame-pointer' option on Linux
--> '-fp' option on Linux```

Example: Finding the Windows equivalent for -fp

```icpc -map-opts -fp
Intel(R) Compiler option mapping tool
mapping Linux options to Windows for C++
'-map-opts' Linux option maps to
--> '-Qmap-opts' option on Windows
--> '-Qmap_opt' option on Windows
'-fp' Linux option maps to
--> '-Oy-' option on Windows```

Output from the Option Mapping Tool also includes:
• option mapping information (not shown here) for options included in the compiler configuration file
• alternate forms of the option that are supported but may not be documented

When you call the Option Mapping Tool with the compiler, your source file is not compiled.

Calling the Option Mapping Tool Directly
Use the following syntax to execute the Option Mapping Tool directly from a command line environment where the full path to the map_opts executable is known (compiler bin directory):

```map_opts [-nologo] -t<target OS> -l<language> -opts <compiler option(s)>```

where values for:
• <target OS> = {l|linux|w|windows}
• <language> = {f|fortran|c}

Example: Finding the Linux equivalent for /Oy-

```map_opts -tlinux -lC -opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for C++
'Oy-' Windows option maps to```
Example: Finding the Windows equivalent for `-fp`

```bash
map_opts -tw -lc -opts -fp
```

Intel(R) Compiler option mapping tool
mapping Linux options to Windows for C++
'
`-fp' Linux option maps to
`-> '-Oy-' option on Windows

**Offload Extract Tool**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**Description**

The Offload Extract tool is a standalone tool that extracts embedded target objects from fat objects and embedded target binaries from fat executables on Windows* and Linux* systems. The tool can be used for Intel® MIC Architecture related offload extraction. For simplicity, in this topic, the Intel® MIC Architecture target objects and executables will be referred to as Intel® MIC target objects and executables.

**Features and Benefits**

By default, you cannot use analyzing and debugging tools like `objdump` and `readelf` to directly examine offload Intel® MIC objects/binaries because they are embedded in the host object or binary.

Use the Offload Extract tool to extract Intel® MIC object/binary from a fat object/binary on 64-bit Linux* or 64-bit Windows* systems. The extracted object/binary is an ELF object that can be analyzed with `objdump` or `readelf` analyzing tools.

**Using the Tool**

To extract the target object files, invoke the offload extract tool as follows:

```bash
offload_extract <fat host object>
```

The Intel® MIC target objects are extracted into object files with the same name as the input object file but with the substring Intel® MIC appended to the filename. Since the target objects are in ELF format the object file name extension will be .o. For example,  

```bash
offload_extract host.obj => hostMIC.o
```

To extract the target executables, invoke the offload extract tool as follows:

```bash
offload_extract <fat host binary>
```

The Intel® MIC target executables are extracted into target executable files with the same name as the input object file but with the file extension Intel® MIC added. For example,

```bash
offload_extract host.exe => hostMIC.mic
```
NOTE
To extract the target object files from an archived library, you must first extract the individual fat objects from the fat archived library and then invoke the offload extract tool on the individual fat objects. For example:

```
ar -x libhost.a
offload_extract <individual fat host object>
```

Using Options

There are two options you can use to fine tune your extraction of offload binaries or executables.

Use the -o option to specify target filename or output directory. The syntax for the option is as follows:

```
offload_extract <fat host object|binary> [-o <output filename>]
offload_extract <fat host object|binary> [-o <output directory>]
```

When you use the -o option the target output filename and directory are generated without the Intel® MIC substring.

Use the -target option to select specific target Intel® MIC objects/executables to be extracted. The syntax for the option is as follows:

```
offload_extract <fat host object|binary> [-target mic]
```
 Compatibility and Portability

Conformance to the C/C++ Standards

The Intel® C++ Compiler conforms to the following ANSI/ISO standards:

- **C++** ISO/IEC 14882:1998
- **C** ISO/IEC 9899:1990

provides conformance to the ANSI/ISO standard for C language compilation (ISO/IEC 9899:1990). This standard requires that conforming C compilers accept minimum translation limits. This compiler exceeds all of the ANSI/ISO requirements for minimum translation limits.

C++ Support

The Intel® C++ Compiler supports many features in C++11. For a list of support features, see *C++ Features Supported by Intel® C++ compiler* at http://software.intel.com/en-us/articles/c0x-features-supported-by-intel-c-compiler.

Template Instatiation

The Intel® C++ Compiler supports *extern template*, which lets you specify that a template in a specific translation unit will not be instantiated because it will be instantiated in a different translation unit or different library. The compiler now includes additional support for:

- **inline template** – instantiates the compiler support data for the class (i.e. the vtable) for a class without instantiating its members.
- **static template** – instantiates the static data members of the template, but not the virtual tables or member functions.

You can now use the following options to gain more control over the point of template instantiation:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fno-implicit-templates</td>
<td>Never emit code for non-inline templates which are instantiated implicitly (i.e. by use). Only emit code for explicit instantiations.</td>
</tr>
<tr>
<td>-fno-implicit-inline-templates</td>
<td>Do not emit code for implicit instantiations of inline templates either. The default is to handle inlines differently so that compilations, with and without optimization, will need the same set of explicit instantiations.</td>
</tr>
</tbody>
</table>
C99 Support

The following C99 features are supported in this version of the Intel® C++ Compiler:

- restricted pointers (`restrict` keyword).
- variable-length Arrays
- flexible array members
- complex number support (`_Complex` keyword)
- hexadecimal floating-point constants
- compound literals
- designated initializers
- mixed declarations and code
- macros with a variable number of arguments
- inline functions (`inline` keyword)
- boolean type (`_Bool` keyword)

These `long double` (128-bit representations) feature is not supported:

See Also

- `-fno-implicit-templates` compiler option
- `-fno-implicit-inline-templates` compiler option

GCC* Compatibility and Interoperability

This topic applies to Linux*/macOS*.

The Intel® C++ Compiler is compatible with most versions of the GNU Compiler Collection (gcc*). The release notes contains a list of compatible versions.

C language object files created with the Intel® C++ Compiler are binary compatible with gcc* and C/C++ language library. You can use the Intel® C++ Compiler or the gcc* compiler to pass object files to the linker.

To pass IPO mock object files or libraries of IPO mock object files produced by the Intel® C++ Compiler to the linker, use the linking tools provided with the Intel® C++ Compiler. Specifically:

Use `icc`, `icpc`, `ifort`, `xild`, and `xiar`.

**NOTE**

When using an Intel software development product that includes an Intel® C++ compiler with a Clang front-end, you can also use `icl` or `icl++`.

Link-time optimization using the `-ffat-lto-objects` compiler option is provided for gcc* compatibility. This implies that `ld` and `ar` can be used to link and archive object files, but by doing so you will lose cross-file optimizations. You can use the `-fno-fat-lto-objects` compiler option when linking using IPO mock object files, provided that you link the IPO mock object files with `xild` and archive them with `xiar`.

The Intel® C++ Compiler supports many of the language extensions provided by the GNU compilers. See http://www.gnu.org for more information.
NOTE
Statement expressions are supported, except the following are prohibited inside them:

- dynamically-initialized local static variables.
- local non-POD class definitions.
- try/catch.
- variable length arrays.

Branching out of a statement expression and statement expressions in constructor initializers are not allowed. Variable-length arrays are no longer allowed in statement expressions.

NOTE
The Intel® C++ Compiler supports gcc-style inline ASM if the assembler code uses AT&T* System V/386 syntax.

GCC Interoperability
C++ compilers are interoperable if they can link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, and the resulting executable runs successfully. The Intel® C++ Compiler is highly compatible with the GNU compilers.

The Intel® C++ Compiler and GNU gcc* compiler support the following predefined macros:

- __GNUC__
- __GNUC_MINOR__
- __GNUC_PATCHLEVEL__

You can specify the -no-gcc option to undefine these macros. If you need gcc* interoperability (-cxxlib), do not use the -no-gcc compiler option.

Caution
Not defining these macros results in different paths through system header files. These alternate paths may be poorly tested or otherwise incompatible.

How the Intel Compiler Uses GCC
The Intel compiler uses the GNU* tools on the system, such as the GNU header files, including stdio.h, and the GNU linker and libraries. So the Intel compiler has to be compatible with the version of gcc or g++ you have on your system. For example, if you have gcc version 4.6 on your system, icc behaves like gcc 4.6, with the compatible features and behaviors.

By default, the compiler determines which version of gcc or g++ you have installed from the PATH environment variable.

If you want use a version of gcc or g++ other than the default version on your system, you need to use either the -gcc-name or -gxx-name compiler option to specify the path to the version of gcc or g++ that you want to use. For example:

- You want to build something that cannot be compiled by the default version of the system compiler, so you need to use a legacy version for compatibility, such as if you want to use third party libraries that are not compatible with the default version of the system compiler.
- You want to use a later version of gcc or g++ than the default system compiler.

The Intel compiler driver uses the default version of gcc/g++, or the version you specify, to extract the location of the headers and libraries.
The **cxxlib** options are connected to linking in the GNU C++ library. These options are not directly related to `-gcc-name` or `-gxx-name`.

- **-cxxlib-nostd** prevents the compiler from searching the C++ system include directories for the C++ standard library `libstdc++`. For example: If you specify `-cxxlib-nostd`, then `#include <iostream>` does not compile but `#include <stdio.h>` does. This option also prevents linking of `libstdc++`, because the driver leaves off the `-lstdc++` option.
- **-no-cxxlib** affects the linking of all C++ runtime libraries, not just `libstdc++`. So a program that only uses `printf`, for example, does not link if you specify `-no-cxxlib`, but it does link if you specify `-cxxlib-nostd`.
- **-cxxlib=dir** modifies the top level location for binaries and libraries. For example, if you specify `icc -gxx-name=/my/directory/g++ -cxxlib=/cxxlib/dir`, the driver attempts to find `g++` in `/cxxlib/dir/my/directory`

**Compatibility with Open Source Tools**

The Intel® C++ Compiler includes improved support for the following open source tools:

- **GNU Libtool** – a script that allows package developers to provide generic shared library support.
- **Valgrind** – a flexible system for debugging and profiling executables running on x86 processors.
- **GNU Automake** – a tool for automatically generating `Makefile.ins` from files called `Makefile.am`.

**See Also**

`ffat-lto-objects`

**Microsoft Compatibility**

The Intel® C++ Compiler is fully source- and binary-compatible (native code only) with the Microsoft® Visual C++® Compiler. You can debug binaries built with the Intel® C++ Compiler from within the Microsoft® Visual Studio® environment.

The Intel® C++ Compiler supports security checks with the /GS option. You can control this option in the Microsoft® Visual Studio® IDE by using **C/C++ > Code Generation > Buffer Security Check**.

The Intel® C++ Compiler also includes support for safe exception handling features with the /Qsafeseh option for 32-bit binaries. This option is on by default. You can control this option in the Microsoft® Visual Studio® IDE by using **C/C++ > Command Line > Additional options**.

**Microsoft® Visual Studio® Integration**

The Intel® C++ Compiler is compatible with Microsoft® Visual Studio® 2013 and 2015 projects.

The Intel® C++ Compiler only supports native C++ project types provided by Microsoft® Visual Studio® development environment. The project types with .NET attributes such as the ones below, cannot be converted to an Intel® C++ project:

- Empty Project (.NET)
- Class Library (.NET)
- Console Application (.NET)
- Windows Control Library (.NET)
- Windows Forms Application (.NET)
- Windows Service (.NET)

**Unsupported Major Features**

- COM Attributes
• C++ Accelerated Massive Parallelism (C++ AMP)
• Managed extensions for C++ (new pragmas, keywords, and command-line options)
• Event handling (new keywords)
  • __abstract keyword
  • __box keyword
  • __delegate keyword
  • gc keyword
  • __gc keyword
  • __identifier keyword
  • __nogc keyword
  • __pin keyword
  • __property keyword
  • __sealed keyword
  • __try_cast keyword
  • __w64 keyword

Unsupported Preprocessor Features
• #import directive changes for attributed code
• #using directive
  • managed, unmanaged pragmas
  • _MANAGED macro
• runtime_checks pragma

Mixing Managed and Unmanaged Code
If you use the managed extensions to the C++ language in Microsoft* Visual Studio .NET*, you can use the Intel® C++ Compiler for your non-managed code for better application performance. Make sure managed keywords do not appear in your non-managed code.

For information on how to mix managed and unmanaged code, refer to the article, "An Overview of Managed/Unmanaged Code Interoperability", on the Microsoft* Web site.

/GS compiler option
/Qsafeseh

Precompiled Header Support
There are some differences in how precompiled header (PCH) files are supported between the Intel® C++ Compiler and the Microsoft* Visual C++* compiler. These differences include the following:
• The PCH information generated by the Intel® C++ Compiler is not compatible with the PCH information generated by the Microsoft* Visual Studio* compiler.
• The Intel® C++ Compiler does not support PCH generation and use in the same translation unit.
• The Intel® C++ Compiler does not generate PCH information beyond a point where a declaration is seen in the primary translation unit. When the /Yu option is specified, the Microsoft* Visual C++* compiler ignores all text, including declarations preceding the #include statement of the specified file.
• The Microsoft* Visual C++* Compiler will not emit an error if a function or variable definition occurs in a PCH file which is included in two different source files and is not referenced. The Intel® C++ Compiler will always give a multiple definition link error under these circumstances.
Compilation and Execution Differences

While the Intel® C++ Compiler is compatible with the Microsoft® Visual C++® compiler, some differences can prevent successful compilation. Also there can be some incompatible generated-code behavior of some source files with the Intel® C++ Compiler. In most cases, a modification of the user source file enables successful compilation with both the Intel® C++ Compiler and the Microsoft® Visual C++® compiler. The differences between the compilers are listed as follows:

Evaluation of Left Shift Operations

The Intel® C++ Compiler differs from the Microsoft® Visual C++® compiler in the evaluation of left shift operations where the right operand, or shift count, is equal to or greater than the size of the left operand expressed in bits. The ANSI C standard states that the behavior of such left-shift operations is undefined, meaning a program should not expect a certain behavior from these operations. This difference is only evident when both operands of the shift operation are constants. The following example illustrates this difference between the Intel® C++ Compiler and the Microsoft® Visual C++® compiler:

```c
int x;
int y = 1; // set y=1
void func() {
    x = 1 << 32;
    // Intel C++ Compiler generates code to set x=1
    // Visual C++ Compiler generates code to set x=0
    y = y << 32;
    // Intel C++ Compiler generates code to set y=1
    // Visual C++ Compiler generates code to set y=0
}
```

Inline Assembly Target Labels (IA-32 Architecture Only)

For compilations targeted for IA-32 architecture, inline assembly target labels of `goto` statements are case sensitive. The Microsoft® Visual C++® compiler treats these labels in a case insensitive manner. For example, the Intel® C++ Compiler issues an error when compiling the following code:

```c
int func(int x) {
    goto LAB2;
    // error: label "LAB2" was referenced but not defined
    __asm lab2: mov x, 1
    return x;
}
```

However, the Microsoft® Visual C++® compiler accepts the preceding code. As a work-around for the Intel® C++ Compiler, when a `goto` statement refers to a label defined in inline assembly, you must match the label reference with the label definition in both name and case.

Inlining Functions Marked for dllimport

The Intel compiler will attempt to inline any functions that are marked dllimport but Microsoft will not. Therefore, any calls or variables used inside a dllimport routine needs to be available at link time or the result will be an unresolved symbol.

Example

The following example contains two files: header.h and bug.cpp.
Declaration in Scope of Function Defined in a Namespace

In accordance with the C++ language specification, if a function declaration is encountered within a function definition, the function referenced is taken to be another member of the namespace of the containing function; regardless of whether the containing function definition is lexically within a namespace definition. The Microsoft* Visual C++* compiler takes the referenced function to be a global function (not in any namespace).

Functions declared in global or namespace scopes are interpreted the same way by both the Intel® C++ Compiler and the Microsoft* Visual C++* compiler.

Enum Bit-Field Signedness

The Intel® C++ Compiler and the Microsoft* Visual C++* compiler differ in how they attribute signedness to bit fields declared with an `enum` type. Microsoft* Visual C++* always considers `enum` bit fields to be signed, even if not all values of the `enum` type can be represented by the bit field.

The Intel® C++ Compiler considers an `enum` bit field to be unsigned, unless the `enum` type has at least one `enum` constant with a negative value. In any case, the Intel® C++ Compiler produces a warning if the bit field is declared with too few bits to represent all the values of the `enum` type.
Portability

Porting from the Microsoft* Compiler to the Intel® C++ Compiler

Overview: Porting from the Microsoft* Compiler to the Intel® C++ Compiler

This section describes a basic approach to porting applications from the Microsoft* Visual C++* Compiler for Windows* to the Intel® C++ Compiler for Windows*.

If you build your applications from the Windows* command line, porting applications from Microsoft* Visual C++ to the Intel® C++ Compiler can be as easy as modifying your makefile to invoke the Intel® C++ Compiler instead of the Microsoft* Compiler.

The Intel® C++ Compiler integration with Microsoft* Visual Studio* provides a conversion path to the Intel® C++ Compiler that allows you to build your Visual C++* projects with the Intel® C++ Compiler. This version of the Intel® C++ Compiler supports:

- Microsoft Visual Studio* 2017
- Microsoft Visual Studio* 2015
- Microsoft Visual Studio* 2013

See the appropriate section in this documentation for details on using the Intel® C++ Compiler with Microsoft* Visual Studio*.

The Intel® C++ Compiler also supports many of the same compiler options, macros, and environment variables you already use in your Microsoft* work.

One challenge in porting applications from one compiler to another is making sure there is support for the compiler options you use to build your application. The Compiler Options reference lists compiler options that are supported by both the Intel® C++ Compiler and the Microsoft* C++* Compiler.

Other Considerations
Modifying Your Makefile

Modifying Your makefile

If you use makefiles to build your Microsoft* application, you need to change the value for the compiler variable to use the Intel® C++ Compiler. You may also want to review the options specified by CPPFLAGS. A simple example follows:

<table>
<thead>
<tr>
<th>Microsoft* makefile Example</th>
</tr>
</thead>
<tbody>
<tr>
<td># name of the program</td>
</tr>
<tr>
<td>PROGRAM = area.exe</td>
</tr>
<tr>
<td># names of source files</td>
</tr>
<tr>
<td>CPPSOURCES = area_main.cpp area_functions.cpp</td>
</tr>
<tr>
<td># names of object files</td>
</tr>
<tr>
<td>CPPOBJECTS = area_main.obj area_functions.obj</td>
</tr>
</tbody>
</table>
Microsoft* makefile Example

```makefile
# Microsoft Compiler options
CPPFLAGS = /RTC1 /EHsc

# Use the Microsoft C++ Compiler
CPP = cl

# link objects
$(PROGRAM): $(CPPOBJECTS)
  link.exe /out:$@ $(CPPOBJECTS)

# build objects
area_main.obj: area_main.cpp area_headers.h
area_functions.obj: area_functions.cpp area_headers.h

# clean
clean: del $(CPPOBJECTS) $(PROGRAM)
```

Modified makefile for the Intel® C++ Compiler

Before you can run `nmake` with the Intel® C++ Compiler, you need to set the proper environment. In this example, only the name of the compiler changed:

```makefile
# name of the program
PROGRAM = area.exe

# names of source files
CPPSOURCES = area_main.cpp area_functions.cpp

# names of object files
CPPOBJECTS = area_main.obj area_functions.obj

# Intel(R) C++ Compiler options
CPPFLAGS = /RTC1 /EHsc

# Use the Intel(R) C++ Compiler
CPP = icl

# link objects
$(PROGRAM): $(CPPOBJECTS)
  link.exe /out:$@ $(CPPOBJECTS)

# build objects
area_main.obj: area_main.cpp area_headers.h
area_functions.obj: area_functions.cpp area_headers.h

# clean
clean: del $(CPPOBJECTS) $(PROGRAM)
```

With the modified makefile, the output of `nmake` is similar to the following:

```
Microsoft (R) Program Maintenance Utility Version 8.00.50727.42
Copyright (C) Microsoft Corporation. All rights reserved.
icl /RTC1 /EHsc /c area_main.cpp area_functions.cpp
```
Using IPO in makefiles

By default, IPO generates "dummy" object files containing interprocedural information used by the compiler. To link or create static libraries with these object files requires specific Intel-provided tools. To use them in your makefile, replace references to "link" with "xilink" and references to "lib" with "xilib":

Example

```bash
# name of the program
PROGRAM = area.exe

# names of source files
CPPSOURCES = area_main.cpp area_functions.cpp

# names of object files
CPPOBJECTS = area_main.obj area_functions.obj

# Intel® C++ Compiler options
CPPFLAGS = /RTC1 /EHsc /Qipo

# Use the Intel® C++ Compiler
CPP = icl

# link objects
$(PROGRAM): $(CPPOBJECTS)
xilink.exe /out:$@ $(CPPOBJECTS)

# build objects
area_main.obj: area_main.cpp area_headers.h
area_functions.obj: area_functions.cpp area_headers.h

# clean
clean: del $(CPPOBJECTS) $(PROGRAM)
```

Other Considerations

There are some notable differences between the Intel® C++ Compiler and the Microsoft* compiler. Consider the following as you begin compiling your code with the Intel® C++ Compiler.

Setting the Environment

The compiler installation provides a batch file, compilervars.bat, that sets the proper environment for the Intel® C++ Compiler. For information on running compilervars.bat, see Using the compilervars File to Specify Location of Components.
Using Optimization

The Intel® C++ Compiler is an optimizing compiler that begins with the assumption that you want improved performance from your application when it is executed on Intel® architecture. Consequently, certain optimizations, such as option \texttt{O2}, are part of the default invocation of the Intel® C++ Compiler. By default, Microsoft® turns off optimization, which is the equivalent of compiling with options \texttt{Od} or \texttt{O0}. Other forms of the \texttt{o[n]} option compare as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Intel® C++ Compiler</th>
<th>Microsoft* Compiler</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{/Od}</td>
<td>Turns off all optimization. Same as \texttt{O0}.</td>
<td>Default. Turns off all optimization.</td>
</tr>
<tr>
<td>\texttt{/O1}</td>
<td>Decreases code size with some increase in speed.</td>
<td>Optimizes code for minimum size.</td>
</tr>
<tr>
<td>\texttt{/O2}</td>
<td>Default. Favors speed optimization with some increase in code size. Intrinsics, loop unrolling, and inlining are performed.</td>
<td>Optimizes code for maximum speed.</td>
</tr>
<tr>
<td>\texttt{/O3}</td>
<td>Enables \texttt{-O2} optimizations plus more aggressive optimizations, such as prefetching, scalar replacement, and loop and memory access transformations.</td>
<td>Not supported.</td>
</tr>
</tbody>
</table>

Targeting Specific Intel® Processors

While many of the same options that target specific processors are supported with both compilers, the Intel® C++ Compiler includes options that utilize processor-specific instructions to target the latest Intel® architecture processors. Consider using the Intel® C++ Compiler \texttt{[Q]x}, \texttt{/arch}, or \texttt{[Q]ax} options for applications that run on IA-32 architecture or Intel® 64 architecture. Refer to the descriptions of these compiler options for more specific information.

Modifying Your Configuration

The Intel® C++ Compiler lets you maintain configuration and response files that are part of compilation. Options stored in the configuration file apply to every compilation, while options stored in response files apply only where they are added on the command line. If you have several options in your makefile that apply to every build, you may find it easier to move these options to the configuration file (\texttt{..\bin\icl.cfg}).

In a multi-user, networked environment, options listed in the \texttt{icl.cfg} file are generally intended for everyone who uses the compiler. If you need a separate configuration, you can use the ICLCFG environment variable to specify the name and location of your own \texttt{.cfg} file, such as \texttt{\my_code\my_config.cfg}. Anytime you instruct the compiler to use a different configuration file, the \texttt{icl.cfg} system configuration file is ignored.

Using the Intel® Libraries

The Intel® C++ Compiler supplies additional libraries that contain optimized implementations of many commonly used functions. Some of these functions are implemented using CPU dispatch. This means that different code may be executed when run on different processors.

Supplied libraries include the Intel® Math Library (\texttt{libm}), the Short Vector Math Library (\texttt{svmlDisp}), \texttt{libirc}, as well as others. These libraries are linked in by default when the compiler sees that references to them have been generated. Some library functions, such as \texttt{sin} or \texttt{memset}, may not require a call to the library, since the compiler may inline the code for the function.

\textbf{Intel® Math Library (\texttt{libm})}
With the Intel® C++ Compiler, the Intel® Math Library, libm, is linked by default when calling math functions that require the library. Some functions, such as \( \sin \), may not require a call to the library, since the compiler already knows how to compute the \( \sin \) function. The Intel® Math Library also includes some functions not found in the standard math library.

**NOTE**
You cannot make calls to the Intel® Math Library with the Microsoft* compiler.

Many routines in the libimf library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**Short Vector Math Library (svmlDisp)**

When vectorization is in progress, the compiler may translate some calls to the libm math library functions into calls to svmlDisp functions. These functions implement the same basic operations as the Intel® Math Library, but operate on short vectors of operands. This results in greater efficiency. In some cases, the svmlDisp functions are slightly less precise than the equivalent libm functions.

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**libirc**

libirc contains optimized implementations of some commonly used string and memory functions. For example, it contains functions that are optimized versions of memcpy and memset. The compiler will automatically generate calls to these functions when it sees calls to memcpy and memset. The compiler may also transform loops that are equivalent to memcpy or memset into calls to these functions.

Many routines in the libirc library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Optimization Notice</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.</td>

**Porting from GCC* to the Intel® C++ Compiler**
Overview: Porting from gcc* to the Intel® C++ Compiler

This section describes a basic approach to porting applications from the gcc* C/C++ compilers to the Intel® C++ Compiler. These compilers correspond to each other as follows:

<table>
<thead>
<tr>
<th>Language</th>
<th>Intel® Compiler</th>
<th>GCC* Compiler</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>icc</td>
<td>gcc</td>
</tr>
<tr>
<td>C++</td>
<td>icpc</td>
<td>g++</td>
</tr>
</tbody>
</table>

**NOTE**

Unless otherwise indicated, the term "gcc" refers to both gcc* and g++* compilers from the GNU Compiler Collection*.

Advantages to Using the Intel® C++ Compiler

In many cases, porting applications from gcc to the Intel® C++ Compiler can be as easy as modifying your makefile to invoke the Intel® C++ Compiler (icc) instead of gcc. Using the Intel® C++ Compiler typically improves the performance of your application, especially for those that run on Intel processors. In many cases, your application's performance may also show improvement when running on non-Intel processors. When you compile your application with the Intel® C++ Compiler, you have access to:

- Compiler options that optimize your code for the latest Intel® architecture processors.
- Advanced profiling tools (PGO) similar to the GNU profiler gprof.
- High-level optimizations (HLO).
- Interprocedural optimization (IPO).
- Intel intrinsic functions that the compiler uses to inline instructions, including various versions of Intel® Streaming SIMD Extensions and Intel® Advanced Vector Extensions.
- Highly-optimized Intel® Math Library for improved accuracy.

Because the Intel® C++ Compiler is compatible and interoperable with gcc, porting your gcc application to the Intel® C++ Compiler includes the benefits of binary compatibility. As a result, you should not have to rebuild libraries from your gcc applications. The Intel® C++ Compiler also supports many of the same compiler options, macros, and environment variables you already use in your gcc work.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Modifying Your makefile
Supported Environment Variables
Modifying Your makefile

If you use makefiles to build your gcc* application, you need to change the value for the GCC compiler variable to use the Intel® C++ compiler. You may also want to review the options specified by CFLAGS. For example:

---

**Sample gcc* makefile**

```makefile
# Use gcc compiler
CC = gcc

# Compile-time flags
CFLAGS = -O2 -std=c99
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(CC) -c -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

**Sample makefile modified for the Intel® C/C++ Compiler**

```makefile
# Use Intel C compiler
CC = icc

# Compile-time flags
CFLAGS = -std=c99
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(CC) -c -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

---

If your gcc* code includes features that are not supported with the Intel® C++ Compiler (compiler options, language extensions, macros, pragmas, and so on), you can compile those sources separately with gcc* if necessary.

In the above makefile, `area_functions.c` is an example of a source file that includes features unique to gcc*. Because the Intel® C++ Compiler uses the O2 option by default and gcc* uses option O0 as the default, we instruct gcc* to compile at option O2. We also include the -fno-asn switch from the original makefile because this switch is not supported with the Intel® C++ Compiler.
Sample makefile modified for using the Intel® C/C++ Compiler and gcc together

```makefile
# Use Intel C compiler
CC = icc
# Use gcc for files that cannot be compiled by icc
GCC = gcc
# Compile-time flags
CFLAGS = -std=c99
all: area_app

area_app: area_main.o area_functions.o
  $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
  $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
  $(GCC) -c -O2 -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

Output of `make` using a modified makefile

```
icc -c -std=c99 area_main.c
gcc -c -O2 -fno-asm -std=c99 area_functions.c
icc area_main.o area_functions.o -o area
```

Using IPO in Makefiles

By default, IPO generates "dummy" object files containing Interprocedural information used by the compiler. To link or create static libraries with these object files requires special Intel-provided tools. To use them in your makefile, simply replace references to "ld" with "xild" and references to "ar" with "xiar", or use icc or icpc to link as shown below.

Sample makefile modified for the Intel® C/C++ Compiler with IPO

```makefile
# Use Intel C compiler
CC = icc

# Compile-time flags
CFLAGS = -std=c99 -ipo
all: area_app

area_app: area_main.o area_functions.o
  $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
  $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
  $(CC) -c $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

Equivalent Macros

The Intel® C++ Compiler is compatible with the predefined GNU macros.
See http://gcc.gnu.org for a list of compatible predefined macros.

Additional Predefined Macros

Other Considerations
There are some notable differences between the Intel® C++ Compiler and gcc*. Consider the following as you begin compiling your source code with the Intel® C++ Compiler.

Setting the Environment
The Intel® C++ Compiler relies on environment variables for the location of compiler binaries, libraries, man pages, and license files. In some cases these are different from the environment variables that gcc* uses. Another difference is that these variables are not set by default after installing the Intel® C++ Compiler. The following environment variables need to be set prior to running the Intel® C++ Compiler:

- PATH: Add the location of the compiler binaries to PATH.
- LD_LIBRARY_PATH: Sets the location where the generated executable picks up the runtime libraries (*.so files).
- MANPATH – add the location of the compiler man pages (icc and icpc) to MANPATH.
- INTEL_LICENSE_FILE – sets the location of the Intel® C++ Compiler license file.

To set these environment variables, run the compilervars.sh script.

**NOTE**
Setting these environment variables with compilervars.sh does not impose a conflict with gcc. You should be able to use both compilers in the same shell.

Using Optimization
The Intel® C++ Compiler is an optimizing compiler that begins with the assumption that you want improved performance from your application when it is executed on Intel® architecture. Consequently, certain optimizations, such as option 02, are part of the default invocation of the Intel® C++ Compiler. Optimization is turned off in gcc by default, the equivalent of compiling with option 00. Other forms of the 0<n> option compare as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Intel® C++ Compiler</th>
<th>gcc*</th>
</tr>
</thead>
<tbody>
<tr>
<td>-00</td>
<td>Turns off optimization.</td>
<td>Default. Turns off optimization.</td>
</tr>
<tr>
<td>-01</td>
<td>Decreases code size with some increase in speed.</td>
<td>Decreases code size with some increase in speed.</td>
</tr>
<tr>
<td>-02</td>
<td><strong>Default.</strong> Favors speed optimization with some increase in code size. Same as option 0. Intrinsics, loop unrolling, and inlining are performed.</td>
<td>Optimizes for speed as long as there is not an increase in code size. Loop unrolling and function inlining, for example, are not performed.</td>
</tr>
<tr>
<td>-03</td>
<td>Enables option 02 optimizations plus more aggressive optimizations, such as prefetching, scalar replacement, and loop and memory access transformations.</td>
<td>Optimizes for speed while generating larger code size. Includes option 02 optimizations plus loop unrolling and inlining. Similar to option 02 -ip on the Intel® C++ Compiler.</td>
</tr>
</tbody>
</table>
Targeting Intel® Processors

While many of the same options that target specific processors are supported with both compilers, Intel includes options that utilize processor-specific instruction scheduling to target the latest Intel® processors. If you compile your gcc* application with the march or mtune option, consider using the Intel® C++ Compiler options x or ax options for applications that run on IA-32 architecture or Intel® 64 architecture.

Modifying Your Configuration

The Intel® C++ Compiler lets you maintain configuration and response files that are part of compilation. Options stored in the configuration file apply to every compilation, while options stored in response files apply only where they are added on the command line. If you have several options in your makefile that apply to every build, you may find it easier to move these options to the configuration file (icc.cfg and icpc.cfg).

In a multi-user, networked environment, options listed in the icc.cfg and icpc.cfg files are generally intended for everyone who uses the compiler. If you need a separate configuration, you can use the ICCCFG or ICPPCFG environment variable to specify the name and location of your own .cfg file, such as /my_code/my_config.cfg. Anytime you instruct the compiler to use a different configuration file, the system configuration files (icc.cfg and icpc.cfg) are ignored.

Using the Intel® Libraries

The Intel® C++ Compiler supplies additional libraries that contain optimized implementations of many commonly used functions. Some of these functions are implemented using CPU dispatch. This means that different code may be executed when run on different processors.

Supplied libraries include the Intel® Math Library (libimf), the Short Vector Math Library (libsvm), libirc, as well as others. These libraries are linked in by default. Some library functions, such as sin or memset, may not require a call to the library, since the compiler may inline the code for the function.

Intel® Math Library (libimf)

With the Intel® Compiler, the Intel® Math Library, libimf, is linked by default. Some functions, such as sin, may not require a call to the library, since the compiler already knows how to compute the sin function. The Intel® Math Library also includes some functions not found in the standard math library.

**NOTE**

You cannot make calls to the Intel® Math Library with gcc*.

Many routines in the libimf library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Short Vector Math Library (libsvm)

When vectorization is being done, the compiler may translate some calls to the libimf math library functions into calls to libsvm functions. These functions implement the same basic operations as the Intel® Math Library, but operate on short vectors of operands. This results in greater efficiency. In some cases, the libsvm functions are slightly less precise than the equivalent libimf functions.

Many routines in the libimf library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

libirc

libirc contains optimized implementations of some commonly used string and memory functions. For example, it contains functions that are optimized versions of memcpy and memset. The compiler will automatically generate calls to these functions when it sees calls to memcpy and memset. The compiler may also transform loops that are equivalent to memcpy or memset into calls to these functions.
Many routines in the *libirc* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Optimization Notice</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.</td>

Understanding the 64-bit Data Model used by macOS*

The 64-bit data model used by macOS* is known as LP64. The use of the LP64 data model ensures that source code created on other platforms can be easily ported to macOS*.

The LP64 data model defines these C/C++ types as follows:

- **int** is 32 bit.
- **long**, **long-long**, and pointers are 64 bit.

The following C/C++ restrictions and guidelines apply:

- An **int** cannot hold pointers since pointers are 64-bit types in the LP64 data model.
- Casting variables from a larger datatype to a smaller one can result in lost data; in general, you should not cast from a 64-bit integer datatype to a 32-bit integer datatype.
- Use the correct *printf* directives for printing types.

supported tools 2459

SVML 1698

symbol names

option using dollar sign when producing 389

symbol visibility

option specifying 476

synchronization

parallel processing model for 2043
thread sleep time 2068
synchronization between cpu and target 2299

sysroot target directory

option returning 583

T

target

applying to multiple declarations 2310
attribute 625
memory management 2280
target-specific code, writing 2277, 2286, 2299
targeting processors manually
cpu_dispatch 2365
target (GCC attribute) 2365
targetptr modifier 2283
test prioritization tool
examples 2439
options 2439
requirements 2439

thread affinity

option specifying 290

thread pooling 2162
thread-private variables 2315
threads 66, 68

threshold control for auto-parallelization

OpenMP* routines for 2062
reordering 2168

timing offload regions 2320
to Microsoft Visual Studio* projects 62
tool options

code coverage tool 2426
profmerge 2445
proforder 2445
test prioritization 2439

tools

option passing options to 428
option specifying directory for supporting 427
topology maps 2078
traceback information

option providing 502
transcendental functions

option replacing calls to 307
transferring data asynchronously 2301, 2302
tselect tool

option producing an instrumented file for 270
option specifying a directory for profiling output for 268
option specifying a file name for summary files for 269

U

universal binaries 82
