Shift packed 16-bit integers in a left by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask \( k \) (elements are copied from src when the corresponding mask bit is not set).

\[
_{\text{mm}512}\_\text{maskz\_sllv\_epi16}
\]

\[
_{\text{mm}512}\_\text{maskz\_sllv\_epi16}(\_\text{mmask32} \ k, \_\text{m512i} \ a, \_\text{m512i} \ count)
\]

CPUID Flags: AVX512BW

Instruction(s): vpsllvw
Shift packed 16-bit integers in a left by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm}512}\_\text{sllv\_epi16}
\]

\[
_{\text{mm}512}\_\text{sllv\_epi16}(\_\text{m512i} \ a, \_\text{m512i} \ count)
\]

CPUID Flags: AVX512BW

Instruction(s): vpsllvw
Shift packed 16-bit integers in a left by the amount specified by the corresponding element in count while shifting in zeros, and return the results.
__mm_mask_sll_epi16

__m128i __mm_mask_sll_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_mask_slli_epi16

__m128i __mm_mask_slli_epi16(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_sll_epi16

__m128i __mm_maskz_sll_epi16(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_maskz_slli_epi16

__m128i __mm_maskz_slli_epi16(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_sll_epi16

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_sll_epi16

__m256i _mm256_maskz_sll_epi16(__mmask16 k, __m256i a, __m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_maskz_slli_epi16

__m256i _mm256_maskz_slli_epi16(__mmask16 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_sll_epi16

__m512i _mm512_mask_sll_epi16(__m512i src, __mmask32 k, __m512i a, __m128i count)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_mask_slli_epi16

__m512i _mm512_mask_slli_epi16(__m512i src, __mmask32 k, __m512i a, unsigned int imm)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_sll_epi16

__m512i _mm512_maskz_sll_epi16(__mmask32 k, __m512i a, __m128i count)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_slli_epi16

__m512i _mm512_maskz_slli_epi16(__mmask32 k, __m512i a, unsigned int imm)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm512_sll_epi16

__m512i _mm512_sll_epi16(__m512i a, __m128i count)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in \textit{a} left by \textit{count} while shifting in zeros, and return the results.

_ mm512 slli_epi16

__m512i _mm512_slli_epi16(__m512i a, unsigned int imm)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in \textit{a} left by \textit{imm} while shifting in zeros, and return the results.

_ mm_mask_sra_epi32

__m128i _mm_mask_sra_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in \textit{a} right by \textit{count} while shifting in sign bits, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

_ mm_mask_srai_epi32

__m128i _mm_mask_srai_epi32(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in \textit{a} right by \textit{imm} while shifting in sign bits, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

_ mm_maskz_sra_epi32

__m128i _mm_maskz_sra_epi32(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in \textit{a} right by \textit{count} while shifting in sign bits, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

_ mm_maskz_srai_epi32

__m128i _mm_maskz_srai_epi32(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in \textit{a} right by \textit{imm} while shifting in sign bits, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_sra_epi32

__m256i _mm256_mask_sra_epi32(__m256i src, __mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in `a` right by `count` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm256_mask_srai_epi32

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm256_maskz_sra_epi32

__m256i _mm256_maskz_sra_epi32(__mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in `a` right by `count` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm256_maskz_srai_epi32

__m256i _mm256_maskz_srai_epi32(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_sra_epi64

__m128i _mm_mask_sra_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq
Shift packed 64-bit integers in `a` right by `count` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm_mask_srai_epi64

__m128i _mm_mask_srai_epi64(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq
Shift packed 64-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
**_mm_maskz_sra_epi64_**

`_m128i _mm_maskz_sra_epi64(__mmask8 k, __m128i a, __m128i count)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `count` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_maskz_srai_epi64_**

`_m128i _mm_maskz_srai_epi64(__mmask8 k, __m128i a, unsigned int imm)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_sra_epi64_**

`_m128i _mm_sra_epi64(__m128i a, __m128i count)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `count` while shifting in sign bits, and return the results.

**_mm_srai_epi64_**

`_m128i _mm_srai_epi64(__m128i a, unsigned int imm)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `imm` while shifting in sign bits, and return the results.

**_mm256_mask_sra_epi64_**

`_m256i _mm256_mask_sra_epi64(__m256i src, __mmask8 k, __m256i a, __m128i count)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `count` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_mask_srai_epi64_**

`_m256i _mm256_mask_srai_epi64(__m256i src, __mmask8 k, __m256i a, unsigned int imm)`

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
_mm256_maskz_sra_epi64

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \( count \) while shifting in sign bits, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\texttt{_mm256\_mask\_srai\_epi16}
\]
\[
\texttt{__m256i _mm256\_mask\_srai\_epi16(__m256i src, __mmask16 k, __m256i a, unsigned int imm)}
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{imm} while shifting in sign bits, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\textbf{\_mm256\_maskz\_sra\_epi16}

\begin{verbatim}
_mm256_maskz_sra_epi16(__mmask16 k, __m256i a, __m128i count)
\end{verbatim}

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{count} while shifting in sign bits, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\textbf{\_mm256\_maskz\_srai\_epi16}

\begin{verbatim}
_mm256_maskz_srai_epi16(__mmask16 k, __m256i a, unsigned int imm)
\end{verbatim}

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{imm} while shifting in sign bits, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\textbf{\_mm512\_mask\_sra\_epi16}

\begin{verbatim}
_mm512_mask_sra_epi16(__m512i src, __mmask32 k, __m512i a, __m128i count)
\end{verbatim}

CPUID Flags: AVX512BW
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{count} while shifting in sign bits, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\textbf{\_mm512\_mask\_srai\_epi16}

\begin{verbatim}
_mm512_mask_srai_epi16(__m512i src, __mmask32 k, __m512i a, unsigned int imm)
\end{verbatim}

CPUID Flags: AVX512BW
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{imm} while shifting in sign bits, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\textbf{\_mm512\_maskz\_sra\_epi16}

\begin{verbatim}
_mm512_maskz_sra_epi16(__mmask32 k, __m512i a, __m128i count)
\end{verbatim}

CPUID Flags: AVX512BW
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by \textit{count} while shifting in sign bits, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).
_mm512_maskz_srai_epi16

```c
__m512i _mm512_maskz_srai_epi16(__mmask32 k, __m512i a, unsigned int imm)
```

CPUID Flags: AVX512BW

Instruction(s): vpsraw

Shift packed 16-bit integers in a right by imm while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sra_epi16

```c
__m512i _mm512_sra_epi16(__m512i a, __m128i count)
```

CPUID Flags: AVX512BW

Instruction(s): vpsraw

Shift packed 16-bit integers in a right by count while shifting in sign bits, and return the results.

_mm512_srai_epi16

```c
__m512i _mm512_srai_epi16(__m512i a, unsigned int imm)
```

CPUID Flags: AVX512BW

Instruction(s): vpsraw

Shift packed 16-bit integers in a right by imm while shifting in sign bits, and return the results.

_mm_mask_srl_epi32

```c
__m128i _mm_mask_srl_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrld

Shift packed 32-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_mask_srli_epi32

```c
__m128i _mm_mask_srli_epi32(__m128i src, __mmask8 k, __m128i a, unsigned int imm)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrld

Shift packed 32-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srl_epi32

```c
__m128i _mm_maskz_srl_epi32(__mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrld

Shift packed 32-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
Intel® C++ Compiler 19.0 Developer Guide and Reference

_mm_maskz_srl_epi32

_m128i _mm_maskz_srl_epi32(__mmask8 k, _m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrld
Shift packed 32-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_srl_epi32

_m256i _mm256_mask_srl_epi32(__m256i src, __mmask8 k, _m256i a, _m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrld
Shift packed 32-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_mask_srl_epi32

_m256i _mm256_mask_srl_epi32(__m256i a, __mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrld
Shift packed 32-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_srl_epi32

_m256i _mm256_maskz_srl_epi32(__mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrld
Shift packed 32-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_maskz_srl_epi32

_m256i _mm256_maskz_srl_epi32(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrld
Shift packed 32-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_bsrli_epi128

_m512i _mm512_bsrli_epi128(_m512i a, int imm)

CPUID Flags: AVX512BW
Instruction(s): vpsrldq
Shift 128-bit lanes in a right by imm bytes while shifting in zeros, and return the results.
_mm_mask_srl_epi64

__m128i _mm_mask_srl_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m128i _mm_mask_srl_epi64(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m128i _mm_maskz_srl_epi64(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__m128i _mm_maskz_srl_epi64(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__m256i _mm_mask_srl_epi64

__m256i _mm256_mask_srl_epi64(__m256i src, __mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m256i _mm256_mask_srl_epi64(__m256i src, __mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq
Shift packed 64-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
__mm256_maskz_srl_epi64

__m256i __mm256_maskz_srl_epi64(__mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq

Shift packed 64-bit integers in \( a \) right by count while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm256_maskz_srli_epi64

__m256i __mm256_maskz_srli_epi64(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlq

Shift packed 64-bit integers in \( a \) right by \( \text{imm} \) while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_srlv_epi32

__m128i __mm_mask_srlv_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlvd

Shift packed 32-bit integers in \( a \) right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm_maskz_srlv_epi32

__m128i __mm_maskz_srlv_epi32(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlvd

Shift packed 32-bit integers in \( a \) right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_srlv_epi32

__m256i __mm256_mask_srlv_epi32(__m256i src, __mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlvd

Shift packed 32-bit integers in \( a \) right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm256_maskz_srlv_epi32

__m256i __mm256_maskz_srlv_epi32(__mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrlvd
Shift packed 32-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_srlv_epi64

_m128i _mm_mask_srlv_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrlvq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srlv_epi64

_m128i _mm_maskz_srlv_epi64(__mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrlvq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_srlv_epi64

_m256i _mm256_mask_srlv_epi64(__m256i src, __mmask8 k, __m256i a, __m256i count)
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrlvq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_srlv_epi64

_m256i _mm256_maskz_srlv_epi64(__mmask8 k, __m256i a, __m256i count)
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrlvq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_srlv_epi16

_m128i _mm_mask_srlv_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm_maskz_srlv_epi16

_m128i _mm_maskz_srlv_epi16(__mmask8 k, _m128i a, _m128i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm_srlv_epi16

_m128i _mm_srlv_epi16(_m128i a, _m128i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results.

```c
_mm256_mask_srlv_epi16

_m256i _mm256_mask_srlv_epi16(__m256i src, __mmask16 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm256_maskz_srlv_epi16

_m256i _mm256_maskz_srlv_epi16(__mmask16 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm256_srlv_epi16

_m256i _mm256_srlv_epi16(__m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results.
_mm512_mask_srlv_epi16

_m512i _mm512_mask_srlv_epi16(_m512i src, __mmask32 k, _m512i a, _m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlvw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srlv_epi16

_m512i _mm512_maskz_srlv_epi16(__mmask32 k, _m512i a, _m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlvw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srlv_epi16

_m512i _mm512_srlv_epi16(_m512i a, _m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlvw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results.

_mm_mask_srl_epi16

_m128i _mm_mask_srl_epi16(__m128i src, __mmask8 k, _m128i a, _m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_mask_srli_epi16

_m128i _mm_mask_srli_epi16(__m128i src, __mmask8 k, _m128i a, int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srl_epi16

_m128i _mm_maskz_srl_epi16(__mmask8 k, _m128i a, _m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm_maskz_srl_epi16
_m128i __mm_maskz_srl_epi16(__mmask8 k, __m128i a, int imm)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm256_mask_srl_epi16
__m256i __mm256_mask_srl_epi16(__m256i src, __mmask16 k, __m256i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__mm256_maskz_srl_epi16
__m256i __mm256_maskz_srl_epi16(__mmask16 k, __m256i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__mm256_maskz_srl_epi16
__m256i __mm256_maskz_srl_epi16(__mmask16 k, __m256i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm512_mask_srl_epi16
__m512i __mm512_mask_srl_epi16(__m512i src, __mmask32 k, __m512i a, __m128i count)
```

CPUID Flags: AVX512BW
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

\_mm512\_mask\_srli\_epi16

\_m512i \_mm512\_mask\_srli\_epi16(\_m512i src, \_mmask32 \(k\), \_m512i a, unsigned int imm)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

\_mm512\_maskz\_srli\_epi16

\_m512i \_mm512\_maskz\_srli\_epi16(\_mmask32 \(k\), \_m512i a, \_m128i count)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_maskz\_srli\_epi16

\_m512i \_mm512\_maskz\_srli\_epi16(\_mmask32 \(k\), \_m512i a, int imm)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_srli\_epi16

\_m512i \_mm512\_srli\_epi16(\_m512i a, \_m128i count)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results.

\_mm512\_srli\_epi16

\_m512i \_mm512\_srli\_epi16(\_m512i a, unsigned int imm)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results.

**Intrinsics for Store Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the \zmmintrin.h header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_addr</td>
<td>pointer to base address in memory to begin load or store operation</td>
</tr>
<tr>
<td>mem_addr</td>
<td>pointer to base address in memory</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
</tbody>
</table>

### `_mm_mask_compressstoreu_pd`

```c
void _mm_mask_compressstoreu_pd(void* base_addr, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vcompresspd`

Contiguously store the active double-precision (64-bit) floating-point elements in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

### `_mm256_mask_compressstoreu_pd`

```c
void _mm256_mask_compressstoreu_pd(void* base_addr, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vcompresspd`

Contiguously store the active double-precision (64-bit) floating-point elements in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

### `_mm_mask_compressstoreu_ps`

```c
void _mm_mask_compressstoreu_ps(void* base_addr, __mmask8 k, __m128 a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vcompressps`

Contiguously store the active single-precision (32-bit) floating-point elements in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

### `_mm256_mask_compressstoreu_ps`

```c
void _mm256_mask_compressstoreu_ps(void* base_addr, __mmask8 k, __m256 a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vcompressps`

Contiguously store the active single-precision (32-bit) floating-point elements in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

### `_mm_mask_store_pd`

```c
void _mm_mask_store_pd(void* mem_addr, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vcompressps`

Contiguously store the active double-precision (64-bit) floating-point elements in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovapd
Store packed double-precision (64-bit) floating-point elements from a into memory using writemask k. mem_addr must be aligned on a 16-byte boundary or a general-protection exception may be generated.

_mm256_mask_store_pd

```
void _mm256_mask_store_pd(void* mem_addr, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovapd
Store packed double-precision (64-bit) floating-point elements from a into memory using writemask k. mem_addr must be aligned on a 32-byte boundary or a general-protection exception may be generated.

_mm_mask_store_ps

```
void _mm_mask_store_ps(void* mem_addr, __mmask8 k, __m128 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovaps
Store packed single-precision (32-bit) floating-point elements from a into memory using writemask k. mem_addr must be aligned on a 16-byte boundary or a general-protection exception may be generated.

_mm256_mask_store_ps

```
void _mm256_mask_store_ps(void* mem_addr, __mmask8 k, __m256 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovaps
Store packed single-precision (32-bit) floating-point elements from a into memory using writemask k. mem_addr must be aligned on a 32-byte boundary or a general-protection exception may be generated.

_mm_mask_storeu_pd

```
void _mm_mask_storeu_pd(void* mem_addr, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovupd
Store packed double-precision (64-bit) floating-point elements from a into memory using writemask k. mem_addr does not need to be aligned on any particular boundary.

_mm256_mask_storeu_pd

```
void _mm256_mask_storeu_pd(void* mem_addr, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovupd
Store packed double-precision (64-bit) floating-point elements from a into memory using writemask k. mem_addr does not need to be aligned on any particular boundary.
**_mm_mask_storeu_ps_**

```c
void _mm_mask_storeu_ps(void* mem_addr, __mmask8 k, __m128 a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovups

Store packed single-precision (32-bit) floating-point elements from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

**_mm256_mask_storeu_ps_**

```c
void _mm256_mask_storeu_ps(void* mem_addr, __mmask8 k, __m256 a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovups

Store packed single-precision (32-bit) floating-point elements from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

**_mm_i32scatter_pd_**

```c
void _mm_i32scatter_pd(void* base_addr, __m128i vindex, __m128d a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterdpd

Scatter double-precision (64-bit) floating-point elements from `a` into memory using 32-bit indices. 64-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). `scale` should be 1, 2, 4 or 8.

**_mm_mask_i32scatter_pd_**

```c
void _mm_mask_i32scatter_pd(void* base_addr, __mmask8 k, __m128i vindex, __m128d a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterdpd

Scatter double-precision (64-bit) floating-point elements from `a` into memory using 32-bit indices. 64-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

**_mm256_i32scatter_pd_**

```c
void _mm256_i32scatter_pd(void* base_addr, __m128i vindex, __m256d a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterdpd

Scatter double-precision (64-bit) floating-point elements from `a` into memory using 32-bit indices. 64-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). `scale` should be 1, 2, 4 or 8.

**_mm256_mask_i32scatter_pd_**

```c
void _mm256_mask_i32scatter_pd(void* base_addr, __mmask8 k, __m128i vindex, __m256d a, const int scale)
```
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vscatterdpd

Scatter double-precision (64-bit) floating-point elements from `a` into memory using 32-bit indices. 64-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

```c
_mm_i32scatter_ps
void _mm_i32scatter_ps(void* base_addr, __m128i vindex, __m128 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vscatterdps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 32-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). `scale` should be 1, 2, 4 or 8.

```c
_mm_mask_i32scatter_ps
void _mm_mask_i32scatter_ps(void* base_addr, __mmask8 k, __m128i vindex, __m128 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vscatterdps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 32-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

```c
_mm256_i32scatter_ps
void _mm256_i32scatter_ps(void* base_addr, __m256i vindex, __m256 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vscatterdps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 32-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

```c
_mm256_mask_i32scatter_ps
void _mm256_mask_i32scatter_ps(void* base_addr, __mmask8 k, __m256i vindex, __m256 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vscatterdps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 32-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.
__mm_i64scatter_pd

void _mm_i64scatter_pd(void* base_addr, __m128i vindex, __m128d a, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqpd

Scatter double-precision (64-bit) floating-point elements from \(a\) into memory using 64-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)). \(scale\) should be 1, 2, 4 or 8.

__mm_mask_i64scatter_pd

void _mm_mask_i64scatter_pd(void* base_addr, __mmask8 k, __m128i vindex, __m128d a, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqpd

Scatter double-precision (64-bit) floating-point elements from \(a\) into memory using 64-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

__mm256_i64scatter_pd

void _mm256_i64scatter_pd(void* base_addr, __m256i vindex, __m256d a, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqpd

Scatter double-precision (64-bit) floating-point elements from \(a\) into memory using 64-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)). \(scale\) should be 1, 2, 4 or 8.

__mm256_mask_i64scatter_pd

void _mm256_mask_i64scatter_pd(void* base_addr, __mmask8 k, __m256i vindex, __m256d a, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqpd

Scatter double-precision (64-bit) floating-point elements from \(a\) into memory using 64-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

__mm_i64scatter_ps

void _mm_i64scatter_ps(void* base_addr, __m128i vindex, __m128 a, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqpd

Scatter single-precision (32-bit) floating-point elements from \(a\) into memory using 64-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.
_mm_mask_i64scatter_ps  

```c
void _mm_mask_i64scatter_ps(void* base_addr, __m128i vindex, __m128 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

_mm256_i64scatter_ps  

```c
void _mm256_i64scatter_ps(void* base_addr, __m256i vindex, __m128 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

_mm256_mask_i64scatter_ps  

```c
void _mm256_mask_i64scatter_ps(void* base_addr, __mmask8 k, __m256i vindex, __m128 a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vscatterqps

Scatter single-precision (32-bit) floating-point elements from `a` into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k` (elements are not stored when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

_mm_mask_store_epi32  

```c
void _mm_mask_store_epi32(void* mem_addr, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovdqa32

Store packed 32-bit integers from `a` into memory using writemask `k`. `mem_addr` must be aligned on a 16-byte boundary or a general-protection exception may be generated.

_mm256_mask_store_epi32  

```c
void _mm256_mask_store_epi32(void* mem_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovdqa32

Store packed 32-bit integers from `a` into memory using writemask `k`. `mem_addr` must be aligned on a 32-byte boundary or a general-protection exception may be generated.
**_mm_mask_store_epi64_**

```c
void _mm_mask_store_epi64(void* mem_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovdqa64

Store packed 64-bit integers from `a` into memory using writemask `k`. `mem_addr` must be aligned on a 16-byte boundary or a general-protection exception may be generated.

**_mm256_mask_store_epi64_**

```c
void _mm256_mask_store_epi64(void* mem_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovdqa64

Store packed 64-bit integers from `a` into memory using writemask `k`. `mem_addr` must be aligned on a 32-byte boundary or a general-protection exception may be generated.

**_mm_mask_storeu_epi16_**

```c
void _mm_mask_storeu_epi16(void* mem_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu16

Store packed 16-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

**_mm256_mask_storeu_epi16_**

```c
void _mm256_mask_storeu_epi16(void* mem_addr, __mmask16 k, __m256i a)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu16

Store packed 16-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

**_mm512_mask_storeu_epi16_**

```c
void _mm512_mask_storeu_epi16(void* mem_addr, __mmask32 k, __m512i a)
```

CPUID Flags: AVX512BW

Instruction(s): vmovdqu16

Store packed 16-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

**_mm_mask_storeu_epi32_**

```c
void _mm_mask_storeu_epi32(void* mem_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovdqu32

Store packed 32-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.
_mm256_mask_storeu_epi32

```c
void _mm256_mask_storeu_epi32(void* mem_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqu32

Store packed 32-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

_mm_mask_storeu_epi64

```c
void _mm_mask_storeu_epi64(void* mem_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqu64

Store packed 64-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

_mm256_mask_storeu_epi64

```c
void _mm256_mask_storeu_epi64(void* mem_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqu64

Store packed 64-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

_mm_mask_storeu_epi8

```c
void _mm_mask_storeu_epi8(void* mem_addr, __mmask16 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu8

Store packed 8-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

_mm256_mask_storeu_epi8

```c
void _mm256_mask_storeu_epi8(void* mem_addr, __mmask32 k, __m256i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu8

Store packed 8-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.

_mm512_mask_storeu_epi8

```c
void _mm512_mask_storeu_epi8(void* mem_addr, __mmask64 k, __m512i a)
```

CPUID Flags: AVX512BW
Instruction(s): vmovdqu8

Store packed 8-bit integers from `a` into memory using writemask `k`. `mem_addr` does not need to be aligned on any particular boundary.
_mm_mask_compressstoreu_epi32

```c
void _mm_mask_compressstoreu_epi32(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressd

Contiguously store the active 32-bit integers in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm256_mask_compressstoreu_epi32

```c
void _mm256_mask_compressstoreu_epi32(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressd

Contiguously store the active 32-bit integers in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm_mask_compressstoreu_epi64

```c
void _mm_mask_compressstoreu_epi64(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressq

Contiguously store the active 64-bit integers in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm256_mask_compressstoreu_epi64

```c
void _mm256_mask_compressstoreu_epi64(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressq

Contiguously store the active 64-bit integers in `a` (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm_i32scatter_epi32

```c
void _mm_i32scatter_epi32(void* base_addr, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpscatterdd

Scatter 32-bit integers from `a` into memory using 32-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). `scale` should be 1, 2, 4 or 8.

_mm_mask_i32scatter_epi32

```c
void _mm_mask_i32scatter_epi32(void* base_addr, __mmask8 k, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpscatterdd
Scatter 32-bit integers from \(a\) into memory using 32-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

_mm256_i32scatter_epi32

```c
void _mm256_i32scatter_epi32(void* base_addr, __m256i vindex, __m256i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterdd

Scatter 32-bit integers from \(a\) into memory using 32-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

_mm256_mask_i32scatter_epi32

```c
void _mm256_mask_i32scatter_epi32(void* base_addr, __mmask8 k, __m256i vindex, __m256i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterdd

Scatter 32-bit integers from \(a\) into memory using 32-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

_mm_i32scatter_epi64

```c
void _mm_i32scatter_epi64(void* base_addr, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterdq

Scatter 64-bit integers from \(a\) into memory using 32-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

_mm_mask_i32scatter_epi64

```c
void _mm_mask_i32scatter_epi64(void* base_addr, __mmask8 k, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterdq

Scatter 64-bit integers from \(a\) into memory using 32-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\) (elements are not stored when the corresponding mask bit is not set). \(scale\) should be 1, 2, 4 or 8.

_mm256_i32scatter_epi64

```c
void _mm256_i32scatter_epi64(void* base_addr, __m128i vindex, __m256i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpscatterdq

Scatter 64-bit integers from a into memory using 32-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). scale should be 1, 2, 4 or 8.

_mm256_mask_i32scatter_epi64

```c
void _mm256_mask_i32scatter_epi64(void* base_addr, __mmask8 k, __m128i vindex, __m256i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterdq

Scatter 64-bit integers from a into memory using 32-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale) subject to mask k (elements are not stored when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm_i64scatter_epi32

```c
void _mm_i64scatter_epi32(void* base_addr, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqd

Scatter 32-bit integers from a into memory using 64-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). scale should be 1, 2, 4 or 8.

_mm_mask_i64scatter_epi32

```c
void _mm_mask_i64scatter_epi32(void* base_addr, __mmask8 k, __m128i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqd

Scatter 32-bit integers from a into memory using 64-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale) subject to mask k (elements are not stored when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm256_i64scatter_epi32

```c
void _mm256_i64scatter_epi32(void* base_addr, __m256i vindex, __m128i a, const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqd

Scatter 32-bit integers from a into memory using 64-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). scale should be 1, 2, 4 or 8.

_mm256_mask_i64scatter_epi32

```c
void _mm256_mask_i64scatter_epi32(void* base_addr, __mmask8 k, __m256i vindex, __m128i a, const int scale)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqd

Scatter 32-bit integers from a into memory using 64-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale) subject to mask k (elements are not stored when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_\_mm\_i64scatter\_epi64

\[ \text{void } _\text{mm}_{\_i64\text{scatter}}_{\_\text{epi64}}(\text{void}\,* \text{base\_addr}, \_\text{m128i } \text{vindex}, \_\text{m128i } a, \text{const } \text{int } \text{scale}) \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqq

Scatter 64-bit integers from a into memory using 64-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). scale should be 1, 2, 4 or 8.

_\_mm\_mask\_i64scatter\_epi64

\[ \text{void } _\text{mm}_{\_\text{mask}\_i64\text{scatter}}_{\_\text{epi64}}(\text{void}\,* \text{base\_addr}, \_\text{mmask8 } k, \_\text{m128i } \text{vindex}, \_\text{m128i } a, \text{const } \text{int } \text{scale}) \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqq

Scatter 64-bit integers from a into memory using 64-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale) subject to mask k (elements are not stored when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_\_mm256\_i64scatter\_epi64

\[ \text{void } _\text{mm256}_{\_i64\text{scatter}}_{\_\text{epi64}}(\text{void}\,* \text{base\_addr}, \_\text{m256i } \text{vindex}, \_\text{m256i } a, \text{const } \text{int } \text{scale}) \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqq

Scatter 64-bit integers from a into memory using 64-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). scale should be 1, 2, 4 or 8.

_\_mm256\_mask\_i64scatter\_epi64

\[ \text{void } _\text{mm256}_{\_\text{mask}\_i64\text{scatter}}_{\_\text{epi64}}(\text{void}\,* \text{base\_addr}, \_\text{mmask8 } k, \_\text{m256i } \text{vindex}, \_\text{m256i } a, \text{const } \text{int } \text{scale}) \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpscatterqq

Scatter 64-bit integers from a into memory using 64-bit indices. 64-bit elements are stored at addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale) subject to mask k (elements are not stored when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.
Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions

Overview: Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions

Functional Overview

Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions extend Intel® Advanced Vector Extensions (Intel® AVX) and Intel® Advanced Vector Extensions 2 (Intel® AVX2) by promoting most of the 256-bit SIMD instructions with 512-bit numeric processing capabilities.

The Intel® AVX-512 instructions follow the same programming model as the Intel® AVX2 instructions, providing enhanced functionality for broadcast, embedded masking to enable predication, embedded floating point rounding control, embedded floating-point fault suppression, scatter instructions, high speed math instructions, and compact representation of large displacement values. Unlike Intel® SSE and Intel® AVX, which cannot be mixed without performance penalties, the mixing of Intel® AVX and Intel® AVX-512 instructions is supported without penalty.

Intel® AVX-512 intrinsics are supported on IA-32 and Intel® 64 architectures built from 32nm process technology. They map directly to the new Intel® AVX-512 instructions and other enhanced 128-bit and 256-bit SIMD instructions.

Intel® AVX-512 Registers

512-bit Register state is managed by the operating system using XSAVE / XRSTOR / XSAVEOPT instructions, introduced in 45nm Intel® 64 processors (see Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B, and Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A).

- Support for sixteen new 512-bit SIMD registers in 64-bit mode (for a total of 32 SIMD registers, representing 2K of register space, ZMM0 through ZMM31).
- Support for eight new opmask registers (k0 through k7) used for conditional execution and efficient merging of destination operands.

Intel® AVX registers YMM0-YMM15 map into Intel® AVX-512 registers ZMM0-ZMM15, very much like Intel® SSE registers map into Intel® AVX registers. In processors with Intel® AVX-512 support, Intel® AVX and Intel® AVX2 instructions operate on the lower 128- or 256-bits of the first sixteen ZMM registers.

Prefix Instruction Encoding Support for Intel® AVX-512

A new encoding prefix (referred to as EVEX) to support additional vector length encoding up to 512 bits. The EVEX prefix builds upon the foundations of VEX prefix, to provide compact, efficient encoding for functionality available to VEX encoding while enhancing vector capabilities.

The Intel® AVX-512 intrinsic functions use three C data types as operands, representing the new registers used as operands to the intrinsic functions. These are __m512, __m512d, and __m512i data types. The __m512 data type is used to represent the contents of the extended SSE register, the ZMM register, used by the Intel® AVX-512 intrinsics. The __m512 data type can hold sixteen 32-bit floating-point values. The __m512d data type can hold eight 64-bit double precision floating-point values. The __m512i data type can hold sixty-four 8-bit, thirty-two 16-bit, sixteen 32-bit, or eight 64-bit integer values.

The compiler aligns the __m512, __m512d, and __m512i local and global data to 64-byte boundaries on the stack. To align integer, float, or double arrays, use the __declspec(align) statement.
**Data Types for Intel® AVX-512 Intrinsics**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file. To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

Intel® AVX-512 intrinsics have vector variants that use `__m128`, `__m128i`, `__m128d`, `__m256`, `__m256i`, `__m256d`, `__m512`, `__m512i`, and `__m512d` data types.

**Naming and Usage Syntax**

Most Intel® AVX-512 intrinsic names use the following notational convention:

```
_mm512[_<maskprefix>]<intrin_op><suffix>
```

The following table explains each item in the syntax.

| _mm512 | Prefix representing the size of the largest vector in the operation considering any of the parameters or the result. |
| <maskprefix> | When present, indicates write-masked (_mask) or zero-masked (_maskz) predication. |
| <intrin_op> | Indicates the basic operation of the intrinsic; for example, add for addition and sub for subtraction. |
| <suffix> | Denotes the type of data the instruction operates on. The first one or two letters of each suffix denote whether the data is packed (p), extended packed (ep), or scalar (s). The remaining letters and numbers denote the type, with notation as follows: |
| • s: single-precision floating point |
| • d: double-precision floating point |
| • i512: signed 512-bit integer |
| • i256: signed 256-bit integer |
| • i128: signed 128-bit integer |
| • i64: signed 64-bit integer |
| • u64: unsigned 64-bit integer |
| • i32: signed 32-bit integer |
| • u32: unsigned 32-bit integer |
| • i16: signed 16-bit integer |
| • u16: unsigned 16-bit integer |
| • i8: signed 8-bit integer |
| • u8: unsigned 8-bit integer |

Programs can pack eight double precision and sixteen single precision floating-point numbers within the 512-bit vectors, as well as eight 64-bit and sixteen 32-bit integers. This enables processing of twice the number of data elements that Intel® AVX or Intel® AVX2 can process with a single instruction and four times the capabilities of Intel® SSE.

**Example: Write-Masking**

Write-masking allows an intrinsic to perform its operation on selected SIMD elements of a source operand, with blending of the other elements from an additional SIMD operand. Consider the declarations below, where the write-mask `k` has a 1 in the even numbered bit positions 0, 3, 5, 7, 9, 11, 13 and 15, and a 0 in the odd numbered bit positions.

```c
__m512 res, src, a, b;
mmsk16  k = 0x5555;
```
Then, given an intrinsic invocation such as this:

```c
res = _mm512_mask_add_ps(src, k, a, b);
```

every even-numbered float32 element of the result res is computed as the sum of the corresponding elements in a and b, while every odd-numbered element is passed through (i.e., blended) from the corresponding float32 element in src.

Typical write-masked intrinsics are declared with a parameter order such that the values to be blended (src in the example above) are in the first parameter, and the write mask k immediately follows this parameter. Some intrinsics provide the blended values from a different SIMD parameter, for example: _mm512_mask2_permutex2var_epi32. In this case too, the mask will follow that parameter.

**Example: Zero-Masking**

Zero-masking is a simplified form of write-masking where there are no blended values. Instead result elements corresponding to zero bits in the write mask are simply set to zero. Given:

```c
res = _mm512_maskz_add_ps(k, a, b);
```

the float32 elements of res corresponding to zeros in the write-mask k, are set to zero. The elements corresponding to ones in k, have the expected sum of corresponding elements in a and b.

Zero-masked intrinsics are typically declared with the write-mask as the first parameter, as there is no parameter for blended values.

**Example: Embedded Rounding and Suppress All Exceptions (SAE)**

Embedded rounding allows the floating point rounding mode to be explicitly specified for an individual operation, without having to modify the rounding controls in the MXCSR control register. The Suppress All Exceptions feature allows signaling of FP exceptions to be suppressed.

AVX-512 provides these capabilities on most 512-bit and scalar floating point operations. An intrinsic supporting these features will typically have "_round" in its name, for example:

```c
__m512d _mm512_add_round_pd(__m512d a, __m512d b, int rounding);
```

To specify round-towards-zero and SAE, an invocation would appear as follows:

```c
__m512d res, a, b;
res = _mm512_add_round_pd(a, b, _MM_FROUND_TO_ZERO | _MM_FROUND_NO_EXC);
```

**Example: Embedded Broadcasting**

Embedded broadcasting allows a single value to be broadcast across a source operand, without requiring an extra instruction. The "set1" family of intrinsics represent a broadcast operation, and the compiler can embed such operations into the EVEX prefix of an AVX-512 instruction. For example,

```c
__m512 res, a;
res = _mm512_add_ps(a, _mm512_set1_ps(3.0f));
```

will add 3.0 to each float32 element of a.

```c
_mm512_add_pd
extern __m512d __cdecl _mm512_add_pd(__m512d a, __m512d b);
```

Adds packed float64 elements in $a$ and $b$, and stores the result.

```c
_mm512_mask_add_pd
extern __m512d __cdecl _mm512_mask_add_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Adds packed float64 elements in $a$ and $b$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
_mm512_maskz_add_pd
extern __m512d __cdecl _mm512_maskz_add_pd(__mmask8 k, __m512d a, __m512d b);
```

Adds packed float64 elements in $a$ and $b$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm512_add_round_pd
extern __m512d __cdecl _mm512_add_round_pd(__m512d a, __m512d b, int round);
```

Adds packed float64 elements in $a$ and $b$ using rounding control $round$, and stores the result.

```c
_mm512_mask_add_round_pd
extern __m512d __cdecl _mm512_mask_add_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int round);
```

Adds packed float64 elements in $a$ and $b$ using rounding control $round$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
_mm512_maskz_add_round_pd
extern __m512d __cdecl _mm512_maskz_add_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Adds packed float64 elements in $a$ and $b$ using rounding control $round$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm512_add_ps
extern __m512 __cdecl _mm512_add_ps(__m512 a, __m512 b);
```
Adds packed float32 elements in \( a \) and \( b \), and stores the result.

\]

Adds the lower float64 element in \( a \) and \( b \) using rounding control \( round \), stores the result in the lower destination element, and copies the upper element from \( a \) to the upper destination element.

\[ \texttt{_mm\_mask\_add\_round\_sd} \]
\[
\text{extern } \texttt{__m128d } \text{ cdecl } \texttt{_mm\_mask\_add\_round\_sd}(\texttt{__m128d } \texttt{src}, \texttt{__mmask8 } \texttt{k}, \texttt{__m128d } \texttt{a}, \texttt{__m128d } \texttt{b}, \texttt{int } \texttt{round});
\]

Adds the lower float64 element in \( a \) and \( b \) using rounding control \( round \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

\[ \texttt{_mm\_maskz\_add\_round\_sd} \]
\[
\text{extern } \texttt{__m128d } \text{ cdecl } \texttt{_mm\_maskz\_add\_round\_sd}(\texttt{__mmask8 } \texttt{k}, \texttt{__m128d } \texttt{a}, \texttt{__m128d } \texttt{b}, \texttt{int } \texttt{round});
\]

Adds the lower float64 element in \( a \) and \( b \) using rounding control \( round \), stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.
_mm_mask_add_sd

extern __m128d __cdecl _mm_mask_add_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);

Adds the lower float64 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_maskz_add_sd

extern __m128d __cdecl _mm_maskz_add_sd(__mmask8 k, __m128d a, __m128d b);

Adds the lower float64 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_add_round_ss

extern __m128 __cdecl _mm_add_round_ss(__m128 a, __m128 b, int round);

Add the lower float32 element in a and b using rounding control round, stores the result in the lower destination element, and copies the upper three packed elements from a to the upper destination elements.

_mm_mask_add_round_ss

extern __m128 __cdecl _mm_mask_add_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int round);

Add the lower float32 element in a and b using rounding control round, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper three packed elements from a to the upper destination elements.

_mm_maskz_add_round_ss

extern __m128 __cdecl _mm_maskz_add_round_ss(__mmask8 k, __m128 a, __m128 b, int round);

Add the lower float32 element in a and b using rounding control round, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from a to the upper destination elements.

_mm_mask_add_ss

extern __m128 __cdecl _mm_mask_add_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);

Add the lower float32 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper three packed elements from a to the upper destination elements.

_mm_maskz_add_ss

extern __m128 __cdecl _mm_maskz_add_ss(__mmask8 k, __m128 a, __m128 b);

Add the lower float32 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from a to the upper destination elements.
Intrinsics for Integer Addition Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm512_add_epi32, _mm512_mask_add_epi32, _mm512_maskz_add_epi32</td>
<td>Add int32 vectors.</td>
<td>VPADDD</td>
</tr>
<tr>
<td>_mm512_add_epi64, _mm512_mask_add_epi64, _mm512_maskz_add_epi64</td>
<td>Add int64 vectors.</td>
<td>VPADDQ</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
<tr>
<td>b</td>
<td>second source vector element</td>
</tr>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
</tbody>
</table>

_mm512_add_epi32

```
extern __m512i __cdecl _mm512_add_epi32(__m512i a, __m512i b);
```

Adds packed int32 elements in a and b, and stores the result.

_mm512_mask_add_epi32

```
extern __m512i __cdecl _mm512_mask_add_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Adds packed int32 elements in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_add_epi32

```
extern __m512i __cdecl _mm512_maskz_add_epi32(__mmask16 k, __m512i a, __m512i b);
```

Adds packed int32 elements in a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_add_epi64

```
extern __m512i __cdecl _mm512_add_epi64(__m512i a, __m512i b);
```

Adds packed int64 elements in a and b, and stores the result.
_mm512_mask_add_epi64

`extern _m512i __cdecl _mm512_mask_add_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);`

Adds packed int64 elements in `a` and `b`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_add_epi64

`extern _m512i __cdecl _mm512_maskz_add_epi64(__mmask8 k, __m512i a, __m512i b);`

Adds packed int64 elements in `a` and `b`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### Intrinsic Name for Determining Minimum and Maximum Values

### Intrinsic Name for Determining Minimum and Maximum FP Values

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

</tbody>
</table>

**variable definition**

- **k**
  - writemask used as a selector
- **a**
  - first source vector element
- **b**
  - second source vector element
- **src**
  - source element to use based on writemask result
- **round**
  - Rounding control values; these can be one of the following (along with the sae suppress all exceptions flag):
    - `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even
    - `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity
    - `_MM_FROUND_TO_POS_INF` - rounds to positive infinity
    - `_MM_FROUND_TO_ZERO` - rounds to zero
    - `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

```c
extern __m512d __cdecl _mm512_max_pd(__m512d a, __m512d b);
```

Compares packed float64 elements in `a` and `b`, and stores packed maximum values.

```c
extern __m512d __cdecl _mm512_mask_max_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```
Compares packed float64 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_maskz_max_pd(__mmask8 k, __m512d a, __m512d b);
```

Compares packed float64 elements in \(a\) and \(b\), and stores packed maximum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_max_round_pd(__m512d a, __m512d b, int round);
```

Compares packed float64 elements in \(a\) and \(b\), and stores packed maximum values.

**NOTE**
Pass \(__MM_FROUND_NO_EXC\) to \textit{round} to suppress all exceptions.

```c
extern __m512d __cdecl _mm512_mask_max_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int round);
```

Compares packed float64 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

**NOTE**
Pass \(__MM_FROUND_NO_EXC\) to \textit{round} to suppress all exceptions.

```c
extern __m512d __cdecl _mm512_maskz_max_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Compares packed float64 elements in \(a\) and \(b\), and stores packed maximum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**
Pass \(__MM_FROUND_NO_EXC\) to \textit{round} to suppress all exceptions.

```c
extern __m512 __cdecl _mm512_max_ps(__m512 a, __m512 b);
```

Compares packed float32 elements in \(a\) and \(b\), and stores packed maximum values.

```c
extern __m512 __cdecl _mm512_mask_max_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```
Compares packed float32 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm512}}_{\text{maskz}}_{\text{max}}_{\text{ps}}
\]

\[
\text{extern } \_\text{m512 }\_\text{cdecl }\_\text{mm512}_{\text{maskz}}_{\text{max}}_{\text{ps}}(\_\text{mmask16 }k,\_\text{m512 }a,\_\text{m512 }b);
\]

Compares packed float32 elements in \(a\) and \(b\), and stores packed maximum values using zeronmask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm512}}_{\text{max}}_{\text{round}}_{\text{ps}}
\]

\[
\text{extern } \_\text{m512 }\_\text{cdecl }\_\text{mm512}_{\text{max}}_{\text{round}}_{\text{ps}}(\_\text{m512 }a,\_\text{m512 }b,\text{int }\text{round});
\]

NOTE
Pass \text{__MM\_FROUND\_NO\_EXC} to \text{round} to suppress all exceptions.

Compares packed float32 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm512}}_{\text{mask}}_{\text{max}}_{\text{round}}_{\text{ps}}
\]

\[
\text{extern } \_\text{m512 }\_\text{cdecl }\_\text{mm512}_{\text{mask}}_{\text{max}}_{\text{round}}_{\text{ps}}(\_\text{m128d }\text{src},\_\text{mmask8 }k,\_\text{m128d }a,\_\text{m128d }b);
\]

Compares packed float32 elements in \(a\) and \(b\), and stores packed maximum values using zeronmask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass \text{__MM\_FROUND\_NO\_EXC} to \text{round} to suppress all exceptions.

Compares the lower float64 elements in \(a\) and \(b\), stores the maximum value in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.
__mm_maskz_max_sd

extern __m128d __cdecl _mm_maskz_max_sd(__mmask8 k, __m128d a, __m128d b);

Compares the lower float64 elements in a and b, stores the maximum value in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

__mm_max_round_sd

extern __m128d __cdecl _mm_max_round_sd(__m128d a, __m128d b, int round);

Compares the lower float64 elements in a and b, stores the maximum value in the lower destination element, and copies the upper element from a to the upper destination element.

NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

__mm_mask_max_round_sd

extern __m128d __cdecl _mm_mask_max_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);

Compares the lower float64 elements in a and b, stores the maximum value in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

__mm_maskz_max_round_sd

extern __m128d __cdecl _mm_maskz_max_round_sd(__mmask8 k, __m128d a, __m128d b, int round);

Compares the lower float64 elements in a and b, stores the maximum value in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

__mm_mask_max_ss

extern __m128 __cdecl _mm_mask_max_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);

Compares the lower float32 elements in a and b, stores the maximum value in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from a to the upper destination element.
_mm_maskz_max_ss

Extern __m128 __cdecl _mm_maskz_max_ss(__mmask8 k, __m128 a, __m128 b);

Compares the lower float32 elements in \(a\) and \(b\), stores the maximum value in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

 NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm_max_round_ss

Extern __m128 __cdecl _mm_max_round_ss(__m128 a, __m128 b, int round);

Compares the lower float32 elements in \(a\) and \(b\), stores the maximum value in the lower destination element, and copies the upper element from \(a\) to the upper destination element.

 NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm_mask_max_round_ss

Extern __m128 __cdecl _mm_mask_max_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int round);

Compares the lower float32 elements in \(a\) and \(b\), stores the maximum value in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

 NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm_maskz_max_round_ss

Extern __m128 __cdecl _mm_maskz_max_round_ss(__mmask8 k, __m128 a, __m128 b, int round);

Compares the lower float32 elements in \(a\) and \(b\), stores the maximum value in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

 NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm512_min_pd

Extern __m512d __cdecl __m512_min_pd(__m512d a, __m512d b);

Compares packed float64 elements in \(a\) and \(b\), and stores packed minimum values.

_mm512_mask_min_pd

Extern __m512d __cdecl _mm512_mask_min_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
Compares packed float64 elements in \(a\) and \(b\), and stores packed minimum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\textbf{_mm512_maskz_min_pd}

\begin{verbatim}
extern _m512d cdecl __m512_maskz_min_pd(__mmask8 k, __m512d a, __m512d b);
\end{verbatim}

Compares packed float64 elements in \(a\) and \(b\), and store packed minimum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\textbf{_mm512_min_round_pd}

\begin{verbatim}
extern _m512d cdecl __m512_min_round_pd(__m512d a, __m512d b, int round);
\end{verbatim}

Compares packed float64 elements in \(a\) and \(b\), and stores packed minimum values.

\textbf{NOTE}

Pass \texttt{__MM_FROUND_NO_EXC} to \texttt{round} to suppress all exceptions.

\textbf{_mm512_mask_min_round_pd}

\begin{verbatim}
extern _m512d cdecl __m512_mask_min_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int round);
\end{verbatim}

Compares packed float64 elements in \(a\) and \(b\), and stores packed minimum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\textbf{NOTE}

Pass \texttt{__MM_FROUND_NO_EXC} to \texttt{round} to suppress all exceptions.

\textbf{_mm512_maskz_min_round_pd}

\begin{verbatim}
extern _m512d cdecl __m512_maskz_min_round_pd(__mmask8 k, __m512d a, __m512d b);
\end{verbatim}

Compares packed float64 elements in \(a\) and \(b\), and stores packed minimum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\textbf{NOTE}

Pass \texttt{__MM_FROUND_NO_EXC} to \texttt{round} to suppress all exceptions.

\textbf{_mm512_min_ps}

\begin{verbatim}
extern _m512 cdecl __m512_min_ps(__m512 a, __m512 b);
\end{verbatim}

Compares packed float32 elements in \(a\) and \(b\), and stores packed minimum values.

\textbf{_mm512_mask_min_ps}

\begin{verbatim}
extern _m512 cdecl __m512_mask_min_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
\end{verbatim}
Compares packed float32 elements in \(a\) and \(b\), and stores packed minimum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_maskz\_min\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_maskz\_min\_ps(\_mmask16 k, \_m512 a, \_m512 b);} \hfill

Compares packed float32 elements in \(a\) and \(b\), and store packed minimum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_min\_round\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_min\_round\_ps(\_m512 a, \_m512 b, int round);} \hfill

Compares packed float32 elements in \(a\) and \(b\), and stores packed minimum values.

\textbf{NOTE}

Pass \texttt{\_MM\_FROUND\_NO\_EXC} to \textit{round} to suppress all exceptions.

\_mm512\_mask\_min\_round\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_mask\_min\_round\_ps(\_m512 src, \_mmask16 k, \_m512 a, \_m512 b, int round);} \hfill

Compares packed float32 elements in \(a\) and \(b\), and stores packed minimum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\textbf{NOTE}

Pass \texttt{\_MM\_FROUND\_NO\_EXC} to \textit{round} to suppress all exceptions.

\_mm512\_maskz\_min\_round\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_maskz\_min\_round\_ps(\_mmask16 k, \_m512 a, \_m512 b, int round);} \hfill

Compares packed float32 elements in \(a\) and \(b\), and stores packed minimum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\textbf{NOTE}

Pass \texttt{\_MM\_FROUND\_NO\_EXC} to \textit{round} to suppress all exceptions.

\_mm\_mask\_min\_sd

\texttt{extern \_m128d \_cdecl \_mm\_mask\_min\_sd(\_m128d src, \_mmask8 k, \_m128d a, \_m128d b);} \hfill

Compares the lower float64 elements in \(a\) and \(b\), stores the minimum value in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.
_mm_maskz_min_sd

extern __m128d __cdecl _mm_maskz_min_sd(__mmask8 k, __m128d a, __m128d b);

Compares the lower float64 elements in \( a \) and \( b \), stores the minimum value in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

_mm_min_round_sd

extern __m128d __cdecl _mm_min_round_sd(__m128d a, __m128d b, int round);

Compares the lower float64 elements in \( a \) and \( b \), stores the minimum value in the lower destination element, and copies the upper element from \( a \) to the upper destination element.

NOTE

Pass __MM_FROUND_NO_EXC to \( \text{round} \) to suppress all exceptions.

_mm_mask_min_round_sd

extern __m128d __cdecl _mm_mask_min_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);

Compares the lower float64 elements in \( a \) and \( b \), stores the minimum value in the lower destination element of using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

NOTE

Pass __MM_FROUND_NO_EXC to \( \text{round} \) to suppress all exceptions.

_mm_maskz_min_round_sd

extern __m128d __cdecl _mm_maskz_min_round_sd(__mmask8 k, __m128d a, __m128d b, int round);

Compares the lower float64 elements in \( a \) and \( b \), stores the minimum value in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

NOTE

Pass __MM_FROUND_NO_EXC to \( \text{round} \) to suppress all exceptions.

_mm_mask_min_ss

extern __m128 __cdecl _mm_mask_min_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);

Compares the lower float32 elements in \( a \) and \( b \), stores the minimum value in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.
Intrinsics for Determining Minimum and Maximum Integer Values

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```
<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm512_max_epi32,</td>
<td>Calculate maximum of packed int32 values.</td>
<td>VPMAXSD</td>

</table>

```c
_mm512_max_epi32
extern __m512i __cdecl _mm512_max_epi32(__m512i a, __m512i b);
```

Compares packed int32 elements in a and b, and stores packed maximum values.

```c
_mm512_mask_max_epi32
extern __m512i __cdecl _mm512_mask_max_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```
Compares packed int32 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\texttt{\_mm512\_maskz\_max\_epi32}
\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_max_epi32(__mmask16 k, __m512i a, __m512i b);
\end{verbatim}
Compares packed int32 elements in \(a\) and \(b\), and stores packed maximum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\texttt{\_mm512\_max\_epi64}
\begin{verbatim}
extern __m512i __cdecl _mm512_max_epi64(__m512i a, __m512i b);
\end{verbatim}
Compares packed int64 elements in \(a\) and \(b\), and stores packed maximum values.

\texttt{\_mm512\_mask\_max\_epi64}
\begin{verbatim}
extern __m512i __cdecl _mm512_mask_max_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
\end{verbatim}
Compares packed int64 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\texttt{\_mm512\_maskz\_max\_epi64}
\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_max_epi64(__mmask8 k, __m512i a, __m512i b);
\end{verbatim}
Compares packed int64 elements in \(a\) and \(b\), and stores packed maximum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\texttt{\_mm512\_max\_epu32}
\begin{verbatim}
extern __m512i __cdecl _mm512_max_epu32(__m512i a, __m512i b);
\end{verbatim}
Compares packed uint32 elements in \(a\) and \(b\), and stores packed maximum values.

\texttt{\_mm512\_mask\_max\_epu32}
\begin{verbatim}
extern __m512i __cdecl _mm512_mask_max_epu32(__m512i src, __mmask16 k, __m512i a, __m512i b);
\end{verbatim}
Compares packed uint32 elements in \(a\) and \(b\), and stores packed maximum values using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\texttt{\_mm512\_maskz\_max\_epu32}
\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_max_epu32(__mmask16 k, __m512i a, __m512i b);
\end{verbatim}
Compares packed uint32 elements in \(a\) and \(b\), and stores packed maximum values using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\texttt{\_mm512\_max\_epu64}
\begin{verbatim}
extern __m512i __cdecl _mm512_max_epu64(__m512i a, __m512i b);
\end{verbatim}
Compares packed uint64 elements in \(a\) and \(b\), and stores packed maximum values.
_mm512_mask_max_epu64

```
EXTERN __m512I __cdecl _mm512_mask_max_epu64(__m512I src, __mmask8 k, __m512I a, __m512I b);
```

Compares packed uint64 elements in $a$ and $b$, and stores packed maximum values in using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mmm512_maskz_max_epu64

```
EXTERN __m512I __cdecl _mm512_maskz_max_epu64(__mmask8 k, __m512I a, __m512I b);
```

Compares packed uint64 elements in $a$ and $b$, and stores packed maximum values using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

_mmm512_min_epi32

```
EXTERN __m512I __cdecl _mm512_min_epi32(__m512I a, __m512I b);
```

Compares packed int32 elements in $a$ and $b$, and stores packed minimum values.

_mmm512_mask_min_epi32

```
EXTERN __m512I __cdecl _mm512_mask_min_epi32(__m512I src, __mmask16 k, __m512I a, __m512I b);
```

Compares packed int32 elements in $a$ and $b$, and stores packed minimum values using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mmm512_maskz_min_epi32

```
EXTERN __m512I __cdecl _mm512_maskz_min_epi32(__mmask16 k, __m512I a, __m512I b);
```

Compares packed int32 elements in $a$ and $b$, and stores packed minimum values using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

_mmm512_min_epi64

```
EXTERN __m512I __cdecl _mm512_min_epi64(__m512I a, __m512I b);
```

Compares packed int64 elements in $a$ and $b$, and stores packed minimum values.

_mmm512_mask_min_epi64

```
EXTERN __m512I __cdecl _mm512_mask_min_epi64(__m512I src, __mmask8 k, __m512I a, __m512I b);
```

Compares packed int64 elements in $a$ and $b$, and stores packed minimum values using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mmm512_maskz_min_epi64

```
EXTERN __m512I __cdecl _mm512_maskz_min_epi64(__mmask8 k, __m512I a, __m512I b);
```

Compares packed int64 elements in $a$ and $b$, and stores packed minimum values using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
Intrinsics for FP Fused Multiply-Add (FMA) Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```
<table>

_mm512_fmadd_pd

extern __m512d __cdecl _mm512_fmadd_pd(__m512d a, __m512d b, __m512d c);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result.

_mm512_mask_fmadd_pd

extern __m512d __cdecl _mm512_mask_fmadd_pd(__m512d a, __mmask8 k, __m512d b, __m512d c);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_mm512_mask3_fmadd_pd

extern __m512d __cdecl _mm512_mask3_fmadd_pd(__m512d a, __m512d b, __m512d c, __mmask8 k);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from c when the corresponding mask bit is not set).

_mm512_maskz_fmadd_pd

extern __m512d __cdecl _mm512_maskz_fmadd_pd(__mmask8 k, __m512d a, __m512d b, __m512d c);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_fmadd_round_pd

extern __m512d __cdecl _mm512_fmadd_round_pd(__m512d a, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result.

_mm512_mask_fmadd_round_pd

extern __m512d __cdecl _mm512_mask_fmadd_round_pd(__m512d a, __mmask8 k, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_mm512_mask3_fmadd_round_pd

extern __m512d __cdecl _mm512_mask3_fmadd_round_pd(__m512d a, __m512d b, __m512d c, __mmask8 k, int round);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from c when the corresponding mask bit is not set).

_mm512_maskz_fmadd_round_pd

extern __m512d __cdecl _mm512_maskz_fmadd_round_pd(__mmask8 k, __m512d a, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm512_fmadd_round_ps

extern __m512 __cdecl _mm512_fmadd_round_ps(__m512 a, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result.

_ mm512_mask_fmadd_round_ps

extern __m512 __cdecl _mm512_mask_fmadd_round_ps(__m512 a, __mmask16 k, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_ mm512_mask3_fmadd_round_ps

extern __m512 __cdecl _mm512_mask3_fmadd_round_ps(__m512 a, __m512 b, __m512 c, __mmask16 k, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from c when the corresponding mask bit is not set).

_ mm512_maskz_fmadd_round_ps

extern __m512 __cdecl _mm512_maskz_fmadd_round_ps(__mmask16 k, __m512 a, __m512 b, __m512 c, const int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result a using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_fmadd_ps

extern __m512 __cdecl _mm512_fmadd_ps(__m512 a, __m512 b, __m512 c);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result.

_ mm512_mask_fmadd_ps

extern __m512 __cdecl _mm512_mask_fmadd_ps(__m512 a, __mmask16 k, __m512 b, __m512 c);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_ mm512_mask3_fmadd_ps

extern __m512 __cdecl _mm512_mask3_fmadd_ps(__m512, __m512 b, __m512 c, __mmask16 k);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from c when the corresponding mask bit is not set).

_ mm512_maskz_fmadd_ps

extern __m512 __cdecl _mm512_maskz_fmadd_ps(__mmask16 k, __m512 a, __m512 b, __m512 c);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm512_fmadd_round_ps

extern __m512 __cdecl _mm512_fmadd_round_ps(__m512 a, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result.

_mm512_mask_fmadd_round_ps

extern __m512 __cdecl _mm512_mask_fmadd_round_ps(__m512 a, __mmask16 k, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_mm512_mask3_fmadd_round_ps

extern __m512 __cdecl _mm512_mask3_fmadd_round_ps(__m512 a, __m512 b, __m512 c, __mmask16 k, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result using writemask k (elements are copied from c when the corresponding mask bit is not set).

_mm512_maskz_fmadd_round_ps

extern __m512 __cdecl _mm512_maskz_fmadd_round_ps(__mmask16 k, __m512 a, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in a and b, adds the intermediate result to packed elements in c, and stores the result a using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_fmadd_sd

extern __m128d __cdecl _mm_mask_fmadd_sd(__m128d a, __mmask8 k, __m128d b, __m128d c);

Multiplies lower float64 elements in a and b, and adds the intermediate result to lower element in c. Stores the result in lower destination element using writemask k (the element is copied from a when mask bit 0 is not set), and copies upper element from a to upper destination element.

_mm_mask3_fmadd_sd

extern __m128d __cdecl _mm_mask3_fmadd_sd(__m128d a, __m128d b, __m128d c, __mmask8 k);

Multiplies lower float64 elements in a and b, and adds the intermediate result to lower element in c. Stores the result in lower destination element using writemask k (the element is copied from c when mask bit 0 is not set), and copies upper element from a to upper destination element.

_mm_maskz_fmadd_sd

extern __m128d __cdecl _mm_maskz_fmadd_sd(__mmask8 k, __m128d a, __m128d b, __m128d c);

Multiplies lower float64 elements in a and b, and adds the intermediate result to lower element in c. Stores the result in lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies upper element from a to upper destination element.

_mm_mask_fmadd_round_sd

extern __m128d __cdecl _mm_mask_fmadd_round_sd(__m128d a, __mmask8 k, __m128d b, __m128d c, int round);

Multiplies lower float64 elements in a and b, and adds the intermediate result to lower element in c. Stores the result in lower destination element using writemask k (the element is copied from c when mask bit 0 is not set), and copies upper element from a to upper destination element.
Multiplies lower float64 elements in \( a \) and \( b \), and adds the intermediate result to lower element in \( c \). Stores the result in lower destination element using writemask \( k \) (the element is copied from \( a \) when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

\[
\text{\_mm\_mask3\_fmadd\_round\_sd}
\]

\[
\text{\_mm\_maskz\_fmadd\_round\_sd}
\]

Multiplies lower float64 elements in \( a \) and \( b \), and adds the intermediate result to lower element in \( c \). Stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

Multiplies lower float32 elements in \( a \) and \( b \), and adds the intermediate result to lower element in \( c \). Stores the result in lower destination element using writemask \( k \) (the element is copied from \( a \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

Multiplies lower float32 elements in \( a \) and \( b \), and adds the intermediate result to lower element in \( c \). Stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

Multiplies lower float32 elements in \( a \) and \( b \), and adds the intermediate result to lower element in \( c \). Stores the result in lower destination element using writemask \( k \) (the element is copied from \( a \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.
Multiplies lower float32 elements in \(a\) and \(b\), and adds the intermediate result to lower element in \(c\). Stores the result in lower destination element using writemask \(k\) (the element is copied from \(c\) when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

```c
extern __m128 __cdecl _mm_maskz_fmadd_round_ss(__mmask8 k, __m128 a, __m128 b, __m128 c, int round);
```

Multiplies lower float32 elements in \(a\) and \(b\), and adds the intermediate result to lower element in \(c\). Stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

```c
extern __m128 __cdecl _mm512_fmaddsub_pd(__m512d a, __m512d b, __m512d c);
```

Multiplies packed float64 elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and stores the result.

```c
extern __m512d __cdecl _mm512_mask_fmaddsub_pd(__m512d, __mmask8 k, __m512d b, __m512d c);
```

Multiplies packed float64 elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_mask3_fmaddsub_pd(__m512d a, __m512d k, __m512d b, __mmask8 c);
```

Multiplies packed float64 elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_maskz_fmaddsub_pd(__mmask8 k, __m512d a, __m512d b, __m512d c);
```

Multiplies packed float64 elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_fmsubadd_round_pd(__m512d a, __m512d b, __m512d c, int round);
```

Multiplies packed float64 elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and stores the result.

__mm512_mask_fmsubadd_ps

```
extern __m512 __cdecl __mm512_mask_fmsubadd_ps(__m512 a, __mmask16 k, __m512 b, __m512 c);
```

Multiplies packed float32 elements in \(a\) and \(b\), alternatively subtract and add packed elements in \(c\) from/to the intermediate result, and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

__mm512_mask3_fmsubadd_ps

```
extern __m512 __cdecl __mm512_mask3_fmsubadd_ps(__m512 a, __m512 b, __m512 c, __mmask16 k);
```

Multiplies packed float32 elements in \(a\) and \(b\), alternatively subtract and add packed elements in \(c\) from/to the intermediate result, and stores the result using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

__mm512_maskz_fmsubadd_ps

```
extern __m512 __cdecl __mm512_maskz_fmsubadd_ps(__mmask16 k, __m512 a, __m512 b, __m512 c);
```

Multiplies packed float32 elements in \(a\) and \(b\), alternatively subtract and add packed elements in \(c\) from/to the intermediate result, and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
_mm512_fmsubadd_round_ps

extern __m512 __cdecl _mm512_fmsubadd_round_ps(__m512 a, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in $a$ and $b$, alternatively subtract and add packed elements in $c$ from/to the intermediate result, and stores the result.

_mm512_mask_fmsubadd_round_ps

extern __m512 __cdecl _mm512_mask_fmsubadd_round_ps(__m512 a, __mmask16 k, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in $a$ and $b$, alternatively subtract and add packed elements in $c$ from/to the intermediate result, and stores the result using writemask $k$ (elements are copied from $a$ when the corresponding mask bit is not set).

_mm512_mask3_fmsubadd_round_ps

extern __m512 __cdecl _mm512_mask3_fmsubadd_round_ps(__m512 a, __m512 b, __m512 c, __mmask16 k, int round);

Multiplies packed float32 elements in $a$ and $b$, alternatively subtract and add packed elements in $c$ from/to the intermediate result, and stores the result using writemask $k$ (elements are copied from $c$ when the corresponding mask bit is not set).

_mm512_maskz_fmsubadd_round_ps

extern __m512 __cdecl _mm512_maskz_fmsubadd_round_ps(__mmask16 k, __m512 a, __m512 b, __m512 c, int round);

Multiplies packed float32 elements in $a$ and $b$, alternatively subtract and add packed elements in $c$ from/to the intermediate result, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

_mm512_fnmadd_pd

extern __m512d __cdecl _mm512_fnmadd_pd(__m512d a, __m512d b, __m512d c);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result.

_mm512_mask_fnmadd_pd

extern __m512d __cdecl _mm512_mask_fnmadd_pd(__m512d a, __mmask8 k, __m512d b, __m512d c);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $a$ when the corresponding mask bit is not set).

_mm512_mask3_fnmadd_pd

extern __m512d __cdecl _mm512_mask3_fnmadd_pd(__m512d a, __m512d b, __m512d c, __mmask8 k);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $c$ when the corresponding mask bit is not set).

_mm512_maskz_fnmadd_pd

extern __m512d __cdecl _mm512_maskz_fnmadd_pd(__mmask8 k, __m512d a, __m512d b, __m512d c);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

_mm512_fnmadd_round_pd

extern __m512d __cdecl _mm512_fnmadd_round_pd(__m512d a, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result.

_mm512_mask_fnmadd_round_pd

extern __m512d __cdecl _mm512_mask_fnmadd_round_pd(__m512d a, __mmask8 k, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $a$ when the corresponding mask bit is not set).

_mm512_mask3_fnmadd_round_pd

extern __m512d __cdecl _mm512_mask3_fnmadd_round_pd(__m512d a, __m512d b, __m512d c, __mmask8 k, int round);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $c$ when the corresponding mask bit is not set).

_mm512_maskz_fnmadd_round_pd

extern __m512d __cdecl _mm512_maskz_fnmadd_round_pd(__mmask8 k, __m512d a, __m512d b, __m512d c, int round);

Multiplies packed float64 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

_mm512_fnmadd_ps

extern __m512 __cdecl _mm512_fnmadd_ps(__m512 a, __m512 b, __m512 c);

Multiplies packed float32 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result.

_mm512_mask_fnmadd_ps

extern __m512 __cdecl _mm512_mask_fnmadd_ps(__m512 a, __mmask16 k, __m512 b, __m512 c);

Multiplies packed float32 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $a$ when the corresponding mask bit is not set).

_mm512_mask3_fnmadd_ps

extern __m512 __cdecl _mm512_mask3_fnmadd_ps(__m512 a, __m512 b, __m512 c, __mmask16 k);

Multiplies packed float32 elements in $a$ and $b$, adds the negated intermediate result to packed elements in $c$, and stores the result using writemask $k$ (elements are copied from $c$ when the corresponding mask bit is not set).
Multiplies packed float32 elements in \(a\) and \(b\), adds the negated intermediate result to packed elements in \(c\), and stores the result using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

\[

\]
Multiplies lower float64 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result in lower destination element using writemask \(k\) (the element is copied from \(c\) when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

```c
extern __m128d __cdecl _mm_maskz_fnmsub_sd(__mmask8 k, __m128d a, __m128d b, __m128d c);
```

Multiplies lower float64 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

```c
extern __m128 __cdecl _mm_mask_fnmsub_ss(__m128 c, __mmask8 k, __m128 a, __m128 b);
```

Multiplies lower float32 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result in lower destination element using writemask \(k\) (the element is copied from \(c\) when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

```c
extern __m128 __cdecl _mm_mask3_fnmsub_ss(__m128 a, __m128 b, __m128 c, __mmask8 k);
```

Multiplies lower float32 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result in lower destination element, and copies upper element from \(a\) to upper destination element using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

```c
extern __m128 __cdecl _mm_maskz_fnmsub_ss(__mmask8 k, __m128 a, __m128 b, __m128 c);
```

Multiplies lower float32 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

```c
extern __m128 __cdecl _mm_mask_fnmsub_round_ss(__m128 c, __mmask8 k, __m128 a, __m128 b, int round);
```

Multiplies lower float32 elements in \(a\) and \(b\), and subtracts lower element in \(c\) from the negated intermediate result. Stores the result in lower destination element using writemask \(k\) (the element is copied from \(c\) when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

```c
extern __m128 __cdecl _mm_mask3_fnmsub_round_ss(__m128 a, __m128 b, __m128 c, __mmask8 k, int round);
```

Multiplies lower float32 elements in \(a\) and \(b\), subtract lower element in \(c\) from the negated intermediate result, Stores the result in lower destination element, and copies upper element from \(a\) to upper destination element using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

```c
extern __m128 __cdecl _mm_maskz_fnmsub_round_ss(__mmask8 k, __m128 a, __m128 b, __m128 c, int round);
```
Multiplies lower float32 elements in \( a \) and \( b \), and subtracts lower element in \( c \) from the negated intermediate result. Stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

```cpp
_mm512_mul_pd
extern __m512d __cdecl _mm512_mul_pd(__m512d a, __m512d b);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result.

```cpp
_mm512_mask_mul_pd
extern __m512d __cdecl _mm512_mask_mul_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

```cpp
_mm512_maskz_mul_pd
extern __m512d __cdecl _mm512_maskz_mul_pd(__mmask8 k, __m512d a, __m512d b);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```cpp
_mm512_mul_round_pd
extern __m512d __cdecl _mm512_mul_round_pd(__m512d a, __m512d b, int round);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result.

```cpp
_mm512_mask_mul_round_pd
extern __m512d __cdecl _mm512_mask_mul_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int round);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

```cpp
_mm512_maskz_mul_round_pd
extern __m512d __cdecl _mm512_maskz_mul_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Multiplies packed float64 elements in \(a\) and \(b\), stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```cpp
_mm512_mul_ps
extern __m512 __cdecl _mm512_mul_ps(__m512 a, __m512 b);
```

Multiplies packed float32 elements in \(a\) and \(b\), stores the result.

```cpp
_mm512_mask_mul_ps
extern __m512 __cdecl _mm512_mask_mul_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Multiplies packed float32 elements in \(a\) and \(b\), stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
_mm512_maskz_mul_ps
extern __m512 __cdecl _mm512_maskz_mul_ps(__mmask16 k, __m512 a, __m512 b);

Multiplies packed float32 elements in a and b, stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mul_round_ps
extern __m512 __cdecl _mm512_mul_round_ps(__m512 a, __m512 b, int round);

Multiplies packed float32 elements in a and b, stores the result.

_mm512_mask_mul_round_ps
extern __m512 __cdecl _mm512_mask_mul_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int round);

Multiplies packed float32 elements in a and b, stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_mul_round_ps
extern __m512 __cdecl _mm512_maskz_mul_round_ps(__mmask16 k, __m512 a, __m512 b, int round);

Multiplies packed float32 elements in a and b, stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mul_round_sd
extern __m128d __cdecl _mm_mul_round_sd(__m128d a, __m128d b, int round);

Multiplies the lower float64 element in a and b, stores the result in the lower destination element, and copy the upper element from a to the upper destination element.

_mm_mask_mul_round_sd
extern __m128d __cdecl _mm_mask_mul_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);

Multiplies the lower float64 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper destination element.

_mm_maskz_mul_round_sd
extern __m128d __cdecl _mm_maskz_mul_round_sd(__mmask8 k, __m128d a, __m128d b, int round);

Multiplies the lower float64 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper element from a to the upper destination element.

_mm_mask_mul_sd
extern __m128d __cdecl _mm_mask_mul_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);

Multiplies the lower float64 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper destination element.
_mm_maskz_mul_sd  
extern __m128d __cdecl _mm_maskz_mul_sd(__mmask8 k, __m128d a, __m128d b);  

Multiplies the lower float64 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper element from a to the upper destination element.

_mm_mul_round_ss  
extern __m128 __cdecl _mm_mul_round_ss(__m128 a, __m128 b, int round);  

Multiplies the lower float32 element in a and b, stores the result in the lower destination element, and copy the upper three packed elements from a to the upper destination elements.

_mm_mask_mul_round_ss  
extern __m128 __cdecl _mm_mask_mul_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int round);  

Multiplies the lower float32 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper three packed elements from a to the upper destination elements.

_mm_maskz_mul_round_ss  
extern __m128 __cdecl _mm_maskz_mul_round_ss(__mmask8 k, __m128 a, __m128 b, int round);  

Multiplies the lower float32 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper three packed elements from a to the upper destination elements.

_mm_mask_mul_ss  
extern __m128 __cdecl _mm_mask_mul_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);  

Multiplies the lower float32 element in a and b, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper three packed elements from a to the upper destination elements.

_mm_maskz_mul_ss  
extern __m128 __cdecl _mm_maskz_mul_ss(__mmask8 k, __m128 a, __m128 b);  

Multiplies the lower float32 element in a and b, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper three packed elements from a to the upper destination elements.

_mm512_sub_pd

extern __m512d __cdecl _mm512_sub_pd(__m512d a, __m512d b);

Subtracts packed float64 elements in vector b from vector a, and stores the result.

_mm512_mask_sub_pd

extern __m512d __cdecl _mm512_mask_sub_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
Subtracts packed float64 elements in \(b\) from packed float64 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{maskz}}\_{\text{sub}}\_{\text{pd}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{maskz}\_\text{sub}\_\text{pd}(\_\_\text{mmask}8 k, \_\_m512d a, \_\_m512d b);
\]

Subtracts packed float64 elements in \(b\) from packed float64 elements in \(a\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{sub}}\_{\text{round}}\_{\text{pd}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{sub}\_\text{round}\_\text{pd}(\_\_m512d a, \_\_m512d b, \_\text{int} round);
\]

Subtracts packed float64 elements in \(b\) from packed float64 elements in \(a\) using rounding control \(round\), and stores the result.

\[\_{\text{mm512}}\_{\text{mask}}\_{\text{sub}}\_{\text{round}}\_{\text{pd}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{mask}\_\text{sub}\_\text{round}\_\text{pd}(\_\_m512d src, \_\_\text{mmask}8 k, \_\_m512d a, \_\_m512d b, \_\text{int} round);
\]

Subtracts packed float64 elements in \(b\) from packed float64 elements in \(a\) using rounding control \(round\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{maskz}}\_{\text{sub}}\_{\text{round}}\_{\text{pd}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{maskz}\_\text{sub}\_\text{round}\_\text{pd}(\_\_\text{mmask}8 k, \_\_m512d a, \_\_m512d b, \_\text{int} round);
\]

Subtracts packed float64 elements in \(b\) from packed float64 elements in \(a\) using rounding control \(round\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{sub}}\_{\text{ps}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{sub}\_\text{ps}(\_\_m512 a, \_\_m512 b);
\]

Subtracts packed float32 elements in \(b\) from packed float32 elements in \(a\), and stores the result.

\[\_{\text{mm512}}\_{\text{mask}}\_{\text{sub}}\_{\text{ps}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{mask}\_\text{sub}\_\text{ps}(\_\_m512 src, \_\_\text{mmask}16 k, \_\_m512 a, \_\_m512 b);
\]

Subtracts packed float32 elements in \(b\) from packed float32 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{maskz}}\_{\text{sub}}\_{\text{ps}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{maskz}\_\text{sub}\_\text{ps}(\_\_\text{mmask}16 k, \_\_m512 a, \_\_m512 b);
\]

Subtracts packed float32 elements in \(b\) from packed float32 elements in \(a\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\_{\text{mm512}}\_{\text{sub}}\_{\text{round}}\_{\text{ps}}\]

\[
\text{extern } \_\_m512d \_\text{cdecl} \_\text{mm512}\_\text{sub}\_\text{round}\_\text{ps}(\_\_m512 a, \_\_m512 b, \_\text{int} round);
\]

Subtracts packed float32 elements in \(b\) from packed float32 elements in \(a\), and stores the result.
_mm512_mask_sub_round_ps
extern __m512 __cdecl _mm512_mask_sub_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int round);
Subtracts packed float32 elements in b from packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_sub_round_ps
extern __m512 __cdecl _mm512_maskz_sub_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
Subtracts packed float32 elements in b from packed float32 elements in a using rounding control round, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_sub_sd
extern __m128d __cdecl _mm_mask_sub_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
Subtracts the lower float64 element in b from the lower float64 element in a, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_maskz_sub_sd
extern __m128d __cdecl _mm_maskz_sub_sd(__mmask8 k, __m128d a, __m128d b);
Subtracts the lower float64 element in b from the lower float64 element in a, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_sub_round_sd
extern __m128d __cdecl _mm_sub_round_sd(__m128d a, __m128d b, int round);
Subtracts the lower float64 element in b from the lower float64 element in a, stores the result in the lower destination element, and copies the upper element from a to the upper destination element.

_mm_mask_sub_round_sd
extern __m128d __cdecl _mm_mask_sub_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);
Subtracts the lower float64 element in b from the lower float64 element in a using rounding control round, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_maskz_sub_round_sd
extern __m128d __cdecl _mm_maskz_sub_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
Subtracts the lower float64 element in b from the lower float64 element in a, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from a to the upper destination element.

_mm_sub_round_ss
extern __m128 __cdecl _mm_sub_round_ss(__m128 a, __m128 b, int round);
Subtracts the lower float32 element in b from the lower float32 element in a, stores the result in the lower destination element, and copies the upper three packed elements from a to the upper destination elements.
Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element, and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtracts the lower float32 element in \( b \) from the lower float32 element in \( a \), stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

Subtraction for Integer Subtraction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>

</tbody>
</table>

**_mm512_sub_epi32**

```c
extern __m512i __cdecl _mm512_sub_epi32(__m512i a, __m512i b);
```

Subtracts packed 32-bit integers in `b` from packed 32-bit integers in `a`, and stores the result.

**_mm512_maskz_sub_epi32**

```c
extern __m512i __cdecl _mm512_maskz_sub_epi32(__mmask16 k, __m512i a, __m512i b);
```

Subtracts packed 32-bit integers in `b` from packed 32-bit integers in `a`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_sub_epi64**

```c
extern __m512i __cdecl _mm512_sub_epi64(__m512i a, __m512i b);
```

Subtracts packed 64-bit integers in `b` from packed 64-bit integers in `a`, and stores the result.

**_mm512_mask_sub_epi64**

```c
extern __m512i __cdecl _mm512_mask_sub_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Subtracts packed 64-bit integers in `b` from packed 64-bit integers in `a`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_sub_epi64**

```c
extern __m512i __cdecl _mm512_maskz_sub_epi64(__mmask8 k, __m512i a, __m512i b);
```

Subtracts packed 64-bit integers in `b` from packed 64-bit integers in `a`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
Intrinsics for Short Vector Math Library (SVML) Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```cpp
#include <immintrin.h>
```

Intrinsics for Division Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```cpp
#include <immintrin.h>
```

</tbody>
</table>

### _mm512_div_pd

```c
extern __m512d __cdecl _mm512_div_pd(__m512d a, __m512d b);
```

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result.

### _mm512_mask_div_pd

```c
extern __m512d __cdecl _mm512_mask_div_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

### _mm512_maskz_div_pd

```c
extern __m512d __cdecl _mm512_maskz_div_pd(__mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

### _mm512_div_round_pd

```c
extern __m512d __cdecl _mm512_div_round_pd(__m512d a, __m512d b, int round);
```

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result.

### _mm512_mask_div_round_pd

```c
extern __m512d __cdecl _mm512_mask_div_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int round);
```
Divides packed float64 elements in \( a \) by packed elements in \( b \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_div\_round\_pd}
\]

\[
\text{extern \_m512d \_cdecl \_mm512\_maskz\_div\_round\_pd(__mmask8 k, \_m512d a, \_m512d b, int round);}
\]

Divides packed float64 elements in \( a \) by packed elements in \( b \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm512\_div\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_div\_ps(__m512 a, __m512 b);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result.

\[
\text{\_mm512\_mask\_div\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_mask\_div\_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_div\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_maskz\_div\_ps(__mmask16 k, __m512 a, __m512 b);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm512\_div\_round\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_div\_round\_ps(__m512 a, __m512 b, int round);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result.

\[
\text{\_mm512\_mask\_div\_round\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_mask\_div\_round\_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int round);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_div\_round\_ps}
\]

\[
\text{extern \_m512 \_cdecl \_mm512\_maskz\_div\_round\_ps(__mmask16 k, __m512 a, __m512 b, int round);}
\]

Divides packed float32 elements in \( a \) by packed elements in \( b \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm\_mask\_div\_sd}
\]

\[
\text{extern \_m128d \_cdecl \_mm\_mask\_div\_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);}
\]

Divides lower float64 element in \( a \) by lower float64 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

\[
\text{\_mm\_maskz\_div\_sd}
\]

\[
\text{extern \_m128d \_cdecl \_mm\_maskz\_div\_sd(__mmask8 k, __m128d a, __m128d b);}
\]
Divides lower float64 element in \( a \) by lower float64 element in \( b \), stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

\_mm\_div\_round\_sd

\begin{verbatim}
extern _m128d __cdecl _mm_div_round_sd(_m128d a, _m128d b, int round);
\end{verbatim}

Divides lower float64 element in \( a \) by lower float64 element in \( b \), stores the result in lower destination element, and copies upper element from \( a \) to upper destination element.

\_mm\_mask\_div\_round\_sd

\begin{verbatim}
extern _m128d __cdecl _mm_mask_div_round_sd(__m128d src, __mmask8 k, _m128d a, _m128d b, int round);
\end{verbatim}

Divides lower float64 element in \( a \) by lower float64 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

\_mm\_maskz\_div\_round\_sd

\begin{verbatim}
extern _m128d __cdecl _mm_maskz_div_round_sd(__mmask8 k, _m128d a, _m128d b, int round);
\end{verbatim}

Divides lower float64 element in \( a \) by lower float64 element in \( b \), stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element.

\_mm\_div\_round\_ss

\begin{verbatim}
extern _m128 __cdecl _mm_div_round_ss(_m128 a, _m128 b, int round);
\end{verbatim}

Divides lower float32 element in \( a \) by lower float32 element in \( b \), stores the result in lower destination element, and copies upper three packed elements from \( a \) to upper destination elements.

\_mm\_mask\_div\_round\_ss

\begin{verbatim}
extern _m128 __cdecl _mm_mask_div_round_ss(__m128 src, __mmask8 k, _m128 a, _m128 b, int round);
\end{verbatim}

Divides lower float32 element in \( a \) by lower float32 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

\_mm\_maskz\_div\_round\_ss

\begin{verbatim}
extern __m128 __cdecl _mm_maskz_div_round_ss(__mmask8 k, _m128 a, _m128 b, int round);
\end{verbatim}

Divides lower float32 element in \( a \) by lower float32 element in \( b \), stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.
### _mm_maskz_div_ss

```c
extern _m128 __cdecl _mm_maskz_div_ss(__mmask8 k, _m128 a, _m128 b);
```

Divides lower float32 element in `a` by lower float32 element in `b`, stores the result in lower destination element using zeromask `k` (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from `a` to upper destination elements.

### Intrinsics for Error Function Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>

**variable** | **definition**
--- | ---

$k$ | writemask used as a selector

$a$ | first source vector element

$src$ | source element to use based on writemask result

---

```c
extern __m512d __cdecl _mm512_cdfnorm_pd(__m512d a);
```

Computes normalized central distribution function for float64 elements in $a$, and stores the result.

```c
extern __m512d __cdecl _mm512_mask_cdfnorm_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes normalized central distribution function for float64 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
extern __m512 __cdecl _mm512_cdfnorm_ps(__m512 a);
```

Computes normalized central distribution function for float32 elements in $a$, and stores the result.

```c
extern __m512 __cdecl _mm512_mask_cdfnorm_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes normalized central distribution function for float32 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_cdfnorminv_pd(__m512d a);
```

Computes inverse normalized central distribution function for float64 elements in $a$, and stores the result.

```c
extern __m512d __cdecl _mm512_mask_cdfnorminv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse normalized central distribution function for float64 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).
__mm512_cdfnorminv_ps
extern __m512 __cdecl __mm512_cdfnorminv_ps(__m512 a);
Computes inverse normalized central distribution function for float32 elements in \( a \), and stores the result.

__mm512_mask_cdfnorminv_ps
extern __m512 __cdecl __mm512_mask_cdfnorminv_ps(__m512 src, __mmask16 k, __m512 a);
Computes inverse normalized central distribution function for float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_erf_pd
extern __m512d __cdecl __mm512_erf_pd(__m512d a);
Computes error function of packed float64 elements in \( a \), and stores the result.

__mm512_mask_erf_pd
extern __m512d __cdecl __mm512_mask_erf_pd(__m512d src, __mmask8 k, __m512d a);
Computes error function of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_erf_ps
extern __m512 __cdecl __mm512_erf_ps(__m512 a);
Computes error function of packed float32 elements in \( a \), and stores the result.

__mm512_mask_erf_ps
extern __m512 __cdecl __mm512_mask_erf_ps(__m512 src, __mmask16 k, __m512 a);
Computes error function of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_mask_erfc_pd
extern __m512d __cdecl __mm512_mask_erfc_pd(__m512d src, __mmask8 k, __m512d a);
Computes complex error function of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_erfc_ps
extern __m512 __cdecl __mm512_erfc_ps(__m512 a);
Computes complex error function of packed float32 elements in \( a \), and stores the result.
_mm512_mask_erfc_ps

```
extern __m512 __cdecl _mm512_mask_erfc_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes complex error function of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_erfinv_pd

```
extern __m512d __cdecl _mm512_erfinv_pd(__m512d a);
```

Calculates the inverse error function of float64 vector a elements.

_mm512_mask_erfinv_pd

```
extern __m512d __cdecl _mm512_mask_erfinv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse error function of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_erfinv_ps

```
extern __m512 __cdecl _mm512_erfinv_ps(__m512 a);
```

Computes inverse error function of packed float32 elements in a, and stores the result.

_mm512_mask_erfinv_ps

```
extern __m512 __cdecl _mm512_mask_erfinv_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes inverse error function of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_erfcinv_pd

```
extern __m512d __cdecl _mm512_erfcinv_pd(__m512d a);
```

Computes inverse complex error function of packed float64 elements in a, and stores the result.

_mm512_mask_erfcinv_pd

```
extern __m512d __cdecl _mm512_mask_erfcinv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse complex error function of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_erfcinv_ps

```
extern __m512 __cdecl _mm512_erfcinv_ps(__m512 a);
```

Computes inverse complex error function of packed float32 elements in a, and stores the result.

_mm512_mask_erfcinv_ps

```
extern __m512 __cdecl _mm512_mask_erfcinv_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes inverse complex error function of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
**Intrinsics for Exponential Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

</tr>
</tbody>
</table>

_mm512_pow_pd

```c
extern __m512d __cdecl _mm512_pow_pd(__m512d a, __m512d b);
```
Calculates the exponential value of each float64 vector $a$ element raised to the power of the corresponding vector $b$ element, and stores the result.

_mm512_mask_pow_pd

```c
extern __m512d __cdecl _mm512_mask_pow_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```
Calculates the exponential value of each float64 vector $a$ element raised to the power of the corresponding vector $b$ element, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_pow_ps

```c
extern __m512 __cdecl _mm512_pow_ps(__m512 a, __m512 b);
```
Calculates the exponential value of each float32 vector $a$ element raised to the power of the corresponding vector $b$ element, and stores the result.

_mm512_mask_pow_ps

```c
extern __m512 __cdecl _mm512_mask_pow_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```
Calculates the exponential value of each float32 vector $a$ element raised to the power of the corresponding vector $b$ element, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_exp10_pd

```c
extern __m512d __cdecl _mm512_exp10_pd(__m512d a);
```
Computes the base-10 exponent of packed float64 elements in $a$, and stores the result.

_mm512_mask_exp10_pd

```c
extern __m512d __cdecl _mm512_mask_exp10_pd(__m512d src, __mmask8 k, __m512d a);
```
Computes the base-10 exponent of packed float64 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_exp10_ps

```c
extern __m512 __cdecl _mm512_exp10_ps(__m512 a);
```
Computes the base-10 exponent of packed float32 elements in $a$, and stores the result.
_mm512_mask_exp10_ps

extern __m512 __cdecl _mm512_mask_exp10_ps(__m512 src, __mmask16 k, __m512 a);

Computes the base-10 exponent of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_exp2_pd

extern __m512d __cdecl _mm512_exp2_pd(__m512d a);

Computes the base-2 exponent of packed float64 elements in a, and stores the result.

_mm512_mask_exp2_pd

extern __m512d __cdecl _mm512_mask_exp2_pd(__m512d src, __mmask8 k, __m512d a);

Computes the base-2 exponent of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_exp2_ps

extern __m512 __cdecl _mm512_exp2_ps(__m512 a);

Computes the base-2 exponent of packed float32 elements in a, and stores the result.

_mm512_mask_exp2_ps

extern __m512 __cdecl _mm512_mask_exp2_ps(__m512 src, __mmask16 k, __m512 a);

Computes the base-2 exponent of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_exp_pd

extern __m512d __cdecl _mm512_exp_pd(__m512d a);

Calculates the exponential value of e (base of natural logarithms) raised to the power of float64 vector a elements.

_mm512_mask_exp_pd

extern __m512d __cdecl _mm512_mask_exp_pd(__m512d src, __mmask8 k, __m512d a);

Calculates the exponential value of e (base of natural logarithms) raised to the power of float64 vector a elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_exp_ps

extern __m512 __cdecl _mm512_exp_ps(__m512 a);

Calculates the exponential value of e (base of natural logarithms) raised to the power of float32 vector a elements.

_mm512_mask_exp_ps

extern __m512 __cdecl _mm512_mask_exp_ps(__m512 src, __mmask16 k, __m512 a);
Calculates the exponential value of e (base of natural logarithms) raised to the power of float32 vector \( a \) elements, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_expm1_pd(__m512d a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float64 vector \( a \) elements minus one.

```c
extern __m512d __cdecl _mm512_mask_expm1_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float64 vector \( a \) elements minus one, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
extern __m512 __cdecl _mm512_expm1_ps(__m512 a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float32 vector \( a \) elements minus one.

```c
extern __m512 __cdecl _mm512_mask_expm1_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float32 vector \( a \) elements minus one, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

</table>

```c
extern __m512d __cdecl _mm512_log10_pd(__m512d a);
```
Calculates the base-10 logarithm of vector a elements.

```c
extern __m512d __cdecl _mm512_mask_log10_pd(__m512d src, __mmask8 k, __m512d a);
```
Calculates the base-10 logarithm of vector a elements.

```c
extern __m512 __cdecl _mm512_log10_ps(__m512 a);
```
Calculates the base-10 logarithm of vector a elements.

```c
extern __m512 __cdecl _mm512_mask_log10_ps(__m512 src, __mmask16 k, __m512 a);
```
Calculates the base-10 logarithm of vector a elements.
`_mm512_log1p_pd`

`extern __m512d __cdecl _mm512_log1p_pd(__m512d a);`

Calculates the natural logarithm of vector `a` elements, defined by: \( \ln(v_1 + 1) \)

`_mm512_mask_log1p_pd`

`extern __m512d __cdecl _mm512_mask_log1p_pd(__m512d src, __mmask8 k, __m512d a);`

Calculates the natural logarithm of vector `a` elements, defined by: \( \ln(v_1 + 1) \)

`_mm512_log1p_ps`

`extern __m512 __cdecl _mm512_log1p_ps(__m512 a);`

Calculates the natural logarithm of vector `a` elements, defined by: \( \ln(v_1 + 1) \)

`_mm512_mask_log1p_ps`

`extern __m512 __cdecl _mm512_mask_log1p_ps(__m512 src, __mmask16 k, __m512 a);`

Calculates the natural logarithm of vector `a` elements, defined by: \( \ln(v_1 + 1) \)

`_mm512_log2_pd`

`extern __m512d __cdecl _mm512_log2_pd(__m512d a);`

Calculates the base-2 logarithm of vector `a` elements.

`_mm512_mask_log2_pd`

`extern __m512d __cdecl _mm512_mask_log2_pd(__m512d src, __mmask8 k, __m512d a);`

Calculates the base-2 logarithm of vector `a` elements.

`_mm512_log_pd`

`extern __m512d __cdecl _mm512_log_pd(__m512d a);`

Calculates the natural (base-e) logarithm of vector `a` elements.

`_mm512_mask_log_pd`

`extern __m512d __cdecl _mm512_mask_log_pd(__m512d src, __mmask8 k, __m512d a);`

Calculates the natural (base-e) logarithm of vector `a` elements.

`_mm512_log_ps`

`extern __m512 __cdecl _mm512_log_ps(__m512 a);`

Calculates the natural (base-e) logarithm of vector `a` elements.

`_mm512_mask_log_ps`

`extern __m512 __cdecl _mm512_mask_log_ps(__m512 src, __mmask16 k, __m512 a);`

Calculates the natural (base-e) logarithm of vector `a` elements.

<td>source element to use based on writemask result</td>
</tr>
</tbody>
</table>

```c
extern __m512d __cdecl _mm512_rcp14_pd(__m512d a);
```

Computes the approximate reciprocal of packed float64 elements in a, and stores the result.
NOTE
The maximum relative error for this approximation is less than $2^{-14}$.

__mm512_mask_rcp14_pd

extern __m512 __cdecl __m512_mask_rcp14_pd(__m512 src, __mmask8 k, __m512 a);

Computes the approximate reciprocal of packed float64 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{-14}$.

__mm512_maskz_rcp14_pd

extern __m512 __cdecl __m512_maskz_rcp14_pd(__mmask8 k, __m512 a);

Computes the approximate reciprocal of packed float64 elements in $a$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{-14}$.

__mm512_rcp14_ps

extern __m512 __cdecl __m512_rcp14_ps(__m512 a);

Computes the approximate reciprocal of packed float32 elements in $a$, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{-14}$.

__mm512_mask_rcp14_ps

extern __m512 __cdecl __m512_mask_rcp14_ps(__m512 src, __mmask16 k, __m512 a);

Computes the approximate reciprocal of packed float32 elements in $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{-14}$.

__mm512_maskz_rcp14_ps

extern __m512 __cdecl __m512_maskz_rcp14_ps(__mmask16 k, __m512 a);

Computes the approximate reciprocal of packed float32 elements in $a$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

`_mm_rcp14_sd`

```c
extern __m128d __cdecl _mm_rcp14_sd(__m128d a, __m128d b);
```
Computes the approximate reciprocal of lower float64 element in `b`, stores the result in lower destination element, and copies upper element from `a` to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

`_mm_mask_rcp14_sd`

```c
extern __m128d __cdecl _mm_mask_rcp14_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```
Computes the approximate reciprocal of lower float64 element in `b`, stores the result in lower destination element using writemask `k` (the element is copied from `src` when mask bit 0 is not set), and copies upper element from `a` to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

`_mm_maskz_rcp14_sd`

```c
extern __m128d __cdecl _mm_maskz_rcp14_sd(__mmask8 k, __m128d a, __m128d b);
```
Computes the approximate reciprocal of lower float64 element in `b`, stores the result in lower destination element using zeromask `k` (the element is zeroed out when mask bit 0 is not set), and copies upper element from `a` to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

`_mm_rcp14_ss`

```c
extern __m128 __cdecl _mm_rcp14_ss(__m128 a, __m128 b);
```
Computes approximate reciprocal of lower float32 element in `b`, stores the result in lower destination element, and copies upper three packed elements from `a` to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

`_mm_mask_rcp14_ss`

```c
extern __m128 __cdecl _mm_mask_rcp14_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Compiler Reference

1187
Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-14)} \).

```c
_mm_maskz_rcp14_ss
extern __m128 __cdecl _mm_maskz_rcp14_ss(__mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-14)} \).

```c
_mm512_rcp28_round_pd
extern __m512d __cdecl _mm512_rcp28_round_pd(__m512d a);
```

Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
_mm512_mask_rcp28_round_pd
extern __m512d __cdecl _mm512_mask_rcp28_round_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
_mm512_maskz_rcp28_round_pd
extern __m512d __cdecl _mm512_maskz_rcp28_round_pd(__mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
_mm512_rcp28_pd
extern __m512d __cdecl _mm512_rcp28_pd(__m512d a);
```
Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result.

**NOTE**  
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
extern __m512d __cdecl _mm512_mask_rcp28_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**NOTE**  
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
extern __m512d __cdecl _mm512_maskz_rcp28_pd(__mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**  
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
extern __m512 __cdecl _mm512_rcp28_round_ps(__m512 a);
```

Computes the approximate reciprocal of packed float32 elements in \( a \), and stores the result.

**NOTE**  
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
extern __m512 __cdecl _mm512_mask_rcp28_round_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**NOTE**  
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

```c
extern __m512 __cdecl _mm512_maskz_rcp28_round_ps(__mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
**NOTE**
The maximum relative error for this approximation is less than $2^{(-28)}$.

```c
__mm512_rcp28_ps

extern __m512 __cdecl __m512_rcp28_ps(__m512 a);
```
Computes the approximate reciprocal of packed float32 elements in a, and stores the result.

**NOTE**
The maximum relative error for this approximation is less than $2^{(-28)}$.

```c
__mm512_mask_rcp28_ps

extern __m512 __cdecl __m512_mask_rcp28_ps(__m512 src, __mmask16 k, __m512 a);
```
Computes the approximate reciprocal of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

**NOTE**
The maximum relative error for this approximation is less than $2^{(-28)}$.

```c
__mm512_maskz_rcp28_ps

extern __m512 __cdecl __m512_maskz_rcp28_ps(__mmask16 k, __m512 a);
```
Computes the approximate reciprocal of packed float32 elements in a, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**
The maximum relative error for this approximation is less than $2^{(-28)}$.

```c
__mm512_rcp28_round_sd

extern __m128d __cdecl __m512_rcp28_round_sd(__m128d b, __m128d a);
```
Computes the approximate reciprocal of lower float64 element in b, stores the result in lower destination element, and copies upper element from a to upper destination element.

**NOTE**
The maximum relative error for this approximation is less than $2^{(-28)}$.

```c
__mm512_mask_rcp28_round_sd

extern __m128d __cdecl __m512_mask_rcp28_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```
Computes the approximate reciprocal of lower float64 element in b, stores the result in lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies upper element from a to upper destination element.
NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_sd

```c
extern _m128d __cdecl_mm512_maskz_rcp28_round_sd(__mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in $b$, stores the result in lower destination element using zeromask $k$ (the element is zeroed out when mask bit 0 is not set), and copies upper element from $a$ to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_sd

```c
extern _m128d __cdecl_mm512_rcp28_round_sd(__m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in $b$, stores the result in lower destination element, and copies upper element from $a$ to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_sd

```c
extern _m128d __cdecl_mm512_mask_rcp28_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in $b$, stores the result in lower destination element using writemask $k$ (the element is copied from $src$ when mask bit 0 is not set), and copies upper element from $a$ to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_sd

```c
extern _m128d __cdecl_mm512_maskz_rcp28_round_sd(__mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in $b$, stores the result in lower destination element using zeromask $k$ (the element is zeroed out when mask bit 0 is not set), and copies upper element from $a$ to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_ss

```c
extern __m128 __cdecl_mm512_rcp28_round_ss(__m128 a, __m128 b);
```
Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element, and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

---

__mm512_mask_rcp28_round_ss__

```c
extern __m128 __cdecl _mm512_mask_rcp28_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

---

__mm512_maskz_rcp28_round_ss__

```c
extern __m128 __cdecl _mm512_maskz_rcp28_round_ss(__mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

---

__mm512_rcp28_ss__

```c
extern __m128 __cdecl _mm512_rcp28_ss(__m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element, and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

---

__mm512_mask_rcp28_ss__

```c
extern __m128 __cdecl _mm512_mask_rcp28_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in \( b \), stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements.

**NOTE**
The maximum relative error for this approximation is less than \( 2^{(-28)} \).

---
_mm512_maskz_rcp28_ss
extern __m128 __cdecl _mm512_maskz_rcp28_ss(__mmask8 k, __m128 a, __m128 b);

Computes approximate reciprocal of lower float32 element in b, stores the result in lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from a to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{-28}$.

_mm512_recip_pd
extern __m512d __cdecl _mm512_recip_pd(__m512d a);

Computes approximate reciprocal of float64 elements in a, and stores the result.

_mm512_mask_recip_pd
extern __m512d __cdecl _mm512_mask_recip_pd(__m512d src, __mmask8 k, __m512d a);

Computes approximate reciprocal of float64 elements in a, and stores the result using writemask k (the element is copied from src when mask bit 0 is not set).

_mm512_recip_ps
extern __m512 __cdecl _mm512_recip_ps(__m512 a);

Computes approximate reciprocal of float32 elements in a, and stores the result.

_mm512_mask_recip_ps
extern __m512 __cdecl _mm512_mask_recip_ps(__m512 src, __mmask16 k, __m512 a);

Computes approximate reciprocal of float32 elements in a, and stores the result using writemask k (the element is copied from src when mask bit 0 is not set).

Intrinsics for Root Function Operations
The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>

```c
extern __m512d __cdecl _mm512_sqrt_pd(__m512d a);
Calculates square root value of float64 vector a elements.
```

```c
extern __m512d __cdecl _mm512_mask_sqrt_pd(__m512d src, __mmask8 k, __m512d a);
Calculates square root value of float64 vector a elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
```

```c
extern __m512 __cdecl _mm512_sqrt_ps(__m512 a);
Calculates square root value of float32 vector a elements.
```

```c
extern __m512 __cdecl _mm512_mask_sqrt_ps(__m512 src, __mmask16 k, __m512 a);
Calculates square root value of float32 vector a elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
```

```c
extern __m512d __cdecl _mm512_invsqrt_pd(__m512d a);
```

Calculates inverse square root value of float64 vector $a$ elements.

_mm512_mask_invsqrt_pd

extern __m512d __cdecl _mm512_mask_invsqrt_pd(__m512d src, __mmask8 k, __m512d a);

Calculates inverse square root value of float64 vector $a$ elements, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_invsqrt_ps

extern __m512 __cdecl _mm512_invsqrt_ps(__m512 a);

Calculates inverse square root value of float32 vector $a$ elements.

_mm512_mask_invsqrt_ps

extern __m512 __cdecl _mm512_mask_invsqrt_ps(__m512 src, __mmask16 k, __m512 a);

Calculates inverse square root value of float32 vector $a$ elements, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_hypot_pd

extern __m512d __cdecl _mm512_hypot_pd(__m512d a, __m512d b);

Computes the length of the hypotenuse of a right angled triangle with sides from float64 vector $a$ and $b$ elements.

_mm512_mask_hypot_pd

extern __m512d __cdecl _mm512_mask_hypot_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);

Computes the length of the hypotenuse of a right angled triangle with sides from float64 vector $a$ and $b$ elements, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_hypot_ps

extern __m512 __cdecl _mm512_hypot_ps(__m512 a, __m512 b);

Computes the length of the hypotenuse of a right angled triangle with sides from float32 vector $a$ and $b$ elements.

_mm512_mask_hypot_ps

extern __m512 __cdecl _mm512_mask_hypot_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);

Computes the length of the hypotenuse of a right angled triangle with sides from float32 vector $a$ and $b$ elements, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

_mm512_cbrt_pd

extern __m512d __cdecl _mm512_cbrt_pd(__m512d a);

Calculates the cube root of float64 vector $a$ elements.

_mm512_mask_cbrt_pd

extern __m512d __cdecl _mm512_mask_cbrt_pd(__m512d src, __mmask8 k, __m512d a);
Calculates the cube root of float64 vector a elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
extern __m512 __cdecl _mm512_cbrt_ps(__m512 a);
```

Calculates the cube root of float32 vector a elements.

```c
extern __m512 __cdecl _mm512_mask_cbrt_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the cube root of float32 vector a elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

### Intrinsic for Rounding Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file. To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>

```c
extern __m512d __cdecl _mm512_ceil_pd(__m512d a);
``` 
Rounds off the elements of float64 vector a to the nearest upper integer value.

```c
extern __m512d __cdecl _mm512_mask_ceil_pd(__m512d src, __mmask8 k, __m512d a);
``` 
Rounds off the elements of float64 vector a to the nearest upper integer value, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
extern __m512 __cdecl _mm512_ceil_ps(__m512 a);
``` 
Rounds off the elements of float32 vector a to the nearest upper integer value.

```c
extern __m512 __cdecl _mm512_mask_ceil_ps(__m512 src, __mmask16 k, __m512 a);
``` 
Rounds off the elements of float32 vector a to the nearest upper integer value, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_floor_pd(__m512d a);
``` 
Rounds off the elements of float64 vector a to the nearest lower integer value.

```c
extern __m512d __cdecl _mm512_mask_floor_pd(__m512d src, __mmask8 k, __m512d a);
``` 
Rounds off the elements of float64 vector a to the nearest lower integer value, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm512_floor_ps

extern __m512 __cdecl _mm512_floor_ps(__m512 a);

Rounds off the elements of float32 vector `a` to the nearest lower integer value.

_mm512_mask_floor_ps

extern __m512 __cdecl _mm512_mask_floor_ps(__m512 src, __mmask16 k, __m512 a);

Rounds off the elements of float32 vector `a` to the nearest lower integer value, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_nearbyint_pd

extern __m512d __cdecl _mm512_nearbyint_pd(__m512d a);

Rounds off the elements of float64 vector `a` to the nearest integer value in floating point format without raising the inexact exception.

_mm512_mask_nearbyint_pd

extern __m512d __cdecl _mm512_mask_nearbyint_pd(__m512d src, __mmask8 k, __m512d a);

Rounds off the elements of float64 vector `a` to the nearest integer value in floating point format without raising the inexact exception, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_nearbyint_ps

extern __m512 __cdecl _mm512_nearbyint_ps(__m512 a);

Rounds off the elements of float32 vector `a` to the nearest integer value in floating point format without raising the inexact exception.

_mm512_mask_nearbyint_ps

extern __m512 __cdecl _mm512_mask_nearbyint_ps(__m512 src, __mmask16 k, __m512 a);

Rounds off the elements of float32 vector `a` to the nearest integer value in floating point format without raising the inexact exception, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_rint_pd

extern __m512d __cdecl _mm512_rint_pd(__m512d a);

Rounds off the elements of float64 vector `a` to the nearest even integer value.

_mm512_mask_rint_pd

extern __m512d __cdecl _mm512_mask_rint_pd(__m512d src, __mmask8 k, __m512d a);

Rounds off the elements of float64 vector `a` to the nearest even integer value, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_rint_ps

extern __m512 __cdecl _mm512_rint_ps(__m512 a);

Rounds off the elements of float32 vector `a` to the nearest even integer value.
_mm512_mask_rint_ps

extern __m512 __cdecl _mm512_mask_rint_ps(__m512 src, __mmask16 k, __m512 a);

Rounds off the elements of float32 vector \(a\) to the nearest even integer value, and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

:_mm512_svmI_round_pD

extern __m512d __cdecl _mm512_svmI_round_pD(__m512d a);

Rounds off the elements of vector \(a\) to the nearest integer value. This intrinsic rounds the halfway cases away from zero regardless of the current rounding direction, instead of to the nearest even integer like the _mm512_rint_pD intrinsic.

:_mm512_mask_svmI_round_pD

extern __m512d __cdecl _mm512_mask_svmI_round_pD(__m512d src, __mmask8 k, __m512d a);

Rounds off the elements of vector \(a\) to the nearest integer value. This intrinsic rounds the halfway cases away from zero regardless of the current rounding direction, instead of to the nearest even integer like the _mm512_rint_pD intrinsic.

The result is stored using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set)

:_mm512_trunc_pD

extern __m512d __cdecl _mm512_trunc_pD(__m512d a);

Rounds off the elements of float64 vector \(a\) to the nearest integer value which is not larger in absolute value.

:_mm512_mask_trunc_pD

extern __m512d __cdecl _mm512_mask_trunc_pD(__m512d src, __mmask8 k, __m512d a);

Rounds off the elements of float64 vector \(a\) to the nearest integer value which is not larger in absolute value, and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

:_mm512_trunc_pS

extern __m512 __cdecl _mm512_trunc_pS(__m512 a);

Rounds off the elements of float32 vector \(a\) to the nearest integer value which is not larger in absolute value.

:_mm512_mask_trunc_pS

extern __m512 __cdecl _mm512_mask_trunc_pS(__m512 src, __mmask16 k, __m512 a);

Rounds off the elements of float32 vector \(a\) to the nearest integer value which is not larger in absolute value, and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

Intrinsics for Trigonometric Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

_mm512_acos_pd
extern __m512d __cdecl _mm512_acos_pd(__m512d a);

Computes the inverse cosine of packed float64 elements in a, and stores the result.

_mm512_mask_acos_pd
extern __m512d __cdecl _mm512_mask_acos_pd(__m512d src, __mmask8 k, __m512d a);

Computes the inverse cosine of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_acos_ps
extern __m512 __cdecl _mm512_acos_ps(__m512 a);

Computes the inverse cosine of packed float32 elements in a, and stores the result.

_mm512_mask_acos_ps
extern __m512 __cdecl _mm512_mask_acos_ps(__m512 src, __mmask16 k, __m512 a);

Computes the inverse cosine of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_acosh_pd
extern __m512d __cdecl _mm512_acosh_pd(__m512d a);

Computes the inverse hyperbolic cosine of packed float64 elements in a, and stores the result.

_mm512_mask_acosh_pd
extern __m512d __cdecl _mm512_mask_acosh_pd(__m512d src, __mmask8 k, __m512d a);

Computes the inverse hyperbolic cosine of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_acosh_ps
extern __m512 __cdecl _mm512_acosh_ps(__m512 a);

Computes the inverse hyperbolic cosine of packed float32 elements in a, and stores the result.

_mm512_mask_acosh_ps
extern __m512 __cdecl _mm512_mask_acosh_ps(__m512 src, __mmask16 k, __m512 a);

Computes the inverse hyperbolic cosine of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_asin_pd
extern __m512d __cdecl _mm512_asin_pd(__m512d a);

Computes the inverse sine of packed float64 elements in a, and stores the result.
__mm512_mask_asin_pd
extern __m512d __cdecl __mm512_mask_asin_pd(__m512d src, __mmask8 k, __m512d a);
Computes the inverse sine of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_asin_ps
extern __m512 __cdecl __mm512_asin_ps(__m512 a);
Computes the inverse sine of packed float32 elements in \( a \), and stores the result.

__mm512_mask_asin_ps
extern __m512 __cdecl __mm512_mask_asin_ps(__m512 src, __mmask16 k, __m512 a);
Computes the inverse sine of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_asinh_pd
extern __m512d __cdecl __mm512_asinh_pd(__m512d a);
Computes the inverse hyperbolic sine of packed float64 elements in \( a \), and stores the result.

__mm512_mask_asinh_pd
extern __m512d __cdecl __mm512_mask_asinh_pd(__m512d src, __mmask8 k, __m512d a);
Computes the inverse hyperbolic sine of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_asinh_ps
extern __m512 __cdecl __mm512_asinh_ps(__m512 a);
Computes the inverse hyperbolic sine of packed float32 elements in \( a \), and stores the result.

__mm512_mask_asinh_ps
extern __m512 __cdecl __mm512_mask_asinh_ps(__m512 src, __mmask16 k, __m512 a);
Computes the inverse hyperbolic sine of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_atan2_pd
extern __m512d __cdecl __mm512_atan2_pd(__m512d a, __m512d b);
Computes the inverse tangent of packed float64 elements in \( a \) and \( b \), and stores the result.

__mm512_mask_atan2_pd
extern __m512d __cdecl __mm512_mask_atan2_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
Computes the inverse tangent of packed float64 elements in \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_atan2\_ps

\begin{verbatim}
extern __m512 __cdecl _mm512_atan2_ps(__m512 a, __m512 b);
\end{verbatim}

Computes the inverse tangent of packed float32 elements in \(a\) and \(b\), and stores the result.

\_mm512\_mask\_atan2\_ps

\begin{verbatim}
extern __m512 __cdecl _mm512_mask_atan2_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
\end{verbatim}

Computes the inverse tangent of packed float32 elements in \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_atan\_pd

\begin{verbatim}
extern __m512d __cdecl _mm512_atan_pd(__m512d a);
\end{verbatim}

Computes the inverse tangent of packed float64 elements in \(a\), and stores the result.

\_mm512\_mask\_atan\_pd

\begin{verbatim}
extern __m512d __cdecl _mm512_mask_atan_pd(__m512d src, __mmask8 k, __m512d a);
\end{verbatim}

Computes the inverse tangent of packed float64 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_atan\_ps

\begin{verbatim}
extern __m512 __cdecl _mm512_atan_ps(__m512 a);
\end{verbatim}

Computes the inverse tangent of packed float32 elements in \(a\), and stores the result.

\_mm512\_mask\_atan\_ps

\begin{verbatim}
extern __m512 __cdecl _mm512_mask_atan_ps(__m512 src, __mmask16 k, __m512 a);
\end{verbatim}

Computes the inverse tangent of packed float32 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_atanh\_pd

\begin{verbatim}
extern __m512d __cdecl _mm512_atanh_pd(__m512d a);
\end{verbatim}

Computes the inverse hyperbolic tangent of packed float64 elements in \(a\), and stores the result.

\_mm512\_mask\_atanh\_pd

\begin{verbatim}
extern __m512d __cdecl _mm512_mask_atanh_pd(__m512d src, __mmask8 k, __m512d a);
\end{verbatim}

Computes the inverse hyperbolic tangent of packed float64 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
_mm512_atanh_ps

extern __m512 __cdecl __m512_atanh_ps(__m512 a);

Computes the inverse hyperbolic tangent of packed float32 elements in a, and stores the result.

_mm512_mask_atanh_ps

extern __m512 __cdecl __m512_mask_atanh_ps(__m512 src, __mmask16 k, __m512 a);

Computes the inverse hyperbolic tangent of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_cos_pd

extern __m512d __cdecl __m512_cos_pd(__m512d a);

Computes the cosine of packed float64 elements in a, and stores the result.

_mm512_mask_cos_pd

extern __m512d __cdecl __m512_mask_cos_pd(__m512d src, __mmask8 k, __m512d a);

Computes the cosine of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_cos_ps

extern __m512 __cdecl __m512_cos_ps(__m512 a);

Computes the cosine of packed float32 elements in a, and stores the result.

_mm512_mask_cos_ps

extern __m512 __cdecl __m512_mask_cos_ps(__m512 src, __mmask16 k, __m512 a);

Computes the cosine of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_cosd_pd

extern __m512d __cdecl __m512_cosd_pd(__m512d a);

Computes the cosine (in degrees) of packed float64 elements in a, and stores the result.

_mm512_mask_cosd_pd

extern __m512d __cdecl __m512_mask_cosd_pd(__m512d src, __mmask8 k, __m512d a);

Computes the cosine (in degrees) of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_cosd_ps

extern __m512 __cdecl __m512_cosd_ps(__m512 a);
Computes the cosine (in degrees) of packed float32 elements in \( a \), and stores the result.

```c
_mm512_mask_cosd_ps
extern __m512 __cdecl _mm512_mask_cosd_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the cosine (in degrees) of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_cosh_pd
extern __m512d __cdecl _mm512_cosh_pd(__m512d a);
```

Computes the hyperbolic cosine of packed float64 elements in \( a \), and stores the result.

```c
_mm512_mask_cosh_pd
extern __m512d __cdecl _mm512_mask_cosh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the hyperbolic cosine of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_cosh_ps
extern __m512 __cdecl _mm512_cosh_ps(__m512 a);
```

Computes the hyperbolic cosine of packed float32 elements in \( a \), and stores the result.

```c
_mm512_mask_cosh_ps
extern __m512 __cdecl _mm512_mask_cosh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the hyperbolic cosine (in degrees) of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_sin_pd
extern __m512d __cdecl _mm512_sin_pd(__m512d a);
```

Computes the sine of packed float64 elements in \( a \), and stores the result.

```c
_mm512_mask_sin_pd
extern __m512d __cdecl _mm512_mask_sin_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the sine of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_sin_ps
extern __m512 __cdecl _mm512_sin_ps(__m512 a);
```

Computes the sine of packed float32 elements in \( a \), and stores the result.
**_mm512_mask_sin_ps_**

`extern __m512 __cdecl _mm512_mask_sin_ps(__m512 src, __mmask16 k, __m512 a);`

Computes the sine (in degrees) of packed float32 elements in `a`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_sinh_pd_**

`extern __m512d __cdecl _mm512_sinh_pd(__m512d a);`

Computes the hyperbolic sine of packed float64 elements in `a`, and stores the result.

**_mm512_mask_sinh_pd_**

`extern __m512d __cdecl _mm512_mask_sinh_pd(__m512d src, __mmask8 k, __m512d a);`

Computes the hyperbolic sine of packed float64 elements in `a`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_sinh_ps_**

`extern __m512 __cdecl _mm512_sinh_ps(__m512 a);`

Computes the hyperbolic sine of packed float32 elements in `a`, and stores the result.

**_mm512_mask_sinh_ps_**

`extern __m512 __cdecl _mm512_mask_sinh_ps(__m512 src, __mmask16 k, __m512 a);`

Computes the hyperbolic cosine of packed float32 elements in `a`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_sind_pd_**

`extern __m512d __cdecl _mm512_sind_pd(__m512d a);`

Computes the sine (in degrees) of packed float64 elements in `a`, and stores the result.

**_mm512_mask_sind_pd_**

`extern __m512d __cdecl _mm512_mask_sind_pd(__m512d src, __mmask8 k, __m512d a);`

Computes the sine (in degrees) packed float64 elements in `a`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_sind_ps_**

`extern __m512 __cdecl _mm512_sind_ps(__m512 a);`

Computes the sine (in degrees) of packed float32 elements in `a`, and stores the result.

**_mm512_mask_sind_ps_**

`extern __m512 __cdecl _mm512_mask_sind_ps(__m512 src, __mmask16 k, __m512 a);`
Computes the sine (in degrees) of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_tan_pd
extern __m512d __cdecl _mm512_tan_pd(__m512d a);
```
Computes the tangent of packed float64 elements in \( a \), and stores the result.

```c
_mm512_mask_tan_pd
extern __m512d __cdecl _mm512_mask_tan_pd(__m512d src, __mmask8 k, __m512d a);
```
Computes the tangent of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_tan_ps
extern __m512 __cdecl _mm512_tan_ps(__m512 a);
```
Computes the tangent of packed float32 elements in \( a \), and stores the result.

```c
_mm512_mask_tan_ps
extern __m512 __cdecl _mm512_mask_tan_ps(__m512 src, __mmask16 k, __m512 a);
```
Computes the tangent of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_tand_pd
extern __m512d __cdecl _mm512_tand_pd(__m512d a);
```
Computes the tangent (in degrees) of packed float64 elements in \( a \), and stores the result.

```c
_mm512_mask_tand_pd
extern __m512d __cdecl _mm512_mask_tand_pd(__m512d src, __mmask8 k, __m512d a);
```
Computes tangent (in degrees) of packed float64 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
_mm512_tand_ps
extern __m512 __cdecl _mm512_tand_ps(__m512 a);
```
Computes the tangent (in degrees) of packed float32 elements in \( a \), and stores the result.

```c
_mm512_mask_tand_ps
extern __m512 __cdecl _mm512_mask_tand_ps(__m512 src, __mmask16 k, __m512 a);
```
Computes the tangent (in degrees) of packed float32 elements in \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).
_mm512_tanh_pd
extern __m512d __cdecl _mm512_tanh_pd(__m512d a);
Computes the hyperbolic tangent of packed float64 elements in a, and stores the result.

__m512_mask_tanh_pd
extern __m512d __cdecl _mm512_mask_tanh_pd(__m512d src, __mmask8 k, __m512d a);
Computes the hyperbolic tangent of packed float64 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_tanh_ps
extern __m512 __cdecl _mm512_tanh_ps(__m512 a);
Computes the hyperbolic tangent of packed float32 elements in a, and stores the result.

__m512_mask_tanh_ps
extern __m512 __cdecl _mm512_mask_tanh_ps(__m512 src, __mmask16 k, __m512 a);
Computes the hyperbolic tangent of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

Intrinsics for Other Mathematics Operations

Intrinsics for FP Division Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

#include <immintrin.h>

<table>
<thead>
<tr>
<th>Intrinsic Name</th>

_**_mm512_div_pd

extern __m512d __cdecl _mm512_div_pd(__m512d a, __m512d b);

Divides packed float64 elements in a by packed elements in b, and stores the result.

_**_mm512_mask_div_pd

extern __m512d __cdecl _mm512_mask_div_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);

Divides packed float64 elements in a by packed elements in b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result.

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

Divides packed float64 elements in \(a\) by packed elements in \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result.

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result.

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
_mm512_maskz_div_round_ps

extern _m512 _cdecl _mm512_maskz_div_round_ps(_mmask16 k, __m512 a, __m512 b, int round);

Divides packed float32 elements in \(a\) by packed elements in \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_div_sd

extern __m128d _cdecl _mm_mask_div_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);

Divides the lower float64 element in \(a\) by the lower float64 element in \(b\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

_mm_maskz_div_sd

extern __m128d _cdecl _mm_maskz_div_sd(__mmask8 k, __m128d a, __m128d b);

Divides the lower float64 element in \(a\) by the lower float64 element in \(b\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

_mm_div_round_sd

extern __m128d _cdecl _mm_div_round_sd(__m128d a, __m128d b, int round);

Divides the lower float64 element in \(a\) by the lower float64 element in \(b\), stores the result in the lower destination element, and copies the upper element from \(a\) to the upper destination element.

_mm_mask_div_round_sd

extern __m128d _cdecl _mm_mask_div_round_sd(__mmask8 src, __m128d k, __m128d a, __m128d b);

Divides the lower float64 element in \(a\) by the lower float64 element in \(b\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

_mm_maskz_div_round_sd

extern __m128d _cdecl _mm_maskz_div_round_sd(__mmask8 k, __m128d a, __m128d b);

Divides the lower float64 element in \(a\) by the lower float64 element in \(b\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \(a\) to the upper destination element.

_mm_div_round_ss

extern __m128 _cdecl _mm_div_round_ss(__m128 a, __m128 b, int round);

Divides the lower float32 element in \(a\) by the lower float32 element in \(b\), stores the result in the lower destination element, and copies the upper three packed elements from \(a\) to the upper destination elements.

_mm_mask_div_round_ss

extern __m128 _cdecl _mm_mask_div_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int round);

Divides the lower float32 element in \(a\) by the lower float32 element in \(b\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper three packed elements from \(a\) to the upper destination elements.
**_mm_maskz_div_round_ss_**

```c
extern __m128 __cdecl _mm_maskz_div_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Divides the lower float32 element in \(a\) by the lower float32 element in \(b\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \(a\) to the upper destination elements.

**_mm_mask_div_ss_**

```c
extern __m128 __cdecl _mm_mask_div_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Divides the lower float32 element in \(a\) by the lower float32 element in \(b\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper three packed elements from \(a\) to the upper destination elements.

**_mm_maskz_div_ss_**

```c
extern __m128 __cdecl _mm_maskz_div_ss(__mmask8 k, __m128 a, __m128 b);
```

Divides the lower float32 element in \(a\) by the lower float32 element in \(b\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \(a\) to the upper destination elements.

</tbody>
</table>

**_mm512_abs_epi32_**

```c
extern __m512i __cdecl _mm512_abs_epi32(__m512i a);
```

Computes absolute value of packed int32 elements in \(a\), and stores unsigned results in destination.
Computes absolute value of packed int32 elements in \(a\), and stores unsigned results in destination using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{extern } \_\_m512i \_\_cdecl \_mm512\_mask\_abs\_epi32(\_\_m512i~\textit{src}, \_\_mmask16~k, \_\_m512i~a);
\]

Computes absolute value of packed int32 elements in \(a\), and stores unsigned results in destination using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{extern } \_\_m512i \_\_cdecl \_mm512\_maskz\_abs\_epi32(\_\_mmask16~k, \_\_m512i~a);
\]

Computes absolute value of packed int64 elements in \(a\), and stores unsigned results in destination.

\[
\text{extern } \_\_m512i \_\_cdecl \_mm512\_abs\_epi64(\_\_m512i~a);

_mm512_roundscale_pd

```
extern __m512d __cdecl _mm512_roundscale_pd(__m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in `a` to the number of fraction bits specified by `imm`, and stores the result.

_mm512_mask_roundscale_pd

```
extern __m512d __cdecl _mm512_mask_roundscale_pd(__m512d src, __mmask8 k, __m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in `a` to the number of fraction bits specified by `imm`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_roundscale_pd

```
extern __m512d __cdecl _mm512_maskz_roundscale_pd(__mmask8 k, __m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in `a` to the number of fraction bits specified by `imm`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_roundscale_ps

```
extern __m512 __cdecl _mm512_roundscale_ps(__m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in `a` to the number of fraction bits specified by `imm`, and stores the result.

_mm512_mask_roundscale_ps

```
extern __m512 __cdecl _mm512_mask_roundscale_ps(__m512 src, __mmask16 k, __m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in `a` to the number of fraction bits specified by `imm`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_roundscale_ps

```
extern __m512 __cdecl _mm512_maskz_roundscale_ps(__mmask16 k, __m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in a to the number of fraction bits specified by imm, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_roundscale_round_sd

extern __m128d __cdecl _mm_roundscale_round_sd(__m128d a, __m128d b, const int imm, const int round);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element, and copies the upper element from b to the upper destination element.

_mm_mask_roundscale_round_sd

extern __m128d __cdecl _mm_mask_roundscale_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, const int imm, const int round);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from b to the upper destination element.

_mm_maskz_roundscale_round_sd

extern __m128d __cdecl _mm_maskz_roundscale_round_sd(__mmask8 k, __m128d a, __m128d b, const int imm, const int round);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from b to the upper destination element.

_mm_roundscale_sd

extern __m128d __cdecl _mm_roundscale_sd(__m128d a, __m128d b, const int imm);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element, and copies the upper element from b to the upper destination element.

_mm_mask_roundscale_sd

extern __m128d __cdecl _mm_mask_roundscale_sd(__m128d old, __mmask8 k, __m128d a, __m128d b, const int imm);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper element from b to the upper destination element.

_mm_maskz_roundscale_sd

extern __m128d __cdecl _mm_maskz_roundscale_sd(__mmask8 k, __m128d a, __m128d b, const int imm);

Rounds the lower float64 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from b to the upper destination element.

_mm_roundscale_round_ss

extern __m128 __cdecl _mm_roundscale_round_ss(__m128 a, __m128 b, const int imm, const int round);

Rounds the lower float32 element in a to the number of fraction bits specified by imm, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from b to the upper destination element.
Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element, and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm\_mask\_roundscale\_round\_ss}
\]

\[
\text{extern } \_m128 \text{ cdecl}_\text{mm\_mask\_roundscale\_round\_ss}(\_m128 \text{ src}, \_mmask8 \text{ k}, \_m128 \text{ a, m128 b, const int imm, const int round});
\]

Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm\_maskz\_roundscale\_round\_ss}
\]

\[
\text{extern } \_m128 \text{ cdecl}_\text{mm\_maskz\_roundscale\_round\_ss}(\_mmask8 \text{ k}, \_m128 \text{ a, m128 b, const int imm, const int round});
\]

Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm\_roundscale\_ss}
\]

\[
\text{extern } \_m128 \text{ cdecl}_\text{mm\_roundscale\_ss}(\_m128 \text{ a, m128 b, const int imm});
\]

Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element, and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm\_mask\_roundscale\_ss}
\]

\[
\text{extern } \_m128 \text{ cdecl}_\text{mm\_mask\_roundscale\_ss}(\_m128 \text{ src, mmask8 k, m128 a, m128 b, const int imm});
\]

Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm\_maskz\_roundscale\_ss}
\]

\[
\text{extern } \_m128 \text{ cdecl}_\text{mm\_maskz\_roundscale\_ss}(\_mmask8 \text{ k, m128 a, m128 b, const int imm});
\]

Rounds the lower float32 element in \(a\) to the number of fraction bits specified by \(imm\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \(b\) to the upper destination elements.

\[
_\text{mm512\_scalef\_pd}
\]

\[
\text{extern } \_m512d \text{ cdecl}_\text{mm512\_scalef\_pd}(\_m512d \text{ a, m512d b});
\]

Performs a floating point scale of the packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result.

\[
_\text{mm512\_mask\_scalef\_pd}
\]

\[
\text{extern } \_m512d \text{ cdecl}_\text{mm512\_mask\_scalef\_pd}(\_m512d \text{ src, mmask8 k, m512d a, m512d b});
\]
Performs a floating point scale of the packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_maskz\_scalef\_pd

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_maskz\_scalef\_pd}(\_mmask8 \ k, \_m512d \ a, \_m512d \ b);
\]

Performs a floating point scale of the packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_scalef\_round\_pd

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_scalef\_round\_pd}(\_m512d \ a, \_m512d \ b, \text{int} \ \text{round});
\]

Performs a floating point scale of the rounded packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result.

\_mm512\_mask\_scalef\_round\_pd

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_mask\_scalef\_round\_pd}(\_m512d \ src, \_mmask8 \ k, \_m512d \ a, \_m512d \ b, \text{int} \ \text{round});
\]

Performs a floating point scale of the rounded packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_maskz\_scalef\_round\_pd

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_maskz\_scalef\_round\_pd}(\_mmask8 \ k, \_m512d \ a, \_m512d \ b, \text{int} \ \text{round});
\]

Performs a floating point scale of the rounded packed float64 elements in source \(a\) by multiplying by \(2^b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_scalef\_ps

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_scalef\_ps}(\_m512d \ a, \_m512d \ b);
\]

Performs a floating point scale of the packed float32 elements in source \(a\) by multiplying by \(2^b\), and stores the result.

\_mm512\_mask\_scalef\_ps

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_mask\_scalef\_ps}(\_m512d \ src, \_mmask16 \ k, \_m512d \ a, \_m512d \ b);
\]

Performs a floating point scale of the packed float32 elements in source \(a\) by multiplying by \(2^b\), and stores the result, using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_maskz\_scalef\_ps

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_maskz\_scalef\_ps}(\_mmask16 \ k, \_m512d \ a, \_m512d \ b);
\]

Performs a floating point scale of the packed single-precision (64-bit) floating-point elements in source \(a\) by multiplying by \(2^b\), and stores the result, using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm512\_scalef\_round\_ps

\[
\text{extern } \_m512d \ _\text{cdecl} \ _\text{mm512\_scalef\_round\_ps}(\_m512d \ a, \_m512d \ b, \text{int} \ \text{round});
\]
Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source \(a\) by multiplying by \(2^b\), and stores the results.

**_mm512_mask_scalef_round_ps**

```c
extern __m512 __cdecl _mm512_mask_scalef_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int round);
```

Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source \(a\) by multiplying by \(2^b\), and stores the results, using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

**_mm512_maskz_scalef_round_ps**

```c
extern __m512 __cdecl _mm512_maskz_scalef_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
```

Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source \(a\) by multiplying by \(2^b\), and stores the results, using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_scalef_round_sd**

```c
extern __m128d __cdecl _mm_scalef_round_sd(__m128d a, __m128d b, int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source \(a\) by multiplying by \(2^b\), stores the result in the lower destination element, and copies the upper element from \(b\) to the upper destination element.

**_mm_mask_scalef_round_sd**

```c
extern __m128d __cdecl _mm_mask_scalef_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source \(a\) by multiplying by \(2^b\), stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copies the upper element from \(b\) to the upper destination element.

**_mm_maskz_scalef_round_sd**

```c
extern __m128d __cdecl _mm_maskz_scalef_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source \(a\) by multiplying by \(2^b\), stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper element from \(b\) to the upper destination element.

**_mm_scalef_sd**

```c
extern __m128d __cdecl _mm_scalef_sd(__m128d a, __m128d b);
```

Performs a floating point scale of the scalar float64 elements in source \(a\) using values from \(b\), stores the result in the lower destination element, and copies the upper element from \(b\) to the upper destination element.

**_mm_mask_scalef_sd**

```c
extern __m128d __cdecl _mm_mask_scalef_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```
Performs a floating point scale of the scalar float64 elements in source $a$ using values from $b$, stores the result in the lower destination element using writemask $k$ (the element is copied from $src$ when mask bit 0 is not set), and copies the upper element from $b$ to the upper destination element.

__mm_maskz_scalef_sd

```c
extern __m128d __cdecl _mm_maskz_scalef_sd(__mmask8 k, __m128d a, __m128d b);
```

Performs a floating point scale of the scalar float64 elements in source $a$ using values from $b$, stores the result in the lower destination element using zeromask $k$ (the element is zeroed out when mask bit 0 is not set), and copies the upper element from $b$ to the upper destination element.

__mm_scalef_round_ss

```c
extern __m128 __cdecl _mm_scalef_round_ss(__m128 a, __m128 b, int round);
```

Performs a floating point scale of the rounded scalar float32 elements in source $a$ by multiplying by $2^b$, stores the result in the lower destination element, and copies the upper element from $b$ to the upper destination elements.

__mm_mask_scalef_round_ss

```c
extern __m128 __cdecl _mm_mask_scalef_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int round);
```

Performs a floating point scale of the rounded scalar float32 elements in source $a$ by multiplying by $2^b$, stores the result in the lower destination element using writemask $k$ (the element is copied from $src$ when mask bit 0 is not set), and copies the upper three packed elements from $b$ to the upper destination elements.

__mm_maskz_scalef_round_ss

```c
extern __m128 __cdecl _mm_maskz_scalef_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Performs a floating point scale of the rounded scalar float32 elements in source $a$ by multiplying by $2^b$, stores the result in the lower destination element using zeromask $k$ (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from $b$ to the upper destination elements.

__mm_scalef_ss

```c
extern __m128 __cdecl _mm_scalef_ss(__m128 a, __m128 b);
```

Performs a floating point scale of the scalar float32 elements in source $a$ using values from $b$, stores the result in the lower destination element, and copies the upper three packed elements from $b$ to the upper destination elements.

__mm_mask_scalef_ss

```c
extern __m128 __cdecl _mm_mask_scalef_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Performs a floating point scale of the scalar float32 elements in source $a$ using values from $b$, stores the result in the lower destination element using writemask $k$ (the element is copied from $src$ when mask bit 0 is not set), and copies the upper three packed elements from $b$ to the upper destination elements.

__mm_maskz_scalef_ss

```c
extern __m128 __cdecl _mm_maskz_scalef_ss(__mmask8 k, __m128 a, __m128 b);
```
Performs a floating point scale of the scalar float32 elements in source \(a\) using values from \(b\), stores the result in the lower destination element, using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \(b\) to the upper destination elements.

**Intrinsics for Blend Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintinr.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

**NOTE**

The opmask register is not used as a writemask for these instructions. Instead, the mask is used as an element selector: every element of the destination is conditionally selected between first source or second source using the value of the related mask bit (‘0’ for the first source operand, ‘1’ for the second source operand), the elements with corresponding mask bit value of ‘0’ in the destination operand are zeroed.

**_mm512_mask_blend_pd**

```c
extern m512d __cdecl _mm512_mask_blend_pd(__mmask8 k, __m512d a, __m512d b);
```

Performs element-by-element blending of float64 source vectors \(a\) and \(b\), using the instruction mask \(k\) as selector.

The result is written into float64 vector destination register.

**_mm512_mask_blend_ps**

```c
extern m512 __cdecl _mm512_mask_blend_ps(__mmask16 k, __m512 a, __m512 b);
```
Performs element-by-element blending of float32 source vectors \( a \) and \( b \), using the instruction mask \( k \) as selector.

The result is written into an float32 vector register.

\_\_m512\_mask\_blend\_epi32

```c
extern m512i __cdecl _mm512_mask_blend_epi32(__mmask16 k, __m512i a, __m512i b);
```

Performs element-by-element blending of int32 source vectors \( a \) and \( b \), using the instruction mask \( k \) as selector.

The result is written into an int32 vector register.

\_\_m512\_mask\_blend\_epi64

```c
extern m512i __cdecl _mm512_mask_blend_epi64(__mmask8 k, __m512i a, __m512i b);
```

Performs element-by-element blending of int64 source vectors \( a \) and \( b \), using the instruction mask \( k \) as selector.

The result is written into an int64 vector register.

_mm512_lzcnt_epi32

```c
extern __m512i __cdecl _mm512_lzcnt_epi32(__m512i a);
```
Counts the number of leading zero bits in each packed 32-bit integer in a, and store the results in destination.

_mm512_mask_lzcnt_epi32

```c
extern __m512i __cdecl _mm512_mask_lzcnt_epi32(__m512i src, __mmask16 k, __m512i a);
```
Counts the number of leading zero bits in each packed 32-bit integer in a, and store the results in destination using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_lzcnt_epi32

```c
extern __m512i __cdecl _mm512_maskz_lzcnt_epi32(__mmask16 k, __m512i a);
```
Counts the number of leading zero bits in each packed 32-bit integer in a, and store the results in destination using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_lzcnt_epi64

```c
extern __m512i __cdecl _mm512_lzcnt_epi64(__m512i a);
```
Counts the number of leading zero bits in each packed 64-bit integer in a, and store the results.

_mm512_mask_lzcnt_epi64

```c
extern __m512i __cdecl _mm512_mask_lzcnt_epi64(__m512i src, __mmask8 k, __m512i a);
```
Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and store the results in using writemask \( k \).

Elements are copied from \( src \) when the corresponding mask bit is not set.

_mm512_maskz_lzcnt_epi64

```c
extern __m512i __cdecl _mm512_maskz_lzcnt_epi64(__mmask8 k, __m512i a);
```

Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and store the results in destination using zeromask \( k \).

Elements are zeroed out when the corresponding mask bit is not set.

_mm512_ternarylogic_epi32

```c
extern __m512i __cdecl _mm512_ternarylogic_epi32(__m512i a, __m512i b, __m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in \( imm8 \).

For each bit in each packed 32-bit integer, the corresponding bit from \( a \), \( b \), and \( c \) are used to form a 3 bit index into \( imm8 \), and the value at that bit in \( imm8 \) is written to the corresponding destination bit.

_mm512_mask_ternarylogic_epi32

```c
extern __m512i __cdecl _mm512_mask_ternarylogic_epi32(__m512i a, __mmask16 k, __m512i, __m512i b, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in \( imm8 \).

For each bit in each packed 32-bit integer, the corresponding bit from \( src \), \( a \), and \( b \) are used to form a 3 bit index into \( imm8 \), and the value at that bit in \( imm8 \) is written to the corresponding destination bit using writemask \( k \) at 32-bit granularity (32-bit elements are copied from \( src \) when the corresponding mask bit is not set).

_mm512_maskz_ternarylogic_epi32

```c
extern __m512i __cdecl _mm512_maskz_ternarylogic_epi32(__mmask16 k, __m512i a, __m512i b, __m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in \( imm8 \).

For each bit in each packed 32-bit integer, the corresponding bit from \( a \), \( b \), and \( c \) are used to form a 3-bit index into \( imm8 \), and the value at that bit in \( imm8 \) is written to the corresponding destination bit using zeromask \( k \) at 32-bit granularity (32-bit elements are zeroed out when the corresponding mask bit is not set).

_mm512_ternarylogic_epi64

```c
extern __m512i __cdecl _mm512_ternarylogic_epi64(__m512i a, __m512i b, __m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in \( imm8 \).

For each bit in each packed 64-bit integer, the corresponding bit from \( a \), \( b \), and \( c \) are used to form a 3-bit index into \( imm8 \), and the value at that bit in \( imm8 \) is written to the corresponding destination bit.
Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in `imm8`.

For each bit in each packed 64-bit integer, the corresponding bit from `src`, `a`, and `b` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding destination bit using writemask `k` at 64-bit granularity (64-bit elements are copied from `src` when the corresponding mask bit is not set).

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in `imm8`.

For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding destination bit using zeromask `k` at 64-bit granularity (64-bit elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Bitwise Logical Operations

**variable** | **definition**
--- | ---
**k** | writemask used as a selector
**a** | first source vector element
**b** | second source vector element
**src** | source element to use based on writemask result

extern __m512i __cdecl _mm512_and_epi32(__m512i a, __m512i b);

Computes the bitwise AND of packed 32-bit integers in \(a\) and \(b\), and stores the result.

extern __m512i __cdecl _mm512_mask_and_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);

Computes the bitwise AND of packed 32-bit integers in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

extern __m512i __cdecl _mm512_maskz_and_epi32(__mmask16 k, __m512i a, __m512i b);

Computes the bitwise AND of packed 32-bit integers in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

extern __m512i __cdecl _mm512_and_epi64(__m512i a, __m512i b);

Computes the bitwise AND of 512 bits (composed of packed 64-bit integers) in \(a\) and \(b\), and stores the result.

extern __m512i __cdecl _mm512_mask_and_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);

Computes the bitwise AND of 512 bits (composed of packed 64-bit integers) in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
Computes the bitwise AND of packed 64-bit integers in \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[\text{_mm512_maskz_and_epi64}\]
\[
\text{extern } \text{__m512i } \text{__cdecl } \text{__m512i } \text{__mp} \text{__cdecl } \text{__m512_maskz_and_epi64}(\text{__mmask8 } k, \text{__m512i } a, \text{__m512i } b);
\]

Computes the bitwise AND of packed 64-bit integers in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\text{_mm512_andnot_epi32}\]
\[

\]

Computes the bitwise AND NOT of 512 bits (composed of packed 64-bit integers) in \(a\) and \(b\), and stores the result.

\[\text{_mm512_mask_andnot_epi64}\]
\[
\text{extern } \text{__m512i } \text{__cdecl } \text{__m512_mask_andnot_epi64}(\text{__m512i } src, \text{__mmask8 } k, \text{__m512i } a, \text{__m512i } b);
\]

Computes the bitwise AND NOT of packed 64-bit integers in \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[\text{_mm512_maskz_andnot_epi64}\]
\[
\text{extern } \text{__m512i } \text{__cdecl } \text{__m512_maskz_andnot_epi64}(\text{__mmask8 } k, \text{__m512i } a, \text{__m512i } b);
\]

Computes the bitwise AND NOT of packed 64-bit integers in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\text{mm512_or_epi32}\]
\[
\text{extern } \text{__m512i } \text{__cdecl } \text{__m512_or_epi32}(\text{__m512i } a, \text{__m512i } b);
\]

Computes the bitwise OR of packed 32-bit integers in \(a\) and \(b\), and stores the result.

\[\text{mm512_mask_or_epi32}\]
\[
\text{extern } \text{__m512i } \text{__cdecl } \text{__m512_mask_or_epi32}(\text{__m512i } src, \text{__mmask16 } k, \text{__m512i } a, \text{__m512i } b);
\]

Computes the bitwise OR of packed 32-bit integers in \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
Computes the bitwise OR of packed 32-bit integers in `a` and `b`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_or_epi64**

```c
extern __m512i __cdecl _mm512_or_epi64(__m512i a, __m512i b);
```

Computes the bitwise OR of packed 64-bit integers in `a` and `b`, and stores the result.

**_mm512_mask_or_epi64**

```c
extern __m512i __cdecl _mm512_mask_or_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise OR of packed 64-bit integers in `a` and `b`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_or_epi64**

```c
extern __m512i __cdecl _mm512_maskz_or_epi64(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise OR of packed 64-bit integers in `a` and `b`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_xor_epi32**

```c
extern __m512i __cdecl _mm512_xor_epi32(__m512i a, __m512i b);
```

Computes the bitwise XOR of packed 32-bit integers in `a` and `b`, and stores the result.

**_mm512_mask_xor_epi32**

```c
extern __m512i __cdecl _mm512_mask_xor_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 32-bit integers in `a` and `b`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_xor_epi32**

```c
extern __m512i __cdecl _mm512_maskz_xor_epi32(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 32-bit integers in `a` and `b`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_xor_epi64**

```c
extern __m512i __cdecl _mm512_xor_epi64(__m512i a, __m512i b);
```

Computes the bitwise XOR of packed 64-bit integers in `a` and `b`, and stores the result.

**_mm512_mask_xor_epi64**

```c
extern __m512i __cdecl _mm512_mask_xor_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 64-bit integers in `a` and `b`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_xor_epi64**

```c
extern __m512i __cdecl _mm512_maskz_xor_epi64(__mmask8 k, __m512i a, __m512i b);
```
Computes the bitwise XOR of packed 64-bit integers in \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

</table>

)`_mm512_rol_epi32`

```c
extern __m512i __cdecl _mm512_rol_epi32(__m512i a, const int imm);
```

Rotates bits in each packed int32 element in a to the left by the number of bits specified in imm, and stores the results.

)`_mm512_mask_rol_epi32`

```c
extern __m512i __cdecl _mm512_mask_rol_epi32(__m512i src, __mmask16 k, __m512i a, const int imm);
```

Rotates bits in each packed int32 element in a to the left by the number of bits specified in imm, and stores the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

)`_mm512_maskz_rol_epi32`

```c
extern __m512i __cdecl _mm512_maskz_rol_epi32(__mmask16 k, __m512i a, const int imm);
```

Rotates bits in each packed int32 element in a to the left by the number of bits specified in imm, and stores the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

)`_mm512_rol_epi64`

```c
extern __m512i __cdecl _mm512_rol_epi64(__m512i a, const int imm);
```

Rotates bits in each packed int64 element in a to the left by the number of bits specified in imm, and stores the results.

)`_mm512_mask_rol_epi64`

```c
extern __m512i __cdecl _mm512_mask_rol_epi64(__m512i src, __mmask8 k, __m512i a, const int imm);
```

Rotates bits in each packed int64 element in a to the left by the number of bits specified in imm, and stores the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

)`_mm512_maskz_rol_epi64`

```c
extern __m512i __cdecl _mm512_maskz_rol_epi64(__mmask8 k, __m512i a, const int imm);
```

Rotates bits in each packed int64 element in a to the left by the number of bits specified in imm, and stores the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

)`_mm512_rolv_epi32`

```c
extern __m512i __cdecl _mm512_rolv_epi32(__m512i a, __m512i b);
```

Rotates bits in each packed int32 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results.

)`_mm512_mask_rolv_epi32`

```c
extern __m512i __cdecl _mm512_mask_rolv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Rotates bits in each packed int32 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm512_maskz_rolv_epi32

extern __m512i __cdecl _mm512_maskz_rolv_epi32(__mmask16 k, __m512i a, __m512i b);

Rotates bits in each packed int32 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rolv_epi64

extern __m512i __cdecl _mm512_rolv_epi64(__m512i a, __m512i b);

Rotates bits in each packed int64 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results.

_mm512_mask_rolv_epi64

extern __m512i __cdecl _mm512_mask_rolv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);

Rotates bits in each packed int64 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_rolv_epi64

extern __m512i __cdecl _mm512_maskz_rolv_epi64(__mmask8 k, __m512i a, __m512i b);

Rotates bits in each packed int64 element in a to the left by the number of bits specified in the corresponding element of b, and stores the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_ror_epi32

extern __m512i __cdecl _mm512_ror_epi32(__m512i a, int imm);

Rotates bits in each packed int32 element in a to the right by the number of bits specified in imm, and stores the results.

_mm512_mask_ror_epi32

extern __m512i __cdecl _mm512_mask_ror_epi32(__m512i src, __mmask16 k, __m512i a, int imm);

Rotates bits in each packed int32 element in a to the right by the number of bits specified in imm, and stores the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_ror_epi32

extern __m512i __cdecl _mm512_maskz_ror_epi32(__mmask16 k, __m512i a, int imm);

Rotates bits in each packed int32 element in a to the right by the number of bits specified in imm, and stores the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_ror_epi64

extern __m512i __cdecl _mm512_ror_epi64(__m512i a, int imm);

Rotates bits in each packed int64 element in a to the right by the number of bits specified in imm, and stores the results.

_mm512_mask_ror_epi64

extern __m512i __cdecl _mm512_mask_ror_epi64(__m512i src, __mmask8 k, __m512i a, int imm);

Rotates bits in each packed int64 element in a to the right by the number of bits specified in imm, and stores the results.
Rotates bits in each packed int64 element in \(a\) to the right by the number of bits specified in \(imm\), and stores the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_ror\_epi64}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_maskz\_ror\_epi64}(\text{mmask8 } k, \text{m512i } a, \text{int } imm);
\]

Rotates bits in each packed int64 element in \(a\) to the right by the number of bits specified in \(imm\), and stores the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm512\_ror\_epi32}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_ror\_epi32}(\text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int32 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results.

\[
\text{\_mm512\_mask\_ror\_epi32}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_mask\_ror\_epi32}(\text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int32 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_ror\_epi32}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_maskz\_ror\_epi32}(\text{mmask16 } k, \text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int32 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm512\_ror\_epi64}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_ror\_epi64}(\text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int64 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results.

\[
\text{\_mm512\_mask\_ror\_epi64}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_mask\_ror\_epi64}(\text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int64 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_ror\_epi64}
\]

\[
\text{extern } \text{m512i } \text{cdecl } \text{mm512\_maskz\_ror\_epi64}(\text{mmask8 } k, \text{m512i } a, \text{m512i } b);
\]

Rotates bits in each packed int64 element in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and stores the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Integer Bit Shift Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the \texttt{zmmintrin.h} header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```cpp
#include <immintrin.h>
```

<table>

**_mm512_sll_epi32**

```c
extern _m512i __cdecl _mm512_sll_epi32(__m512i a, __m128i count);
```

Shifts packed int32 elements in a left by `count` while shifting in zeros, and stores the result.

**_mm512_mask_sll_epi32**

```c
extern __m512i __cdecl _mm512_mask_sll_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in `a` left by `count` while shifting in zeros, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_sll_epi32**

```c
extern _m512i __cdecl _mm512_maskz_sll_epi32(__mmask16 k, __m512i a, __m128i count);
```
Shifts packed int32 elements in \( a \) left by \( \text{count} \) while shifting in zeros, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm}512}_{\text{sl}l\text{i}}_{\text{e}pi32}
\]

\[
\text{extern } \_\text{m}512i \text{ __cdecl } _{\text{mm}512}_{\text{sl}l\text{i}}_{\text{e}pi32}(\_\text{m}512i \ a, \ \text{unsigned int} \ \text{imm});
\]

Shifts packed int32 elements in \( a \) left by \( \text{imm} \) while shifting in zeros, and stores the result.

\[
_{\text{mm}512}_{\text{mask}_{\text{sl}l\text{i}}}_{\text{e}pi32}
\]

\[
\text{extern } \_\text{m}512i \text{ __cdecl } _{\text{mm}512}_{\text{m}ask_{\text{sl}l\text{i}}}_{\text{e}pi32}(\_\text{m}512i \ src, \ _m\text{m}ask16 \ k, \ _\text{m}512i \ a, \ \text{unsigned int} \ \text{imm});
\]

Shifts packed int32 elements in \( a \) left by \( \text{imm} \) while shifting in zeros, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
_{\text{mm}512}_{\text{maskz}_{\text{sl}l\text{i}}}_{\text{e}pi32}
\]

\[
\text{extern } \_\text{m}512i \text{ __cdecl } _{\text{mm}512}_{\text{m}askz_{\text{sl}l\text{i}}}_{\text{e}pi32}(\_\text{mm}ask16 \ k, \ _\text{m}512i \ a, \ \text{unsigned int} \ \text{imm});
\]

Shifts packed int32 elements in \( a \) left by \( \text{imm} \) while shifting in zeros, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm}512}_{\text{sl}l\text{l}}_{\text{e}pi64}
\]

\[

\]

Shifts packed int64 elements in \( a \) left by \( \text{count} \) while shifting in zeros, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm}512}_{\text{sl}l\text{l}}_{\text{e}pi64}
\]

\[
\text{extern } \_\text{m}512i \text{ __cdecl } _{\text{mm}512}_{\text{sl}l\text{l}}_{\text{e}pi64}(\_\text{m}512i \ a, \ \text{unsigned int} \ \text{imm});
\]

Shifts packed int64 elements in \( a \) left by \( \text{imm} \) while shifting in zeros, and stores the result.

\[
_{\text{mm}512}_{\text{mask}_{\text{sl}l\text{l}}}_{\text{e}pi64}
\]

\[
\text{extern } \_\text{m}512i \text{ __cdecl } _{\text{mm}512}_{\text{m}ask_{\text{sl}l\text{l}}}_{\text{e}pi64}(\_\text{m}512i \ src, \ _\text{mm}ask8 \ k, \ _\text{m}512i \ a, \ \text{unsigned int} \ \text{imm});
\]
Shifts packed int64 elements in `a` left by `imm` while shifting in zeros, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_maskz_slli_epi64(__mmask8 k, __m512i a, unsigned int imm);
```

Shifts packed int64 elements in `a` left by `imm` while shifting in zeros, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_sllv_epi32(__m512i a, __m512i count);
```

Shifts packed int32 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result.

```c
extern __m512i __cdecl _mm512_mask_sllv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i count);
```

Shifts packed int32 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_maskz_sllv_epi32(__mmask16 k, __m512i a, __m512i count);
```

Shifts packed int32 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_sllv_epi64(__m512i a, __m512i count);
```

Shifts packed int64 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result.

```c
extern __m512i __cdecl _mm512_mask_sllv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_maskz_sllv_epi64(__mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in `a` left by the amount specified by the corresponding element in `count` while shifting in zeros, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm512_sra_epi32

extern __m512i __cdecl _mm512_sra_epi32(__m512i a, __m128i count);
Shifts packed int32 elements in a right by count while shifting in sign bits, and stores the result.

_mm512_mask_sra_epi32

extern __m512i __cdecl _mm512_mask_sra_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
Shifts packed int32 elements in a right by count while shifting in sign bits, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_sra_epi32

extern __m512i __cdecl _mm512_maskz_sra_epi32(__mmask16 k, __m512i a, __m128i count);
Shifts packed int32 elements in a right by count while shifting in sign bits, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sra_epi64

extern __m512i __cdecl _mm512_sra_epi64(__m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in sign bits, and stores the result.

_mm512_mask_sra_epi64

extern __m512i __cdecl _mm512_mask_sra_epi64(__m512i src, __mmask8 k, __m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in sign bits, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_sra_epi64

extern __m512i __cdecl _mm512_maskz_sra_epi64(__mmask8 k, __m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in sign bits, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srai_epi32

extern __m512i __cdecl _mm512_srai_epi32(__m512i a, unsigned int imm);
Shifts packed int32 elements in a right by imm while shifting in sign bits, and stores the result.

_mm512_mask_srai_epi32

extern __m512i __cdecl _mm512_mask_srai_epi32(__m512i src, __mmask16 k, __m512i a, unsigned int imm);
Shifts packed int32 elements in a right by imm while shifting in sign bits, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm512_maskz_srai_epi32
extern __m512i __cdecl _mm512_maskz_srai_epi32(__mmask16 k, __m512i a, unsigned int imm);
Shifts packed int32 elements in a right by imm while shifting in sign bits, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srai_epi64
extern __m512i __cdecl _mm512_srai_epi64(__m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in sign bits, and stores the result.

_mm512_mask_srai_epi64
extern __m512i __cdecl _mm512_mask_srai_epi64(__m512i src, __mmask8 k, __m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in sign bits, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srai_epi64
extern __m512i __cdecl _mm512_maskz_srai_epi64(__mmask8 k, __m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in sign bits, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srav_epi32
extern __m512i __cdecl _mm512_srav_epi32(__m512i a, __m512i count);
Shifts packed int32 elements in a right by the amount specified by the corresponding element in count while shifting in sign bits, and stores the result.

_mm512_mask_srav_epi32
extern __m512i __cdecl _mm512_mask_srav_epi32(__m512i src, __mmask16 k, __m512i a, __m512i count);
Shifts packed int32 elements in a right by the amount specified by the corresponding element in count while shifting in sign bits, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srav_epi32
extern __m512i __cdecl _mm512_maskz_srav_epi32(__mmask16 k, __m512i a, __m512i count);
Shifts packed int32 elements in a right by the amount specified by the corresponding element in count while shifting in sign bits, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srav_epi64
extern __m512i __cdecl _mm512_srav_epi64(__m512i a, __m512i count);
Shifts packed int64 elements in a right by the amount specified by the corresponding element in \textit{count} while shifting in sign bits, and stores the result.

\texttt{__m512\_mask\_srav\_epi64}

\begin{verbatim}
extern __m512i __cdecl _mm512_mask_srav_epi64(__m512i src, __mmask8 k, __m512i a, __m512i count);
\end{verbatim}

Shifts packed int64 elements in \textit{a} right by the amount specified by the corresponding element in \textit{count} while shifting in sign bits, and stores the result using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\texttt{__m512\_maskz\_srav\_epi64}

\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_srav_epi64(__mmask8 k, __m512i a, __m512i count);
\end{verbatim}

Shifts packed int64 elements in \textit{a} right by the amount specified by the corresponding element in \textit{count} while shifting in sign bits, and stores the result using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\texttt{__m512\_srl\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_srl_epi32(__m512i a, __m128i count);
\end{verbatim}

Shifts packed int32 elements in \textit{a} right by \textit{count} while shifting in zeros, and stores the result.

\texttt{__m512\_mask\_srl\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_mask_srl_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
\end{verbatim}

Shifts packed int32 elements in \textit{a} right by \textit{count} while shifting in zeros, and stores the result using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\texttt{__m512\_maskz\_srl\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_srl_epi32(__mmask16 k, __m512i a, __m128i count);
\end{verbatim}

Shifts packed int32 elements in \textit{a} right by \textit{count} while shifting in zeros, and stores the result using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\texttt{__m512\_srli\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_srli_epi32(__m512i a, unsigned int imm);
\end{verbatim}

Shifts packed int32 elements in \textit{a} right by \textit{imm} while shifting in zeros, and stores the result.

\texttt{__m512\_mask\_srli\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_mask_srli_epi32(__m512i src, __mmask16 k, __m512i a, unsigned int imm);
\end{verbatim}

Shifts packed int32 elements in \textit{a} right by \textit{imm} while shifting in zeros, and stores the result using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\texttt{__m512\_maskz\_srli\_epi32}

\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_srli_epi32(__mmask16 k, __m512i a, unsigned int imm);
\end{verbatim}
Shifts packed int32 elements in a right by imm while shifting in zeros, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srl_epi64
extern __m512i __cdecl _mm512_srl_epi64(__m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in zeros, and stores the result.

_mm512_mask_srl_epi64
extern __m512i __cdecl _mm512_mask_srl_epi64(__m512i src, __mmask8 k, __m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in zeros, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srl_epi64
extern __m512i __cdecl _mm512_maskz_srl_epi64(__mmask8 k, __m512i a, __m128i count);
Shifts packed int64 elements in a right by count while shifting in zeros, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srl_epi64
extern __m512i __cdecl _mm512_srl_epi64(__m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in zeros, and stores the result.

_mm512_mask_srl_epi64
extern __m512i __cdecl _mm512_mask_srl_epi64(__m512i src, __mmask8 k, __m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in zeros, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srl_epi64
extern __m512i __cdecl _mm512_maskz_srl_epi64(__mmask8 k, __m512i a, unsigned int imm);
Shifts packed int64 elements in a right by imm while shifting in zeros, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srlv_epi32
extern __m512i __cdecl _mm512_srlv_epi32(__m512i a, __m512i count);
Shifts packed int32 elements in a right by the amount specified by the corresponding element in count while shifting in zeros, and stores the result.

_mm512_mask_srlv_epi32
extern __m512i __cdecl _mm512_mask_srlv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i count);
Shifts packed int32 elements in \(a\) right by the amount specified by the corresponding element in \(count\) while shifting in zeros, and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\texttt{\_mm512\_maskz\_srlv\_epi32}}

```c
extern __m512 __cdecl _mm512广播_f32x4(__m128 a);
```

Broadcasts four packed float32 elements from a to all destination elements.

```c
extern __m512 __cdecl _mm512_mask广播_f32x4(__m512 src, __mmask16 k, __m128 a);
```

Broadcasts four packed float32 elements from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
extern __m512 __cdecl _mm512_maskz广播_f32x4(__mmask16 k, __m128 a);
```

Broadcasts four packed float32 elements from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512d __cdecl _mm512_broadcast_f64x4(__m256d a);
```

Broadcasts four packed float64 elements from a to all destination elements.

```c
extern __m512d __cdecl _mm512_mask广播_f64x4(__m512d src, __mmask8 k, __m256d a);
```

Broadcasts four packed float64 elements from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).
Broadcasts four packed float64 elements from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Broadcasts low float64 element from a to all destination elements.

Broadcasts low float64 element from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

Broadcasts low float64 element from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Broadcasts low float32 element from a to all destination elements.

Broadcasts low float32 element from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

Broadcasts low float32 element from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Broadcast Operations

</tbody>
</table>
_mm512_maskz_broadcast_i32x4
extern __m512i __cdecl _mm512_maskz_broadcast_i32x4(__mmask16 k, __m128i a);
Broadcasts four packed int32 elements from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_broadcast_i64x4
extern __m512i __cdecl _mm512_broadcast_i64x4(__m256i a);
Broadcasts four packed int64 elements from a to all destination elements.

_ mm512_mask_broadcast_i64x4
extern __m512i __cdecl _mm512_mask_broadcast_i64x4(__m512i src, __mmask8 k, __m256i a);
Broadcasts four packed int64 elements from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

_ mm512_maskz_broadcast_i64x4
extern __m512i __cdecl _mm512_maskz_broadcast_i64x4(__mmask8 k, __m256i a);
Broadcasts four packed int64 elements from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_broadcastd_epi32
extern __m512i __cdecl _mm512_broadcastd_epi32(__m128i a);
Broadcasts low packed 32-bit integer from a to all elements.

_ mm512_mask_broadcastd_epi32
extern __m512i __cdecl _mm512_mask BroadcastReceiverd_epi32(__m512i src, __mmask16 k, __m128i a);
Broadcasts low packed 32-bit integer from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

_ mm512_maskz_broadcastd_epi32
extern __m512i __cdecl _mm512_maskz_broadcastd_epi32(__mmask16 k, __m128i a);
Broadcasts low packed 32-bit integer from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_broadcastq_epi64
extern __m512i __cdecl _mm512_broadcastq_epi64(__m128i a);
Broadcasts low packed 64-bit integer from a to all destination elements.

_ mm512_mask_broadcastq_epi64
extern __m512i __cdecl _mm512_mask_broadcastq_epi64(__m512i src, __mmask8 k, __m128i a);
Broadcasts low packed 64-bit integer from a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_maskz_broadcastq_epi64(__mmask8 k, __m128i a);
```

Broadcasts low packed 64-bit integer from a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m512i __cdecl _mm512_broadcastmw_epi32(__mmask16 k);
```

Broadcasts low 16-bits from input mask k to all 32-bit elements of destination.

```c
extern __m512i __cdecl _mm512_broadcastmb_epi64(__mmask8 k);
```

Broadcasts the low 8-bits from input mask k to all 64-bit elements of destination.

### Intrinsics for Comparison Operations

### Intrinsics for FP Comparison Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

_mm512_cmp_pd_mask

extern __mmask8 __cdecl _mm512_cmp_pd_mask(__m512d a, __m512d b, const int imm);

Compares float64 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector.

_mm512_cmp_round_pd_mask

extern __mmask8 __cdecl _mm512_cmp_round_pd_mask(__m512d a, __m512d b, const int imm, const int round);

Compares float64 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector.

**NOTE**
Pass _MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm512_mask_cmp_round_pd_mask

extern __mmask8 __cdecl _mm512_mask_cmp_round_pd_mask(__mmask8 k, __m512d a, __m512d b, const int imm, const int round);

Compares float64 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm512_mask_cmp_pd_mask

extern __m512d __cdecl _mm512_mask_cmp_pd_mask(__m512 k, __m512d a, __m512d b, const int imm);

Compares float64 elements in a and b based on the comparison operand specified by imm.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_pd_mask

extern __m512d __cdecl _mm512_cmpeq_pd_mask(__m512d a, __m512d b);

Compares float64 elements in a and b for equality.
The result is stored in mask vector.

_mm512_mask_cmpeq_pd_mask

extern __m512d __cdecl _mm512_mask_cmpeq_pd_mask(__m512k k, __m512d a, __m512d b);

Compares float64 elements in a and b for equality.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_pd_mask

extern __m512d __cdecl _mm512_cmple_pd_mask(__m512d a, __m512d b);

Compares float64 elements in a and b for less-than-or-equal.
The result is stored in mask vector.

_mm512_mask_cmple_pd_mask

extern __m512d __cdecl _mm512_mask_cmple_pd_mask(__m512k k, __m512d a, __m512d b);

Compares float64 elements in a and b for less-than-or-equal.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_pd_mask

extern __m512d __cdecl _mm512_cmplt_pd_mask(__m512d a, __m512d b);

Compares float64 elements in a and b for less-than.
The result is stored in mask vector.

_mm512_mask_cmplt_pd_mask

extern __m512d __cdecl _mm512_mask_cmplt_pd_mask(__m512k k, __m512d a, __m512d b);

Compares float64 elements in a and b for less-than.
The result is stored in mask vector using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_cmpneq\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_cmpneq\_pd\_mask(\_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-equal.
The result is stored in mask vector.

\_\_mm512\_mask\_cmpneq\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_mask\_cmpneq\_pd\_mask(\_mmask8 k, \_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-equal.
The result is stored in mask vector using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_cmpnle\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_cmpnle\_pd\_mask(\_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-less-than-or-equal.
The result is stored in mask vector.

\_\_mm512\_mask\_cmpnle\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_mask\_cmpnle\_pd\_mask(\_mmask8 k, \_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-less-than-or-equal.
The result is stored in mask vector using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_cmpnlt\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_cmpnlt\_pd\_mask(\_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-less-than.
The result is stored in mask vector.

\_\_mm512\_mask\_cmpnlt\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_mask\_cmpnlt\_pd\_mask(\_mmask8 k, \_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ for not-less-than.
The result is stored in mask vector using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_cmpord\_pd\_mask

\texttt{extern \_mmask8 \_cdecl \_mm512\_cmpord\_pd\_mask(\_m512d a, \_m512d b);}\

Compares float64 elements in $a$ and $b$ to see if neither is NaN.
The result is stored in mask vector.
Compares float64 elements in a and b to see if neither is NaN. The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Compares float64 elements in a and b to see if either is NaN. The result is stored in mask vector.

Compares float64 elements in a and b to see if neither is NaN. The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Compares float64 elements in a and b to see if either is NaN. The result is stored in mask vector.

Compares float32 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector.

Compares float32 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

Compares float32 elements in a and b based on the comparison operand specified by imm. The result is stored in mask vector.
NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm512_mask_cmp_round_ps_mask

extern __mmask16 __cdecl _mm512_mask_cmp_round_ps_mask(__mmask16 k, __m512 a, __m512 b, const int imm, const int round);

Compares float32 elements in a and b based on the comparison operand specified by imm.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to round to suppress all exceptions.

_mm512_cmpeq_ps_mask

extern __mmask16 __cdecl _mm512_cmpeq_ps_mask(__m512 a, __m512 b);

Compares float32 elements in a and b for equality.
The result is stored in mask vector.

_mm512_mask_cmpeq_ps_mask

extern __mmask16 __cdecl _mm512_mask_cmpeq_ps_mask(__mmask16 k, __m512 a, __m512 b);

Compares float32 elements in a and b for equality.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_ps_mask

extern __mmask16 __cdecl _mm512_cmple_ps_mask(__m512 a, __m512 b);

Compares float32 elements in a and b for less-than-or-equal.
The result is stored in mask vector.

_mm512_mask_cmple_ps_mask

extern __mmask16 __cdecl _mm512_mask_cmple_ps_mask(__mmask16 k, __m512 a, __m512 b);

Compares float32 elements in a and b for less-than-or-equal.
The result is stored in mask vector using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpunord_ps_mask

extern __mmask16 __cdecl _mm512_cmpunord_ps_mask(__m512 a, __m512 b);

Compares float32 elements in a and b to see if either is NaN.
The result is stored in mask vector.
_mm512_mask_cmpunord_ps_mask
    extern __mmask16 __cdecl _mm512_mask_cmpunord_ps_mask(__mmask16 k, __m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) to see if neither is NaN.
The result is stored in mask vector using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_ps_mask
    extern __mmask16 __cdecl _mm512_cmplt_ps_mask(__m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) for less-than.
The result is stored in mask vector.

_mm512_mask_cmplt_ps_mask
    extern __mmask16 __cdecl _mm512_mask_cmplt_ps_mask(__mmask16 k, __m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) for less-than.
The result is stored in mask vector using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_ps_mask
    extern __mmask16 __cdecl _mm512_cmpneq_ps_mask(__m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) for not-equal.
The result is stored in mask vector.

_mm512_mask_cmpneq_ps_mask
    extern __mmask16 __cdecl _mm512_mask_cmpneq_ps_mask(__mmask16 k, __m512 a, __m512 b, const int round);
Compares float32 elements in \( a \) and \( b \) for not-equal.
The result is stored in mask vector using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpnle_ps_mask
    extern __mmask16 __cdecl _mm512_cmpnle_ps_mask(__m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) for not-less-than-or-equal.
The result is stored in mask vector.

_mm512_mask_cmpnle_ps_mask
    extern __mmask16 __cdecl _mm512_mask_cmpnle_ps_mask(__mmask16 k, __m512 a, __m512 b);
Compares float32 elements in \( a \) and \( b \) for not-less-than-or-equal.
The result is stored in mask vector using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
**_mm512_cmpnlt_ps_mask_**

```c
extern __mmask16 __cdecl _mm512_cmpnlt_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in `a` and `b` for not-less-than.
The result is stored in mask vector.

**_mm512_mask_cmpnlt_ps_mask_**

```c
extern __mmask16 __cdecl _mm512_mask_cmpnlt_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in `a` and `b` for not-less-than.
The result is stored in mask vector using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_cmpord_ps_mask_**

```c
extern __mmask16 __cdecl _mm512_cmpord_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in `a` and `b` to see if either is NaN.
The result is stored in mask vector.

**_mm512_mask_cmpord_ps_mask_**

```c
extern __mmask16 __cdecl _mm512_mask_cmpord_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in `a` and `b` to see if either is NaN.
The result is stored in mask vector using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_cmp_round_sd_mask_**

```c
extern __mmask8 __cdecl _mm_cmp_round_sd_mask(__m128d a, __m128d b, const int imm, const round);
```

Compares lower float64 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector.

**NOTE**

Pass `__MM_FROUND_NO_EXC` to `round` to suppress all exceptions.

**_mm_mask_cmp_round_sd_mask_**

```c
extern __mmask8 __cdecl _mm_mask_cmp_round_sd_mask(__mmask8 k, __m128d a, __m128d b, const int round);
```

Compares lower float64 elements in `a` and `b` based on the comparison operand specified by `imm`, and store the result in mask vector `k` using zeromask `k` (the element is zeroed out when mask bit 0 is not set).

**NOTE**

Pass `__MM_FROUND_NO_EXC` to `round` to suppress all exceptions.
**_mm_cmp_sd_mask_**

```c
extern __m128d __cdecl _mm_cmp_sd_mask(__m128d a, __m128d b, const int imm);
```

Compares lower float64 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector.

**_mm_mask_cmp_sd_mask_**

```c
extern __m128d __cdecl _mm_mask_cmp_sd_mask(__m128d a, __m128d b, const int imm);
```

Compares lower float64 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector using zeromask `k` (the element is zeroed out when mask bit 0 is not set).

**_mm_cmp_round_ss_mask_**

```c
extern __m128d __cdecl _mm_cmp_round_ss_mask(__m128d a, __m128d b, const int imm, const int round);
```

Compares lower float32 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector.

**NOTE**
Pass `__MM_FROUND_NO_EXC` to `round` to suppress all exceptions.

**_mm_mask_cmp_round_ss_mask_**

```c
extern __m128d __cdecl _mm_mask_cmp_round_ss_mask(__m128d a, __m128d b, const int imm, const int round);
```

Compares lower float32 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector using zeromask `k` (the element is zeroed out when mask bit 0 is not set).

**NOTE**
Pass `__MM_FROUND_NO_EXC` to `round` to suppress all exceptions.

**_mm_cmp_ss_mask_**

```c
extern __m128d __cdecl _mm_cmp_ss_mask(__m128d a, __m128d b, const int imm);
```

Compares lower float32 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector.

**_mm_mask_cmp_ss_mask_**

```c
extern __m128d __cdecl _mm_mask_cmp_ss_mask(__m128d a, __m128d b, const int imm, const int round);
```

Compares lower float32 elements in `a` and `b` based on the comparison operand specified by `imm`.
The result is stored in mask vector using zeromask `k` (the element is zeroed out when mask bit 0 is not set).
# Intrinsics for Integer Comparison Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file. To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>

_mm_comi_round_sd

extern int __cdecl _mm_comi_round_sd(__m128d a, __m128d b, const int imm, const int sae);

Compare the lower double-precision (64-bit) floating-point element in \( a \) and \( b \) based on the comparison operand specified by \( imm \), and return the boolean result (0 or 1).

**NOTE**
Pass **__MM_FROUND_NO_EXC** to \( sae \) to suppress all exceptions.

_mm_comi_round_ss

extern int __cdecl _mm_comi_round_ss(__m128 a, __m128 b, const int imm, const int sae);

Compare the lower single-precision (32-bit) floating-point element in \( a \) and \( b \) based on the comparison operand specified by \( imm \), and return the boolean result (0 or 1).

**NOTE**
Pass **__MM_FROUND_NO_EXC** to \( sae \) to suppress all exceptions.

_mm512_cmp_epi32_mask

extern __mmask16 __cdecl _mm512_cmp_epi32_mask(__m512i a, __m512i b, const int imm);

Compare packed int32 elements in \( a \) and \( b \) based on the comparison operand specified by \( imm \), and store the results in mask vector \( k \).
_mm512_mask_cmp_epi32_mask

extern __mmask16 __cdecl __mm512_mask_cmp_epi32_mask(__mmask16 k, __m512i a, __m512i b, const int imm);

Compare packed int32 elements in \(a\) and \(b\) based on the comparison operand specified by \(imm\), and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cmpeq_epi32_mask

extern __mmask16 __cdecl __mm512_cmpeq_epi32_mask(__m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for equality, and store the results in mask vector \(k\).

__mm512_mask_cmpeq_epi32_mask

extern __mmask16 __cdecl __mm512_mask_cmpeq_epi32_mask(__mmask16 k, __m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for equality, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cmpge_epi32_mask

extern __m512i __cdecl __mm512_cmpge_epi32_mask(__m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for greater-than-or-equal, and store the results in mask vector \(k\).

__mm512_mask_cmpge_epi32_mask

extern __mmask16 __cdecl __mm512_mask_cmpge_epi32_mask(__mmask16 k, __m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for greater-than-or-equal, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cmpgt_epi32_mask

extern __m512i __cdecl __mm512_cmpgt_epi32_mask(__m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for greater-than, and store the results in mask vector \(k\).

__mm512_mask_cmpgt_epi32_mask

extern __mmask16 __cdecl __mm512_mask_cmpgt_epi32_mask(__mmask16 k, __m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for greater-than, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cmple_epi32_mask

extern __m512i __cdecl __mm512_cmple_epi32_mask(__m512i a, __m512i b);

Compare packed int32 elements in \(a\) and \(b\) for less-than-or-equal, and store the results in mask vector \(k\).
```c
extern __mmask16 __cdecl _mm512_mask_cmple_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in \(a\) and \(b\) for less-than, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __mmask16 __cdecl _mm512_cmplt_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in \(a\) and \(b\) for less-than, and store the results in mask vector \(k\).

```c
extern __mmask16 __cdecl _mm512_mask_cmplt_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in \(a\) and \(b\) for less-than-or-equal, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __mmask16 __cdecl _mm512_cmpneq_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in \(a\) and \(b\) for not-equal, and store the results in mask vector \(k\).

```c
extern __mmask16 __cdecl _mm512_mask_cmpneq_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in \(a\) and \(b\) for not-equal, and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __mmask8 __cdecl _mm512_cmp_epi64_mask(__m512i a, __m512i b, const int imm);
```

Compare packed int64 elements in \(a\) and \(b\) based on the comparison operand specified by \(imm\), and store the results in mask vector \(k\).

```c
extern __mmask8 __cdecl _mm512_mask_cmp_epi64_mask(__mmask8 k, __m512i a, __m512i b, const int imm);
```

Compare packed int64 elements in \(a\) and \(b\) based on the comparison operand specified by \(imm\), and store the results in mask vector \(k\) using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __mmask8 __cdecl _mm512_cmpeq_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in \(a\) and \(b\) for equality, and store the results in mask vector \(k\).
_mm512_mask_cmpeq_epi64_mask

`extern __mmask8 __cdecl _mm512_mask_cmpeq_epi64_mask(__mmask8 k, __m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for equality, and store the results in mask vector `k` using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epi64_mask

`extern __mmask8 __cdecl _mm512_cmpge_epi64_mask(__m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for greater-than-or-equal, and store the results in mask vector `k`.

_mm512_mask_cmpge_epi64_mask

`extern __mmask8 __cdecl _mm512_mask_cmpge_epi64_mask(__mmask8 k, __m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for greater-than-or-equal, and store the results in mask vector `k` using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epi64_mask

`extern __mmask8 __cdecl _mm512_cmpgt_epi64_mask(__m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for greater-than, and store the results in mask vector `k`.

_mm512_mask_cmpgt_epi64_mask

`extern __mmask8 __cdecl _mm512_mask_cmpgt_epi64_mask(__mmask8 k, __m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for greater-than, and store the results in mask vector `k` using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epi64_mask

`extern __mmask8 __cdecl _mm512_cmple_epi64_mask(__m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for less-than-or-equal, and store the results in mask vector `k`.

_mm512_mask_cmple_epi64_mask

`extern __mmask8 __cdecl _mm512_mask_cmple_epi64_mask(__mmask8 k, __m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for less-than-or-equal, and store the results in mask vector `k` using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_epi64_mask

`extern __mmask8 __cdecl _mm512_cmplt_epi64_mask(__m512i a, __m512i b);`

Compare packed int64 elements in `a` and `b` for less-than, and store the results in mask vector `k`.

_mm512_mask_cmplt_epi64_mask

`extern __mmask8 __cdecl _mm512_mask_cmplt_epi64_mask(__mmask8 k, __m512i a, __m512i b);`
Compare packed int64 elements in \( a \) and \( b \) for less-than, and store the results in mask vector \( k \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

```

Compare packed unsigned int32 elements in $a$ and $b$ for not-equal, and store the results in mask vector $k$ using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
_mm512_cmp_epu64_mask

extern __mmask8 __cdecl _mm512_cmp_epu64_mask(__m512i a, __m512i b, const _MM_CMPINT_ENUM imm);

Compare packed unsigned int64 elements in \( a \) and \( b \) based on the comparison operand specified by \( imm \), and store the results in mask vector \( k \).

_mm512_mask_cmp_epu64_mask

extern __mmask8 __cdecl _mm512_mask_cmp_epu64_mask(__mmask8 k, __m512i a, __m512i b, const _MM_CMPINT_ENUM imm);

Compare packed unsigned int64 elements in \( a \) and \( b \) based on the comparison operand specified by \( imm \), and store the results in mask vector \( k \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epu64_mask

extern __mmask8 __cdecl _mm512_cmpge_epu64_mask(__m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for greater-than-or-equal, and store the results in mask vector \( k \).

_mm512_mask_cmpge_epu64_mask

extern __mmask8 __cdecl _mm512_mask_cmpge_epu64_mask(__mmask8 k, __m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for greater-than-or-equal, and store the results in mask vector \( k \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epu64_mask

extern __mmask8 __cdecl _mm512_cmpgt_epu64_mask(__m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for greater-than, and store the results in mask vector \( k \).

_mm512_mask_cmpgt_epu64_mask

extern __mmask8 __cdecl _mm512_mask_cmpgt_epu64_mask(__mmask8 k, __m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for greater-than, and store the results in mask vector \( k \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epu64_mask

extern __mmask8 __cdecl _mm512_cmple_epu64_mask(__m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for less-than-or-equal, and store the results in mask vector \( k \).

_mm512_mask_cmple_epu64_mask

extern __mmask8 __cdecl _mm512_mask_cmple_epu64_mask(__mmask8 k, __m512i a, __m512i b);

Compare packed unsigned int64 elements in \( a \) and \( b \) for less-than-or-equal, and store the results in mask vector \( k \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
Intrinsics for Compression Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>

</tbody>
</table>

extern __m512d __cdecl _mm512_mask_compress_pd(__m512d a, __mmask8 k, __m512d src);

Contiguously stores the active float64 elements in a (those with their respective bit set in writemask k) to destination, and passes through the remaining elements from src.

extern __m512d __cdecl _mm512_maskz_compress_pd(__mmask8 k, __m512d a);

Contiguously stores the active float64 elements in a (those with their respective bit set in zeromask k) to destination, and set the remaining elements to zero.

extern __m512 __cdecl _mm512_mask_compress_ps(__m512 a, __mmask16 k, __m512 src);

Contiguously stores the active float32 elements in a (those with their respective bit set in writemask k) to destination, and passes through the remaining elements from src.

extern __m512 __cdecl _mm512_maskz_compress_ps(__mmask16 k, __m512 a);

Contiguously stores the active float32 elements in a (those with their respective bit set in zeromask k) to destination, and set the remaining elements to zero.

extern void __cdecl _mm512_mask_compressstoreu_pd(void* base_addr, __mmask8 k, __m512d a);
Contiguously stores the active float64 elements in \(a\) (those with their respective bit set in writemask \(k\)) to unaligned memory at \(base\_addr\).

\_mm512\_mask\_compressstoreu\_ps

```c
extern void __cdecl _mm512_mask_compressstoreu_ps(void* base_addr, __mmask16 k, __m512 a);
```

Contiguously stores the active float32 elements in \(a\) (those with their respective bit set in writemask \(k\)) to unaligned memory at \(base\_addr\).

\_mm512\_mask\_compress\_epi32

```c
extern __m512i __cdecl _mm512_mask_compress_epi32(__m512i a, __mmask16 k, __m512i src);
```

Contiguously stores the active int32 elements in \(a\) (those with their respective bit set in writemask \(k\)) to destination, and passes through the remaining elements from \(src\).

\_mm512\_maskz\_compress\_epi32

```c
extern __m512i __cdecl _mm512_maskz_compress_epi32(__mmask16 k, __m512i a);
```

Contiguously stores the active int32 elements in \(a\) (those with their respective bit set in zeromask \(k\)) to destination, and set the remaining elements to zero.

\_mm512\_mask\_compress\_epi64

```c
extern __m512i __cdecl _mm512_mask_compress_epi64(__m512i a, __mmask8 k, __m512i src);
```

Contiguously stores the active int64 elements in \(a\) (those with their respective bit set in writemask \(k\)) to destination, and passes through the remaining elements from \(src\).

\_mm512\_maskz\_compress\_epi64

```c
extern __m512i __cdecl _mm512_maskz_compress_epi64(__mmask8 k, __m512i a);
```

Contiguously stores the active int64 elements in \(a\) (those with their respective bit set in zeromask \(k\)) to destination, and set the remaining elements to zero.

\_mm512\_mask\_compressstoreu\_epi32

```c
extern void __cdecl _mm512_mask_compressstoreu_epi32(void* base_addr, __mmask16 k, __m512i a);
```

Contiguously stores the active int32 elements in \(a\) (those with their respective bit set in writemask \(k\)) to unaligned memory at \(base\_addr\).

\_mm512\_mask\_compressstoreu\_epi64

```c
extern void __cdecl _mm512_mask_compressstoreu_epi64(void* base_addr, __mmask8 k, __m512i a);
```

Contiguously stores the active int64 elements in \(a\) (those with their respective bit set in writemask \(k\)) to unaligned memory at \(base\_addr\).

### _mm512_cvt_roundpd_ps

extern __m256 __cdecl _mm512_cvt_roundpd_ps(__m512d a, int round);

Converts float64 elements in `a` to float32 elements, and stores the result.

### _mm512_mask_cvt_roundpd_ps

extern __m256 __cdecl _mm512_mask_cvt_roundpd_ps(__m256 src, __mmask8 k, __m512d a, int round);
Converts float64 elements in \( a \) to float32 elements, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\texttt{\_mm512\_maskz\_cvt\_roundpd\_ps}
\]

\[
\text{extern } \texttt{m256 } \texttt{\_cdec1 \_mm512\_maskz\_cvt\_roundpd\_ps(\_mmask8 } \texttt{k, } \texttt{\_m512d } \texttt{a, } \texttt{int } \texttt{round);}
\]

Converts float64 elements in \( a \) to float32 elements, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\texttt{\_mm512\_cvt\_pd\_ps}
\]

\[
\text{extern } \texttt{m256 } \texttt{\_cdec1 \_mm512\_cvt\_pd\_ps(\_m512d } \texttt{a);}
\]

Converts float64 elements in \( a \) to float32 elements, and stores the result.

\[
\texttt{\_mm512\_mask\_cvt\_pd\_ps}
\]

\[
\text{extern } \texttt{m256 } \texttt{\_cdec1 \_mm512\_mask\_cvt\_pd\_ps(\_m256 } \texttt{src, } \texttt{\_mmask8 } \texttt{k, } \texttt{\_m512d } \texttt{a);} \]

Converts float64 elements in \( a \) to float32 elements, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\texttt{\_mm512\_mask\_cvt\_pd\_ps}
\]

\[
\text{extern } \texttt{m256 } \texttt{\_cdec1 \_mm512\_mask\_cvt\_pd\_ps(\_mmask8 } \texttt{k, } \texttt{\_m512d } \texttt{a);} \]

Converts float64 elements in \( a \) to float32 elements, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\texttt{\_mm512\_cvt\_roundpd\_epi32}
\]

\[
\text{extern } \texttt{m512i } \texttt{\_cdec1 \_mm512\_cvt\_roundpd\_epi32(\_m512d } \texttt{a, int } \texttt{round);} \]

Converts float64 elements in \( a \) to int32 elements, and stores the results.

**NOTE**

Pass \texttt{\_MM\_FROUND\_NO\_EXC} to \texttt{sae} to suppress all exceptions.

\[
\texttt{\_mm512\_mask\_cvt\_roundpd\_epi32}
\]

\[
\text{extern } \texttt{m512i } \texttt{\_cdec1 \_mm512\_mask\_cvt\_roundpd\_epi32(\_m256i } \texttt{src, } \texttt{\_mmask8 } \texttt{k, } \texttt{\_m512d } \texttt{a, int } \texttt{round);} \]

Converts float64 elements in \( a \) to int32 elements, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**NOTE**

Pass \texttt{\_MM\_FROUND\_NO\_EXC} to \texttt{sae} to suppress all exceptions.

\[
\texttt{\_mm512\_maskz\_cvt\_roundpd\_epi32}
\]

\[
\text{extern } \texttt{m512i } \texttt{\_cdec1 \_mm512\_maskz\_cvt\_roundpd\_epi32(\_mmask8 } \texttt{k, } \texttt{\_m512d } \texttt{a, int } \texttt{round);} \]

Converts float64 elements in \( a \) to int32 elements, and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_cvtpd_epi32

extern __m512i __cdecl _mm512_cvtpd_epi32(__m512d a);

Converts float64 elements in a int32 elements, and stores the result.

_mm512_mask_cvtpd_epi32

extern __m512i __cdecl _mm512_mask_cvtpd_epi32(__m256i src, __mmask8 k, __m512d a);

Converts float64 elements in a to int32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epi32

extern __m512i __cdecl _mm512_maskz_cvtpd_epi32(__mmask8 k, __m512d a);

Converts float64 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtt_roundpd_epi32

extern __m512i __cdecl _mm512_cvtt_roundpd_epi32(__m512d a, int round);

Converts float32 elements in a to int32 elements, and stores the results.

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_mask_cvtt_roundpd_epi32

extern __m512i __cdecl _mm512_mask_cvtt_roundpd_epi32(__m256i src, __mmask8 k, __m512d a, int round);

Converts float32 elements in a to int32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_maskz_cvtt_roundpd_epi32

extern __m512i __cdecl _mm512_maskz_cvtt_roundpd_epi32(__mmask8 k, __m512d a, int round);

Converts float32 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.
_mm512_cvtpd_epi32
extern __m512i __cdecl _mm512_cvtpd_epi32(__m512d a);
Converts float64 elements in a int32 elements, and stores the result.

_mm512_mask_cvtpd_epi32
extern __m512i __cdecl _mm512_mask_cvtpd_epi32(__m256i src, __mmask8 k, __m512d a);
Converts float64 elements in a to int32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epi32
extern __m512i __cdecl _mm512_maskz_cvtpd_epi32(__mmask8 k, __m512d a);
Converts float64 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundpd_epu32
extern __m512i __cdecl _mm512_cvt_roundpd_epu32(__m512 a, int round);
Converts float64 elements in a to int32 elements, and stores the results.

**NOTE**
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_mask_cvt_roundpd_epu32
extern __m512i __cdecl _mm512_mask_cvt_roundpd_epu32(__m256i src, __mmask16 k, __m512 a, int round);
Converts float64 elements in a to int32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

**NOTE**
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_maskz_cvt_roundpd_epu32
extern __m512i __cdecl _mm512_maskz_cvt_roundpd_epu32(__mmask16 k, __m512 a, int round);
Converts float64 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_cvtpd_epi32
extern __m512i __cdecl _mm512_cvtpd_epi32(__m512 a);
Converts float64 elements in a int32 elements, and stores the result.
**_mm512_mask_cvtpd_epu32**

```
extern __m512i __cdecl _mm512_mask_cvtpd_epu32(__m256i src, __mmask16 k, __m512 a);
```

Converts float64 elements in `a` to int32 elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_cvtpd_epu32**

```
extern __m512i __cdecl _mm512_maskz_cvtpd_epu32(__mmask16 k, __m512 a);
```

Converts float64 elements in `a` to int32 elements, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_cvtt_roundpd_epu32**

```
extern __m512i __cdecl _mm512_cvtt_roundpd_epu32(__m512 a, int round);
```

Converts float64 elements in `a` to int32 elements, and stores the results.

**NOTE**

Pass `__MM_FROUND_NO_EXC` to `sae` to suppress all exceptions.

**_mm512_mask_cvtt_roundpd_epu32**

```
extern __m512i __cdecl _mm512_mask_cvtt_roundpd_epu32(__m256i src, __mmask16 k, __m512 a, int round);
```

Converts float64 elements in `a` to int32 elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**NOTE**

Pass `__MM_FROUND_NO_EXC` to `sae` to suppress all exceptions.

**_mm512_maskz_cvtt_roundpd_epu32**

```
extern __m512i __cdecl _mm512_maskz_cvtt_roundpd_epu32(__mmask16 k, __m512 a, int round);
```

Converts float64 elements in `a` to int32 elements, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**NOTE**

Pass `__MM_FROUND_NO_EXC` to `sae` to suppress all exceptions.

**_mm512_cvttpd_epu32**

```
extern __m512i __cdecl _mm512_cvttpd_epu32(__m512 a);
```

Converts float64 elements in `a` to int32 elements, and stores the result.

**_mm512_mask_cvttpd_epu32**

```
extern __m512i __cdecl _mm512_mask_cvttpd_epu32(__m256i src, __mmask16 k, __m512 a);
```

Converts float64 elements in `a` to int32 elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
_mm512_maskz_cvttpd_epu32

extern __m512i __cdecl _mm512_maskz_cvttpd_epu32(__mmask16 k, __m512 a);

Converts float64 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtph_ps

extern __m512i __cdecl _mm512_cvtph_ps(__m256i a);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the results.

_mm512_mask_cvtph_ps

extern __m512i __cdecl _mm512_mask_cvtph_ps(__m512 src, __mmask16 k, __m256i a);

Converts packed half-precision (16-bit) floating-point elements in src to float32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvtph_ps

extern __m512i __cdecl _mm512_maskz_cvtph_ps(__mmask16 k, __m256i a);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundph_ps

extern __m512i __cdecl _mm512_cvt_roundph_ps(__m256i a, int round);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the result.

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_mask_cvt_roundph_ps

extern __m512i __cdecl _mm512_mask_cvt_roundph_ps(__m512 src, __mmask16 k, __m256i a, int round);

Converts packed half-precision (16-bit) floating-point elements in src to float32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_maskz_cvt_roundph_ps

extern __m512i __cdecl _mm512_maskz_cvt_roundph_ps(__mmask16 k, __m256i a, int round);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm512_cvt_roundps_ph

extern __m256i __cdecl _mm512_cvt_roundps_ph(__m512 a, int round);

Converts float32 elements in a to packed half-precision (16-bit) floating-point elements, and stores the results.

 NOTE
 Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_mask_cvt_roundps_ph

extern __m256i __cdecl _mm512_mask_cvt_roundps_ph(__m512i src, __mmask16 k, __m512 a, int round);

Converts float32 elements in a to packed half-precision (16-bit) floating-point elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

 NOTE
 Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_maskz_cvt_roundps_ph

extern __m256i __cdecl _mm512_maskz_cvt_roundps_ph(__mmask16 k, __m512 a, int round);

Converts float32 elements in a to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

 NOTE
 Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_cvtph_ps

extern __m256i __cdecl _mm512_cvtph_ps(__m512 a);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the results.

_mm512_mask_cvtph_ps

extern __m256i __cdecl _mm512_mask_cvtph_ps(__m256i src, __mmask16 k, __m512 a);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvtph_ps

extern __m256i __cdecl _mm512_maskz_cvtph_ps(__mmask16 k, __m512 a);

Converts packed half-precision (16-bit) floating-point elements in a to float32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm512_cvt_roundps_pd
extern __m512d __cdecl _mm512_cvt_roundps_pd(__m256 a, int round);
Converts float32 elements in a to float64 elements, and stores the results.

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_mask_cvt_roundps_pd
extern __m512d __cdecl _mm512_mask_cvt_roundps_pd(__m512d src, __mmask8 k, __m256 a, int round);
Converts float32 elements in a to float64 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_maskz_cvt_roundps_pd
extern __m512d __cdecl _mm512_maskz_cvt_roundps_pd(__mmask8 k, __m256 a, int round);
Converts float32 elements in a to float64 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_cvtps_pd
extern __m512d __cdecl _mm512_cvtps_pd(__m256 a);
Converts float32 elements in a to float64 elements, and stores the result.

_mm512_mask_cvtps_pd
extern __m512d __cdecl _mm512_mask_cvt_ps_pd(__m512d src, __mmask8 k, __m256 a);
Converts float32 elements in a to float64 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvtps_pd
extern __m512d __cdecl _mm512_maskz_cvt_ps_pd(__mmask8 k, __m256 a);
Converts float32 elements in a to float64 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundps_epi32

Converts float32 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass __MM_FROUND_NO_EXC to sae to suppress all exceptions.

_mm512_cvttps_epu32
extern __m512i __cdecl _mm512_cvttps_epu32(__m512 a);
Converts float32 elements in a int32 elements, and stores the result.

_mm512_mask_cvttps_epu32
extern __m512i __cdecl _mm512_mask_cvttps_epu32(__m512i src, __mmask16 k, __m512 a);
Converts float32 elements in a to int32 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvttps_epu32
extern __m512i __cdecl _mm512_maskz_cvttps_epu32(__mmask16 k, __m512 a);
Converts float32 elements in a to int32 elements, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_cvt_roundss_sd
extern __m128d __cdecl _mm_cvt_roundss_sd(__m128d a, __m128 b, int round);
Converts the lower float32 element in b to a float64 element, stores the result in the lower destination element, and copies the upper element from a to the upper destination element.

_mm_mask_cvt_roundss_sd
extern __m128d __cdecl _mm_mask_cvt_roundss_sd(__m128d src, __mmask8 k, __m128d a, __m128 b, int round);
Converts the lower float32 element in b to a float64 element, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper destination element.

_mm_maskz_cvt_roundss_sd
extern __m128d __cdecl _mm_maskz_cvt_roundss_sd(__mmask8 k, __m128d a, __m128 b, int round);
Converts the lower float32 element in b to a float64 element, store the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper element from a to the upper destination element.

_mm_mask_cvttss_sd
extern __m128d __cdecl _mm_mask_cvttss_sd(__m128d src, __mmask8 k, __m128d a, __m128 b);
Converts the lower float32 element in b to a float64 element, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper destination element.
\texttt{\_mm\_maskz\_cvtss\_sd}

\texttt{extern \_m128d \_cdecl \_mm\_maskz\_cvtss\_sd(\_mmask8 k, \_m128d a, \_m128 b);}

Converts the lower float32 element in \(b\) to a float64 element, stores the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copy the upper element from \(a\) to the upper destination element.

\texttt{\_mm\_cvt\_roundsd\_ss}

\texttt{extern \_m128 \_cdecl \_mm\_cvt\_roundsd\_ss(\_m128 a, \_m128d b, int round);}

Converts float64 elements in \(b\) to a single-precision (64-bit) floating-point elements, stores the result in the lower destination element, and copies the upper element from \(a\) to the upper destination element.

\texttt{\_mm\_masked\_cvt\_roundsd\_ss}

\texttt{extern \_m128 \_cdecl \_mm\_masked\_cvt\_roundsd\_ss(\_m128 src, \_mmask8 k, \_m128 a, \_m128d b, int round);}

Converts float64 elements in \(b\) to a single-precision (64-bit) floating-point elements, stores the result in the lower destination element using writemask \(k\) (the element is copied from \(src\) when mask bit 0 is not set), and copy the upper element from \(a\) to the upper destination element.

\texttt{\_mm\_maskz\_cvt\_roundsd\_ss}

\texttt{extern \_m128 \_cdecl \_mm\_maskz\_cvt\_roundsd\_ss(\_mmask8 k, \_m128 a, \_m128d b, int round);}

Converts float64 elements in \(b\) to a single-precision (64-bit) floating-point elements, the result in the lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copy the upper element from \(a\) to the upper destination element.

### Intrinsics for Integer Conversion Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>

extern __m256i __cdecl _mm512_maskz_cvt_roundpd_epu32(__mmask8 k, __m512d a, int round);

Converts packed float64 elements in a to packed unsigned 32-bit integers, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_maskz_cvtvpd_epu32

extern __m256i __cdecl _mm512_maskz_cvtvpd_epu32(__mmask8 k, __m512d a);

Converts packed float64 elements in a to packed unsigned 32-bit integers, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_ mm512_cvt_roundps_epi32

extern __m512i __cdecl _mm512_cvt_roundps_epi32(__m512 a, int round);

Converts packed float32 elements in a to packed 32-bit integers, and stores the result.

_ mm512_cvtps_epi32

extern __m512i __cdecl _mm512_cvtps_epi32(__m512 a);

Converts packed float32 elements in a to packed 32-bit integers, and stores the result.

_ mm512_mask_cvt_roundps_epi32

extern __m512i __cdecl _mm512_mask_cvt_roundps_epi32(__m512i src, __mmask16 k, __m512 a, int round);

Converts packed float32 elements in a to packed 32-bit integers, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_ mm512_mask_cvtps_epi32

extern __m512i __cdecl _mm512_mask_cvtps_epi32(__m512i src, __mmask16 k, __m512 a);

Converts packed float32 elements in a to packed 32-bit integers, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
**_mm512_maskz_cvt_roundps_epi32**

```c
extern __m512i __cdecl _mm512_maskz_cvt_roundps_epi32(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in `a` to packed 32-bit integers, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_maskz_cvtps_epi32**

```c
extern __m512i __cdecl _mm512_maskz_cvtps_epi32(__mmask16 k, __m512 a);
```

Converts packed float32 elements in `a` to packed 32-bit integers, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_cvt_roundps_ph**

```c
extern __m256i __cdecl _mm512_cvt_roundps_ph(__m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result.

**_mm512_cvtps_ph**

```c
extern __m256i __cdecl _mm512_cvtps_ph(__m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result.

**_mm512_mask_cvt_roundps_ph**

```c
extern __m256i __cdecl _mm512_mask_cvt_roundps_ph(__m256i src, __mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_mask_cvtps_ph**

```c
extern __m256i __cdecl _mm512_mask_cvtps_ph(__m256i src, __mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_cvt_roundps_ph**

```c
extern __m256i __cdecl _mm512_maskz_cvt_roundps_ph(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_maskz_cvtps_ph**

```c
extern __m256i __cdecl _mm512_maskz_cvtps_ph(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in `a` to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm512_cvt_roundps_epu32
extern __m512i __cdecl _mm512_cvt_roundps_epu32(__m512 a, int round);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result.

_mm512_cvtps_epu32
extern __m512i __cdecl _mm512_cvtps_epu32(__m512 a);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result.

extern __m512i __cdecl _mm512_mask_cvt_roundps_epu32(__m512i src, __mmask16 k, __m512 a, int round);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_mask_cvtps_epu32
extern __m512i __cdecl _mm512_mask_cvtps_epu32(__m512i src, __mmask16 k, __m512 a);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundps_epu32
extern __m512i __cdecl _mm512_maskz_cvt_roundps_epu32(__mmask16 k, __m512 a, int round);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtps_epu32
extern __m512i __cdecl _mm512_maskz_cvtps_epu32(__mmask16 k, __m512 a);
Converts packed float32 elements in a to packed unsigned 32-bit integers, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_cvt_roundsd_i32
extern int __cdecl _mm_cvt_roundsd_i32(__m128d, int);
Convert the lower float64 element in a to a 32-bit integer, and stores the result.

_mm_cvt_roundsd_i64
extern __int64 __cdecl _mm_cvt_roundsd_i64(__m128d, int);
Convert the lower float64 element in a to a 64-bit integer, and stores the result.

_mm_cvt_roundsd_si32
extern int __cdecl _mm_cvt_roundsd_i32(__m128d, int);
Convert the lower float64 element in \( a \) to a 32-bit integer, and stores the result.

\[ \text{\_mm\_cvt\_roundsd\_si64} \]
\[
\text{extern \_int64 \_cdecl \_mm\_cvt\_roundsd\_i64(\_m128d, int);}\
\]

Convert the lower float64 element in \( a \) to a 64-bit integer, and stores the result.

\[ \text{\_mm\_cvtsd\_i32} \]
\[
\text{extern int \_cdecl \_mm\_cvtsd\_i32(\_m128d, int);}\
\]

Convert the lower float64 element in \( a \) to a 32-bit integer, and stores the result.

\[ \text{\_mm\_cvtsd\_i64} \]
\[
\text{extern \_int64 \_cdecl \_mm\_cvtsd\_i64(\_m128d, int);}\
\]

Convert the lower float64 element in \( a \) to a 64-bit integer, and stores the result.

\[ \text{\_mm\_cvt\_roundsd\_ss} \]
\[
\text{extern \_m128 \_cdecl \_mm\_cvt\_roundsd\_ss(\_m128 a, \_m128d b, int round);}\
\]

Convert the lower float64 element in \( b \) to a float32 element, and stores the result in the lower destination element, and copies the upper three packed elements from \( a \) to the upper destination elements.

\[ \text{\_mm\_mask\_cvt\_roundsd\_ss} \]
\[
\text{extern \_m128 \_cdecl \_mm\_mask\_cvt\_roundsd\_ss(\_m128 src, \_mmask8 k, \_m128 a, \_m128d b, int round);}\
\]

Convert the lower float64 element in \( b \) to a float32 element, and stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

\[ \text{\_mm\_mask\_cvtsd\_ss} \]
\[
\text{extern \_m128 \_cdecl \_mm\_mask\_cvtsd\_ss(\_m128 src, \_mmask8 k, \_m128 a, \_m128d b, int round);}\
\]

Convert the lower float64 element in \( b \) to a float32 element, and stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( a \) to the upper destination element.

\[ \text{\_mm\_maskz\_cvt\_roundsd\_ss} \]
\[
\text{extern \_m128 \_cdecl \_mm\_maskz\_cvt\_roundsd\_ss(\_mmask8 k, \_m128 a, \_m128d b, int round);}\
\]

Convert the lower float64 element in \( b \) to a float32 element, and stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

\[ \text{\_mm\_maskz\_cvtsd\_ss} \]
\[
\text{extern \_m128 \_cdecl \_mm\_maskz\_cvtsd\_ss(\_mmask8 k, \_m128 a, \_m128d b, int round);}\
\]
Convert the lower float64 element in \( b \) to a float32 element, and stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \( a \) to the upper destination elements.

\[
\text{\_mm_cvt_roundsd\_u32}
\]

\begin{verbatim}
extern unsigned int __cdecl _mm_cvt_roundsd_u32(__m128d a, int round);
\end{verbatim}

Convert the lower float64 element in \( a \) to an unsigned 32-bit integer, and stores the result.

\[
\text{\_mm_cvt_roundsd\_u64}
\]

\begin{verbatim}
extern unsigned __int64 __cdecl _mm_cvt_roundsd_u64(__m128d a, int round);
\end{verbatim}

Convert the lower float64 element in \( a \) to an unsigned 64-bit integer, and stores the result.

\[
\text{\_mm_cvtsd\_u32}
\]

\begin{verbatim}
extern unsigned int __cdecl _mm_cvtsd_u32(__m128d a);
\end{verbatim}

Convert the lower float64 element in \( a \) to an unsigned 32-bit integer, and stores the result.

\[
\text{\_mm_cvtsd\_u64}
\]

\begin{verbatim}
extern unsigned __int64 __cdecl _mm_cvtsd_u64(__m128d a);
\end{verbatim}

Convert the lower float64 element in \( a \) to an unsigned 64-bit integer, and stores the result.

\[
\text{\_mm_cvt_roundss\_i32}
\]

\begin{verbatim}
extern int __cdecl _mm_cvt_roundss_i32(__m128 a, int round);
\end{verbatim}

Convert the lower float32 element in \( a \) to a 32-bit integer, and stores the result.

\[
\text{\_mm_cvt_roundss\_i64}
\]

\begin{verbatim}
extern __int64 __cdecl _mm_cvt_roundss_i64(__m128 a, int round);
\end{verbatim}

Convert the lower float32 element in \( a \) to a 64-bit integer, and stores the result.

\[
\text{\_mm_cvt_roundss\_si32}
\]

\begin{verbatim}
extern int __cdecl _mm_cvt_roundss_si32(__m128 a, int round);

extern void __cdecl _mm512_mask_cvtsepi32_storeu_epi16(void* base_addr, __mmask16 k, __m512i a);
```

Converts packed int32 elements in `a` to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

```c
extern __m256i __cdecl _mm512_maskz_cvtsepi32_epi16(__mmask16 k, __m512i a);
```

Converts packed int32 elements in `a` to packed 8-bit integers with signed saturation, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m128i __cdecl _mm512_cvtsepi64_epi8(__m512i a);
```

Converts packed int64 elements in `a` to packed 8-bit integers with signed saturation, and stores the result.

```c
extern __m128i __cdecl _mm512_mask_cvtsepi64_epi8(__m128i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in `a` to packed 8-bit integers with signed saturation, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
extern void __cdecl _mm512_mask_cvtsepi64_storeu_epi8(void* base_addr, __mmask8 k, __m512i a);
```

Converts packed int64 elements in `a` to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

```c
extern __m128i __cdecl _mm512_maskz_cvtsepi64_epi8(__mmask8 k, __m512i a);
```

Converts packed int64 elements in `a` to packed 8-bit integers with signed saturation, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
extern __m256i __cdecl _mm512_cvtsepi64_epi32(__m512i a);
```

Converts packed int64 elements in `a` to packed int32 elements with signed saturation, and stores the result.

```c
extern __m256i __cdecl _mm512_mask_cvtsepi64_epi32(__m256i src, __mmask8 k, __m512i a);
```
Converts packed int64 elements in $a$ to packed int32 elements with signed saturation, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```
_mm512_mask_cvtsepi64_storeu_epi32
extern void __cdecl _mm512_mask_cvtsepi64_storeu_epi32(void* base_addr, __mmask8 k, __m512i a);
```

Converts packed int64 elements in $a$ to packed int32 elements with signed saturation, and store the active results (those with their respective bit set in writemask $k$) to unaligned memory at $base\_addr$.

```
_mm512_maskz_cvtsepi64_epi32
extern __m256i __cdecl _mm512_maskz_cvtsepi64_epi32(__mmask8 k, __m512i a);
```

Converts packed int64 elements in $a$ to packed int32 elements with signed saturation, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```
_mm512_cvtsepi64_epi16
extern __m128i __cdecl _mm512_cvtsepi64_epi16(__m512i a);
```

Converts packed int64 elements in $a$ to packed 16-bit integers with signed saturation, and stores the result.

```
_mm512_mask_cvtsepi64_epi16
extern __m128i __cdecl _mm512_mask_cvtsepi64_epi16(__m128i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in $a$ to packed 16-bit integers with signed saturation, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```
_mm512_maskz_cvtsepi64_epi16
extern __m128i __cdecl _mm512_maskz_cvtsepi64_epi16(__mmask8 k, __m512i a);
```

Converts packed int64 elements in $a$ to packed 16-bit integers with signed saturation, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```
_mm512_cvtepi8_epi32
extern __m512i __cdecl _mm512_cvtepi8_epi32(__m128i a);
```

Sign extend packed 8-bit integers in $a$ to packed 32-bit integers, and stores the result.

```
_mm512_mask_cvtepi8_epi32
extern __m512i __cdecl _mm512_mask_cvtepi8_epi32(__m128i src, __mmask16 k, __m128i a);
```
Sign extend packed 8-bit integers in \( a \) to packed 32-bit integers, and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

_mm512_cvtepu8_epi64

extern __m512i __cdecl _mm512_cvtepu8_epi64(__m128i a);

Zero extend packed unsigned 8-bit integers in the low 8 bytes of a to packed int64 elements, and stores the result.

_mm512_mask_cvtepu8_epi64

extern __m512i __cdecl _mm512_mask_cvtepu8_epi64(__m512i src, __mmask8 k, __m512i a);

Zero extend packed unsigned 8-bit integers in the low 8 bytes of a to packed int64 elements, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
__mm512_maskz_cvtepu8_epi64
extern __m512i __cdecl __mm512_maskz_cvtepu8_epi64(__mmask8 k, __m128i a);
Zero extend packed unsigned 8-bit integers in the low 8 bytes of \texttt{a} to packed int64 elements, and stores the result using zeromask \texttt{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cvtepu32_epi64
extern __m512i __cdecl __mm512_cvtepu32_epi64(__m256i a);
Zero extend packed unsigned int32 elements in \texttt{a} to packed int64 elements, and stores the result.

__mm512_mask_cvtepu32_epi64
extern __m512i __cdecl __mm512_mask_cvtepu32_epi64(__m512i src, __mmask8 k, __m256i a);
Zero extend packed unsigned int32 elements in \texttt{a} to packed int64 elements, and stores the result using writemask \texttt{k} (elements are copied from \texttt{src} when the corresponding mask bit is not set).

__mm512_maskz_cvtepu32_epi64
extern __m512i __cdecl __mm512_maskz_cvtepu32_epi64(__mmask8 k, __m256i a);
Zero extend packed unsigned int32 elements in \texttt{a} to packed int64 elements, and stores the result using zeromask \texttt{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cvtepu16_epi32
extern __m512i __cdecl __mm512_cvtepu16_epi32(__m256i a);
Zero extend packed unsigned 16-bit integers in \texttt{a} to packed 32-bit integers, and stores the result.

__mm512_mask_cvtepu16_epi32
extern __m512i __cdecl __mm512_mask_cvtepu16_epi32(__m512i src, __mmask16 k, __m256i a);
Zero extend packed unsigned 16-bit integers in \texttt{a} to packed 32-bit integers, and stores the result using writemask \texttt{k} (elements are copied from \texttt{src} when the corresponding mask bit is not set).

__mm512_maskz_cvtepu16_epi32
extern __m512i __cdecl __mm512_maskz_cvtepu16_epi32(__mmask16 k, __m256i a);
Zero extend packed unsigned 16-bit integers in \texttt{a} to packed 32-bit integers, and stores the result using zeromask \texttt{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm512_cvtepu16_epi64
extern __m512i __cdecl __mm512_cvtepu16_epi64(__m128i a);
Zero extend packed unsigned 16-bit integers in \texttt{a} to packed int64 elements, and stores the result.
_mm512_mask_cvtepu16_epi64

```c
extern __m512i __cdecl _mm512_mask_cvtepu16_epi64(__m512i src, __mmask8 k, __m128i a);
```

Zero extend packed unsigned 16-bit integers in `a` to packed int64 elements, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_cvtepu16_epi64

```c
extern __m512i __cdecl _mm512_maskz_cvtepu16_epi64(__mmask8 k, __m128i a);
```

Zero extend packed unsigned 16-bit integers in `a` to packed int64 elements, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsi512_si32

```c
int _mm512_cvtsi512_si32(__m512i a);
```

Moves the least significant 32 bits of `a` to a 32-bit integer.

### Intrinsics for Expand and Load Operations

#### Intrinsics for FP Expand and Load Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

_mm512_expand_pd

```
extern __m512d __cdecl _mm512_expand_pd(__m512d a);
```

Loads contiguous active float64 elements from `a` (those with their respective bit set in mask `k`), and stores the result.

_mm512_mask_expand_pd

```
extern __m512d __cdecl _mm512_mask_expand_pd(__m512d src, __mmask8 k, __m512d a);
```

Loads contiguous active float64 elements from `a` (those with their respective bit set in mask `k`), and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_expand_pd

```
extern __m512d __cdecl _mm512_maskz_expand_pd(__mmask8 k, __m512d a);
```

Loads contiguous active float64 elements from `a` (those with their respective bit set in mask `k`), and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_expand_ps

```
extern __m512 __cdecl _mm512_expand_ps(__m512 a);
```

Loads contiguous active float32 elements from `a` (those with their respective bit set in mask `k`), and stores the result.

_mm512_mask_expand_ps

```
extern __m512 __cdecl _mm512_mask_expand_ps(__m512 src, __mmask16 k, __m512 a);
```

Loads contiguous active float32 elements from `a` (those with their respective bit set in mask `k`), and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm512_maskz_expand_ps

```
extern __m512 __cdecl _mm512_maskz_expand_ps(__mmask16 k, __m512 a);
```

Loads contiguous active float32 elements from `a` (those with their respective bit set in mask `k`), and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expandloadu_pd

```
extern __m512d __cdecl _mm512_mask_expandloadu_pd(__m512d src, __mmask8 k, void * mem_addr);
```

Loads contiguous active float64 elements from unaligned memory at `mem_addr` (those with their respective bit set in mask `k`), and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
**_mm512_maskz_expandloadu_pd_**

```c
extern __m512d __cdecl _mm512_maskz_expandloadu_pd(__mmask8 k, void * mem_addr);
```

Loads contiguous active float64 elements from unaligned memory at `mem_addr` (those with their respective bit set in mask `k`), and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_expandloadu_ps_**

```c
extern __m512 __cdecl _mm512_mask_expandloadu_ps(__m512 src, __mmask16 k, void * mem_addr);
```

Loads contiguous active float32 elements from unaligned memory at `mem_addr` (those with their respective bit set in mask `k`), and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_expandloadu_ps_**

```c
extern __m512 __cdecl _mm512_maskz_expandloadu_ps(__mmask16 k, void * mem_addr);
```

Loads contiguous active float32 elements from unaligned memory at `mem_addr` (those with their respective bit set in mask `k`), and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### Intrinsics for Integer Expand and Load Operations

_mm512_maskz_expandloadu_epi64
extern __m512i __cdecl _mm512_maskz_expandloadu_epi64(__mmask8 k, void * mem_addr);
Loads contiguous active int64 elements from unaligned memory at mem_addr (those with their respective bit set in mask k), and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
Loads contiguous active int64 elements from \( a \) (those with their respective bit set in mask \( k \)), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Gather and Scatter Operations**

**Intrinsics for FP Gather and Scatter Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

index: a vector containing indexes in memory `mv`

downconv: Where _MM_DOWNCONV_PS_ENUM is the following:
- _MM_DOWNCONV_PS_NONE - no conversion

hint: Indicates which cache level to bring values into. _MM_HINT_ENUM is the following:
- _MM_HINT_NONE 0x0 - Off

On Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing), the hint parameter can be one of the following for the _mm512_prefetch* and _mm512_mask_prefetch* intrinsics:
- 1 (_MM_HINT_T0) for prefetching to L1 cache
- 2 (_MM_HINT_T1) for prefetching to L2 cache

---

### _mm512_i32gather_pd

```c
__m512d _mm512_i32gather_pd (__m256i vindex, void const* base_addr, int scale)
```

Gathers double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`).

### _mm512_mask_i32gather_pd

```c
__m512d _mm512_mask_i32gather_pd (__m512 src, __mmask8 k, __m256i vindex, void const* base_addr, int scale)
```

Gathers double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). Gathered elements are merged with `src` using mask `k`. When the corresponding mask bit is not set, elements are copied from `src`.

### _mm512_i32gather_ps

```c
__m512 _mm512_i32gather_ps (__m512i vindex, void const* base_addr, int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`).

### _mm512_mask_i32gather_ps

```c
__m512 _mm512_mask_i32gather_ps (__m512 src, __mmask16 k, __m512i vindex, void const* base_addr, int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`). Gathered elements are merged with `src` using mask `k`. When the corresponding mask bit is not set, elements are copied from `src`.

### _mm512_i32extgather_ps

```c
__m512 _mm512_i32extgather_ps (__m512i index, void const * mv, _MM_UPCONV_PS_ENUM upconv, int scale, int hint)
```

Compiler Reference
Up-converts 16 memory locations starting at location \( mv \) using packed 32-bit integer indices stored in \( index \) scaled by \( scale \) using \( upconv \) to single-precision (32-bit) floating-point elements and stores them in \( dst \).

\[ \texttt{__m512\_mask\_i32extgather\_ps} \]

\[ \texttt{m512} \_\texttt{mm512\_mask\_i32extgather\_ps} (\_\texttt{m512} src, \_\texttt{mmask16} k, \_\texttt{m512i} index, void const * \texttt{mv}, \texttt{MM\_UPCONV\_PS\_ENUM} upconv, int scale, int hint) \]

Up-converts 16 single-precision memory locations starting at location \( mv \) at packed 32-bit integer indices stored in \( index \) scaled by \( scale \) using \( upconv \) to single-precision (32-bit) floating-point elements and merges them with \( src \) using mask \( k \). When the corresponding mask bit is not set, elements are copied from \( src \).

\[ \texttt{__m512\_i64gather\_pd} \]

\[ \texttt{m512d} \_\texttt{mm512\_i64gather\_pd} (\_\texttt{m512i} vindex, void const* \texttt{base\_addr}, int scale) \]

Gathers double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at \( base\_addr \) and offset by each 64-bit element in \( vindex \) (each index is scaled by the factor in \( scale \)).

\[ \texttt{__m512\_mask\_i64gather\_pd} \]

\[ \texttt{m512d} \_\texttt{mm512\_mask\_i64gather\_pd} (\_\texttt{m512d} src, \_\texttt{mmask8} k, \_\texttt{m512i} vindex, void const* \texttt{base\_addr}, int scale) \]

Gathers double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at \( base\_addr \) and offset by each 64-bit element in \( vindex \) (each index is scaled by the factor in \( scale \)). Gathered elements are merged with \( src \) using mask \( k \). When the corresponding mask bit is not set, elements are copied from \( src \).

\[ \texttt{__m512\_i64gather\_ps} \]

\[ \texttt{m256} \_\texttt{mm512\_i64gather\_ps} (\_\texttt{m512i} vindex, void const* \texttt{base\_addr}, int scale) \]

Gathers single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at \( base\_addr \) and offset by each 64-bit element in \( vindex \) (each index is scaled by the factor in \( scale \)).

\[ \texttt{__m512\_mask\_i64gather\_ps} \]

\[ \texttt{m256} \_\texttt{mm512\_mask\_i64gather\_ps} (\_\texttt{m256} src, \_\texttt{mmask8} k, \_\texttt{m512i} vindex, void const* \texttt{base\_addr}, int scale) \]

Gathers single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at \( base\_addr \) and offset by each 64-bit element in \( vindex \) (each index is scaled by the factor in \( scale \)). Gathered elements are merged with \( src \) using mask \( k \). When the corresponding mask bit is not set, elements are copied from \( src \).

\[ \texttt{__m512\_prefetch\_i32gather\_pd} \]

\[ \texttt{void} \_\texttt{mm512\_prefetch\_i32gather\_pd} (\_\texttt{m256i} vindex, void const* \texttt{base\_addr}, int scale, int hint) \]

Prefetches double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at \( base\_addr \) and offset by each 32-bit element in \( vindex \) (each index is scaled by the factor in \( scale \)).

\[ \texttt{__m512\_mask\_prefetch\_i32gather\_pd} \]

\[ \texttt{void} \_\texttt{mm512\_mask\_prefetch\_i32gather\_pd} (\_\texttt{m256i} vindex, \_\texttt{mmask8} mask, void const* \texttt{base\_addr}, int scale, int hint) \]
Prefetches double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with cache using mask $k$. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i32gather_ps

```c
void _mm512_prefetch_i32gather_ps (__m512i index, void const* mv, int scale, int hint)
```
Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location $mv$ at packed 32-bit integer indices stored in $index$ (each index is scaled by the factor in $scale$).

_mm512_mask_prefetch_i32gather_ps

```c
void _mm512_mask_prefetch_i32gather_ps (__m512i vindex, __mmask16 mask, void const* base_addr,
int scale, int hint)
```
Prefetches single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with cache using mask $k$. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i64gather_pd

```c
void _mm512_prefetch_i64gather_pd (__m512i vindex, void const* base_addr, int scale, int hint)
```
Prefetches double-precision (64-bit) floating-point elements from memory into cache level specified by hint using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale).

_mm512_mask_prefetch_i64gather_pd

```c
void _mm512_mask_prefetch_i64gather_pd (__m512i vindex, __mmask8 mask, void const* base_addr,
int scale, int hint)
```
Prefetches double-precision (64-bit) floating-point elements from memory into cache level specified by hint using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Prefetched elements are merged with cache using mask $k$. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i64gather_ps

```c
void _mm512_prefetch_i64gather_ps (__m256i vindex, void const* base_addr, int scale, int hint)
```
Prefetches single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale).

_mm512_mask_prefetch_i64gather_ps

```c
void _mm512_mask_prefetch_i64gather_ps (__m512i vindex, __mmask8 mask, void const* base_addr,
int scale, int hint)
```
Prefetches single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with cache using mask $k$. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i32scatter_pd

```c
void _mm512_i32scatter_pd (void* base_addr, __m256i vindex, __m512d a, int scale)
```
Scatters double-precision (64-bit) floating-point elements from \(a\) into memory using 32-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)).

**\_mm512\_mask\_i32scatter\_pd**

```c
void _mm512_mask_i32scatter_pd (void* base_addr, __mmask8 k, __m256i vindex, __m512d a, int scale)
```

Scatters double-precision (64-bit) floating-point elements from \(a\) into memory using 32-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\). Elements are brought into cache only when their corresponding mask bits are set.

**\_mm512\_i32scatter\_ps**

```c
void _mm512_i32scatter_ps (void* base_addr, __m512i vindex, __m512 a, int scale)
```

Scatters single-precision (32-bit) floating-point elements from \(a\) into memory using 32-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)).

**\_mm512\_mask\_i32scatter\_ps**

```c
void _mm512_mask_i32scatter_ps (void* base_addr, __mmask16 k, __m512i vindex, __m512 a, int scale)
```

Scatters single-precision (32-bit) floating-point elements from \(a\) into memory using 32-bit indices. 32-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 32-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)) subject to mask \(k\). Elements are brought into cache only when their corresponding mask bits are set.

**\_mm512\_i32extscatter\_ps**

```c
void _mm512_i32extscatter_ps (void * mv, __m512i index, __m512 v1, _MM_DOWNCONV_PS_ENUM downconv, int scale, int hint)
```

Down-converts 16 packed single-precision (32-bit) floating-point elements in \(v1\) and stores them in memory locations starting at location \(mv\) at packed 32-bit integer indices stored in \(index\) scaled by \(scale\) using \(downconv\).

**\_mm512\_mask\_i32extscatter\_ps**

```c
void _mm512_mask_i32extscatter_ps (void * mv, __mmask16 k, __m512i index, __m512 v1, _MM_DOWNCONV_PS_ENUM downconv, int scale, int hint)
```

Down-converts 16 packed single-precision (32-bit) floating-point elements in \(v1\) according to \(downconv\) and stores them in memory locations starting at location \(mv\) at packed 32-bit integer indices stored in \(index\) scaled by \(scale\) using mask \(k\). Elements are brought into cache only when their corresponding mask bits are set.

**\_mm512\_i64scatter\_pd**

```c
void _mm512_i64scatter_pd (void* base_addr, __m512i vindex, __m512d a, int scale)
```

Scatters double-precision (64-bit) floating-point elements from \(a\) into memory using 64-bit indices. 64-bit elements are stored at addresses starting at \(base\_addr\) and offset by each 64-bit element in \(vindex\) (each index is scaled by the factor in \(scale\)).
_mm512_mask_i64scatter_pd

void _mm512_mask_i64scatter_pd (void* base_addr, __mmask8 k, __m512i vindex, __m512d a, int scale)

Scatters double-precision (64-bit) floating-point elements from `a` into memory using 64-bit indices. 64-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k`. Elements are brought into cache only when their corresponding mask bits are set.

__mm512_i64scatter_ps

void _mm512_i64scatter_ps (void* base_addr, __m512i vindex, __m256 a, int scale)

Scatters single-precision (32-bit) floating-point elements from `a` into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`).

__mm512_mask_i64scatter_ps

void _mm512_mask_i64scatter_ps (void* base_addr, __mmask8 k, __m512i vindex, __m256 a, int scale)

Scatters single-precision (32-bit) floating-point elements from `a` into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k`. Elements are brought into cache only when their corresponding mask bits are set.

__mm512 PREFETCH I32SCATTER_PD

void _mm512 PREFETCH I32SCATTER_PD (void* base_addr, __m256i vindex, int scale, int hint)

Prefetches double-precision (64-bit) floating-point elements with intent to write using 32-bit indices. 64-bit elements are brought into cache from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`).

__mm512_mask PREFETCH I32SCATTER_PD

extern void __cdecl _mm512_mask PREFETCH I32GATHER_PD(__m256i vindex, __mmask8 k, void const* base_addr, int scale, int hint);

Prefetches double-precision (64-bit) floating-point elements with intent to write using 32-bit indices. 64-bit elements are brought into cache from addresses starting at `base_addr` and offset by each 32-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k`. Elements are brought into cache only when their corresponding mask bits are set.

__mm512 PREFETCH I32SCATTER_PS

void _mm512 PREFETCH I32SCATTER_PS (void* mv, __m512i index, int scale, int hint)

Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location `mv` at packed 32-bit integer indices stored in `index` scaled by `scale`.

__mm512_mask PREFETCH I32SCATTER_PS

void _mm512_mask PREFETCH I32SCATTER_PS (void* mv, __mmask16 k, __m512i index, int scale, int hint)

Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location `mv` at packed 32-bit integer indices stored in `index` scaled by `scale`. Elements are brought into cache only when their corresponding mask bits in mask `k` are set.
_mm512_prefetch_i64scatter_pd

```c
void _mm512_prefetch_i64scatter_pd (void* base_addr, __m512i vindex, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements with intent to write into memory using 64-bit indices. 64-bit elements are brought into cache from addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`).

_.mm512_mask_prefetch_i64scatter_pd

```c
void _mm512_mask_prefetch_i64scatter_pd (void* base_addr, __mmask8 mask, __m512i vindex, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements with intent to write into memory using 64-bit indices. 64-bit elements are brought into cache from addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k`. Elements are brought into cache only when their corresponding mask bits are set.

_ mm512_prefetch_i64scatter_ps

```c
void _mm512_prefetch_i64scatter_ps (void* base_addr, __m512i vindex, int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements with intent to write into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`).

_ mm512_mask_prefetch_i64scatter_ps

```c
void _mm512_mask_prefetch_i64scatter_ps (void* base_addr, __mmask8 mask, __m512i vindex, int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements with intent to write into memory using 64-bit indices. 32-bit elements are stored at addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`) subject to mask `k`. Elements are brought into cache only when their corresponding mask bits are set.

Intrinsics for Integer Gather and Scatter Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

_mm512_i32gather_epi32

__m512i _mm512_i32gather_epi32(__m512i vindex, void const* base_addr, int scale)

Gathers 32-bit integers from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale).

_mm512_mask_i32gather_epi32

__m512i _mm512_mask_i32gather_epi32(__m512i src, __mmask16 k, __m512i vindex, void const* base_addr, int scale)

Gathers 32-bit integers from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with src using mask k. When the corresponding mask bit is not set, elements are copied from src.

_mm512_i32gather_epi64

__m512i _mm512_mask_i32gather_epi64 (__m512i src, __mmask8 k, __m256i vindex, void const* base_addr, int scale)

Gathers 64-bit integers from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale).
__mm512_mask_i32gather_epi64

__m512i __mm512_mask_i32gather_epi64 (__m512i src, __mmask8 k, __m256i vindex, void const* base_addr, int scale)

Gathers 64-bit integers from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with src using mask k. When the corresponding mask bit is not set, elements are copied from src.

__mm512_i64gather_epi32

__m256i __mm512_i64gather_epi32 (__m512i vindex, void const* base_addr, int scale)

Gathers 32-bit integers from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale).

__mm512_mask_i64gather_epi32

__m256i __mm512_mask_i64gather_epi32 (__m256i src, __mmask8 k, __m512i vindex, void const* base_addr, int scale)

Gathers 32-bit integers from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with src using mask k. When the corresponding mask bit is not set, elements are copied from src.

__mm512_i64gather_epi64

__m512i __mm512_i64gather_epi64 (__m512i vindex, void const* base_addr, int scale)

Gathers 64-bit integers from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale).

__mm512_mask_i64gather_epi64

__m512i __mm512_mask_i64gather_epi64 (__m512i src, __mmask8 k, __m512i vindex, void const* base_addr, int scale)

Gathers 64-bit integers from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged with src using mask k. When the corresponding mask bit is not set, elements are copied from src.

__mm512_i32scatter_epi32

void mm512_i32scatter_epi32(void* base_addr, __m512i vindex, __m512i a, int scale)

Scatters 32-bit integers from a into memory using 32-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale).

__mm512_mask_i32scatter_epi32

void __mm512_mask_i32scatter_epi32(void* base_addr, __mmask16 k, __m512i vindex, __m512i a, int scale)

Scatters 32-bit integers from a into memory using 32-bit indices. 32-bit elements are stored at addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale) subject to mask k. When the corresponding mask bit is not set, elements are not stored.
Intrinsics for Insert and Extract Operations

Intrinsics for FP Insert and Extract Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

#### interval

Where `MM_MANTISSA_NORM_ENUM` can be one of the following:

- `MM_MANT_NORM_1_2` - interval `[1, 2)`
- `MM_MANT_NORM_p5_2` - interval `[1.5, 2)`
- `MM_MANT_NORM_p5_1` - interval `[1.5, 1)`
- `MM_MANT_NORM_p75_1p5` - interval `[0.75, 1.5)`

#### sign

Where `MM_MANTISSA_SIGN_ENUM` can be one of the following:

- `MM_MANT_SIGN_src` - `sign = sign(SRC)`
- `MM_MANT_SIGN_zero` - `sign = 0`
- `MM_MANT_SIGN_nan` - `DEST = NaN if sign(SRC) = 1`

#### round

Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag):

- `MM_FROUND_TO_NEAREST_INT` - rounds to nearest even
- `MM_FROUND_TO_NEG_INF` - rounds to negative infinity
- `MM_FROUND_TO_POS_INF` - rounds to positive infinity
- `MM_FROUND_TO_ZERO` - rounds to zero
- `MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

### Function Definitions

#### _mm512_extractf32x4_ps

```c
extern __m128 __cdecl _mm512_extractf32x4_ps(__m512 a, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from `a`, selected with `imm`, and stores the result.

#### _mm512_mask_extractf32x4_ps

```c
extern __m128 __cdecl _mm512_mask_extractf32x4_ps(__m128 src, __mmask8 k, __m512 a, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from `a`, selected with `imm`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

#### _mm512_maskz_extractf32x4_ps

```c
extern __m128 __cdecl _mm512_maskz_extractf32x4_ps(__mmask8 k, __m512, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from `a`, selected with `imm`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm512_extractf64x4_pd

extern __m256d __cdecl _mm512_extractf64x4_pd(__m512d a, int imm);

Extracts 256 bits (composed of four packed float64 elements) from a, selected with imm, and stores the result.

_mm512_mask_extractf64x4_pd

extern __m256d __cdecl _mm512_mask_extractf64x4_pd(__m256d src, __mmask8 k, __m512d a, int imm);

Extracts 256 bits (composed of four packed float64 elements) from a, selected with imm, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_extractf64x4_pd

extern __m256d __cdecl _mm512_maskz_extractf64x4_pd(__mmask8 k, __m512d a, int imm);

Extracts 256 bits (composed of four packed float64 elements) from a, selected with imm, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_insertf32x4

extern __m512 __cdecl _mm512_insertf32x4(__m512 a, __m128 b, int imm);

Copies a to destination, then inserts 128 bits (composed of four packed float32 elements) from b into destination at the location specified by imm.

_mm512_mask_insertf32x4

extern __m512 __cdecl _mm512_mask_insertf32x4(__m512 src, __mmask16 k, __m512 a, __m128 b, int imm);

Copies a to destination, then inserts 128 bits (composed of four packed float32 elements) from b into destination at the location specified by imm.

_mm512_maskz_insertf32x4

extern __m512 __cdecl _mm512_maskz_insertf32x4(__mmask16 k, __m512 a, __m128 b, int imm);

Copies a to tmp, then inserts 128 bits (composed of four packed float32 elements) from b into tmp at the location specified by imm. Stores tmp to destination using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_insertf64x4

extern __m512d __cdecl _mm512_insertf64x4(__m512d a, __m256d b, int imm);

Copies a to tmp, then inserts 128 bits (composed of four packed float32 elements) from b into tmp at the location specified by imm. Stores tmp to destination using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_insertf64x4

extern __m512d __cdecl _mm512_mask_insertf64x4(__m512d src, __mmask8 k, __m512d a, __m256d b, int imm);

Copies a to destination, then inserts 256 bits (composed of four packed float64 elements) from b into destination at the location specified by imm.
\_mm512\_maskz\_insertf64x4

```c
extern _m512d __cdecl _mm512_maskz_insertf64x4(__mmask8 k, __m512d a, __m256d b, int imm);
```
Copies \(a\) to \(tmp\), then inserts 256 bits (composed of four packed float64 elements) from \(b\) into \(tmp\) at the location specified by \(imm\). Store \(tmp\) to destination using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm512\_getmant\_pd

```c
extern _m512d __cdecl _mm512_getmant_pd(__m512d a, _MM_MANTISSA\_NORM\_ENUM interval,
                                _MM_MANTISSA\_SIGN\_ENUM sign);
```
Normalizes the mantissas of packed float64 elements in \(a\), and stores the result. This intrinsic essentially calculates \(\pm(2^k)\times|x.\text{significand}|\), where \(k\) depends on the interval range defined by \(interval\) and the sign depends on \(sign\) and the source sign.

\_mm512\_mask\_getmant\_pd

```c
extern _m512d __cdecl _mm512_mask_getmant_pd(__m512d src, __mmask8 k, __m512d a,
                                _MM_MANTISSA\_NORM\_ENUM interval, _MM_MANTISSA\_SIGN\_ENUM sign);
```
Normalizes the mantissas of packed float64 elements in \(a\), and stores the result. This intrinsic essentially calculates \(\pm(2^k)\times|x.\text{significand}|\), where \(k\) depends on the interval range defined by \(interval\) and the sign depends on \(sign\) and the source sign.

\_mm512\_maskz\_getmant\_pd

```c
extern _m512d __cdecl _mm512_maskz_getmant_pd(__mmask8 k, __m512d a,
                                _MM_MANTISSA\_NORM\_ENUM interval, _MM_MANTISSA\_SIGN\_ENUM sign);
```
Normalizes the mantissas of packed float64 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). This intrinsic essentially calculates \(\pm(2^k)\times|x.\text{significand}|\), where \(k\) depends on the interval range defined by \(interval\) and the sign depends on \(sign\) and the source sign.

\_mm512\_getmant\_round\_pd

```c
extern _m512d __cdecl _mm512_getmant_round_pd(__m512d a, _MM_MANTISSA\_NORM\_ENUM interval,
                                _MM_MANTISSA\_SIGN\_ENUM sign, int round);
```
Normalizes the mantissas of packed float64 elements in \(a\), and stores the result. This intrinsic essentially calculates \(\pm(2^k)\times|x.\text{significand}|\), where \(k\) depends on the interval range defined by \(interval\) and the sign depends on \(sign\) and the source sign.

\_mm512\_mask\_getmant\_round\_pd

```c
extern _m512d __cdecl _mm512_mask_getmant_round_pd(__m512d src, __mmask8 k, __m512d a,
                                _MM_MANTISSA\_NORM\_ENUM interval, _MM_MANTISSA\_SIGN\_ENUM sign, int round);
```
Normalizes the mantissas of packed float64 elements in \(a\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). This intrinsic essentially calculates \(\pm(2^k)\times|x.\text{significand}|\), where \(k\) depends on the interval range defined by \(interval\) and the sign depends on \(sign\) and the source sign.

\_mm512\_maskz\_getmant\_round\_pd

```c
extern _m512d __cdecl _mm512_maskz_getmant_round_pd(__mmask8 k, __m512d a,
                                _MM_MANTISSA\_NORM\_ENUM interval, _MM_MANTISSA\_SIGN\_ENUM sign, int round);
```
Normalizes the mantissas of packed float64 elements in a, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_getmant_ps

extern __m512 __cdecl _mm512_getmant_ps(__m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of packed float32 elements in a, and stores the result. This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_mask_getmant_ps

extern __m512 __cdecl _mm512_mask_getmant_ps(__m512 src, __mmask16 k, __m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of packed float32 elements in a, and stores the result. This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_maskz_getmant_ps

extern __m512 __cdecl _mm512_maskz_getmant_ps(__mmask16 k, __m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_getmant_round_ps

extern __m512 __cdecl _mm512_getmant_round_ps(__m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);

Normalizes the mantissas of packed float32 elements in a, and stores the result. This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_mask_getmant_round_ps

extern __m512 __cdecl _mm512_mask_getmant_round_ps(__m512 src, __mmask16 k, __m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);

Normalizes the mantissas of packed float32 elements in a, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates $\pm(2^k)\cdot|x|.significand|$, where $k$ depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm512_maskz_getmant_round_ps

extern __m512 __cdecl _mm512_maskz_getmant_round_ps(__mmask16 k, __m512 a, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
Normalizes the mantissas of packed float32 elements in \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.

\[ \text{__mm_getmant_round_sd} \]

```c
extern __m128d __cdecl _mm_getmant_round_sd(__m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in \( a \), stores the result in the lower destination element, and copies the upper element from \( b \) to the upper destination element. This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.

\[ \text{__mm_mask_getmant_round_sd} \]

```c
extern __m128d __cdecl _mm_mask_getmant_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in \( a \), store the result in the lower destination element, and copies the upper element from \( b \) to the upper destination element. This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.

\[ \text{__mm_maskz_getmant_round_sd} \]

```c
extern __m128d __cdecl _mm_maskz_getmant_round_sd(__mmask8 k, __m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in \( a \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper element from \( b \) to the upper destination element. This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.

\[ \text{__mm_getmant_sd} \]

```c
extern __m128d __cdecl _mm_getmant_sd(__m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float64 element in \( a \), store the result in the lower destination element, and copies the upper element from \( b \) to the upper destination element. This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.

\[ \text{__mm_mask_getmant_sd} \]

```c
extern __m128d __cdecl _mm_mask_getmant_sd(__m128d a, __mmask8 k, __m128d b, __m128d c, _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalize the mantissas of the lower float64 element in \( a \), store the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copy the upper element from \( b \) to the upper destination element. This intrinsic essentially calculates \( \pm(2^k)\cdot|x\.significand| \), where \( k \) depends on the interval range defined by \( interval \) and the sign depends on \( sign \) and the source sign.
_mm_maskz_getmant_sd

extern __m128d cdecl _mm_maskz_getmant_sd(__mmask8 k, __m128d a, __m128d b,
    _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of the lower float64 element in a, stores the result in the lower destination element using zeromask k (the element is zeroed out when mask bit 0 is not set), and copies the upper element from b to the upper destination element. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm_getmant_round_ss

extern __m128 cdecl _mm_getmant_round_ss(__m128 a, __m128 b, _MM_MANTISSA_NORM_ENUM interval,
    _MM_MANTISSA_SIGN_ENUM sign, int round);

Normalizes the mantissas of the lower float32 element in a, stores the result in the lower destination element, and copies the upper three packed elements from b to the upper destination elements. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm_mask_getmant_round_ss

extern __m128 cdecl _mm_mask_getmant_round_ss(__m128 a, __mmask8 k, __m128 b, __m128 c,
    _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);

Normalizes the mantissas of the lower float32 element in a, stores the result in the lower destination element, and copies the upper three packed elements from b to the upper destination elements. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm_maskz_getmant_round_ss

extern __m128 __cdecl _mm_maskz_getmant_round_ss(__mmask8 k, __m128 a, __m128 b,
    _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of the lower float32 element in a, stores the result in the lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies the upper three packed elements from b to the upper destination elements. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm_getmant_ss

extern __m128 __cdecl _mm_getmant_ss(__m128 a, __m128 b, _MM_MANTISSA_NORM_ENUM interval,
    _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of the lower float32 element in a, stores the result in the lower destination element, and copies the upper three packed elements from b to the upper destination elements. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.

_mm_mask_getmant_ss

extern __m128 __cdecl _mm_mask_getmant_ss(__m128 a, __mmask8 k, __m128 b, __m128 c,
    _MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);

Normalizes the mantissas of the lower float32 element in a, stores the result in the lower destination element, and copies the upper three packed elements from b to the upper destination elements. This intrinsic essentially calculates ±(2^k)*|x.significand|, where k depends on the interval range defined by interval and the sign depends on sign and the source sign.
Normalizes the mantissas of the lower float32 element in \( a \), stores the result in the lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies the upper three packed elements from \( b \) to the upper destination elements. This intrinsic essentially calculates \( \pm (2^k) \times |x\text{.significand}| \), where \( k \) depends on the interval range defined by \( \text{interval} \) and the sign depends on \( \text{sign} \) and the source sign.

\[
\_\text{mm} \_\text{maskz} \_\text{getmant} \_\text{ss}
\]

\[
\text{extern } \_\text{m128 } \_\text{cdecl } \_\text{mm} \_\text{maskz} \_\text{getmant} \_\text{ss}(\_\text{mmask8 } k, \_\text{m128 } a, \_\text{m128 } b, \_\text{MM} \_\text{MANTISSA} \_\text{NORM} \_\text{ENUM} \text{ interval}, \_\text{MM} \_\text{MANTISSA} \_\text{SIGN} \_\text{ENUM} \text{ sign});
\]

Normalizes the mantissas of the lower float32 element in \( a \), stores the result in the lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from \( b \) to the upper destination elements. This intrinsic essentially calculates \( \pm (2^k) \times |x\text{.significand}| \), where \( k \) depends on the interval range defined by \( \text{interval} \) and the sign depends on \( \text{sign} \) and the source sign.

**Intrinsics for Integer Insert and Extract Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the \text{zmmintrin.h} header file.

To use these intrinsics, include the \text{immintrin.h} file as follows:

```
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>

**variable** | **definition**
---|---
`tmp` | temporary location specified by `imm`
`imm` | specifies temporary location `tmp`

_**mm512_extracti32x4_epi32**_

```
extern __m128i __cdecl _mm512_extracti32x4_epi32(__m512i a, int imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from `a`, selected with `imm`, and stores the result.

_**mm512_mask_extracti32x4_epi32**_

```
extern __m128i __cdecl _mm512_mask_extracti32x4_epi32(__m128i src, __mmask8 k, __m512i a, int imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from `a`, selected with `imm`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_**mm512_maskz_extracti32x4_epi32**_

```
extern __m128i __cdecl _mm512_maskz_extracti32x4_epi32(__mmask8 k, __m512i a, int imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from `a`, selected with `imm`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_**mm512_extracti64x4_epi64**_

```
extern __m256i __cdecl _mm512_extracti64x4_epi64(__m512i a, int imm);
```

Extracts 256 bits (composed of four packed int64 elements) from `a`, selected with `imm`, and stores the result.

_**mm512_mask_extracti64x4_epi64**_

```
extern __m256i __cdecl _mm512_mask_extracti64x4_epi64(__m256i src, __mmask8 k, __m512i a, int imm);
```

Extracts 256 bits (composed of four packed int64 elements) from `a`, selected with `imm`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_**mm512_maskz_extracti64x4_epi64**_

```
extern __m256i __cdecl _mm512_maskz_extracti64x4_epi64(__mmask8 k, __m512i a, int imm);
```

Extracts 256 bits (composed of four packed int64 elements) from `a`, selected with `imm`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_**mm512_inserti32x4**_

```
extern __m512i __cdecl _mm512_inserti32x4(__m512i a, __m128i b, int imm);
```

Copies \( a \) to destination, then inserts 128 bits (composed of four packed 32-bit integers) from \( b \) into destination at the location specified by \( \text{imm} \).

\textbf{\texttt{_mm512_mask_inserti32x4}}
\begin{verbatim}
extern __m512i __cdecl _mm512_mask_inserti32x4(__m512i src, __mmask16 k, __m512i a, __m128i b, int imm);
\end{verbatim}

Copies \( a \) to \( tmp \), then inserts 128 bits (composed of four packed 32-bit integers) from \( b \) into \( tmp \) at the location specified by \( \text{imm} \). Store \( tmp \) to using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\textbf{\texttt{_mm512_maskz_inserti32x4}}
\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_inserti32x4(__mmask16 k, __m512i a, __m128i b, int imm);
\end{verbatim}

Copies \( a \) to \( tmp \), then inserts 256 bits (composed of four packed double-precision (64-bit) floating-point elements) from \( b \) into \( tmp \) at the location specified by \( \text{imm} \).

Store \( tmp \) to destination using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\textbf{\texttt{_mm512_inserti64x4}}
\begin{verbatim}
extern __m512i __cdecl _mm512_inserti64x4(__m512i a, __m256i b, int imm);
\end{verbatim}

Copies \( a \) to \( tmp \), then inserts 256 bits (composed of four packed int64 elements ) from \( b \) into \( tmp \) at the location specified by \( \text{imm} \).

\textbf{\texttt{_mm512_mask_inserti64x4}}
\begin{verbatim}
extern __m512i __cdecl _mm512_mask_inserti64x4(__m512i src, __mmask8 k, __m512i a, __m256i b, int imm);
\end{verbatim}

Copies \( a \) to \( tmp \), then inserts 256 bits (composed of four packed int64 elements ) from \( b \) into \( tmp \) at the location specified by \( \text{imm} \). Store \( tmp \) to using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\textbf{\texttt{_mm512_maskz_inserti64x4}}
\begin{verbatim}
extern __m512i __cdecl _mm512_maskz_inserti64x4(__mmask8 k, __m512i a, __m256i b, int imm);
\end{verbatim}

Copies \( a \) to \( tmp \), then inserts 128 bits (composed of four packed 32-bit integers) from \( b \) into \( tmp \) at the location specified by \( \text{imm} \). Store \( tmp \) to using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

</tbody>
</table>

_mm512_load_pd

extern __m512d __cdecl _mm512_load_pd(void const* mem_addr);

Loads 512-bits (composed of eight packed float64 elements) from `mem_addr` into destination.
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_pd

extern __m512d __cdecl _mm512_mask_load_pd(__m512d src, __mmask8 k, void const* mem_addr);

Loads packed float64 elements from `mem_addr` into destination using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_pd

extern __m512d __cdecl _mm512_maskz_load_pd(__mmask8 k, void const* mem_addr);

Loads packed float64 elements from `mem_addr` into destination using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_load_ps

extern __m512 __cdecl _mm512_load_ps(void const* mem_addr);

Loads 512-bits (composed of sixteen packed float32 elements) from `mem_addr` into destination.
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_ps

extern __m512 __cdecl _mm512_mask_load_ps(__m512 src, __mmask16 k, void const* mem_addr);

Loads packed float32 elements from `mem_addr` into destination using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_ps

extern __m512 __cdecl _mm512_maskz_load_ps(__mmask16 k, void const* mem_addr);

Loads packed float32 elements from `mem_addr` into destination using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
`mem_addr` must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm_mask_load_sd

extern __m128d __cdecl _mm_mask_load_sd(__m128d src, __mmask8 k, const double* mem_addr);

Loads float64 element from `mem_addr` into lower element of destination using writemask `k` (the element is copied from `src` when mask bit 0 is not set), and sets upper destination element to zero.
`mem_addr` must be aligned on a 16-byte boundary or a general-protection exception will be generated.
_mm_maskz_load_sd

extern __m128d _cdecl _mm_maskz_load_sd(__mmask8 k, const double* mem_addr);

Loads a float64 element from `mem_addr` into lower destination element using zeromask `k` (the element is zeroed out when mask bit 0 is not set), and sets upper destination elements to zero.

`mem_addr` must be aligned on a 16-byte boundary or a general-protection exception will be generated.

__mm_mask_load_ss

extern __m128 __cdecl _mm_mask_load_ss(__m128 src, __mmask8 k, const float* mem_addr);

Loads float32 element from `mem_addr` into lower destination element using writemask `k` (the element is copied from `src` when mask bit 0 is not set), and sets upper destination elements to zero.

`mem_addr` must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_maskz_load_ss

extern __m128 __cdecl _mm_maskz_load_ss(__mmask8 k, const float* mem_addr);

Loads float32 element from `mem_addr` into lower element of destination using zeromask `k` (the element is zeroed out when mask bit 0 is not set), and sets upper destination elements to zero.

`mem_addr` must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm512_loadu_pd

extern __m512d __cdecl _mm512_loadu_pd(void const* mem_addr);

Loads 512-bits (composed of eight packed float64 elements) from `mem_addr` into destination.

`mem_addr` does not need to be aligned on any particular boundary.

_mm512_mask_loadu_pd

extern __m512d __cdecl _mm512_mask_loadu_pd(__m512d src, __mmask8 k, void const* mem_addr);

Loads packed float64 elements from `mem_addr` into destination using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

`mem_addr` does not need to be aligned on any particular boundary.

_mm512_maskz_loadu_pd

extern __m512d __cdecl _mm512_maskz_loadu_pd(__mmask8 k, void const* mem_addr);

Loads packed float64 elements from `mem_addr` into destination using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

`mem_addr` does not need to be aligned on any particular boundary.

_mm512_loadu_ps

extern __m512 __cdecl _mm512_loadu_ps(void const* mem_addr);

Loads 512-bits (composed of sixteen packed float32 elements) from `mem_addr` into destination.

_mm512_mask_loadu_ps

extern __m512 __cdecl _mm512_mask_loadu_ps(__m512 src, __mmask16 k, void const* mem_addr);

Loads packed float32 elements from `mem_addr` into destination using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
_mm512_maskz_loadu_ps

extern __m512 __cdecl _mm512_maskz_loadu_ps(__mmask16 k, void const* mem_addr);

Loads packed float32 elements from mem_addr into destination using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_store_pd

extern void __cdecl _mm512_store_pd(void* mem_addr, __m512d a);

Stores 512-bits (composed of eight packed float64 elements) from a into mem_addr.

_mm512_mask_store_pd

extern void __cdecl _mm512_mask_store_pd(void* mem_addr, __mmask8 k, __m512d a);

Stores packed float64 elements from a into mem_addr using writemask k.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_ps

extern void __cdecl _mm512_store_ps(void* mem_addr, __m512 a);

Store 512-bits (composed of sixteen packed float32 elements) from a into mem_addr.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_ps

extern void __cdecl _mm512_mask_store_ps(void* mem_addr, __mmask16 k, __m512 a);

Store packed float32 elements from a into mem_addr using writemask k.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_stream_pd

extern void __cdecl _mm512_stream_pd(void* mem_addr, __m512d a);

Stores 512-bits (composed of eight packed float64 elements) from a into mem_addr using a non-temporal memory hint.

_mm512_stream_ps

extern void __cdecl _mm512_stream_ps(void* mem_addr, __m512 a);

Stores 512-bits (composed of sixteen packed float32 elements) from a into mem_addr using a non-temporal memory hint.

_mm_mask_store_sd

extern void __cdecl _mm_mask_store_sd(double* mem_addr, __mmask8 k, __m128d a);

Stores lower float64 element from a into mem_addr using writemask k.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_mask_store_ss

extern void __cdecl _mm_mask_store_ss(float* mem_addr, __mmask8 k, __m128 a);
Stores lower float32 element from a into \textit{mem\_addr} using writemask \textit{k}.  
\textit{mem\_addr} must be aligned on a 16-byte boundary or a general-protection exception will be generated.

\textbf{\_mm512\_storeu\_pd}

\begin{verbatim}
 extern void __cdecl \_mm512\_storeu\_pd(void* mem\_addr, __m512d a);
\end{verbatim}
Stores 512-bits (composed of eight packed float64 elements) from \textit{a} into \textit{mem\_addr}.  
\textit{mem\_addr} does not need to be aligned on any particular boundary.

\textbf{\_mm512\_mask\_storeu\_pd}

\begin{verbatim}
 extern void __cdecl \_mm512\_mask\_storeu\_pd(void* mem\_addr, __mmask8 k, __m512d a);
\end{verbatim}
Stores packed float64 elements from \textit{a} into \textit{mem\_addr} using writemask \textit{k}.  
\textit{mem\_addr} does not need to be aligned on any particular boundary.

\textbf{\_mm512\_storeu\_ps}

\begin{verbatim}
 extern void __cdecl \_mm512\_storeu\_ps(void* mem\_addr, __m512 a);
\end{verbatim}
Stores 512-bits (composed of sixteen packed float32 elements) from \textit{a} into \textit{mem\_addr}.  
\textit{mem\_addr} does not need to be aligned on any particular boundary.

\textbf{\_mm512\_mask\_storeu\_ps}

\begin{verbatim}
 extern void __cdecl \_mm512\_mask\_storeu\_ps(void* mem\_addr, __mmask16 k, __m512 a);
\end{verbatim}
Stores packed float32 elements from \textit{a} into \textit{mem\_addr} using writemask \textit{k}.

\section*{Intrinsics for Integer Load and Store Operations}

The prototypes for Intel\textsuperscript{\textregistered} Advanced Vector Extensions 512 (Intel\textsuperscript{\textregistered} AVX-512) intrinsics are located in the \textit{zmmintrin.h} header file.  
To use these intrinsics, include the \textit{immintrin.h} file as follows:

\begin{verbatim}
#include <immintrin.h>
\end{verbatim}

\begin{center}
\begin{tabular}{|l|l|l|}
\hline
\textbf{Intrinsic Name} & \textbf{Operation} & \textbf{Corresponding Intel\textsuperscript{\textregistered} AVX-512 Instruction} \\
\hline
\_mm512\_load\_epi32, & Load packed int32 elements from \textit{memory} & \textit{VMOVQ}\_A32 \\
\_mm512\_mask\_load\_epi32, & & \\
\_mm512\_maskz\_load\_epi32 & & \\
\_mm512\_load\_epi64, & Load packed int64 elements from \textit{memory} & \textit{VMOVQ}\_A64 \\
\_mm512\_mask\_load\_epi64, & & \\
\_mm512\_maskz\_load\_epi64 & & \\
\_mm512\_loadu\_si512 & Unaligned load of 512-bit scalar integer & \textit{VMOVDQ}\_U32 \\
\_mm512\_mask\_loadu\_epi32, & Unaligned load of packed int32 elements & \textit{VMOVDQ}\_U32 \\
\_mm512\_maskz\_loadu\_epi32 & & \\
\hline
\end{tabular}
\end{center}

</table>

### _mm512_load_si512

```c
extern __m512i __cdecl _mm512_load_si512(void const* mem_addr);
```

Load 512-bits of integer data from memory into destination.

*mem_addr* must be aligned on a 64-byte boundary or a general-protection exception will be generated.

### _mm512_loadu_si512

```c
extern __m512i __cdecl _mm512_loadu_si512(void const* mem_addr);
```

Load 512-bits of integer data from memory into destination.

*mem_addr* does not need to be aligned on any particular boundary.

### _mm512_load_epi32

```c
extern __m512i __cdecl _mm512_load_epi32(void const* mem_addr);
```

Load 512-bits (composed of sixteen packed 32-bit integers) from memory into destination.

*mem_addr* must be aligned on a 64-byte boundary or a general-protection exception will be generated.

### _mm512_mask_load_epi32

```c
extern __m512i __cdecl _mm512_mask_load_epi32(__m512i src, __mmask16 k, void const* mem_addr);
```

Load packed int32 elements from memory into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

*mem_addr* must be aligned on a 64-byte boundary or a general-protection exception will be generated.
_mm512_maskz_load_epi32
extern __m512i __cdecl _mm512_maskz_load_epi32(__mmask16 k, void const* mem_addr);
Load packed int32 elements from memory into destination using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\textit{mem_addr} must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_load_epi64
extern __m512i __cdecl _mm512_load_epi64(void const* mem_addr);
Load 512-bits (composed of eight packed int64 elements) from memory into destination.

\textit{mem_addr} must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_epi64
extern __m512i __cdecl _mm512_mask_load_epi64(__m512i src, __mmask8 k, void const* mem_addr);
Load packed int64 elements from memory into destination using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\textit{mem_addr} must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_epi64
extern __m512i __cdecl _mm512_maskz_load_epi64(__mmask8 k, void const* mem_addr);
Load packed int64 elements from memory into destination using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\textit{mem_addr} must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_loadu_epi32
extern __m512i __cdecl _mm512_mask_loadu_epi32(__m512i src, __mmask16 k, void const* mem_addr);
Load packed int32 elements from memory into destination using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\textit{mem_addr} does not need to be aligned on any particular boundary.

_mm512_maskz_loadu_epi32
extern __m512i __cdecl _mm512_maskz_loadu_epi32(__mmask16 k, void const* mem_addr);
Load packed int32 elements from memory into destination using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\textit{mem_addr} does not need to be aligned on any particular boundary.

_mm512_mask_loadu_epi64
extern __m512i __cdecl _mm512_mask_loadu_epi64(__m512i src, __mmask8 k, void const* mem_addr);
Load packed int64 elements from memory into destination using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).
mem_addr does not need to be aligned on any particular boundary.

_mm512_stream_load_si512

extern _m512i __cdecl _mm512_stream_load_si512(void * mem_addr);

Load 512-bits of integer data from memory into destination using a non-temporal memory hint.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_epi32

extern void __cdecl _mm512_store_epi32(void* mem_addr, __m512i a);

Store 512-bits (composed of sixteen packed 32-bit integers) from a into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_epi32

extern void __cdecl _mm512_mask_store_epi32(void* mem_addr, __mmask16 k, __m512i a);

Store packed int32 elements from a into memory using writemask k.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_si512

extern void __cdecl _mm512_store_si512(void* mem_addr, __m512i a);

Store 512-bits of integer data from a into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_epi64

extern void __cdecl _mm512_store_epi64(void* mem_addr, __m512i a);

Store 512-bits (composed of eight packed int64 elements ) from a into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_epi64

extern void __cdecl _mm512_mask_store_epi64(void* mem_addr, __mmask8 k, __m512i a);

Store packed int64 elements from a into memory using writemask k.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_storeu_epi32

extern void __cdecl _mm512_mask_storeu_epi32(void* mem_addr, __mmask16 k, __m512i a);

Store packed int32 elements from a into memory using writemask k.

mem_addr does not need to be aligned on any particular boundary.
__mm512_mask_storeu_epi64

extern void __cdecl __mm512_mask_storeu_epi64(void* mem_addr, __mmask8 k, __m512i a);

Store packed int64 elements from \( a \) into memory using writemask \( k \).

\( mem\_addr \) does not need to be aligned on any particular boundary.

__mm512_storeu_si512

extern void __cdecl __mm512_storeu_si512(void* mem_addr, __m512i a);

Store 512-bits of integer data from \( a \) into memory.

\( mem\_addr \) does not need to be aligned on any particular boundary.

__mm512_stream_si512

extern void __cdecl __mm512_stream_si512(void* mem_addr, __m512i a);

Store 512-bits of integer data from \( a \) into memory using a non-temporal memory hint.

_**_mm512_fixupimm_pd_**_

```c
extern __m512d __cdecl _mm512_fixupimm_pd(__m512d a, __m512d b, __m512i c, int imm);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result.

*imm* is used to set the required flags reporting.

_**_mm512_mask_fixupimm_pd_**_

```c
extern __m512d __cdecl _mm512_mask_fixupimm_pd(__m512d a, __mmask8 k, __m512d b, __m512i c, int imm);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result using writemask *k* (elements are copied from a when the corresponding mask bit is not set).

*imm* is used to set the required flags reporting.

_**_mm512_maskz_fixupimm_pd_**_

```c
extern __m512d __cdecl _mm512_maskz_fixupimm_pd(__mmask8 k, __m512d a, __m512d b, __m512i c, int imm);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

*imm* is used to set the required flags reporting.

_**_mm512_fixupimm_round_pd_**_

```c
extern __m512d __cdecl _mm512_fixupimm_round_pd(__m512d a, __m512d b, __m512i c, int imm, int round);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result.

*imm* is used to set the required flags reporting.

_**_mm512_mask_fixupimm_round_pd_**_

```c
extern __m512d __cdecl _mm512_mask_fixupimm_round_pd(__m512d a, __mmask8 k, __m512d b, __m512i c, int imm, int round);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result using writemask *k* (elements are copied from a when the corresponding mask bit is not set).

*imm* is used to set the required flags reporting.

_**_mm512_maskz_fixupimm_round_pd_**_

```c
extern __m512d __cdecl _mm512_maskz_fixupimm_round_pd(__mmask8 k, __m512d a, __m512d b, __m512i c, int imm, int round);
```

Fixes up packed float64 elements in a and b using packed 64-bit integers in c, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

*imm* is used to set the required flags reporting.
Fixes up packed float64 elements in \(a\) and \(b\) using packed 64-bit integers in \(c\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_fixupimm\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_fixupimm_ps(__m512 a, __m512 b, __m512i c, int imm);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result. \(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_mask\_fixupimm\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_mask_fixupimm_ps(__m512 a, __mmask16 k, __m512 b, __m512i c, int imm);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

\(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_maskz\_fixupimm\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_maskz_fixupimm_ps(__mmask16 k, __m512 a, __m512 b, __m512i c, int imm);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_fixupimm\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_fixupimm_round_ps(__m512 a, __m512 b, __m512i c, int imm, int round);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result. \(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_mask\_fixupimm\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_mask_fixupimm_round_ps(__m512 a, __mmask16 k, __m512 b, __m512i c, int imm, int round);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

\(imm\) is used to set the required flags reporting.

\textbf{\_mm512\_maskz\_fixupimm\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl _mm512_maskz_fixupimm_round_ps(__mmask16 k, __m512 a, __m512 b, __m512i c, int imm, int round);
\end{verbatim}

Fixes up packed float32 elements in \(a\) and \(b\) using packed 32-bit integers in \(c\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\(imm\) is used to set the required flags reporting.

\textbf{\_mm\_fixupimm\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_fixupimm_sd(__m128d a, __m128d b, __m128i c, int imm);
\end{verbatim}
Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element, and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_mask\_fixupimm\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_mask_fixupimm_sd(__m128d a, __mmask8 k, __m128d b, __m128i c, int imm);
\end{verbatim}

Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element using writemask \(k\) (the element is copied from \(a\) when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_maskz\_fixupimm\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_maskz_fixupimm_sd(__mmask8 k, __m128d a, __m128d b, __m128i c, int imm);
\end{verbatim}

Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_fixupimm\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_fixupimm_round_sd(__m128d a, __m128d b, __m128i c, int imm, int round);
\end{verbatim}

Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element, and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_mask\_fixupimm\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_mask_fixupimm_round_sd(__m128d a, __mmask8 k, __m128d b, __m128i c, int imm, int round);
\end{verbatim}

Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element using writemask \(k\) (the element is copied from \(a\) when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_maskz\_fixupimm\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl _mm_maskz_fixupimm_round_sd(__mmask8 k, __m128d a, __m128d b, __m128i c, int imm, int round);
\end{verbatim}

Fixes up lower float64 elements in \(a\) and \(b\) using lower 64-bit integer in \(c\), stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \(a\) to upper destination element.

\(imm\) is used to set the required flags reporting.

\texttt{\_mm\_fixupimm\_round\_ss}

\begin{verbatim}
extern __m128 __cdecl _mm_fixupimm_round_ss(__m128 a, __m128 b, __m128i c, int imm, int round);
\end{verbatim}
Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element, and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm\_mask\_fixupimm\_round\_ss}

\begin{verbatim}
extern _m128 __cdecl _mm_mask_fixupimm_round_ss(__m128 a, __mmask8 k, __m128 b, __m128i c, int imm, int round);
\end{verbatim}

Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element using writemask \(k\) (the element is copied from \(a\) when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm\_maskz\_fixupimm\_round\_ss}

\begin{verbatim}
extern _m128 __cdecl _mm_maskz_fixupimm_round_ss(__mmask8 k, __m128 a, __m128 b, __m128i c, int imm, int round);
\end{verbatim}

Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm\_fixupimm\_ss}

\begin{verbatim}
extern _m128 __cdecl _mm_fixupimm_ss(__m128 a, __m128 b, __m128i c, int imm);
\end{verbatim}

Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element, and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm\_mask\_fixupimm\_ss}

\begin{verbatim}
extern _m128 __cdecl _mm_mask_fixupimm_ss(__m128 a, __mmask8 k, __m128 b, __m128i c, int imm);
\end{verbatim}

Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element using writemask \(k\) (the element is copied from \(a\) when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm\_maskz\_fixupimm\_ss}

\begin{verbatim}
extern _m128 __cdecl _mm_maskz_fixupimm_ss(__mmask8 k, __m128 a, __m128 b, __m128i c, int imm);
\end{verbatim}

Fixes up lower float32 elements in \(a\) and \(b\) using lower 32-bit integer in \(c\), stores the result in lower destination element using zeromask \(k\) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \(a\) to upper destination elements.

\textit{imm} is used to set the required flags reporting.

\textbf{\_mm512\_getexp\_pd}

\begin{verbatim}
extern __m512d __cdecl _mm512_getexp_pd(__m512d a);
\end{verbatim}

Converts the exponent of each packed float64 element in \(a\) to a float64 number representing the integer exponent, and stores the result. This intrinsic essentially calculates \(\text{floor}(\log_2(x))\) for each element.
__mm512_mask_getexp_pd

extern __m512d __cdecl _mm512_mask_getexp_pd(__m512d src, __mmask8 k, __m512d a);

Converts the exponent of each packed float64 element in a to a float64 number representing the integer exponent, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_maskz_getexp_pd

extern __m512d __cdecl _mm512_maskz_getexp_pd(__mmask8 k, __m512d a);

Converts the exponent of each packed float64 element in a to a float64 number representing the integer exponent, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_getexp_round_pd

extern __m512d __cdecl _mm512_getexp_round_pd(__m512d a, int round);

Converts the exponent of each packed float64 element in a to a float64 number representing the integer exponent, and stores the result. This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_mask_getexp_round_pd

extern __m512d __cdecl _mm512_mask_getexp_round_pd(__m512d src, __mmask8 a, __m512d, int round);

Converts the exponent of each packed float64 element in a to a float64 number representing the integer exponent, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_maskz_getexp_round_pd

extern __m512d __cdecl _mm512_maskz_getexp_round_pd(__mmask8 k, __m512d a, int round);

Converts the exponent of each packed float64 element in a to a float64 number representing the integer exponent, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_getexp_ps

extern __m512 __cdecl _mm512_getexp_ps(__m512 a);

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result. This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_mask_getexp_ps

extern __m512 __cdecl _mm512_mask_getexp_ps(__m512 src, __mmask16 k, __m512 a);

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.

__mm512_maskz_getexp_ps

extern __m512d __cdecl _mm512_maskz_getexp_ps(__mmask16 k, __m512 a);

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates floor(log2(x)) for each element.
Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for each element.

\texttt{\_mm512\_getexp\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl \_mm512\_getexp\_round\_ps(__m512 a, int round);
\end{verbatim}

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result. This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for each element.

\texttt{\_mm512\_mask\_getexp\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl \_mm512\_mask\_getexp\_round\_ps(__m512 src, __mmask16 k, __m512 a, int round);
\end{verbatim}

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set). This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for each element.

\texttt{\_mm512\_maskz\_getexp\_round\_ps}

\begin{verbatim}
extern __m512 __cdecl \_mm512\_maskz\_getexp\_round\_ps(__mmask16 k, __m512 a, int round);
\end{verbatim}

Converts the exponent of each packed float32 element in a to a float32 number representing the integer exponent, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for each element.

\texttt{\_mm\_getexp\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl \_mm\_getexp\_round\_sd(__m128d a, __m128d b, int round);
\end{verbatim}

Converts lower exponent of float64 element in b to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from a to upper destination element. This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for lower element.

\texttt{\_mm\_mask\_getexp\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl \_mm\_mask\_getexp\_round\_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int round);
\end{verbatim}

Converts lower exponent of float64 element in b to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from a to upper destination element. This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for lower element.

\texttt{\_mm\_maskz\_getexp\_round\_sd}

\begin{verbatim}
extern __m128d __cdecl \_mm\_maskz\_getexp\_round\_sd(__mmask8 k, __m128d a, __m128d b, int round);
\end{verbatim}

Converts lower exponent of float64 element in b to a float64 number representing the integer exponent, stores the result in lower destination element using writemask k (the element is copied from src when mask bit 0 is not set), and copies upper element from a to upper destination element. This intrinsic essentially calculates $\text{floor}(\log_2(x))$ for lower element.

\texttt{\_mm\_getexp\_sd}

\begin{verbatim}
extern __m128d __cdecl \_mm\_getexp\_sd(__m128d a, __m128d b);
\end{verbatim}
Converts lower exponent of float64 element in \( b \) to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from \( a \) to upper destination element. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_mask\_getexp\_sd}
\]

\[
\text{extern } \_\text{m128d } \_\text{cdecl } \_\text{mm\_mask\_getexp\_sd}(\_\text{m128d } \text{src}, \_\text{mmask8 } \text{k}, \_\text{m128d } \text{a}, \_\text{m128d } \text{b});
\]

Converts lower exponent of float64 element in \( b \) to a float64 number representing the integer exponent, stores the result in lower destination element using writemask \( k \) (the element is copied from \( \text{src} \) when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_maskz\_getexp\_sd}
\]

\[
\text{extern } \_\text{m128d } \_\text{cdecl } \_\text{mm\_maskz\_getexp\_sd}(\_\text{mmask8 } \text{k}, \_\text{m128d } \text{a}, \_\text{m128d } \text{b});
\]

Converts lower exponent of float64 element in \( b \) to a float64 number representing the integer exponent, stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper element from \( a \) to upper destination element. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_getexp\_round\_ss}
\]

\[
\text{extern } \_\text{m128 } \_\text{cdecl } \_\text{mm\_getexp\_round\_ss}(\_\text{m128 } \text{a}, \_\text{m128 } \text{b}, \text{int } \text{round});
\]

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element, and copies upper three packed elements from \( a \) to upper destination elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_mask\_getexp\_round\_ss}
\]

\[
\text{extern } \_\text{m128 } \_\text{cdecl } \_\text{mm\_mask\_getexp\_round\_ss}(\_\text{m128 src}, \_\text{mmask8 k}, \_\text{m128 a}, \_\text{m128 b}, \text{int } \text{round});
\]

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element using writemask \( k \) (the element is copied from \( \text{src} \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_maskz\_getexp\_round\_ss}
\]

\[
\text{extern } \_\text{m128 } \_\text{cdecl } \_\text{mm\_maskz\_getexp\_round\_ss}(\_\text{mmask8 k}, \_\text{m128 a}, \_\text{m128 b}, \text{int } \text{round});
\]

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

\[
\_\text{mm\_getexp\_ss}
\]

\[
\text{extern } \_\text{m128 } \_\text{cdecl } \_\text{mm\_getexp\_ss}(\_\text{m128 a}, \_\text{m128 b});
\]

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element, and copies upper three packed elements from \( a \) to upper destination elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.
**_mm_mask_getexp_ss**

Extern __m128 __cdecl _mm_mask_getexp_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

**_mm_maskz_getexp_ss**

Extern __m128 __cdecl _mm_maskz_getexp_ss(__mmask8 k, __m128 a, __m128 b);

Converts lower exponent of float32 element in \( b \) to a float32 number representing the integer exponent, stores the result in lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from \( a \) to upper destination elements. This intrinsic essentially calculates \( \text{floor}(\log_2(x)) \) for lower element.

**Intrinsics for Miscellaneous Integer Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file. To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm512_alignr_epi32, _mm512_mask_alignr_epi32, _mm512_maskz_alignr_epi32</td>
<td>Aligns elements of two source vectors depending on bits in a mask.</td>
<td>VALIGND</td>
</tr>
<tr>
<td>_mm512_alignr_epi64, _mm512_mask_alignr_epi64, _mm512_maskz_alignr_epi64</td>
<td>Aligns elements of two source vectors depending on bits in a mask.</td>
<td>VALIGNQ</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>( k )</td>
<td>writemask used as a selector</td>

</tbody>
</table>

**_mm512_mask_mov_pd**

```c
extern __m512 __cdecl _mm512_mask_mov_pd(__m512 src, __mmask8 k, __m512 a);
```

Moves packed float64 elements from *a* using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

**_mm512_maskz_mov_pd**

```c
extern __m512 __cdecl _mm512_maskz_mov_pd(__mmask8 k, __m512 a);
```

Moves packed float64 elements from *a* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_mov_ps**

```c
extern __m512 __cdecl _mm512_mask_mov_ps(__m512 src, __mmask16 k, __m512 a);
```

Moves packed float32 elements from *a* using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).
_mm512_maskz_mov_ps
extern __m512 __cdecl _mm512_maskz_mov_ps(__mmask16 k, __m512 a);
Moves packed float32 elements from \( a \) using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__m512_movedup_pd
extern __m512d __cdecl _mm512_movedup_pd(__m512d a);
Duplicates even-indexed float64 elements from \( a \), and stores the result.

__mm512_mask_movedup_pd
extern __m512d __cdecl _mm512_mask_movedup_pd(__m512d src, __mmask8 k, __m512d a);
Duplicates even-indexed float64 elements from \( a \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_maskz_movedup_pd
extern __m512d __cdecl _mm512_maskz_movedup_pd(__mmask8 k, __m512d a);
Duplicates even-indexed float64 elements from \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_move_sd
extern __m128d __cdecl _mm_mask_move_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
Moves lower float64 element from \( b \) to lower destination element using writemask \( k \) (the element is copied from \( src \) when mask bit 0 is not set), and copy upper element from \( a \) to upper destination element.

__mm_maskz_move_sd
extern __m128d __cdecl _mm_maskz_move_sd(__mmask8 k, __m128d a, __m128d b);
Moves lower float64 element from \( b \) to lower destination element using zeromask \( k \) (the element is zeroed out when mask bit 0 is not set), and copy upper element from \( a \) to upper destination element.

__mm512_movehdup_ps
extern __m512 __cdecl _mm512_movehdup_ps(__m512 a);
Duplicates odd-indexed float32 elements from \( a \), and stores the result.

__mm512_mask_movehdup_ps
extern __m512 __cdecl _mm512_mask_movehdup_ps(__m512 src, __mmask16 k, __m512 a);
Duplicates odd-indexed float32 elements from \( a \), and store the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm512_maskz_movehdup_ps
extern __m512 __cdecl _mm512_maskz_movehdup_ps(__mmask16 k, __m512 a);
Duplicates odd-indexed float32 elements from \( a \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
_mm512_moveldup_ps
extern __m512 __cdecl _mm512_moveldup_ps(__m512 a);
Duplicates even-indexed float32 elements from $a$, and stores the result.

__mm512_mask_moveldup_ps
extern __m512 __cdecl __m512_mask_moveldup_ps(__m512 src, __mmask16 k, __m512 a);
Duplicates even-indexed float32 elements from $a$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

__mm512_maskz_moveldup_ps
extern __m512 __cdecl __m512_maskz_moveldup_ps(__mmask16 k, __m512 a);
Duplicates even-indexed float32 elements from $a$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_move_ss
extern __m128 __cdecl __m128_mask_move_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
Moves lower float32 element from $b$ to lower destination element using writemask $k$ (the element is copied from $src$ when mask bit 0 is not set), and copies upper three packed elements from $a$ to upper destination elements.

__mm_maskz_move_ss
extern __m128 __cdecl __m128_maskz_move_ss(__mmask8 k, __m128 a, __m128 b);
Moves lower float32 element from $b$ to lower destination element using zeromask $k$ (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from $a$ to upper destination elements.

**Intrinsics for Integer Move Operations**
The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:
```
#include <immintrin.h>

</tbody>
</table>

`_mm512_unpackhi_pd`

extern __m512d __cdecl _mm512_unpackhi_pd(__m512d a, __m512d b);

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in a and b, and stores the result.

`_mm512_mask_unpackhi_pd`

extern __m512d __cdecl _mm512_mask_unpackhi_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

`_mm512_maskz_unpackhi_pd`

extern __m512d __cdecl _mm512_maskz_unpackhi_pd(__mmask8 k, __m512d a, __m512d b);

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

`_mm512_unpackhi_ps`

extern __m512 __cdecl _mm512_unpackhi_ps(__m512 a, __m512 b);

Unpacks and interleaves float32 elements from the high half of each 128-bit lane in a and b, and stores the result.

`_mm512_mask_unpackhi_ps`

extern __m512 __cdecl _mm512_mask_unpackhi_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);

Unpacks and interleaves float32 elements from the high half of each 128-bit lane in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
Intrinsics for Integer Pack and Unpack Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the \texttt{zmmintrin.h} header file.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

\begin{verbatim}
#include <immintrin.h>
\end{verbatim}
<table>
<thead>
<tr>

</tbody>
</table>

_\_mm512\_unpackhi\_epi32_

extern __m512i __cdecl _mm512_unpackhi_epi32(__m512i a, __m512i b);

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in \( a \) and \( b \), and stores the result.

_\_mm512\_mask\_unpackhi\_epi32_

extern __m512i __cdecl _mm512_mask_unpackhi_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in \( a \) and \( b \), and stores the result using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

_\_mm512\_maskkz\_unpackhi\_epi32_

extern __m512i __cdecl _mm512_maskz_unpackhi_epi32(__mmask16 k, __m512i a, __m512i b);

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in \( a \) and \( b \), and stores the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
_mm512_unpackhi_epi64
extern __m512i __cdecl _mm512_unpackhi_epi64(__m512i a, __m512i b);
Unpacks and interleaves int64 elements from the high half of each 128-bit lane in a and b, and stores the result.

__m512_mask_unpackhi_epi64
extern __m512i __cdecl _mm512_mask_unpackhi_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
Unpacks and interleaves int64 elements from the high half of each 128-bit lane in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m512_maskz_unpackhi_epi64
extern __m512i __cdecl _mm512_maskz_unpackhi_epi64(__mmask8 k, __m512i a, __m512i b);
Unpacks and interleaves int64 elements from the high half of each 128-bit lane in a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__m512_unpacklo_epi32
extern __m512i __cdecl _mm512_unpacklo_epi32(__m512i a, __m512i b);
Unpacks and interleaves int32 elements from the low half of each 128-bit lane in a and b, and stores the result.

__m512_mask_unpacklo_epi32
extern __m512i __cdecl _mm512_mask_unpacklo_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
Unpacks and interleaves int32 elements from the low half of each 128-bit lane in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m512_maskz_unpacklo_epi32
extern __m512i __cdecl _mm512_maskz_unpacklo_epi32(__mmask16 k, __m512i a, __m512i b);
Unpacks and interleaves int32 elements from the low half of each 128-bit lane in a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__m512_unpacklo_epi64
extern __m512i __cdecl _mm512_unpacklo_epi64(__m512i a, __m512i b);
Unpacks and interleaves int64 elements from the low half of each 128-bit lane in a and b, and stores the result.

__m512_mask_unpacklo_epi64
extern __m512i __cdecl _mm512_mask_unpacklo_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
Unpacks and interleaves int64 elements from the low half of each 128-bit lane in a and b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m512_maskz_unpacklo_epi64
extern __m512i __cdecl _mm512_maskz_unpacklo_epi64(__mmask8 k, __m512i a, __m512i b);
Unpacks and interleaves int64 elements from the low half of each 128-bit lane in a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
**Intrinsics for Permutation Operations**

**Intrinsics for FP Permutation Operations**

</table>

_mm512_permutex2var_pd

extern __m512d _cdecl _mm512_permutex2var_pd(__m512d a, __m512i idx, __m512d b);

Shuffles float64 elements in a and b across lanes using the corresponding selector and index in idx, and stores the result.

_mm512_mask_permutex2var_pd

extern __m512d _cdecl _mm512_mask_permutex2var_pd(__m512d a, __mmask8 k, __m512i idx, __m512d b);

Shuffles float64 elements in a and b across lanes using the corresponding selector and index in idx, and stores the result using writemask k (elements are copied from a when the corresponding mask bit is not set).

_mm512_mask2_permutex2var_pd

extern __m512d _cdecl _mm512_mask2_permutex2var_pd(__m512d a, __m512i idx, __mmask8 k, __m512d b);

Shuffles float64 elements in a and b across lanes using the corresponding selector and index in idx, and stores the results using writemask k (elements are copied from idx when the corresponding mask bit is not set).

_mm512_maskz_permutex2var_pd

extern __m512d _cdecl _mm512_maskz_permutex2var_pd(__mmask8 k, __m512d a, __m512i idx, __m512d b);

Shuffles float64 elements in a and b across lanes using the corresponding selector and index in idx, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex2var_ps

extern __m512d _cdecl _mm512_permutex2var_ps(__m512 d a, __m512i idx, __m512 d b);
Shuffles float32 elements in $a$ and $b$ across lanes using the corresponding selector and index in $idx$, and stores the result.

\_\_mm512\_mask\_permute2var\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_mask\_permute2var\_ps(\_m512 a, \_mmask16 k, \_m512i idx, \_m512 b);}\
Shuffles float32 elements in $a$ and $b$ across lanes using the corresponding selector and index in $idx$, and stores the result using writemask $k$ (elements are copied from $idx$ when the corresponding mask bit is not set).

\_\_mm512\_mask\_permute2var\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_mask\_permute2var\_ps(\_m512 a, \_m512i idx, \_mmask16 k, \_m512 b);}\
Shuffles float32 elements in $a$ and $b$ across lanes using the corresponding selector and index in $idx$, and stores the result using writemask $k$ (elements are copied from $a$ when the corresponding mask bit is not set).

\_\_mm512\_maskz\_permute2var\_ps

\texttt{extern \_m512 \_cdecl \_mm512\_maskz\_permute2var\_ps(\_mmask16 k, \_m512 a, \_m512i idx, \_m512 b);}\
Shuffles float32 elements in $a$ and $b$ across lanes using the corresponding selector and index in $idx$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_permute\_pd

\texttt{extern \_m512d \_cdecl \_mm512\_permute\_pd(\_m512d a, const int imm);}\
Shuffles float64 elements in $a$ within 128-bit lanes using the control in $imm$, and stores the result.

\_\_mm512\_mask\_permute\_pd

\texttt{extern \_m512d \_cdecl \_mm512\_mask\_permute\_pd(\_m512d src, \_mmask8 k, \_m512d a, const int imm);}\
Shuffles float64 elements in $a$ within 128-bit lanes using the control in $imm$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

\_\_mm512\_maskz\_permute\_pd

\texttt{extern \_m512d \_cdecl \_mm512\_maskz\_permute\_pd(\_mmask8 k, \_m512d a, const int imm);}\
Shuffles float64 elements in $a$ within 128-bit lanes using the control in $imm$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm512\_permutevar\_pd

\texttt{extern \_m512d \_cdecl \_mm512\_permutevar\_pd(\_m512d a, \_m512i b);}\
Shuffles float64 elements in $a$ within 128-bit lanes using the control in $b$, and stores the result.

\_\_mm512\_mask\_permutevar\_pd

\texttt{extern \_m512d \_cdecl \_mm512\_mask\_permutevar\_pd(\_m512d src, \_mmask8 k, \_m512d a, \_m512i b);}\
Shuffles float64 elements in $a$ within 128-bit lanes using the control in $b$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).
_mm512_maskz_permutevar_pd
extern __m512d __cdecl _mm512_maskz_permutevar_pd(__m5ask8 k, __m512d a, __m512i b);
Shuffles float64 elements in a within 128-bit lanes using the control in b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permute_ps
extern __m512 __cdecl _mm512_permute_ps(__m512 a, const int imm);
Shuffles float32 elements in a within 128-bit lanes using the control in imm, and stores the result.

_mm512_mask_permute_ps
extern __m512 __cdecl _mm512_mask_permute_ps(__m512 src, __mmask16 k, __m512 a, const int imm);
Shuffles float32 elements in a within 128-bit lanes using the control in imm, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_permute_ps
extern __m512 __cdecl _mm512_maskz_permute_ps(__mmask16 k, __m512 a, const int imm);
Shuffles float32 elements in a within 128-bit lanes using the control in imm, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutevar_ps
extern __m512 __cdecl _mm512_permutevar_ps(__m512 a, __m512i b);
Shuffles float32 elements in a within 128-bit lanes using the control in b, and stores the result.

_mm512_mask_permutevar_ps
extern __m512 __cdecl _mm512_mask_permutevar_ps(__m512 src, __mmask16 k, __m512 a, __m512i b);
Shuffles float32 elements in a within 128-bit lanes using the control in b, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_permutevar_ps
extern __m512 __cdecl _mm512_maskz_permutevar_ps(__mmask16 k, __m512 a, __m512i b);
Shuffles float32 elements in a within 128-bit lanes using the control in b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex_pd
extern __m512d __cdecl _mm512_permutex_pd(__m512d a, const int imm);
Shuffles float64 elements in a within 256-bit lanes using the control in imm, and stores the result.

_mm512_mask_permutex_pd
extern __m512d __cdecl _mm512_mask_permutex_pd(__m512d src, __mmask8 k, __m512d a, const int imm);
Shuffles float64 elements in a within 256-bit lanes using the control in imm, and stores the result using writemask k (elements are copied from src when the corresponding mask bit is not set).
Intrinsics for Integer Permutation Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```c

</table>

_mm512_permutevar_epi32

```c
extern __m512i __cdecl _mm512_permutevar_epi32(__m512i a, __m512i idx);
```

Shuffle int32 elements in $a$ across lanes using the corresponding index in $idx$, and stores the result.
NOTE
This intrinsic shuffles across 128-bit lanes, unlike past intrinsics that use the `permutevar` name. This intrinsic is identical to `_mm512_mask_permutexvar_epi32`, and it is recommended that you use that intrinsic name.

```cpp
extern __m512i __cdecl _mm512_mask_permutevar_epi32(__m512i src, __mmask16 k, __m512i a, __m512i idx);
```

Shuffle int32 elements in `a` across lanes using the corresponding index in `idx`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

NOTE
This intrinsic shuffles across 128-bit lanes, unlike past intrinsics that use the `permutevar` name. This intrinsic is identical to `_mm512_mask_permutexvar_epi32`, and it is recommended that you use that intrinsic name.

```cpp
extern __m512i __cdecl _mm512_permutevar_epi32(__m512i idx, __m512i a);
```

Shuffles int32 elements in `a` across lanes using the corresponding index in `idx`, and stores the result.

```cpp
extern __m512i __cdecl _mm512_mask_permutevar_epi32(__m512i src, __mmask16 k, __m512i idx, __m512i a);
```

Shuffles int32 elements in `a` across lanes using the corresponding index in `idx`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```cpp
extern __m512i __cdecl _mm512_maskz_permutevar_epi32(__mmask16 k, __m512i idx, __m512i a);
```

Shuffles int32 elements in `a` across lanes using the corresponding index in `idx`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```cpp
extern __m512i __cdecl _mm512_permutex2var_epi32(__m512i a, __m512i idx, __m512i b);
```

Shuffles int32 elements in `a` and `b` across lanes using the corresponding selector and index in `idx`, and stores the result.

```cpp
extern __m512i __cdecl _mm512_mask_permutex2var_epi32(__m512i a, __mmask16 k, __m512i idx, __m512i b);
```

Shuffles int32 elements in `a` and `b` across lanes using the corresponding selector and index in `idx`, and stores the result using writemask `k` (elements are copied from `a` when the corresponding mask bit is not set).
__m512_mask2_permutex2var_epi32

extern _m512i __cdecl _mm512_mask2_permutex2var_epi32(__m512i a, __m512i idx, __mmask16 k, 
__m512i b);

Shuffles int32 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result using writemask \(k\) (elements are copied from \(idx\) when the corresponding mask bit is not set).

__m512_maskz_permutex2var_epi32

extern _m512i __cdecl _mm512_maskz_permutex2var_epi32(__mmask16 k, __m512i a, __m512i idx, 
__m512i b);

Shuffles int32 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__m512_permutex2var_epi64

extern _m512i __cdecl _mm512_permutex2var_epi64(__m512i a, __m512i idx, __m512i b);

Shuffles int64 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result.

__m512_mask_permutex2var_epi64

extern _m512i __cdecl _mm512_mask_permutex2var_epi64(__m512i a, __mmask8 k, __m512i idx, 
__m512i b);

Shuffles int64 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

__m512_mask2_permutex2var_epi64

extern _m512i __cdecl _mm512_mask2_permutex2var_epi64(__m512i a, __m512i idx, __mmask8 k, 
__m512i b);

Shuffles int64 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result using writemask \(k\) (elements are copied from \(idx\) when the corresponding mask bit is not set).

__m512_maskz_permutex2var_epi64

extern _m512i __cdecl _mm512_maskz_permutex2var_epi64(__mmask8 k, __m512i a, __m512i idx, 
__m512i b);

Shuffles int64 elements in \(a\) and \(b\) across lanes using the corresponding selector and index in \(idx\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__m512_permutex_epi64

extern _m512i __cdecl _mm512_permutex_epi64(__m512i a, const int imm);

Shuffles int64 elements in \(a\) within 256-bit lanes using the control in \(imm\), and stores the result.

__m512_mask_permutex_epi64

extern _m512i __cdecl _mm512_mask_permutex_epi64(__m512i src, __mmask8 k, __m512i a, const int 
imm);

Shuffles int64 elements in \(a\) within 256-bit lanes using the control in \(imm\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
**mm512_maskz_permutex_epi64**

```c
extern __m512i __cdecl _mm512_maskz_permutex_epi64(__mmask8 k, __m512i a, const int imm);
```

Shuffles int64 elements in `a` within 256-bit lanes using the control in `imm`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**mm512_permutexvar_epi64**

```c
extern __m512i __cdecl _mm512_permutexvar_epi64(__m512i a, __m512i idx);
```

Shuffles int64 elements in `a` across lanes using the corresponding index `idx`, and stores the result.

**mm512_mask_permutexvar_epi64**

```c
extern __m512i __cdecl _mm512_mask_permutexvar_epi64(__m512i src, __mmask8 k, __m512i a, __m512i idx);
```

Shuffles int64 elements in `a` across lanes using the corresponding index `idx`, and stores the result using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**mm512_maskz_permutexvar_epi64**

```c
extern __m512i __cdecl _mm512_maskz_permutexvar_epi64(__mmask8 k, __m512i a, __m512i idx);
```

Shuffles int64 elements in `a` across lanes using the corresponding index `idx`, and stores the result using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### Intrinsics for Reduction Operations

#### Intrinsics for FP Reduction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® AVX-512 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm512_reduce_add_pd, _mm512_mask_reduce_add_pd</td>
<td>Reduce float64 elements by addition.</td>
<td>None.</td>
</tr>
<tr>
<td>_mm512_reduce_add_ps, _mm512_mask_reduce_add_ps</td>
<td>Reduce float32 elements by addition.</td>
<td>None.</td>
</tr>
<tr>
<td>_mm512_reduce_max_pd, _mm512_mask_reduce_max_pd</td>
<td>Reduce float64 elements by maximum.</td>
<td>None.</td>
</tr>
<tr>
<td>_mm512_reduce_max_ps, _mm512_mask_reduce_max_ps</td>
<td>Reduce float32 elements by maximum.</td>
<td>None.</td>
</tr>
<tr>
<td>_mm512_reduce_min_pd, _mm512_mask_reduce_min_pd</td>
<td>Reduce float64 elements by minimum.</td>
<td>None.</td>
</tr>
<tr>

</tbody>
</table>

`_mm512_reduce_add_pd`

```c
extern double __cdecl _mm512_reduce_add_pd(__m512d a);
```

Reduces packed float64 elements in `a` by addition.
Returns the sum of all elements in `a`.

`_mm512_mask_reduce_add_pd`

```c
extern double __cdecl _mm512_mask_reduce_add_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in `a` by addition using writemask `k`.
Returns the sum of all active elements in `a`.

`_mm512_reduce_add_ps`

```c
extern float __cdecl _mm512_reduce_add_ps(__m512 a);
```

Reduces packed float32 elements in `a` by addition.
Returns the sum of all elements in `a`.

`_mm512_mask_reduce_add_ps`

```c
extern float __cdecl _mm512_mask_reduce_add_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in `a` by addition using writemask `k`.
Returns the sum of all active elements in `a`.

`_mm512_reduce_max_pd`

```c
extern double __cdecl _mm512_reduce_max_pd(__m512d a);
```

Reduces packed float64 elements in `a` by maximum.
Returns the maximum of all elements in `a`.

1374
_mm512_mask_reduce_max_pd
extern double __cdecl _mm512_mask_reduce_max_pd(__mmask8 k, __m512d a);
Reduces packed float64 elements in a by maximum, using writemask k.
Returns the maximum of all active elements in a.

_mm512_reduce_max_ps
extern float __cdecl _mm512_reduce_max_ps(__m512 a);
Reduces packed float32 elements in a by maximum.
Returns the maximum of all elements in a.

_mm512_mask_reduce_max_ps
extern float __cdecl _mm512_mask_reduce_max_ps(__mmask16 k, __m512 a);
Reduces packed float32 elements in a by maximum, using writemask k.
Returns the maximum of all active elements in a.

_mm512_reduce_min_pd
extern double __cdecl _mm512_reduce_min_pd(__m512d a);
Reduces packed float64 elements in a by minimum.
Returns the minimum of all elements in a.

_mm512_mask_reduce_min_pd
extern double __cdecl _mm512_mask_reduce_min_pd(__mmask8 k, __m512d a);
Reduces packed float64 elements in a by minimum, using writemask k.
Returns the minimum of all active elements in a.

_mm512_reduce_min_ps
extern float __cdecl _mm512_reduce_min_ps(__m512 a);
Reduces packed float32 elements in a by minimum.
Returns the minimum of all elements in a.

_mm512_mask_reduce_min_ps
extern float __cdecl _mm512_mask_reduce_min_ps(__mmask16 k, __m512 a);
Reduces packed float32 elements in a by minimum, using writemask k.
Returns the minimum of all active elements in a.

_mm512_reduce_mul_pd
extern double __cdecl _mm512_reduce_mul_pd(__m512d a);
Reduces packed float64 elements in a by multiplication.
Returns the product of all elements in a.
### _mm512_mask_reduce_mul_pd

```c
extern double __cdecl __m512_mask_reduce_mul_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in `a` by multiplication, using writemask `k`.
Returns the product of all active elements in `a`.

### _mm512_reduce_mul_ps

```c
extern float __cdecl __m512_reduce_mul_ps(__m512 a);
```

Reduces packed float32 elements in `a` by multiplication.
Returns the product of all elements in `a`.

### _mm512_mask_reduce_mul_ps

```c
extern float __cdecl __m512_mask_reduce_mul_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in `a` by multiplication, using writemask `k`.
Returns the product of all active elements in `a`.

### _mm512_reduce_and_epi32

```c
extern int __cdecl _mm512_reduce_and_epi32(__m512i a);
```

Reduces the packed int32 elements in `a` by bitwise AND.

Returns the bitwise AND of all elements in `a`.

### _mm512_mask_reduce_and_epi32

```c
extern int __cdecl _mm512_mask_reduce_and_epi32(__mmask16 k, __m512i a);
```

Reduces the packed int32 elements in `a` by bitwise AND using mask `k`.

Returns the bitwise AND of all active elements in `a`.

### _mm512_reduce_and_epi64

```c
extern __int64 __cdecl _mm512_reduce_and_epi64(__m512i a);
```

Reduces the packed int64 elements in `a` by bitwise AND.

Returns the bitwise AND of all elements in `a`. 1377
Reduces the packed int64 elements in \( a \) by bitwise AND using mask \( k \).

Only those elements in the source registers with the corresponding bit set in vector mask \( k \) are used for computing. Elements in \( a \) with corresponding bit clear in \( k \) are copied as is to the resulting vector.

Returns the bitwise AND of all active elements in \( a \).

Reduces the packed int32 elements in \( a \) by addition.

Returns the sum of all elements in \( a \).

Reduces the packed int32 elements in \( a \) by addition using mask \( k \).

Returns the sum of all active elements in \( a \).

Reduces the packed int64 elements in \( a \) by addition.

Returns the sum of all elements in \( a \).

Reduce the packed int64 elements in \( a \) by addition, using mask \( k \).

Only those elements in the source registers with the corresponding bit set in vector mask \( k \) are used for computing. Elements in \( a \) with corresponding bit clear in \( k \) are copied as is to the resulting vector.

Returns the sum of all active elements in \( a \).

Reduce the packed int32 elements in \( a \) by maximum.

Returns the maximum of all elements in \( a \).

Reduce the packed int32 elements in \( a \) by maximum using mask \( k \).

Returns the maximum of all active elements in \( a \).

Reduce the packed int64 elements in \( a \) by maximum.
Reduce the packed int64 elements in \( a \) by maximum.

Returns the maximum of all elements in \( a \).

**__mm512_mask_reduce_max_epi64**

\[
\text{extern } \_\text{int64 } \_\text{cdecl } \text{mm512_mask_reduce_max_epi64(}\_\text{mmask8 } k, \_\text{m512i } a);\\
\]

Reduce the packed int64 elements in \( a \) by maximum using mask \( k \).

Only those elements in the source registers with the corresponding bit set in vector mask \( k \) are used for computing. Elements in \( a \) with corresponding bit clear in \( k \) are copied as is to the resulting vector.

Returns the maximum of all active elements in \( a \).

\[
\text{extern int } \_\text{cdecl } \text{mm512_reduce_min_epi32(}\_\text{m512i } a);\\
\]

Reduce the packed int32 elements in \( a \) by minimum.

Returns the minimum of all elements in \( a \).

**__mm512_mask_reduce_min_epi32**

\[
\text{extern int } \_\text{cdecl } \text{mm512_mask_reduce_min_epi32(}\_\text{mmask16 } k, \_\text{m512i } a);\\
\]

Reduce the packed int32 elements in \( a \) by maximum using mask \( k \).

Returns the minimum of all active elements in \( a \).
_mm512_reduce_min_epi64

extern __int64 __cdecl _mm512_reduce_min_epi64(__m512i a);

Reduce the packed int64 elements in a by minimum.
Returns the minimum of all elements in a.

_mm512_mask_reduce_min_epi64

extern __int64 __cdecl _mm512_mask_reduce_min_epi64(__mmask8 k, __m512i a);

Reduce the packed int64 elements in a by maximum, using mask k.
Only those elements in the source registers with the corresponding bit set in vector mask k are used for computing. Elements in a with corresponding bit clear in k are copied as is to the resulting vector.
Returns the minimum of all active elements in a.

_mm512_reduce_min_epu32

extern unsigned int __cdecl _mm512_reduce_min_epu32(__m512i a);

Reduce the packed unsigned int32 elements in a by minimum.
Returns the minimum of all elements in a.

_mm512_mask_reduce_min_epu32

extern unsigned int __cdecl _mm512_mask_reduce_min_epu32(__mmask16 k, __m512i a);

Reduce the packed unsigned int32 elements in a by maximum using mask k.
Returns the minimum of all active elements in a.

_mm512_reduce_min_epu64

extern unsigned __int64 __cdecl _mm512_reduce_min_epu64(__m512i a);

Reduce the packed unsigned int64 elements in a by minimum.
Returns the minimum of all elements in a.

_mm512_mask_reduce_min_epu64

extern unsigned __int64 __cdecl _mm512_mask_reduce_min_epu64(__mmask8 k, __m512i a);

Reduce the packed unsigned int64 elements in a by minimum using mask k.
Only those elements in the source registers with the corresponding bit set in vector mask k are used for computing. Elements in a with corresponding bit clear in k are copied as is to the resulting vector.
Returns the minimum of all active elements in a.

_mm512_reduce_mul_epi32

extern int __cdecl _mm512_reduce_mul_epi32(__m512i a);

Reduce the packed int32 elements in a by multiplication.
Returns the product of all elements in a.

_mm512_mask_reduce_mul_epi32

extern int __cdecl _mm512_mask_reduce_mul_epi32(__mmask16 k, __m512i a);
Reduce the packed int32 elements in \( a \) by multiplication using mask \( k \).
Returns the product of all active elements in \( a \).

\_mm512\_reduce\_mul\_epi64

\texttt{extern \_int64 \_cdecl \_mm512\_reduce\_mul\_epi64(__m512i a);}  
Reduce the packed int64 elements in \( a \) by multiplication.
Returns the product of all elements in \( a \).

\_mm512\_mask\_reduce\_mul\_epi64

\texttt{extern \_int64 \_cdecl \_mm512\_mask\_reduce\_mul\_epi64(__mmask8 k, __m512i a);}  
Reduce the packed int64 elements in \( a \) by multiplication using mask \( k \).
Only those elements in the source registers with the corresponding bit set in vector mask \( k \) are used for computing. Elements in \( a \) with corresponding bit clear in \( k \) are copied as is to the resulting vector.
Returns the product of all active elements in \( a \).

\_mm512\_reduce\_or\_epi32

\texttt{extern \ int \ _cdecl \_mm512\_reduce\_or\_epi32(__m512i a);}  
Reduce the packed int32 elements in \( a \) by bitwise OR.
Returns the bitwise OR of all elements in \( a \).

\_mm512\_mask\_reduce\_or\_epi32

\texttt{extern \ int \ _cdecl \_mm512\_mask\_reduce\_or\_epi32(__mmask16 k, __m512i a);}  
Reduce the packed int32 elements in \( a \) by bitwise OR using mask \( k \).
Returns the bitwise OR of all active elements in \( a \).

\_mm512\_reduce\_or\_epi64

\texttt{extern \ int \ _cdecl \_mm512\_reduce\_or\_epi64(__m512i a);}  
Reduce the packed int64 elements in \( a \) by bitwise OR.
Returns the bitwise OR of all elements in \( a \).

\_mm512\_mask\_reduce\_or\_epi64

\texttt{extern \ int \ _cdecl \_mm512\_mask\_reduce\_or\_epi64(__mmask8 k, __m512i a);}  
Reduce the packed int64 elements in \( a \) by bitwise OR using mask \( k \).
Only those elements in the source registers with the corresponding bit set in vector mask \( k \) are used for computing. Elements in \( a \) with corresponding bit clear in \( k \) are copied as is to the resulting vector.
Returns the bitwise OR of all active elements in \( a \).

\textbf{Intrinsics for Set Operations}

The prototypes for Intel\textsuperscript{®} Advanced Vector Extensions 512 (Intel\textsuperscript{®} AVX-512) intrinsics are located in the \texttt{zmmintrin.h} header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

__mm512_set1_pd__

```c
extern __m512d __cdecl _mm512_set1_pd(double a);
```
Broadcasts float64 value `a` to all destination elements.

__mm512_set1_ps__

```c
extern __m512 __cdecl _mm512_set1_ps(float a);
```
Broadcasts float32 value `a` to all destination elements.

__mm512_set4_pd__

```c
extern __m512d __cdecl _mm512_set4_pd(double d, double c, double b, double a);
```
Sets packed float64 elements in destination with the repeated four element sequence (dcba dcba).

__mm512_set4_ps__

```c
extern __m512 __cdecl _mm512_set4_ps(float d, float c, float b, float a);
```
Sets packed float32 elements in destination with the repeated four element sequence. (dcba dcba dcba dcba).

__mm512_set_pd__

```c
extern __m512 __cdecl _mm512_set_pd(float e7, float e6, float e5, float e4, float e3, float e2, float e1, float e0);
```
Sets packed float64 elements in destination with supplied values.

__mm512_set_ps__

```c
extern __m512 __cdecl _mm512_set_ps(float e15, float e14, float e13, float e12, float e11, float e10, float e9, float e8, float e7, float e6, float e5, float e4, float e3, float e2, float e1, float e0);
```
Sets packed float32 elements in destination with supplied values.
**_mm512_setr4_pd**

```c
extern __m512d __cdecl _mm512_setr4_pd(double a, double b, double c, double d);
```

Broadcast packed float64 elements in destination with the repeated four element sequence in reverse order.

**_mm512_setr4_ps**

```c
extern __m512 __cdecl _mm512_setr4_ps(float a, float b, float c, float d);
```

Sets packed float32 elements in destination with the repeated four element sequence in reverse order.

**_mm512_setr_pd**

```c
extern __m512d __cdecl _mm512_setr_pd(double e0, double e1, double e2, double e3, double e4,
 double e5, double e6, double e7);
```

Sets packed float64 elements in destination with supplied values in reverse order.

**_mm512_setr_ps**

```c
extern __m512 __cdecl _mm512_setr_ps(float e0, float e1, float e2, float e3, float e4,
 float e5, float e6, float e7, float e8, float e9, float e10, float e11, float e12, float e13, float e14,
 float e15);
```

Sets packed float32 elements in destination with supplied values in reverse order.

**_mm512_setzero_pd**

```c
extern __m512 __cdecl _mm512_setzero_pd(void);
```

Returns vector of type __m512d with all elements set to zero.

**_mm512_setzero_ps**

```c
extern __m512 __cdecl _mm512_setzero_ps(void);
```

Returns vector of type __m512 with all elements set to zero.

**_mm512_undefined_pd**

```c
extern __m512d __cdecl _mm512_undefined_pd(void)
```

Returns vector of type __m512d with undefined elements.

**_mm512_undefined_ps**

```c
extern __m512 __cdecl _mm512_undefined_ps(void)
```

Returns vector of type __m512 with undefined elements.

**_mm512_set1_epi16**

```c
extern __m512i __cdecl _mm512_set1_epi16(short a);
```

Broadcast int16 a to all destination elements.

**_mm512_set1_epi8**

```c
extern __m512i __cdecl _mm512_set1_epi8(char a);
```
Broadcasts int8 a to all destination elements.

_mm512_set1_epi32
extern __m512i __cdecl _mm512_set1_epi32(int a);
Broadcasts int32 a to all destination elements.

_mm512_mask_set1_epi32
extern __m512i __cdecl _mm512_mask_set1_epi32(__m512i src, __mmask16 k, int a);
Broadcasts int32 a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_set1_epi32
extern __m512i __cdecl _mm512_maskz_set1_epi32(__mmask16 k, int a);
Broadcasts int32 a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_set1_epi64
extern __m512i __cdecl _mm512_set1_epi64(__int64 a);
Broadcasts int64 a to all destination elements.

_mm512_mask_set1_epi64
extern __m512i __cdecl _mm512_mask_set1_epi64(__m512i src, __mmask8 k, __int64 a);
Broadcasts int64 a to all destination elements using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_set1_epi64
extern __m512i __cdecl _mm512_maskz_set1_epi64(__mmask8 k, __int64 a);
Broadcasts int64 a to all destination elements using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_set4_epi32
extern __m512i __cdecl _mm512_set4_epi32(int d, int c, int b, int a);
Sets packed int32 in destination with the repeated four element sequence.

_mm512_set4_epi64
extern __m512i __cdecl _mm512_set4_epi64(__int64 d, __int64 c, __int64 b, __int64 a);
Sets packed int64 in destination with the repeated four element sequence.
_mm512_set_epi32
extern __m512i __cdecl _mm512_set_epi32(int e15, int e14, int e13, int e12, int e11, int e10,
int e9, int e8, int e7, int e6, int e5, int e4, int e3, int e2, int e1, int e0);
Sets packed int32 in destination with supplied values.

__m512i __cdecl _mm512_set_epi64(__int64 e7, __int64 e6, __int64 e5, __int64 e4, __int64
e3, __int64 e2, __int64 e1, __int64 e0);
Sets packed int64 in destination with supplied values.

__m512_setr4_epi32
extern __m512i __cdecl _mm512_setr4_epi32(int a, int b, int c, int d);
Sets packed int32 in destination with the repeated four element sequence in reverse order.

__m512_setr4_epi64
extern __m512i __cdecl _mm512_setr4_epi64(__int64 a, __int64 b, __int64 c, __int64 d);
Sets packed int64 in destination with the repeated four element sequence in reverse order.

__m512_setr_epi32
extern __m512i __cdecl _mm512_setr_epi32(int a, int b, int c, int d);
Sets packed int32 in destination with supplied values in reverse order.

__m512_setr_epi64
extern __m512i __cdecl _mm512_setr_epi64(__int64 e0, __int64 e1, __int64 e2, __int64 e3, __int64
e4, __int64 e5, __int64 e6, __int64 e7);
Sets packed int64 in destination with supplied values in reverse order.

__m512_setzero_epi32
extern __m512 __cdecl _mm512_setzero(void);
Returns vector of type __m512i with all elements set to zero.

__m512_setzero_si512
extern __m512 __cdecl _mm512_setzero(void);
Returns vector of type __m512i with all elements set to zero.

__m512_undefined_epi32
extern __m512 __cdecl _mm512_undefined_epi32(void);
Returns vector of type __m512i with undefined elements.
_mm512_setzero
extern __m512 __cdecl _mm512_setzero(void);

Returns vector of type __m512 with all elements set to zero.

_mm512_undefined
extern __m512 __cdecl _mm512_undefined(void);

Returns vector of type __m512 with undefined elements.

Intrinsics for Shuffle Operations

Intrinsics for FP Shuffle Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

#include <immintrin.h>

<table>
<thead>
<tr>

</tbody>
</table>
__mm512_shuffle_f32x4

extern __m512 __cdecl _mm512_shuffle_f32x4(__m512 a, __m512 b, const int imm);

Shuffles four float32 elements from $a$ and $b$, selected by $imm$, and stores the result.

__mm512_mask_shuffle_f32x4

extern __m512 __cdecl _mm512_mask_shuffle_f32x4(__m512 src, __mmask16 k, __m512 a, __m512 b, const int imm);

Shuffles four float32 elements from $a$ and $b$, selected by $imm$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

__mm512_maskz_shuffle_f32x4

extern __m512 __cdecl _mm512_maskz_shuffle_f32x4(__mmask16 k, __m512 a, __m512 b, const int imm);

Shuffles four float32 elements from $a$ and $b$, selected by $imm$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

__mm512_shuffle_f64x2

extern __m512d __cdecl _mm512_shuffle_f64x2(__m512d a, __m512d b, const int imm);

Shuffles 128-bits (composed of two float64 elements from $a$ and $b$, selected by $imm$, and stores the result.

__mm512_mask_shuffle_f64x2

extern __m512d __cdecl _mm512_mask_shuffle_f64x2(__m512d src, __mmask8 k, __m512d a, __m512d b, const int imm);

Shuffles 128-bits (composed of two float64 elements from $a$ and $b$, selected by $imm$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

__mm512_maskz_shuffle_f64x2

extern __m512d __cdecl _mm512_maskz_shuffle_f64x2(__mmask8 k, __m512d a, __m512d b, const int imm);

Shuffles 128-bits (composed of two float64 elements from $a$ and $b$, selected by $imm$, and stores the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

__mm512_shuffle_pd

extern __m512d __cdecl _mm512_shuffle_pd(__m512d a, __m512d b, const int imm);

Shuffles float64 elements from vectors $a$ and $b$ within 128-bit lanes using the control in $imm$, and stores the result.

__mm512_mask_shuffle_pd

extern __m512d __cdecl _mm512_mask_shuffle_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, const int imm);

Shuffle float64 elements from vectors $a$ and $b$ within 128-bit lanes using the control in $imm$, and stores the result using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

__mm512_maskz_shuffle_pd

extern __m512d __cdecl _mm512_maskz_shuffle_pd(__mmask8 k, __m512d a, __m512d b, const int imm);
Shuffle float64 elements from vectors \(a\) and \(b\) within 128-bit lanes using the control in \(imm\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm512\_shuffle\_ps}
\]

\[
\text{extern } \_\text{m512 } \_\text{cdecl } \_\text{mm512\_shuffle\_ps}(\_\text{m512 } a, \_\text{m512 } b, \text{const int } imm);
\]

Shuffles float32 elements from vectors \(a\) and \(b\) within 128-bit lanes using the control in \(imm\), and stores the result.

\[
\text{\_mm512\_mask\_shuffle\_ps}
\]

\[
\text{extern } \_\text{m512 } \_\text{cdecl } \_\text{mm512\_mask\_shuffle\_ps}(\_\text{m512 } \text{src}, \_\text{mmask16 } k, \_\text{m512 } a, \_\text{m512 } b, \text{const int } imm);
\]

Shuffle float32 elements from vectors \(a\) and \(b\) within 128-bit lanes using the control in \(imm\), and stores the result using writemask \(k\).

Elements are copied from \(\text{src}\) when the corresponding mask bit is not set.

\[
\text{\_mm512\_maskz\_shuffle\_ps}
\]

\[
\text{extern } \_\text{m512 } \_\text{cdecl } \_\text{mm512\_maskz\_shuffle\_ps}(\_\text{mmask16 } k, \_\text{m512 } a, \_\text{m512 } b, \text{const int } imm);
\]

Shuffle float32 elements from vectors \(a\) and \(b\) within 128-bit lanes using the control in \(imm\), and stores the result using zeromask \(k\).

Elements are zeroed out when the corresponding mask bit is not set.

.extern __m512i cdecl __m512_maskz_shuffle_i32x4(__mmask16 k, __m512i a, __m512i b, _MM_PERM_ENUM imm);

Shuffles 128-bits (composed of four int32) selected by imm from a and b, and stores the result using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_shuffle_i64x2
.extern _m512i cdecl _m512_shuffle_i64x2(__m512i a, __m512i b, _MM_PERM_ENUM imm);

Shuffles 128-bits (composed of two int64) selected by imm from a and b, and stores the result.

__mm512_mask_shuffle_i64x2
.extern _m512i cdecl _m512_mask_shuffle_i64x2(__m512i src, __mmask8 k, __m512i b, _MM_PERM_ENUM imm);

Shuffles 128-bits (composed of two int64) selected by imm from a and b, and stores the result.
Shuffles 128-bits (composed of two int64) selected by \(imm\) from \(a\) and \(b\), and stores the result using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm512}} \_\text{maskz} \_\text{shuffle} \_i64x2
\]

\[
\text{extern} \_\text{m512i} \_\text{cdecl} \_\text{mm512} \_\text{maskz} \_\text{shuffle} \_i64x2(\_\text{mmask8} \ k, \_\text{m512i} \ a, \_\text{m512i} \ b, \_\text{MM\_PERM\_ENUM} \ \text{imm});
\]

Shuffles 128-bits (composed of two int64) selected by \(imm\) from \(a\) and \(b\), and stores the result using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Test Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

_mm512_conflict_epi32
extern __m512i __cdecl _mm512_conflict_epi32(__m512i a);
Tests each 32-bit element of \( a \) for equality with all other elements in \( a \) closer to the least significant bit. Each element’s comparison forms a zero extended bit vector in the destination.

_mm512_mask_conflict_epi32
extern __m512i __cdecl _mm512_mask_conflict_epi32(__m512i src, __mmask16 k, __m512i a);
Tests each 32-bit element of \( a \) for equality with all other elements in \( a \) closer to the least significant bit using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set). Each element’s comparison forms a zero extended bit vector in the destination.

_mm512_maskz_conflict_epi32
extern __m512i __cdecl _mm512_maskz_conflict_epi32(__mmask16 k, __m512i a);
Tests each 32-bit element of \( a \) for equality with other elements in \( a \) closer to the least significant bit using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set). Each element’s comparison forms a zero extended bit vector in the destination.

_mm512_conflict_epi64
extern __m512i __cdecl _mm512_conflict_epi64(__m512i a);
Tests each 64-bit element of \( a \) for equality with other elements in \( a \) closer to the least significant bit. Each element’s comparison forms a zero extended bit vector in the destination.

_mm512_mask_conflict_epi64
extern __m512i __cdecl _mm512_mask_conflict_epi64(__m512i src, __mmask8 k, __m512i a);
Tests each 64-bit element of \( a \) for equality with other elements in \( a \) closer to the least significant bit using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set). Each element’s comparison forms a zero extended bit vector in the destination.

_mm512_maskz_conflict_epi64
extern __m512i __cdecl _mm512_maskz_conflict_epi64(__mmask8 k, __m512i a);
Tests each 64-bit element of \( a \) for equality with other elements in \( a \) closer to the least significant bit using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set). Each element’s comparison forms a zero extended bit vector in the destination.
_mm512_test_epi32_mask

extern __m512i __cdecl _mm512_test_epi32_mask(__m512i a, __m512i b);

Computes the bitwise **AND** of packed 32-bit integers in \(a\) and \(b\), producing intermediate 32-bit values, and sets the corresponding bit in result mask \(k\) if the intermediate value is non-zero.

_\_mm512_mask_test_epi32_mask

extern __mmask16 __cdecl _mm512_mask_test_epi32_mask(__m512i k, __m512i a, __m512i b);

Computes the bitwise **AND** of packed 32-bit integers in \(a\) and \(b\), producing intermediate 32-bit values, and sets the corresponding bit in result mask \(k\) (subject to writemask \(k\)) if the intermediate value is non-zero.

_\_mm512_test_epi64_mask

extern __m512i __cdecl _mm512_test_epi64_mask(__m512i a, __m512i b);

Computes the bitwise **AND** of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and sets the corresponding bit in result mask \(k\) if the intermediate value is non-zero.

_\_mm512_mask_test_epi64_mask

extern __mmask8 __cdecl _mm512_mask_test_epi64_mask(__mmask8 k, __m512i a, __m512i b);

Computes the bitwise **AND** of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and sets the corresponding bit in result mask \(k\) (subject to writemask \(k\)) if the intermediate value is non-zero.

_\_mm512_testn_epi32_mask

extern __m512i __cdecl _mm512_testn_epi32_mask(__m512i a, __m512i b);

Computes the bitwise **AND NOT** of packed 32-bit integers in \(a\) and \(b\), producing intermediate 32-bit values, and sets the corresponding bit in result mask \(k\) if the intermediate value is zero.

_\_mm512_mask_testn_epi32_mask

extern __mmask16 __cdecl _mm512_mask_testn_epi32_mask(__mmask16 k, __m512i a, __m512i b);

Computes the bitwise **AND NOT** of packed 32-bit integers in \(a\) and \(b\), producing intermediate 32-bit values, and sets the corresponding bit in result mask \(k\) (subject to writemask \(k\)) if the intermediate value is zero.

_\_mm512_testn_epi64_mask

extern __m512i __cdecl _mm512_testn_epi64_mask(__m512i a, __m512i b);

Computes the bitwise **AND NOT** of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and sets the corresponding bit in result mask \(k\) if the intermediate value is zero.

_\_mm512_mask_testn_epi64_mask

extern __mmask8 __cdecl _mm512_mask_testn_epi64_mask(__mmask8 k, __m512i a, __m512i b);

Computes the bitwise **AND NOT** of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and sets the corresponding bit in result mask \(k\) (subject to writemask \(k\)) if the intermediate value is zero.
Intrinsics for Typecast Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file. To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

**NOTE**

These intrinsics are used for compilation and do not generate any instructions.

_mm512_kand

extern mmask16 cdecl _mm512_kand(_mmask16 a, _mmask16 b);

Computes the bitwise AND of 16-bit masks \( a \) and \( b \), and stores the result in \( k \).

_mm512_kandn

extern mmask16 cdecl _mm512_kandn(_mmask16 a, _mmask16 b);

Computes the bitwise AND NOT of 16-bit masks \( a \) and \( b \), and stores the result in \( k \).

_mm512_knot

extern mmask16 cdecl _mm512_knot(_mmask16 a);

Computes the bitwise NOT of 16-bit mask \( a \), and stores the result in \( k \).

_mm512_kor

extern mmask16 cdecl _mm512_kor(_mmask16 a, _mmask16 b);

Computes the bitwise OR of 16-bit masks \( a \) and \( b \), and stores the result in \( k \).

_mm512_kxnor

extern mmask16 cdecl _mm512_kxnor(_mmask16 a, _mmask16 b);

Computes the bitwise XNOR of 16-bit masks \( a \) and \( b \), and stores the result in \( k \).
Intrinsics for Later Generation Intel® Core™ Processor Instruction Extensions

Overview: Intrinsics for 3rd Generation Intel® Core™ Processor Instruction Extensions

The 3rd Generation Intel® Core™ Processor Instruction Extension intrinsics are assembly-coded functions that call on 3rd Generation Intel® Core™ Processor Instructions that include new vector SIMD and scalar instructions targeted for Intel® 64 architecture processors in process technology smaller than 32nm.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

These intrinsics map directly to the instructions defined in the "CHAPTER 9. ADDITIONAL NEW INSTRUCTIONS" section of "Intel® Advanced Vector Extensions Programming Reference" (http://software.intel.com/en-us/avx/).

Functional Overview

The 3rd Generation Intel® Core™ Processor Instruction Extensions include:

- Four intrinsics that map to two hardware instructions VCVTPS2PH and VCVTPH2PS performing 16-bit floating-point data type conversion to and from single-precision floating-point data type. The intrinsics for conversion to packed 16-bit floating-point values from packed single-precision floating-point values also provide rounding control using an immediate byte.
- Three intrinsics that map to the hardware instruction RDRAND. The intrinsics generate random numbers of 16/32/64 bit wide random integers.
- Eight intrinsics that map to the hardware instructions RDFSBASE, RDGSBASE, WRFSBASE, and WRGSBASE. The intrinsics allow software that works in the 64-bit environment to read and write the FS base and GS base registers at all privileged levels.

Overview: Intrinsics for 4th Generation Intel® Core™ Processor Instruction Extensions

The 4th Generation Intel® Core™ Processor Instruction Extensions intrinsics are assembly-coded functions that call on 4th Generation Intel® Core™ Processor Instructions that include scalar instructions targeted for Intel® 64 architecture processors in process technology smaller than 32nm.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

These intrinsics map directly to the instructions defined in the "CHAPTER 9. ADDITIONAL NEW INSTRUCTIONS" section of "Intel® Advanced Vector Extensions Programming Reference" (http://software.intel.com/en-us/avx/).

**Functional Overview**

The 4th Generation Intel® Core™ Processor Instruction Extensions include:

- Four intrinsics that map to two hardware instructions `ADOX` and `ADCX` performing 32-bit or 64-bit arithmetic operations with flags.
- One intrinsic that maps to the hardware instruction, `PREFETCHW`. This intrinsic allows data to be to prefetched into the cache in anticipation of a write. This intrinsic can be found in the Cacheability Support Intrinsics section.
- Three intrinsics that map to the hardware instruction `RDSEED`. The intrinsics generate random numbers of 16/32/64 bit wide random integers.

**Intrinsics for Converting Half Floats that Map to 3rd Generation Intel® Core™ Processor Instructions**

There are four intrinsics for converting the half-float values.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

These intrinsics convert packed half-precision values starting from the first CPUs with the Intel® AVX instructions support that do not really have any special instructions performing FP16 conversions. Therefore, the intrinsics are lowered to runtime library function calls and map to 3rd Generation Intel® Core™ Processor instructions only when such a processor is specified as target CPU using the `-Qx<CPU>` option, where `<CPU>` is the name of a CPU with support of 3rd Generation Intel® Core™ Processor Instruction Extensions.

**See Also**

Intrinsics for Converting Half Floats

- `__m128 _mm_cvtph_ps(__m128i x, int imm);`

  **_mm_cvtph_ps()**
  
  Converts four half-precision (16-bit) floating point values to single-precision floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is `VCVTPH2PS`.

  **Syntax**

  ```c
  extern __m128 _mm_cvtph_ps(__m128i x, int imm);
  ```

  **Arguments**

  - `x` a vector containing four 16-bit FP values
  - `imm` a conversion control constant

  **Description**

  This intrinsic converts four half-precision (16-bit) floating point values to single-precision floating point values.
Returns
A vector containing four single-precision floating point elements.

_mm256_cvtph_ps()
Converts eight half-precision (16-bit) floating point values to single-precision floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is VCVTPH2PS.

Syntax
extern __m256 _mm256_cvtph_ps(__m128i x);

Arguments
x a vector containing eight 16-bit FP values

Description
This intrinsic converts eight half-precision (16-bit) floating point values to single-precision floating point values.

Returns
A vector containing eight single-precision floating point elements.

_mm_cvtps_ph()
Converts four single-precision floating point values to half-precision (16-bit) floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is VCVTPS2PH.

Syntax
extern __m128i _mm_cvtps_ph(__m128 x, int imm);

Arguments
x a vector containing four single-precision FP values
imm a conversion control constant

Description
This intrinsic converts four single-precision floating point values to half-precision (16-bit) floating point values.

Returns
A vector containing eight half-precision (16-bit) floating point elements.

_mm256_cvtps_ph()
Converts eight single-precision floating point values to half-precision (16-bit) floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is VCVTPS2PH.
Syntax

extern __m128i _mm_cvtps_ph(__m256 x, int imm);

Arguments

$X$  
a vector containing eight single-precision FP values

$Imm$  
a conversion control constant

Description

This intrinsic converts eight single-precision floating point values to half-precision (16-bit) floating point values.

Intrinsics that Generate Random Numbers of 16/32/64 Bit Wide Random Integers

To use these intrinsics, include the <immintrin.h> file as follows:

```c
#include <immintrin.h>
```

RDRAND

There are three intrinsics returning a hardware-generated random value.

These intrinsics are mapped to a single RDRAND instruction. The exception is the intrinsic `_rdrand64_step()`, which is mapped to two 32-bit RDRAND instructions and several shift and conditional jump/move instructions on 32-bit platforms.

RDSEED

There are three intrinsics returning a hardware-generated random value.

These intrinsics are mapped to a code-sequence based on the RDSEED instruction. The result code depends on the context in which the intrinsics were used and on the target OS.

_rdrand16_step(), _rdrand32_step(), _rdrand64_step()

Generate random numbers of 16/32/64 bit wide random integers. These intrinsics are mapped to the hardware instruction RDRAND.

Syntax

```c
extern int _rdrand16_step(unsigned short *random_val);
extern int _rdrand32_step(unsigned int *random_val);
extern int _rdrand64_step(unsigned __int64 *random_val);
```

Description

These intrinsics generate random numbers of 16/32/64 bit wide random integers. The generated random value is written to the given memory location and the success status is returned: '1' if the hardware returned a valid random value, and '0' otherwise.

Returns

1 : if the hardware returns a 16/32/64 random value.
0 : if the hardware does not return any random value.
Generates random numbers of 16/32/64 bit wide random integers. The corresponding 4th Generation Intel® Core™ instruction is RDSEED.

**Syntax**

```c
extern int _rdseed16_step(unsigned short *random_val);
extern int _rdseed32_step(unsigned int *random_val);
extern int _rdseed64_step(unsigned __int64 *random_val);
```

**Parameters**

*random_val Random value written to the given memory location

**Description**

These intrinsics generate random numbers of 16/32/64 bit wide random integers. These intrinsics are mapped to a code-sequence based on the RDSEED instruction. The result code depends on the context in which the intrinsics were used and on the target operating system.

**NOTE**
The _rdrand64_step() intrinsic can be used only on systems with the 64-bit registers support.

The generated random value is written to the given memory location and the success status is returned: '1' if the hardware returned a valid random value, and '0' otherwise.

**NOTE** The difference between RDSEED and RDRAND intrinsics is that RDSEED intrinsics meet the NIST SP 800-90B and NIST SP 800-90C standards, while the RDRAND meets the NIST SP 800-90A standard.

**Returns**

The generated random value is written to the given memory location and the success status is returned. Returns '1' if the hardware returns a random 16/32/64 bit value (success). Returns '0' otherwise (failure).

**Intrinsics for Multi-Precision Arithmetic**

**_addcarry_u32(), _addcarry_u64()**

Computes sum of two 32/64 bit wide unsigned integer values and a carry-in and returns the value of carry-out produced by the sum. The corresponding 4th Generation Intel® Core™ Processor extension instructions are ADCX and ADOX.

**Syntax**

```c
extern unsigned char _addcarry_u32(unsigned char c_in, unsigned int src1, unsigned int src2, unsigned int *sum_out);
extern unsigned char _addcarry_u64(unsigned char c_in, unsigned __int64 src1, unsigned __int64 src2, unsigned __int64 *sum_out);
```
Parameters

- **c_in**: Value used for determining carry-in value
- **src1**: 32/64 bit source integer
- **src2**: 32/64 bit source integer
- ***sum_out**: Pointer to memory location where result is stored

Description

The intrinsic computes sum of two 32/64 bit wide integer values, `src1` and `src2`, and a carry-in value. The carry-in value is considered '1' for any non-zero `c_in` input value or '0' otherwise. The sum is stored to a memory location referenced by `sum_out` argument:

\[ *\text{sum	extunderscore out} = \text{src1} + \text{src2} + (\text{c	extunderscore in} \neq 0 ? 1 : 0) \]

**NOTE**

This intrinsic does not perform validity checking of the memory address pointed to by `sum_out`, thus it cannot be used to find out if the sum produces carry-out without storing result of the sum.

Returns

Returns the value of the intrinsic is a carry-out value generated by sum. The sum result is stored into memory location pointed by `sum_out` argument.

_`_addcarryx_u32(), _`_addcarryx_u64()_

Computes sum of two 32/64 bit wide unsigned integer values and a carry-in and returns the value of carry-out produced by the sum. The corresponding 4th Generation Intel® Core™ Processor extension instructions are ADCX and ADOX.

Syntax

```
extern unsigned char _addcarryx_u32(unsigned char c_in, unsigned int src1, unsigned int src2, unsigned int *sum_out);
extern unsigned char _addcarryx_u64(unsigned char c_in, unsigned __int64 src1, unsigned __int64 src2, unsigned __int64 *sum_out);
```

Parameters

- **c_in**: Value used for determining carry-in value
- **src1**: 32/64 bit source integer
- **src2**: 32/64 bit source integer
- ***sum_out**: Pointer to memory location where result is stored

Description

Computes the sum of two 32/64 bit wide integer values (src1, src2) and a carry-in value. The carry-in value is considered '1' for any non-zero `c_in` input value, or '0' otherwise. The sum is stored to a memory location referenced by `sum_out` argument:

\[ *\text{sum	extunderscore out} = \text{src1} + \text{src2} + (\text{c	extunderscore in} \neq 0 ? 1 : 0) \]
NOTE
This intrinsic does not perform validity checking of the memory address pointed to by \textit{sum\_out}, thus it cannot be used to find out if the sum produces carry-out without storing result of the sum.

The intrinsic is translated to either \texttt{ADCX}/\texttt{ADOX} instruction, chosen by the compiler. By design, these instructions allow running of two interleaved add-with-carry instruction sequences in parallel via using \texttt{ADCX} and \texttt{ADOX} instructions for these sequences respectively.

Returns
Returns carry-out value generated by the sum. The sum result is stored into memory location pointed by \textit{sum\_out} argument.

\texttt{\_subborrow\_u32()}, \texttt{\_subborrow\_u64()}

Computes sum of 32/64 bit unsigned integer value with borrow-in value and then subtracts the result from a 32/64 bit unsigned integer value. The corresponding 4th Generation Intel\textsuperscript{®} Core\textsuperscript{™} Processor extension instruction is \texttt{V}.

Syntax
extern unsigned char \_subborrow\_u32(unsigned char \textit{b\_in}, unsigned int \textit{src1}, unsigned int \textit{src2}, unsigned int *\textit{diff\_out});
extern unsigned char \_subborrow\_u64(unsigned char \textit{b\_in}, unsigned \__int64 \textit{src1}, unsigned \__int64 \textit{src2}, unsigned \__int64 *\textit{diff\_out});

Parameters
\begin{itemize}
    \item \textit{b\_in} \hspace{1cm} \text{Borrow-in value for addition operation}
    \item \textit{src1} \hspace{1cm} \text{32/64 bit source integer for addition operation}
    \item \textit{src2} \hspace{1cm} \text{32/64 bit source integer for subtraction operation}
    \item *\textit{diff\_out} \hspace{1cm} \text{Pointer to memory location where result is stored}
\end{itemize}

Description
Computes the sum of a 32/64 bit wide unsigned integer value \textit{src2} and a borrow-in value \textit{b\_in} and then subtracts result of the sum from 32/64 bit wide unsigned integer value \textit{src1}. The borrow-in value is considered '1' for any non-zero \textit{b\_in} input value, or '0' otherwise. The difference is then stored to a memory location referenced by \textit{diff\_out} argument:

\begin{equation}
\text{*\textit{diff\_out} = \textit{src1} - (\textit{src2} + (\textit{b\_in} !=0 \ ? 1 : 0))}
\end{equation}

NOTE
This intrinsic does not perform validity checking of the memory address pointed to by \textit{diff\_out}, thus it cannot be used to find out if a subtraction produces borrow-out without storing the result of the subtraction.

Returns
Returns borrow-out value generated by subtraction operation. The result of the subtraction is stored into memory location pointed by \textit{diff\_out} argument.
Intrinsics that Allow Reading from and Writing to the FS Base and GS Base Registers

There are eight intrinsics that allow reading and writing the value of the FS base and GS base registers at all privilege levels and in 64-bit mode only.

These intrinsics are mapped to corresponding 3rd Generation Intel® Core™ Processor extension instructions.

**_readfsbase_u32(), _readfsbase_u64()**

*Read the value of the FS base register. Both intrinsics are mapped to RDFSBASE instruction.*

**Syntax**

```c
extern unsigned int _readfsbase_u32();
extern unsigned __int64 _readfsbase_u64();
```

**Description**

These intrinsics read the value of the FS base register.

**Returns**

The value of the FS base segment register.

**_readgsbase_u32(), _readgsbase_u64()**

*Read the value of the GS base register. Both intrinsics are mapped to RDGSBASE instruction.*

**Syntax**

```c
extern unsigned int _readgsbase_u32();
extern unsigned int _readgsbase_u32();
```

**Description**

These intrinsics read the value of the GS base register.

**Returns**

The value of the GS base segment register.

**_writefsbase_u32(), _writefsbase_u64()**

*Write the value to the FS base register. Both intrinsics are mapped to WRFSBASE instruction.*

**Syntax**

```c
extern void _writefsbase_u32(int 32 val);
extern void _writefsbase_u64(unsigned __int64 val);
```

**Arguments**

`val` the value to be written to the FS base register

**Description**

These intrinsics write the given value to the FS segment base register.
_writegsbase_u32(), _writegsbase_u64()
Write the value to the GS base register. Both intrinsics are mapped to WRGSBASE instruction.

Syntax
_writegsbase_u32(int 32 val)
extern void _writegsbase_u64(unsigned __int64 val);

Arguments
val the value to be written to the GS base register

Description
These intrinsics write the given value to the GS segment base register.

Intrinsics for Intel® Advanced Vector Extensions 2

Overview: Intrinsics for Intel® Advanced Vector Extensions 2 (Intel® AVX2) Instructions
Intel® Advanced Vector Extensions 2 (Intel® AVX2) extends Intel® Advanced Vector Extensions (Intel® AVX) by promoting most of the 128-bit SIMD integer instructions with 256-bit numeric processing capabilities. The Intel® AVX2 instructions follow the same programming model as the Intel® AVX instructions.

Intel® AVX2 also provides enhanced functionality for broadcast/permute operations on data elements, vector shift instructions with variable-shift count per data element, and instructions to fetch non-contiguous data elements from memory.

Intel® AVX2 intrinsics have vector variants that use __m128, __m128i, __m256, and __m256i data types.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The Intel® AVX2 intrinsics are supported on the IA-32 and Intel® 64 architectures built from 32nm process technology. They map directly to the Intel® AVX2 new instructions and other enhanced 128-bit SIMD instructions.

Functional Overview
Intel® AVX2 instructions promote the vast majority of 128-bit integer SIMD instruction sets to operate with 256-bit wide YMM registers. Intel® AVX2 instructions are encoded using the VEX prefix and require the same operating system support as Intel® AVX. Generally, most of the promoted 256-bit vector integer instructions follow the 128-bit lane operation, similar to the promoted 256-bit floating-point SIMD instructions in Intel® AVX.

The Intel® AVX2 instructions may be broadly categorized as follows:

- **Intel® AVX complementary integer instructions**: Intel® AVX2 instructions complement the Intel® AVX instructions that are typed for integer operations with a full complement of equivalent instruction set for operating with integer data elements.
- **BROADCAST and PERMUTE instructions**: These instructions provide cross-lane functionality for floating-point and integer operations. In addition, some of the Intel® AVX2 256-bit vector integer instructions promoted from legacy SSE instruction sets also exhibiting cross-lane behavior fall into this category; for example, instructions of the VPMOVZ/VPMOVS family.
• **SHIFT instructions**: Intel® AVX2 vector SHIFT instructions operate with per-element shift count and support data element sizes of 32- and 64-bits.
• **GATHER instructions**: The Intel® AVX2 vector GATHER instructions are used for fetching non-contiguous data elements from memory using vector-index memory addressing. They introduce a new memory addressing form consisting of a base register and multiple indices specified by a vector register (XMM or YMM). Data element sizes of 32- and 64-bits are supported as well as data types for floating-point and integer elements.

Details about the Intel® AVX Intrinsics

**Intrinsics for Arithmetic Operations**

**_mm256_abs_epi8/16/32**

*Computes the absolute value of the signed packed integer data elements of a given vector. The corresponding Intel® AVX2 instruction is VPABSB, VPABSW, or VPABSD.*

**Syntax**

```c
extern __m256i _mm256_abs_epi8(__m256i s1);
extern __m256i _mm256_abs_epi16(__m256i s1);
extern __m256i _mm256_abs_epi32(__m256i s1);
```

**Arguments**

`s1`  
integer source vector used for the operation

**Description**

Computes the absolute value of each data element, either signed bytes, 16-bit words, or 32-bit integers, of the source vector and stores the UNSIGNED results in the destination vector.

**Returns**

Result of the operation.

**_mm256_add_epi8/16/32/64**

*Adds signed/unsigned packed 8/16/32/64-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is VPADDB, VPADDW, VPADDD, or VPADDQ.*

**Syntax**

```c
extern __m256i _mm256_add_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_add_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_add_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_add_epi64(__m256i s1, __m256i s2);
```
Arguments

\(s1\) integer source vector used for the operation

\(s2\) integer source vector used for the operation

Description

Adds packed signed/unsigned 8-, 16-, 32-, or 64-bit integers from source vector \(s1\) and corresponding bits of source vector \(s2\) and stores the packed integer result in the destination vector. When an individual result is too large to be represented in 8/16/32/64 bits (overflow), the result is wrapped around and the low 8/16/32/64 bits are written to the destination vector (that is, the carry is ignored).

You must control the range of values operated upon to prevent undetected overflow conditions.

Returns

Result of the addition operation.

_mm256_adds_epi8/16

Adds the signed 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel\textsuperscript{®} AVX2 instruction is VPADDSB or VPADDSW.

Syntax

extern __m256i _mm256_adds_epi8(__m256i s1, __m256i s2);

extern __m256i _mm256_adds_epi16(__m256i s1, __m256i s2);

Arguments

\(s1\) integer source vector used for the operation

\(s2\) integer source vector used for the operation

Description

Performs a SIMD add of the packed, signed, 8- or 16-bit integer data elements with saturation from the first source vector, \(s1\), and corresponding elements of the second source vector, \(s2\), and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a signed byte/word integer (that is, greater than 7FH/7FFFH or less than 80H/8000H), the saturated value of 7FH/7FFFH or 80H/8000H, respectively, is written to the destination vector.

Returns

Result of the addition operation.

_mm256_adds_epu8/16

Adds the unsigned 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel\textsuperscript{®} AVX2 instruction is VPADDUSB or VPADDUSW.

Syntax

extern __m256i _mm256_adds_epu8(__m256i s1, __m256i s2);

extern __m256i _mm256_adds_epu16(__m256i s1, __m256i s2);
Arguments

$s1$  
integer source vector used for the operation

$s2$  
integer source vector used for the operation

Description

Performs a SIMD add of the packed, unsigned, 8- or 16-bit integer data elements with saturation from the first source vector, $s1$, and corresponding elements of the second source vector, $s2$, and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a unsigned byte/word integer (that is, greater than FFH/FFFFH), the saturated value of FFH/FFFFH, respectively, is written to the destination vector.

Returns

Result of the addition operation.

_mm256_sub_epi8/16/32/64

Subtracts signed/unsigned packed 8/16/32/64-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is VPSUBB, VPSUBW, VPADDD, or VPSUBQ.

Syntax

extern __m256i _mm256_sub_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi64(__m256i s1, __m256i s2);

Arguments

$s1$  
integer source vector used for the operation

$s2$  
integer source vector used for the operation

Description

Subtracts packed signed/unsigned 8-, 16-, 32-, or 64-bit integers of the second source vector $s2$ from corresponding bits of the first source vector $s1$ and stores the packed integer result in the destination vector. When an individual result is too large to be represented in 8/16/32/64 bits (overflow), the result is wrapped around and the low 8/16/32/64 bits are written to the destination vector (that is, the carry is ignored).

You must control the range of values operated upon to prevent undetected overflow conditions.

Returns

Result of the subtraction operation.

_mm256_subs_epi8/16

Subtracts the signed 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is VPSUBSB or VPSUBSW.

Syntax

extern __m256i _mm256_subs_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_subs_epi16(__m256i s1, __m256i s2);

Arguments

s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description

Performs a SIMD subtract of the packed, signed, 8- or 16-bit integer data elements with saturation of the second source vector s2 from the corresponding elements of the first source vector s1 and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a signed byte/word integer (that is, greater than 7FH/7FFFH or less than 80H/8000H), the saturated value of 7FH/7FFFH or 80H/8000H, respectively, is written to the destination vector.

Returns

Result of the subtraction operation.

_mm256_subs_epu8/16

Subtracts the unsigned 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is VPSUBUSB or VPSUBUSW.

Syntax

extern __m256i _mm256_subs_epu8(__m256i s1, __m256i s2);
extern __m256i _mm256_subs_epu16(__m256i s1, __m256i s2);

Arguments

s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description

Performs a SIMD subtract of the packed, unsigned, 8- or 16-bit integer data elements with saturation of the second source vector s2 from the corresponding elements of the first source vector s1 and stores the packed integer results in the destination vector. When an individual byte/word result is less than zero (that is, 00H/0000H), the saturated value of 00H/0000H is written to the destination vector.

Returns

Result of the subtraction operation.

_mm256_avg_epu8/16

Computes the average of unsigned 8/16-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is VPAVGB or VPAVGW.

Syntax

extern __m256i _mm256_avg_epu8(__m256i s1, __m256i s2);
extern __m256i _mm256_avg_epu16(__m256i s1, __m256i s2);
Arguments

\( s1 \) integer source vector used for the operation

\( s2 \) integer source vector used for the operation

Description

Performs a SIMD average of the packed unsigned integers from source vector \( s2 \) and source vector \( s1 \) and stores the results in the destination vector. For each corresponding pair of data elements in the first and second vectors, the elements are added together, a 1 is added to the temporary sum, and that result is shifted right by one bit position.

Returns

Result of the operation.

__mm256_hadd_epi16/32

Horizontally adds adjacent signed packed 16/32-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is VPHADDW or VPHADDD.

Syntax

extern __m256i __mm256_hadd_epi16(__m256i s1, __m256i s2);
extern __m256i __mm256_hadd_epi32(__m256i s1, __m256i s2);

Arguments

\( s1 \) integer source vector used for the operation

\( s2 \) integer source vector used for the operation

Description

Adds two adjacent 16- or 32-bit signed integers horizontally from source vectors, \( s1 \) and \( s2 \) and packs the 16 or 32-bit signed results to the destination vector.

Horizontal addition of two adjacent data elements of the low 16- or 32-bytes of the first and second source vectors are packed into the low 16- or 32-bytes of the destination vector. Horizontal addition of two adjacent data elements of the high 16- or 32-bytes of the first and second source vectors are packed into the high 16- or 32-bytes of the destination vector.

Returns

Result of the horizontal addition operation.

__mm256_hadds_epi16

Horizontally adds adjacent signed packed 16-bit integer data elements of two vectors with saturation. The corresponding Intel® AVX2 instruction is VPHADDSW.

Syntax

extern __m256i __mm256_hadds_epi16(__m256i s1, __m256i s2);
Arguments

\( s_1 \) integer source vector used for the operation

\( s_2 \) integer source vector used for the operation

Description

Adds two adjacent, signed 16-bit integers horizontally from the source vectors \( s_1 \) and \( s_2 \), saturates the signed results, and packs the signed, saturated 16-bit results to the destination vector.

Returns

Result of the horizontal addition operation with saturation.

\_mm256_hsub_epi16/32

Horizontally subtracts adjacent signed packed 16/32-bit integer data elements of two vectors. The corresponding Intel\textsuperscript® AVX2 instruction is VPHSUBW or VPHSUBD.

Syntax

extern __m256i _mm256_hsub_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_hsub_epi32(__m256i s1, __m256i s2);

Arguments

\( s_1 \) integer source vector used for the operation

\( s_2 \) integer source vector used for the operation

Description

Performs horizontal subtraction on each adjacent pair of 16- or 32-bit signed integers by subtracting the most significant word from the least significant word of each pair source vectors \( s_2 \) and \( s_2 \), and packs the signed 16- or 32-bit results to the destination vector.

Returns

Result of the horizontal subtraction operation.

\_mm256_hsubs_epi16

Horizontally subtracts adjacent signed packed 16-bit integer data elements of two vectors with saturation. The corresponding Intel\textsuperscript® AVX2 instruction is VPHSUBSW.

Syntax

extern __m256i _mm256_hsubs_epi16(__m256i s1, __m256i s2);

Arguments

\( s_1 \) integer source vector used for the operation

\( s_2 \) integer source vector used for the operation
Description
Performs horizontal subtraction on each adjacent pair of 16-bit signed integers by subtracting the most significant word from the least significant word of each pair in source vectors s1 and s2. The signed, saturated 16-bit results are packed to the destination vector.

Returns
Result of the horizontal subtraction operation with saturation.

_mm256_madd_epi16
Multiplies signed packed 16-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is VPMADDW.

Syntax
extern __m256i _mm256_madd_epi16(__m256i s1, __m256i s2);

Arguments
s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description
Multiplies individual, signed 16-bit integers of source vector s1 by the corresponding signed 16-bit integers of source vector s2, producing temporary, signed, 32-bit [doubleword] results. The adjacent doubleword results are then summed and stored in the destination vector.

For example, the corresponding low-order words (15:0) and (31-16) in s2 and s1 vectors are multiplied, and the doubleword results are added together and stored in the low doubleword of the destination vector (31-0). The same operation is performed on the other pairs of adjacent words.

Returns
Result of the multiplication operation.

_mm256_maddubs_epi16
Multiplies unsigned packed 16-bit integer data elements of one vector with signed elements of second vector. The corresponding Intel® AVX2 instruction is VPMADDUBSW.

Syntax
extern __m256i _mm256_maddubs_epi16(__m256i s1, __m256i s2);

Arguments
s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description
Multiplies vertically each unsigned byte of source vector s1 with the corresponding signed byte of source vector s2, producing intermediate, signed 16-bit integers. Each adjacent pair of signed words is added, and the saturated result is packed to the destination vector.
For example, the lowest-order bytes (bits 7:0) in s1 and s2 vectors are multiplied and the intermediate signed word result is added with the corresponding intermediate result from the 2nd lowest-order bytes (bits 15:8) of the vectors. The sign-saturated result is stored in the lowest word of the destination vector (15:0). The same operation is performed on the other pairs of adjacent bytes.

**Returns**
Result of the multiplication operation.

_mm256_mul_epi32

*Multiplies two vectors with packed doubleword signed integer values. The corresponding Intel® AVX2 instruction is VPMULDQ.*

**Syntax**
`extern __m256i _mm256_mul_epi32(__m256i s1, __m256i s2);`

**Arguments**
- `s1` integer source vector used for the operation
- `s2` integer source vector used for the operation

**Description**
Multiplies the value of packed signed doubleword integer in source vector s1 by the value in source vector s2 and stores the result in the destination vector.

When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

**Returns**
Result of the multiplication operation.

_mm256_mul_epu32

*Multiplies two vectors with packed doubleword unsigned integer values. The corresponding Intel® AVX2 instruction is VPMULUDQ.*

**Syntax**
`extern __m256i _mm256_mul_epu32(__m256i s1, __m256i s2);`

**Arguments**
- `s1` integer source vector used for the operation
- `s2` integer source vector used for the operation

**Description**
Multiplies the value of packed unsigned doubleword integer in source vector s1 by the value in source vector s2 and stores the result in the destination vector.

When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).
Returns
Result of the multiplication operation.

_mm256_mulhi_epi16
Multiplies signed packed 16/32-bit integer data elements of two vectors and stores high bits. The corresponding Intel® AVX2 instruction is VPMULHW.

Syntax
extern __m256i _mm256_mulhi_epi16(__m256i s1, __m256i s2);

Arguments
s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description
Performs a SIMD signed multiply of the packed signed 16-bit integers in source vectors s1 and s2 and stores the high 16 bits of each intermediate 32-bit result in the destination vector.

Returns
Result of the multiplication operation.

_mm256_mulhi_epu16
Multiplies unsigned packed 16/32-bit integer data elements of two vectors and stores high bits. The corresponding Intel® AVX2 instruction is VPMULHUW.

Syntax
extern __m256i _mm256_mulhi_epu16(__m256i s1, __m256i s2);

Arguments
s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description
Performs a SIMD unsigned multiply of the packed unsigned 16-bit integers in source vectors s1 and s2 and stores the high 16 bits of each intermediate 32-bit result in the destination vector.

Returns
Result of the multiplication operation.

_mm256_mullo_epi16/32
Multiplies signed packed 16/32-bit integer data elements of two vectors and stores low bits. The corresponding Intel® AVX2 instruction is VPMULLW or VPMULLD.
**Syntax**

extern __m256i _mm256_mullo_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_mullo_epi32(__m256i s1, __m256i s2);

**Arguments**

s1  
integer source vector used for the operation

s2  
integer source vector used for the operation

**Description**

Performs a SIMD signed multiply of the packed signed 16- or 32-bit integers in source vectors \( s1 \) and \( s2 \) and stores the low 16- or 32-bits of each intermediate 32- or 64-bit result in the destination vector.

**Returns**

Result of the multiplication operation.

---

**_mm256_mulhrs_epi16**

*Multiplies extended packed unsigned integers of two vectors with round and scale. The corresponding Intel® AVX2 instruction is VPMULHRSW.*

**Syntax**

extern __m256i _mm256_mulhrs_epi16(__m256i s1, __m256i s2);

**Arguments**

s1  
integer source vector used for the operation

s2  
integer source vector used for the operation

**Description**

Vertically multiplies each signed 16-bit integer from \( s1 \) vector with the corresponding signed 16-bit integer of \( s2 \) vector, producing intermediate, signed 32-bit integers. Each intermediate 32-bit integer is truncated to the 18 most-significant-bits. Rounding is performed by adding 1 to the least-significant-bit of the 18-bit intermediate result.

The final result is obtained by selecting the 16 bits immediately to the right of the most-significant-bit of each 18-bit intermediate result and packing them to the destination operand.

**Returns**

Result of the multiply, round, and scale operation.

---

**_mm256_sign_epi8/16/32**

*Changes the sign of elements in one source vector depending on the sign of corresponding element in other source vector. The corresponding Intel® AVX2 instruction is VPSIGNB, VPSIGNW, or VPSIGND.*

**Syntax**

extern __m256i _mm256_sign_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_sign_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_sign_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_sign_epi32(__m256i s1, __m256i s2);

**Arguments**

- **s1**: integer source vector used for the operation
- **s2**: integer source vector used for the operation

**Description**

Modifies the sign of data elements in the source vector `s1` depending on the sign of corresponding element in vector `s2` as follows:

- If sign of data element in `s2` vector is < 0 then the sign of corresponding data element in vector `s1` is made negative.
- If sign of data element in `s2` vector is > 0 then the sign of corresponding data element in vector `s1` is left unchanged.
- If the data element in `s2` vector is = 0 then the corresponding data element in vector `s1` is set to 0.

The `_mm256_sign_epi8` intrinsic operates on 8-bit signed bytes. The `_mm256_sign_epi16` intrinsic operates on 16-bit signed words. The `_mm256_sign_epi32` intrinsic operates on 32-bit signed integers.

**Returns**

Result of the operation.

---

`_mm256_mpsadbw_epu8`

*Performs multiple sum of absolute differences on extended packed unsigned integer values of two vectors. The corresponding Intel® AVX2 instruction is VMPSADBW.*

**Syntax**

extern __m256i _mm256_mpsadbw_epu8(__m256i s1, __m256i s2, const int mask);

**Arguments**

- **s1**: integer source vector used for the operation
- **s2**: integer source vector used for the operation
- **mask**: integer constant specifying offset

**Description**

Performs multiple sum operations of the absolute difference of blocks of four packed unsigned bytes of vector `s2` with sequential blocks of four packed unsigned bytes in vector `s1`. The offset granularity in both vectors is 32 bits.

The sum-absolute-difference (SAD) operation is repeated 16 times by the intrinsic between the `s2` vector with a fixed offset and a variable `s1` vector where the offset is shifted by eight bits for each SAD operation. The integer constant specified in `mask` provides bit fields that specify the initial offset for `s2` and `s1` vectors. Each 16-bit result of eight SAD operations is written to the respective word in the result vector.

**Returns**

Result of the multiple sum-absolute-difference operation.
### _mm256_sad_epu8

*Computes sum of absolute differences between extended packed unsigned values of two vectors. The corresponding Intel® AVX2 instruction is VPSADBW.*

**Syntax**

```c
extern __m256i _mm256_sad_epu8(__m256i s1, __m256i s2);
```

**Arguments**

- `s1`: integer source vector used for the operation
- `s2`: integer source vector used for the operation

**Description**

Computes the absolute value of the difference of packed groups of eight unsigned byte integers from the source vectors `s1` and `s2`. Four blocks of eight differences are stored at specific locations in the destination vector. Remaining bits in the destination vector are set to zero.

**Returns**

Result of the single sum-absolute-difference operation.

### Intrinsics for Arithmetic Shift Operations

#### _mm256_sra_epi16/32

*Arithmetic shift of word/doubleword elements to right according to specified number. The corresponding Intel® AVX2 instruction is VPSRAW, or VPSRAD.*

**Syntax**

```c
extern __m256i _mm256_sra_epi16(__m256i s1, __m128i count);
extern __m256i _mm256_sra_epi32(__m256i s1, __m128i count);
```

**Arguments**

- `s1`: integer source vector used for the operation
- `count`: 128-bit memory location used for the operation

**Description**

Performs an arithmetic shift of bits in the individual data elements (16-bit word or 32-bit doubleword) in the first source vector `s1` to the right by the number of bits specified in `count`. The empty high-order bits are filled with the initial value of the sign bit. If the value specified by `count` is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is filled with the initial value of the sign bit.

The `count` argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

**Returns**

Result of the right-shift operation.
_mm256_srai_epi16/32

Arithmetic shift of word/doubleword elements to right according to specified number. The corresponding Intel® AVX2 instruction is VPSRAW or VPSRAD.

Syntax

extern __m256i _mm256_srai_epi16(__m256i s1, const int count);
extern __m256i _mm256_srai_epi32(__m256i s1, const int count);

Arguments

s1          integer source vector used for the operation
count       8-bit immediate used for the operation

Description

Performs an arithmetic shift of 16-bit [word] or 32-bit [doubleword] elements within a 128-bit lane of source vector s1 to the right by the number of bits specified in count. The empty high-order bits are filled with the initial value of the sign bit. If the value specified by count is greater than 15 or 31, the whole destination vector is filled with the initial value of the sign bit. The count argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srav_epi32

Arithmetic shift of doubleword elements to right according variable values. The corresponding Intel® AVX2 instruction is VPSRAVD.

Syntax

extern __m256i _mm256_srav_epi32(__m256i s1, __m256i s2);

Arguments

s1          integer source vector used for the operation
s2          integer source vector providing variable values for shift operation

Description

Performs an arithmetic shift of 32 bits (doublewords) in the individual data elements in source vector s1 to the right by the count value of corresponding data elements in source vector s2. As the bits in the data elements are shifted right, the empty high-order bits are filled with the initial value of the sign bit.

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), then the destination data elements are filled with the initial value of the sign bit.

Returns

Result of the right-shift operation.
Arithmetic shift of doubleword elements to right according variable values. The corresponding Intel® AVX2 instruction is \texttt{VPSRAVD}.

**Syntax**

\begin{verbatim}
extern __m128i _mm_srav_epi32(__m128i s1, __m128i s2);
\end{verbatim}

**Arguments**

- \texttt{s1}  
  128-bit integer source vector used for the operation
- \texttt{s2}  
  128-bit integer source vector providing variable values for shift operation

**Description**

Performs an arithmetic shift of the 32 bits (doublewords) in the individual data elements in source vector \texttt{s1} to the right by the count value of corresponding data elements in source vector \texttt{s2}. As the bits in the data elements are shifted right, the empty high-order bits are filled with the initial value of the sign bit.

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), then the destination data elements are filled with the initial value of the sign bit.

**Returns**

Result of the right-shift operation.

**Intrinsics for Blend Operations**

\texttt{_mm_blend_epi32, _mm256_blend_epi16/32}

Conditionally blends data elements of source vector depending on bits in a mask. The corresponding Intel® AVX2 instruction is \texttt{VPBLENDD} or \texttt{VPBLENDW}.

**Syntax**

\begin{verbatim}
extern __m128i _mm_blend_epi32(__m128i s1, __m128i s2, const int mask);
extern __m256i _mm256_blend_epi16(__m256i s1, __m256i s2, const int mask);
extern __m256i _mm256_blend_epi32(__m256i s1, __m256i s2, const int mask);
\end{verbatim}

**Arguments**

- \texttt{s1}  
  integer source vector used for the operation
- \texttt{s2}  
  integer source vector used for the operation
- \texttt{mask}  
  8-bit immediate used for the operation

**Description**

Performs a blend operation by conditionally copying 16/32-bit [word/doubleword] elements from source vectors \texttt{s2} and \texttt{s1}, depending on mask bits defined in \texttt{mask}. The mask bits are the least significant 8 bits in \texttt{mask} when the 256-bit intrinsics, \texttt{_mm256_blend_epi16/_mm256_blend_epi32}, are used, and 4 bits when the 128-bit intrinsic, \texttt{_mm_blend_epi32}, is used.
Each word/doubleword element of the destination vector is copied from the corresponding word/doubleword element in \( s2 \) if a mask bit is 1, or is copied from the corresponding word/doubleword element in \( s1 \) if a mask bit is 0.

**Returns**

Result of the blend operation.

```
_mm256_blendv_epi8
```

*Conditionally blends word elements of source vector depending on bits in a mask vector. The corresponding Intel\(^\text{®}\) AVX2 instruction is **VPBLENDVB**.*

**Syntax**

```c
extern __m256i _mm256_blendv_epi8(__m256i s1, __m256i s2, __m256i mask);
```

**Arguments**

- \( s1 \) integer source vector used for the operation
- \( s2 \) integer source vector used for the operation
- \( mask \) integer vector used for the operation

**Description**

Performs a blend operation by conditionally copying 8-bit byte elements from source vectors \( s2 \) and \( s1 \), depending on mask bits defined in \( mask \) vector. The mask bits are the most significant bit in each byte element of \( mask \).

Each byte element of the destination vector is copied from the corresponding byte element in \( s2 \) if a mask bit is 1, or the corresponding byte element in \( s1 \) if a mask bit is 0.

**Returns**

Result of the blend operation.

**Intrinsics for Bitwise Operations**

```
_mm256_and_si256
```

*Performs bitwise logical AND operation on signed integer vectors. The corresponding Intel\(^\text{®}\) AVX2 instruction is **VPAND**.*

**Syntax**

```c
extern __m256i _mm256_and_si256(__m256i s1, __m256i s2);
```

**Arguments**

- \( s1 \) signed integer vector used for the operation
- \( s2 \) signed integer vector also used for the operation
**Description**
Performs a bitwise logical AND operation of the signed integer elements of source vector \( s1 \) and corresponding elements in source vector \( s2 \), and stores the result in the destination vector. If the corresponding bits of the first and second vectors are 1, each bit of the result is set to 1, otherwise it is set to 0.

**Returns**
Result of the bitwise logical AND operation.

**_mm256_andnot_si256**
*Performs bitwise logical AND NOT operation on signed integer vectors. The corresponding Intel® AVX2 instruction is VPANDN.*

**Syntax**
```c
extern __m256i _mm256_andnot_si256(__m256i s1, __m256i s2);
```

**Arguments**
- \( s1 \) signed integer vector used for the operation
- \( s2 \) signed integer vector also used for the operation

**Description**
Performs a bitwise logical NOT operation on source vector \( s1 \) then performs bitwise AND with source vector \( s2 \) and stores the result in the destination vector. If the corresponding bit in the first vector is 0 and the corresponding bit in the second vector is 1, each bit of the result is set to 1, otherwise it is set to 0.

**Returns**
Result of the bitwise logical AND NOT operation.

**_mm256_or_si256**
*Performs bitwise logical OR operation on signed integer vectors. The corresponding Intel® AVX2 instruction is VPOR.*

**Syntax**
```c
extern __m256i _mm256_or_si256(__m256i s1, __m256i s2);
```

**Arguments**
- \( s1 \) signed integer vector used for the operation
- \( s2 \) signed integer vector also used for the operation

**Description**
Performs a bitwise logical OR operation of the signed integer elements of source vector \( s2 \) and the corresponding elements in source vector \( s1 \) and stores the result in the destination vector. If either of the corresponding bits of the first and second vectors are 1, each bit of the result is set to 1, otherwise it is set to 0.
Returns
Result of the bitwise logical OR operation.

_mm256_xor_si256
Performs bitwise logical XOR operation on signed integer vectors. The corresponding Intel® AVX2 instruction is VPXOR.

Syntax
extern __m256i _mm256_xor_si256(__m256i s1, __m256i s2);

Arguments
s1 signed integer vector used for the operation
s2 signed integer vector also used for the operation

Description
Performs a bitwise logical XOR operation of the signed integer elements of source vector s2 and the corresponding elements in source vector s1 and stores the result in the destination vector. If the corresponding bits of the first and second vectors differ, each bit of the result is set to 1, otherwise it is set to 0.

Returns
Result of the bitwise logical XOR operation.

Intrinsics for Broadcast Operations

_mm_broadcastss_ps, _mm256_broadcastss_ps
Take the low packed single-precision floating-point data element from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is VBROADCASTSS.

Syntax
extern __m128 _mm_broadcastss_ps(__m128 val);
extern __m256 _mm256_broadcastss_ps(__m128 val);

Arguments
val __m128 vector containing the 32-bit element to be broadcasted

Description
Takes the low packed single-precision floating-point (float32) data element from the source operand and broadcasts it to all elements of the result vector. The source operand is __m128; only the low 32 bits of this operand are broadcasted.

Returns
Return result of the broadcast operation.
_mm256_broadcastsd_pd
Takes the low packed double-precision floating-point data element from the source operand and broadcasts to all elements of the result vector. The corresponding Intel® AVX2 instruction is VBROADCASTSD.

Syntax
extern __m256d _mm256_broadcastsd_pd(__m128d val);

Arguments
val
__m128 vector containing the 64-bit element to be broadcasted

Description
Takes the low packed double-precision floating-point (float64) data element from the source operand and broadcasts it to all elements of the result vector. The source operand is __m128d; only the low 64 bits of this operand are broadcasted.

The 128-bit version of this intrinsics is _mm_broadcastsd_pd. The intrinsic's syntax is extern __m128d _mm_broadcastsd_pd(__m128d val); This intrinsic is an alias for _mm_movedup_pd() intrinsic. Please, see Double-precision Floating-point Vector Intrinsics for details.

Returns
Return result of the broadcast operation.

_mm_broadcastb_epi8, _mm256_broadcastb_epi8
Take byte elements from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is VPBROADCASTB.

Syntax
extern __m128i _mm_broadcastb_epi8(__m128i val);
extern __m256i _mm256_broadcastb_epi8(__m128i val);

Arguments
val
__m128i vector containing the elements to be broadcasted

Description
Takes a byte integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns
Returns result of the broadcast operation.

_mm_broadcastw_epi16, _mm256_broadcastw_epi16
Take word elements from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is VPBROADCASTW.
Syntax

extern __m128i _mm_broadcastw_epi16(__m128i val);
extern __m256i _mm256_broadcastw_epi16(__m128i val);

Arguments

val
__m128i vector containing the elements to be broadcasted

Description

Takes a word integer in the low bits of the source operand and broadcasts to all eight or sixteen elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm_broadcastd_epi32, _mm256_broadcastd_epi32
Take doublewords from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is VPBROADCASTD.

Syntax

extern __m128i _mm_broadcastd_epi32(__m128i val);
extern __m256i _mm256_broadcastd_epi32(__m128i val);

Arguments

val
__m128i vector containing 32-bit element to be broadcasted

Description

Takes a dword integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm_broadcastq_epi64, _mm256_broadcastq_epi64
Take qwords from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is VPBROADCASTQ.

Syntax

extern __m128i _mm_broadcastq_epi64(__m128i val);
extern __m256i _mm256_broadcastq_epi64(__m128i val);
Arguments
val
  __m128i vector containing 64-bit element to be broadcasted

Description
Takes a qword integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns
Returns result of the broadcast operation.

_mm256_broadcastsi128_si256
Takes 128-bit data from the source operand and broadcasts it to all 128-bit elements of the result 256-bit vector. The corresponding Intel® AVX2 instructions are VBROADCASTI128 and VPERM2I128.

Syntax
extern __m256i _mm256_broadcastsi128_si256(__m128i val);

Arguments
val
  the value to be broadcasted

Description
Takes 128-bit data from the source operand and broadcasts it to all 128-bit elements of the result 256-bit vector.

Returns
Returns result of the broadcast operation.

Intrinsics for Compare Operations

_mm256_cmpeq_epi8/16/32/64
Compares packed bytes/words/doublewords/quadwords of two source vectors. The corresponding Intel® AVX2 instruction is VPCMPEQB, VPCMPEQW, VPCMPEQD, or VPCMPEQQ.

Syntax
extern __m256i _mm256_cmpeq_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi64(__m256i s1, __m256i s2);

Arguments
s1
  integer source vector used for the operation
s2 integer source vector used for the operation

Description
Performs a SIMD compare for equality of packed bytes, words, doublewords, or quadwords in source vectors \(s1\) and \(s2\). If a pair of data elements is equal, the corresponding data element in the destination vector is set to all 1s. If a pair of data elements is unequal, the corresponding data element in the destination vector is set to 0.

Returns
Destination vector with result of the compare equal operation.

\_mm256\_cmpgt\_epi8/16/32/64
Compares packed bytes/words/doublewords/quadwords of two source vectors. The corresponding Intel\textsuperscript{®} AVX2 instruction is VPCMPGTB, VPCMPGTW, VPCMPGTD, or VPCMPGTQ.

Syntax
extern __m256i \_mm256\_cmpgt\_epi8(__m256i s1, __m256i s2);
extern __m256i \_mm256\_cmpgt\_epi16(__m256i s1, __m256i s2);
extern __m256i \_mm256\_cmpgt\_epi32(__m256i s1, __m256i s2);
extern __m256i \_mm256\_cmpgt\_epi64(__m256i s1, __m256i s2);

Arguments
\(s1\) integer destination vector used for the operation
\(s2\) integer source vector used for the operation

Description
Performs a SIMD signed compare to determine which of the data elements [packed bytes, words, doublewords, or quadwords] in destination vector \(s1\) is greater than the corresponding element in the source vector \(s2\).

For each pair of data elements in \(s1\) and \(s2\), if the \(s1\) data element is greater than the corresponding element in \(s2\), then the corresponding element in the destination vector is set to all 1s. If the \(s1\) data element is less than the corresponding data element in \(s2\), then the corresponding data element in destination vector is set to all 0s.

If the data elements are equal, the destination vector is set to 0.

Returns
Destination vector with result of the compare greater-than operation.

\_mm256\_max\_epi8/16/32
Determines the maximum value between two vectors with packed signed byte/word/doubleword integers. The corresponding Intel\textsuperscript{®} AVX2 instruction is VPMAXSB, VPMAXSW, or VPMAXSD.

Syntax
extern __m256i \_mm256\_max\_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi32(__m256i s1, __m256i s2);

Arguments

s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description

Performs a SIMD compare of the packed signed byte, word, or doubleword integers in source vectors s1 and s2 and returns the maximum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

_mm256_max_epi8/16/32

Determines the maximum value between two vectors with packed unsigned byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is VPMAXUB, VPMAXUW, or VPMAXUD.

Syntax

extern __m256i _mm256_max_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi32(__m256i s1, __m256i s2);

Arguments

s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description

Performs a SIMD compare of the packed unsigned byte, word, or doubleword integers in source vectors s1 and s2 and returns the maximum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

_mm256_min_epi8/16/32

Determines the minimum value between two vectors with packed signed byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is VPMINSB, VPMINSW, or VPMINSD.

Syntax

extern __m256i _mm256_min_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epi32(__m256i s1, __m256i s2);

Arguments

s1 integer source vector used for the operation
s2 integer source vector used for the operation

Description

Performs a SIMD compare of the packed signed byte, word, or doubleword integers in source vectors s1 and s2 and returns the minimum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.
Arguments

s1  integer source vector used for the operation
s2  integer source vector used for the operation

Description
Performs a SIMD compare of the packed signed byte, word, or doubleword integers in source vectors s1 and s2 and returns the minimum value for each pair of integers to the destination vector.

Returns
Destination vector with result of the compare operation.

_mm256_min_epu8/16/32

Determines the minimum value between two vectors with packed unsigned byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is VPMINUB, VPMINUW, or VPMINUD.

Syntax

extern __m256i _mm256_min_epu8(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epu16(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epu32(__m256i s1, __m256i s2);

Arguments

s1  integer source vector used for the operation
s2  integer source vector used for the operation

Description
Performs a SIMD compare of the packed unsigned byte, word, or doubleword integers in source vectors s1 and s2 and returns the minimum value for each pair of integers to the destination vector.

Returns
Destination vector with result of the compare operation.

Intrinsics for Fused Multiply Add Operations

_mm_fmadd_pd, _mm256_fmadd_pd

Multiply-adds packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is VFMADD<XXX>PD, where XXX could be 132, 213, or 231.

Syntax

For 128-bit vector
extern __m128d _mm_fmadd_pd(__m128d a, __m128d b, __m128d c);

For 256-bit vector
extern __m256d _mm256_fmadd_pd(__m256d a, __m256d b, __m256d c);

**Arguments**

- **a**: float64 vector used for the operation
- **b**: float64 vector also used for the operation
- **c**: float64 vector also used for the operation

**Description**

Performs a set of SIMD multiply-add computation on packed double-precision floating-point values using three source vectors/operands, a, b, and c. Corresponding values in two operands, a and b, are multiplied and the infinite precision intermediate results are added to corresponding values in the third operand, after which the final results are rounded to the nearest float64 values.

The compiler defaults to using the **VFMADD213PD** instruction and uses the other forms **VFMADD132PD** or **VFMADD231PD** only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the multiply-add operation.

---

__mm_fmadd_ps, __mm256_fmadd_ps__

*Multiply-adds packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is VFMADD<XXX>PS, where XXX could be 132, 213, or 231.*

**Syntax**

**For 128-bit vector**

extern __m128 _mm_fmadd_ps(__m128 a, __m128 b, __m128 c);

**For 256-bit vector**

extern __m256 _mm256_fmadd_ps(__m256 a, __m256 b, __m256 c);

**Arguments**

- **a**: float32 vector used for the operation
- **b**: float32 vector also used for the operation
- **c**: float32 vector also used for the operation

**Description**

Performs a set of SIMD multiply-add computation on packed single-precision floating-point values using three source vectors/operands, a, b, and c. Corresponding values in two operands, a and b, are multiplied and the infinite precision intermediate results are added to corresponding values in the third operand, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the **VFMADD213PS** instruction and uses the other forms **VFMADD132PS** or **VFMADD231PS** only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.
Returns
Result of the multiply-add operation.

_mm_fmadd_sd
Multiply-adds scalar double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is VFMADD<XXX>SD, where XXX could be 132, 213, or 231.

Syntax
extern __m128d _mm_fmadd_sd(__m128d a, __m128d b, __m128d c);

Arguments
a
  float64 vector used for the operation
b
  float64 vector also used for the operation
c
  float64 vector also used for the operation

Description
Performs a set of scalar SIMD multiply-add computation on scalar double-precision floating-point values in the low 32-bits of three source operands, a, b, and c. The float64 values in two operands, a and b, are multiplied and the infinite precision intermediate result is obtained. The float64 value in the third operand, c, is added to the infinite precision intermediate result. The final result is rounded to the nearest float64 value.

The compiler defaults to using the VFMADD213SD instruction and uses the other forms VFMADD132SD or VFMADD231SD only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the multiply-add operation.

_mm_fmadd_ss
Multiply-adds scalar single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is VFMADD<XXX>SS, where XXX could be 132, 213, or 231.

Syntax
extern __m128 _mm_fmadd_ss(__m128 a, __m128 b, __m128 c);

Arguments
a
  float32 vector used for the operation
b
  float32 vector also used for the operation
c
  float32 vector also used for the operation
Description
Perform a set of scalar SIMD multiply-add computation on scalar single-precision floating-point values in the low 32-bits of three source operands, $a$, $b$, and $c$. The float32 values in two operands, $a$ and $b$, are multiplied and the infinite precision intermediate result is obtained. The float32 value in the third operand, $c$, is added to the infinite precision intermediate result. The final result is rounded to the nearest float32 value.

The compiler defaults to using the \texttt{VFMADD213SS} instruction and uses the other forms \texttt{VFMADD132SS} or \texttt{VFMADD231SS} only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the multiply-add operation.

\_mm\_fmaddsub\_pd, \_mm256\_fmaddsub\_pd
Multiply-adds and subtracts packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is \texttt{VFMADDSUB<XXX>PD}, where \texttt{XXX} could be 132, 213, or 231.

Syntax
For 128-bit vector
\begin{verbatim}
extern _m128d _mm_fmaddsub_pd(_m128d a, _m128d b, _m128d c);
\end{verbatim}

For 256-bit vector
\begin{verbatim}
extern _m256d _mm256_fmaddsub_pd(_m256d a, _m256d b, _m256d c);
\end{verbatim}

Arguments
\begin{itemize}
\item $a$ float64 vector used for the operation
\item $b$ float64 vector also used for the operation
\item $c$ float64 vector also used for the operation
\end{itemize}

Description
Perform a set of SIMD multiply-add-subtract computation on packed double-precision floating-point values using three source vectors/operands, $a$, $b$, and $c$. Corresponding values in two operands, $a$ and $b$, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, $c$, are added to the intermediate results while the even values are subtracted from them. The final results are rounded to the nearest float64 values.

The compiler defaults to using the \texttt{VFMADDSUB213PD} instruction and uses the other forms \texttt{VFMADDSUB132PD} or \texttt{VFMADDSUB231PD} only if a low-level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the multiply-add-subtract operation.
Multiply-adds and subtracts packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is VFMADDSUB<XXX>PS, where XXX could be 132, 213, or 231.

Syntax

For 128-bit vector
extern __m128 _mm_fmaddsub_ps(__m128 a, __m128 b, __m128 c);

For 256-bit vector
extern __m256 _mm256_fmaddsub_ps(__m256 a, __m256 b, __m256 c);

Arguments

- **a**
  float32 vector used for the operation
- **b**
  float32 vector also used for the operation
- **c**
  float32 vector also used for the operation

Description

Performs a set of SIMD multiply-add-subtract computation on packed single-precision floating-point values using three source vectors/operands, a, b, and c. Corresponding values in two operands, a and b, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, c, are added to the intermediate results while the even values are subtracted from them. The final results are rounded to the nearest float32 values.

The compiler defaults to using the VFMADDSUB213PS instruction and uses the other forms VFMADDSUB132PS or VFMADDSUB231PS only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add-subtract operation.

Multiply-subtracts packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is VFMSUB<XXX>PD, where XXX could be 132, 213, or 231.

Syntax

For 128-bit vector
extern __m128d _mm_fmsub_pd(__m128d a, __m128d b, __m128d c);

For 256-bit vector
extern __m256d _mm256_fmsub_pd(__m256d a, __m256d b, __m256d c);

Arguments

- **a**
  float64 vector used for the operation
Description

Performs a set of SIMD multiply-subtract computation on packed double-precision floating-point values using three source vectors/operands, \(a\), \(b\), and \(c\). Corresponding values in two operands, \(a\) and \(b\), are multiplied and the infinite precision intermediate results are obtained. From the infinite precision intermediate results, the values in the third operand, \(c\), are subtracted. The final results are rounded to the nearest float64 values.

The compiler defaults to using the \texttt{VFMSUB213PD} instruction and uses the other forms \texttt{VFMSUB132PD} or \texttt{VFMSUB231PD} only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.

\_mm\_fmsub\_ps, \_mm256\_fmsub\_ps

\textit{Multiply-subtracts packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is VFMSUB<XXX>PS, where XXX could be 132, 213, or 231.}

Syntax

\textbf{For 128-bit vector}

\begin{verbatim}
extern __m128 \_mm\_fmsub\_ps(__m128 a, __m128 b, __m128 c);
\end{verbatim}

\textbf{For 256-bit vector}

\begin{verbatim}
extern __m256 \_mm256\_fmsub\_ps(__m256 a, __m256 b, __m256 c);
\end{verbatim}

Arguments

\(a\) float32 vector used for the operation

\(b\) float32 vector also used for the operation

\(c\) float32 vector also used for the operation

Description

Performs a set of SIMD multiply-subtract computation on packed single-precision floating-point values using three source vectors/operands, \(a\), \(b\), and \(c\). Corresponding values in two operands, \(a\) and \(b\), are multiplied and the infinite precision intermediate results are obtained. From the infinite precision intermediate results, the values in the third operand, \(c\), are subtracted. The final results are rounded to the nearest float32 values.

The compiler defaults to using the \texttt{VFMSUB213PS} instruction and uses the other forms \texttt{VFMSUB132PS} or \texttt{VFMSUB231PS} only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.
Multiply-subtracts scalar double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is \texttt{VFMSUB<XXX>SD}, where \texttt{XXX} could be 132, 213, or 231.

**Syntax**

\texttt{extern \_m128d \_mm\_fmsub\_sd(\_m128d a, \_m128d b, \_m128d c);} 

**Arguments**

- \(a\) float64 vector used for the operation
- \(b\) float64 vector also used for the operation
- \(c\) float64 vector also used for the operation

**Description**

Performs a set of scalar SIMD multiply-subtract computation on scalar double-precision floating-point values in the low 64-bits of three source operands, \(a\), \(b\), and \(c\). The float64 values in two operands, \(a\) and \(b\), are multiplied and the infinite precision intermediate result is obtained. From the infinite precision intermediate result, the float64 value in the third operand, \(c\), is subtracted. The final result is rounded to the nearest float64 value.

The compiler defaults to using the \texttt{VFMSUB213SD} instruction and uses the other forms \texttt{VFMSUB132SD} or \texttt{VFMSUB231SD} only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the multiply-subtract operation.

Multiply-subtracts scalar single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is \texttt{VFMSUB<XXX>SS}, where \texttt{XXX} could be 132, 213, or 231.

**Syntax**

\texttt{extern \_m128 \_mm\_fmsub\_ss(\_m128 a, \_m128 b, \_m128 c);} 

**Arguments**

- \(a\) float32 vector used for the operation
- \(b\) float32 vector also used for the operation
- \(c\) float32 vector also used for the operation

**Description**

Performs a set of scalar SIMD multiply-subtract computation on scalar single-precision floating-point values in the low 32-bits of three source operands, \(a\), \(b\), and \(c\). The float32 values in two operands, \(a\) and \(b\), are multiplied and the infinite precision intermediate result is obtained. From the infinite precision intermediate result, the float32 value in the third operand, \(c\), is subtracted. The final result is rounded to the nearest float32 value.
The compiler defaults to using the \texttt{VFMSUB213SS} instruction and uses the other forms \texttt{VFMSUB132SS} or \texttt{VFMSUB231SS} only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the multiply-subtract operation.

\_\_m\_fmsubadd\_pd, \_\_m256\_fmsubadd\_pd

\textit{Multiply-subtracts and adds packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is VFMSUBADD<XXX>PD, where XXX could be 132, 213, or 231.}

**Syntax**

For 128-bit vector

\begin{verbatim}
extern __m128d _mm_fmsubadd_pd(__m128d a, __m128d b, __m128d c);
\end{verbatim}

For 256-bit vector

\begin{verbatim}
extern __m256d _mm256_fmsubadd_pd(__m256d a, __m256d b, __m256d c);
\end{verbatim}

**Arguments**

- \emph{a} float64 vector used for the operation
- \emph{b} float64 vector also used for the operation
- \emph{c} float64 vector also used for the operation

**Description**

Performs a set of SIMD multiply-subtract-add computation on packed double-precision floating-point values using three source vectors/operands, \emph{a}, \emph{b}, and \emph{c}. Corresponding values in two operands, \emph{a} and \emph{b}, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, \emph{c}, are subtracted from the intermediate results while the even values are added to them. The final results are rounded to the nearest float64 values.

The compiler defaults to using the \texttt{VFMSUBADD213PD} instruction and uses the other forms \texttt{VFMSUBADD132PD} or \texttt{VFMSUBADD231PD} only if a low-level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the multiply-subtract-add operation.

\_\_m\_fmsubadd\_ps, \_\_m256\_fmsubadd\_ps

\textit{Multiply-subtracts and adds packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is VFMSUBADD<XXX>PS, where XXX could be 132, 213, or 231.}

**Syntax**

For 128-bit vector

\begin{verbatim}
extern __m128 _mm_fmsubadd_ps(__m128 a, __m128 b, __m128 c);
\end{verbatim}
For 256-bit vector

```c
extern __m256 _mm256_fmsubadd_ps(__m256 a, __m256 b, __m256 c);
```

**Arguments**

- `a`: float32 vector used for the operation
- `b`: float32 vector also used for the operation
- `c`: float32 vector also used for the operation

**Description**

Performs a set of SIMD multiply-subtract-add computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, `c`, are subtracted from the intermediate results while the even values are added to them. The final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFMSUBADD213PS` instruction and uses the other forms `VFMSUBADD132PS` or `VFMSUBADDS231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the multiply-add-subtract operation.

---

For 128-bit vector

```c
extern __m128d _mm_fnmadd_pd(__m128d a, __m128d b, __m128d c);
```

**Arguments**

- `a`: float64 vector used for the operation
- `b`: float64 vector also used for the operation
- `c`: float64 vector also used for the operation

**Description**

Performs a set of SIMD negated multiply-add computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate results are added to the values in the third operand, `c`, after which the final results are rounded to the nearest float64 values.
The compiler defaults to using the `VFNMADD213PD` instruction and uses the other forms `VFNMADD132PD` or `VFNMADD231PD` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the negated multiply-add operation.

```c
_mm_fnmadd_ps, _mm256_fnmadd_ps
```

* Multiply-adds negated packed single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMADD<XXX>PS`, where `XXX` could be `132, 213, or 231`.

**Syntax**

For 128-bit vector

```c
extern __m128 _mm_fnmadd_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```c
extern __m256 _mm256_fnmadd_ps(__m256 a, __m256 b, __m256 c);
```

**Arguments**

- `a`: float64 vector used for the operation
- `b`: float64 vector also used for the operation
- `c`: float64 vector also used for the operation

**Description**

Performs a set of SIMD negated multiply-add computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate results are added to the values in the third operand, `c`, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFNMADD213PS` instruction and uses the other forms `VFNMADD132PS` or `VFNMADD231PS` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the negated multiply-add operation.

```c
_mm_fnmadd_sd
```

* Multiply-adds negated scalar double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is `VFNMADD<XXX>SD`, where `XXX` could be `132, 213, or 231`.

**Syntax**

```c
extern __m128d _mm_fnmadd_sd(__m128d a, __m128d b, __m128d c);
```
Arguments

\(a\)  
float64 vector used for the operation

\(b\)  
float64 vector also used for the operation

\(c\)  
float64 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-add computation on scalar double-precision floating-point values in the low 64-bits of three source operands, \(a\), \(b\), and \(c\). The float64 values in two operands, \(a\) and \(b\), are multiplied and the negated infinite precision intermediate result obtained is added to the float64 value in the third operand, \(c\). The final result is rounded to the nearest float64 value.

The compiler defaults to using the \texttt{VFNMADD213SD} instruction and uses the other forms \texttt{VFNMADD132SD} or \texttt{VFNMADD231SD} only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.

\_mm\_fnmadd\_ss

Multiply-adds negated scalar single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is \texttt{VFNMADD<XXX>SS}, where \(XXX\) could be 132, 213, or 231.

Syntax

\[
\texttt{extern \_m128 \_mm\_fnmadd\_ss(\_m128 a, \_m128 b, \_m128 c);} \]

Arguments

\(a\)  
float64 vector used for the operation

\(b\)  
float64 vector also used for the operation

\(c\)  
float64 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-add computation on scalar single-precision floating-point values in the low 32-bits of three source operands, \(a\), \(b\), and \(c\). The float32 values in two operands, \(a\) and \(b\), are multiplied and the negated infinite precision intermediate result obtained is added to the float32 value in the third operand, \(c\). The final result is rounded to the nearest float32 value.

The compiler defaults to using the \texttt{VFNMADD213SS} instruction and uses the other forms \texttt{VFNMADD132SS} or \texttt{VFNMADD231SS} only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.
Multiply-subtracts negated packed double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is \texttt{VFNMSUB<XXX>PD}, where \texttt{XXX} could be 132, 213, or 231.

**Syntax**

For 128-bit vector

\texttt{extern __m128d \_mm\_fnmsub\_pd(__m128d a, __m128d b, __m128d c);}  

For 256-bit vector

\texttt{extern __m256d \_mm256\_fnmsub\_pd(__m256d a, __m256d b, __m256d c);}  

**Arguments**

- \texttt{a} float64 vector used for the operation  
- \texttt{b} float64 vector also used for the operation  
- \texttt{c} float64 vector also used for the operation

**Description**

Performs a set of SIMD negated multiply-subtract computation on packed double-precision floating-point values using three source vectors/operands, \texttt{a}, \texttt{b}, and \texttt{c}. Corresponding values in two operands, \texttt{a} and \texttt{b}, are multiplied and the negated infinite precision intermediate result is obtained. From this intermediate result the value in the third operand, \texttt{c}, is subtracted, after which the final results are rounded to the nearest float64 values.

The compiler defaults to using the \texttt{VFNMSUB213PD} instruction and uses the other forms \texttt{VFNMSUB132PD} or \texttt{VFNMSUB231PD} only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

**Returns**

Result of the negated multiply-subtract operation.

Multiply-subtracts negated packed single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is \texttt{VFNMSUB<XXX>PS}, where \texttt{XXX} could be 132, 213, or 231.

**Syntax**

For 128-bit vector

\texttt{extern __m128 \_mm\_fnmsub\_ps(__m128 a, __m128 b, __m128 c);}  

For 256-bit vector

\texttt{extern __m256 \_mm256\_fnmsub\_ps(__m256 a, __m256 b, __m256 c);}  

**Arguments**

- \texttt{a} float32 vector used for the operation
Description
Performs a set of SIMD negated multiply-subtract computation on packed single-precision floating-point values using three source vectors/operands, a, b, and c. Corresponding values in two operands, a and b, are multiplied and the negated infinite precision intermediate result is obtained. From this intermediate result the value in the third operand, c, is subtracted, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the VFNMSUB213PS instruction and uses the other forms VFNMSUB132PS or VFNMSUB231PS only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the negated multiply-subtract operation.

_mm_fnmsub_sd
Multiply-subtracts negated scalar double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is VFNMSUB<XXX>SD, where XXX could be 132, 213, or 231.

Syntax
extern __m128d _mm_fnmsub_sd(__m128d a, __m128d b, __m128d c);

Arguments
a            float64 vector used for the operation
b            float64 vector also used for the operation
c            float64 vector also used for the operation

Description
Performs a set of scalar SIMD negated multiply-subtract computation on scalar double-precision floating-point values in the low 64-bits of three source operands, a, b, and c. The float64 values in two operands, a and b, are multiplied and the negated infinite precision intermediate result is obtained. From this negated intermediate result, the float64 value in the third operand, c, is subtracted. The final result is rounded to the nearest float64 value.

The compiler defaults to using the VFNMSUB213SD instruction and uses the other forms VFNMSUB132SD or VFNMSUB231SD only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the negated multiply-subtract operation.
Multiply-subtracts negated scalar single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMSUB<XXX>SS`, where XXX could be 132, 213, or 231.

Syntax
```
extern __m128 _mm_fnmsub_ss(__m128 a, __m128 b, __m128 c);
```

Arguments
- `a`: float32 vector used for the operation
- `b`: float32 vector also used for the operation
- `c`: float32 vector also used for the operation

Description
Performs a set of scalar SIMD negated multiply-subtract computation on scalar single-precision floating-point values in the low 32-bits of three source operands, `a`, `b`, and `c`. The float32 values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate result is obtained. From this negated intermediate result, the float32 value in the third operand, `c`, is subtracted. The final result is rounded to the nearest float32 value.

The compiler defaults to using the `VFNMSUB213SS` instruction and uses the other forms `VFNMSUB132SS` or `VFNMSUB231SS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns
Result of the negated multiply-subtract operation.

Intrinsics for GATHER Operations

Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, dword indices and scale, and using the given double-precision FP mask values. The corresponding Intel® AVX2 instruction is `VGATHERDPD`.

Syntax
```
extern __m128d _mm_mask_i32gather_pd(__m128d def_vals, double const * base, __m128i vindex __m128d vmask, const int scale);
extern __m256d _mm256_mask_i32gather_pd(__m256d def_vals, double const * base, __m128i vindex __m256d vmask, const int scale);
```

Arguments
- `def_vals`: the vector of double-precision FP values copied to the destination when the corresponding element of the double-precision FP mask is '0'.
- `base`: the base address used to reference the loaded FP elements.
**vindex**
the vector of dword indices used to reference the loaded FP elements.

**vmask**
the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.

**scale**
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

**Description**
The intrinsics conditionally load 2/4 packed double-precision floating-point values from memory using dword indices according to mask values and updates the destination operand.

Below is the pseudo-code for the intrinsics:

```c
_mm_mask_i32gather_pd():
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);

_mm256_mask_i32gather_pd():
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[255:192]);
```

**Returns**
A 128/256-bit vector with conditionally gathered double-precision FP values.

**_mm_i32gather_pd, _mm256_i32gather_pd**
Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, dword indices and scale. The corresponding Intel® AVX2 instruction is **VGATHERDPD**.

**Syntax**
```c
extern __m128d _mm_i32gather_pd(double const * base, __m128i vindex, const int scale);
extern __m256d _mm256_i32gather_pd(double const * base, __m128i vindex, const int scale);
```

**Arguments**
- **base**
the base address used to reference the loaded FP elements.
- **vindex**
the vector of dword indices used to reference the loaded FP elements.
- **scale**
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

**Description**
The intrinsics load 2/4 packed double-precision floating-point values from memory using dword indices and updates the destination operand.

Below is the pseudo-code for the intrinsics:
_mm_i32gather_pd():
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];

_mm256_i32gather_pd():
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];
result[191:128] = mem[base+vindex[95:64]*scale];
result[255:192] = mem[base+vindex[127:96]*scale];

Returns
A 128/256-bit vector with unconditionally gathered double-precision FP values.

_mm_mask_i64gather_pd, _mm256_mask_i64gather_pd
Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, qword indices and scale, and using the given double precision FP mask values. The corresponding Intel® AVX2 instruction is VGATHERQPD.

Syntax
extern __m128d _mm_mask_i64gather_pd(__m128d def_vals, double const * base, __m128i vindex __m128d vmask, const int scale);
extern __m256d _mm256_mask_i64gather_pd(__m256d def_vals, double const * base, __m128i vindex __m256d vmask, const int scale);

Arguments

def_vals
the vector of double-precision FP values copied to the destination when the corresponding element of the double-precision FP mask is '0'.

base
the base address used to reference the loaded FP elements.

vindex
the vector of qword indices used to reference the loaded FP elements.

vmask
the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.

scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics conditionally load 2/4 packed double-precision floating-point values from memory using qword indices according to mask values.

Below is the pseudo-code for the intrinsics:
_mm_mask_i64gather_pd():
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
_mm256_mask_i64gather_pd():

result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);

Returns
A 128/256-bit vector with conditionally gathered double-precision values.

_mm_i64gather_pd, _mm256_i64gather_pd
Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is VGATHERQPD.

Syntax
extern __m128d _mm_i64gather_pd(double const * base, __m128i vindex, const int scale);
extern __m256d _mm256_mask_i64gather_pd(double const * base, __m128i vindex, const int scale);

Arguments
base
the base address used to reference the loaded FP elements.

vindex
the vector of qword indices used to reference the loaded FP elements.

scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics load 2/4 packed double-precision floating-point values from memory using qword indices and updates the destination operand.

Below is the pseudo-code for the intrinsics:

_mm_i64gather_pd():

result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];

_mm256_i64gather_pd():

result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
result[191:128] = mem[base+vindex[191:128]*scale];
result[255:192] = mem[base+vindex[255:192]*scale];

Returns
A 128/256-bit vector with unconditionally gathered double-precision FP values.
_mm_mask_i32gather_ps, _mm256_mask_i32gather_ps
Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, dword indices and scale, and using the given single-precision FP mask values. The corresponding Intel® AVX2 instruction is VGATHERDPS.

Syntax
extern __m128 _mm_mask_i32gather_ps(__m128 def_vals, float const * base, __m128i vindex __m128 vmask, const int scale);
extern __m256 _mm256_mask_i32gather_ps(__m256 def_vals, float const * base, __m256i vindex __m256 vmask, const int scale);

Arguments

def_vals
the vector of single-precision FP values copied to the destination when the corresponding element of the single-precision FP mask is '0'.

base
the base address used to reference the loaded FP elements.

vindex
the vector of dword indices used to reference the loaded FP elements.

vmask
the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.

scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics conditionally load 2/4 packed single-precision floating-point values from memory using dword indices according to mask values.

Below is the pseudo-code for the intrinsics:

_mm_mask_i32gather_ps():

```c
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
```

_mm256_mask_i32gather_ps():

```c
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
result[159:128] = (vmask[159]==1) ? (mem[base+vindex[159:128]*scale]) : (def_vals[159:128]);
```

Returns
A 128/256-bit vector with conditionally gathered single-precision FP values.
_mm_i32gather_ps, _mm256_i32gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, dword indices, and scale. The corresponding Intel® AVX2 instruction is VGATHERDPS.

Syntax

extern __m128 _mm_mask_i32gather_ps(float const * base, __m128i vindex, const int scale);
extern __m256 _mm256_mask_i32gather_ps(float const * base, __m256i vindex, const int scale);

Arguments

base

the base address used to reference the loaded FP elements.

vindex

the vector of dword indices used to reference the loaded FP elements.

scale

The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed single-precision floating-point values from memory using dword indices.

Below is the pseudo-code for the intrinsics:

_mm_i32gather_ps():

result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result[127:96] = mem[base+vindex[127:96]*scale];

_mm256_i32gather_ps():

result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result[127:96] = mem[base+vindex[127:96]*scale];
result[159:128] = mem[base+vindex[159:128]*scale];
result[191:160] = mem[base+vindex[191:160]*scale];
result[223:192] = mem[base+vindex[223:192]*scale];
result[255:224] = mem[base+vindex[255:224]*scale];

Returns

A 128/256-bit vector with unconditionally gathered single-precision FP values.

_mm_mask_i64gather_ps, _mm256_mask_i64gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, qword indices and scale, and using the given single-precision FP mask values. The corresponding Intel® AVX2 instruction is VGATHERQPS.
Syntax

extern __m128 _mm_mask_i64gather_ps(__m128 def_vals, float const * base, __m128i vindex, __m128 vmask, const int scale);
extern __m128 _mm256_mask_i64gather_ps(float const * base, __m256i vindex, __m256i vmask, const int scale);

Arguments

*def_vals*  
the vector of single-precision FP values copied to the destination when the corresponding element of the single-precision FP mask is ‘0’.

*base*  
the base address used to reference the loaded FP elements.

*vindex*  
the vector of qword indices used to reference the loaded FP elements.

*vmask*  
the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.

*scale*  
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 packed single-precision floating-point values from memory using qword indices and updates the destination operand. The intrinsic `_mm_mask_i64gather_ps()` also sets the upper 64-bits of the result to ‘0’.

Below is the pseudo-code for the intrinsics:

```c
_mm_mask_i64gather_ps():

result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[127:64] = 0;

_mm256_mask_i64gather_ps():

result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[127:96]);
```

Returns

A 256/128-bit vector with conditionally gathered single-precision FP values.

**_mm_i64gather_ps, _mm256_i64gather_ps**

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, qword indices and scale. The corresponding Intel® AVX2 instruction is `VGATHERQPS`.

Syntax

extern __m128 __m_mask_i64gather_ps(float const * base, __m128i vindex, const int scale);
extern __m128 __m256_mask_i64gather_ps(float const * base, __m256i vindex, const int scale);
Arguments

**base**
the base address used to reference the loaded FP elements.

**vindex**
the vector of qword indices used to reference the loaded FP elements.

**scale**
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed single-precision floating-point values from memory using qword indices and updates the destination operand. The intrinsic `_mm_i64gather_ps()` also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

```c
_mm_i64gather_ps()

result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[127:64] = 0;
```

```c
_mm256_i64gather_ps()

result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[95:64] = mem[base+vindex[191:128]*scale];
result[127:96] = mem[base+vindex[255:192]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered single-precision FP values.

`_mm_mask_i32gather_epi32, _mm256_mask_i32gather_epi32`

Gathers 2/4 doubleword values from memory referenced by the given base address, dword indices, and scale, using the given dword mask values. The corresponding Intel® AVX2 instruction is `VPGATHERDD`.

Syntax

```c
extern __m128i _mm_mask_i32gather_epi32(__m128i def_vals, int const * base, __m128i vindex, __m128i vmask, const int scale);
```

```c
extern __m256i _mm256_mask_i32gather_epi32(__m256i def_vals, int const * base, __m256i vindex, __m256i vmask, const int scale);
```

Arguments

**def_val**
the vector of dword values copied to the destination when the corresponding element of the vector mask is '0'.

**base**
the base address used to reference the loaded dword elements.

**vindex**
the vector of dword indices used to reference the loaded dword elements.

**vmask**
the vector of dword elements used as a vector mask; only the most significant bit of each dword is used as a mask.
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics conditionally loads 2/4 doubleword values from memory referenced by the given base address, dword indices, and scale, and using the given dword mask values.

Below is the pseudo-code for the intrinsics:

```c
_mm_mask_i32gather_epi32():
```

```c
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
```

```c
_mm256_mask_i32gather_epi32():
```

```c
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
result[159:128] = (vmask[159]==1) ? (mem[base+vindex[159:128]*scale]) : (def_vals[159:128]);
```

Returns
A 128/256 vector with conditionally gathered integer32 values.

**_mm_i32gather_epi32, _mm256_i32gather_epi32**

Gathers 2/4 doubleword values from memory referenced by the given base address, dword indices, and scale. The corresponding Intel® AVX2 instruction is `VPGATHERDD`.

Syntax

```c
extern __m128i _mm_i32gather_epi32(int const * base, __m128i vindex, const int scale);
extern __m256i _mm256_i32gather_epi32(int const * base, __m256i vindex, const int scale);
```

Arguments

- **base**
  the base address used to reference the loaded dword elements.

- **vindex**
  the vector of dword indices used to reference the loaded dword elements.

- **scale**
  The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics load 2/4 doubleword values from memory using the base address, qword indices, and 32-bit scale.

Below is the pseudo-code for the intrinsics:
_mm_i32gather_epi32():

result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result[127:96] = mem[base+vindex[127:96]*scale];

_mm256_i32gather_epi32():

result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result[127:96] = mem[base+vindex[127:96]*scale];
result[159:128] = mem[base+vindex[159:128]*scale];
result[191:160] = mem[base+vindex[191:160]*scale];
result[223:192] = mem[base+vindex[223:192]*scale];
result[255:224] = mem[base+vindex[255:224]*scale];

Returns

A 128/256-bit vector with unconditionally gathered integer32 values.

_mm_mask_i32gather_epi64, _mm256_mask_i32gather_epi64

Gathers 2/4 quadword values from memory referenced by the given base address, dword indices, and scale, and using the given qword mask values. The corresponding Intel® AVX2 instruction is VPGATHERDQ.

Syntax

extern __m128i _mm_mask_i32gather_epi64(__m128i def_vals, __int64 const * base, __m128i vindex, __m128i vmask, const int scale);
extern __m256i _mm256_mask_i32gather_epi64(__m256i def_vals, __int64 const * base, __m128i vindex, __m256i vmask, const int scale);

Arguments

def_val

the vector of qword values copied to the destination when the corresponding element of the vector mask is '0'.

base

the base address used to reference the loaded qword elements.

vindex

the vector of dword indices used to reference the loaded qword elements.

vmask

the vector of qword elements used as a vector mask; only the most significant bit of each qword is used as a mask.

scale

The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 quadword values from memory referenced by the given base address, dword indices and scale, and using the given qword mask values.

Below is the pseudo-code for the intrinsics:
_mm_mask_i32gather_epi64():
result[63:0] = (vmask[63]==1) ? (mem;base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem;base+vindex[63:32]*scale]) : (def_vals[127:64]);

_mm256_mask_i32gather_epi64():
result[63:0] = (vmask[63]==1) ? (mem;base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem;base+vindex[63:32]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem;base+vindex[95:64]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem;base+vindex[127:96]*scale]) : (def_vals[255:192]);

Returns
A 256/128-bit vector with conditionally gathered integer64 values.

_mm_i32gather_epi64, mm256_i32gather_epi64
Gathers 2/4 quadword values from memory referenced by the given base address, dword indices and scale. The corresponding Intel® AVX2 instruction is VPGATHERDQ.

Syntax
extern __m128i _mm_i32gather_epi64(__int64 const * base, __m128i vindex, const int scale);
extern __m256i _mm256_i32gather_epi64(__int64 const * base, __m128i vindex, const int scale);

Arguments
base
the base address used to reference the loaded qword elements.
vindex
the vector of dword indices used to reference the loaded qword elements.
scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics load 2/4 quadword values from memory using the base address, dword indices, and 64-bit scale.

Below is the pseudo-code for the intrinsics:

_mm_i32gather_epi64():
result[63:0] = mem;base+vindex[31:0]*scale];
result[127:64] = mem;base+vindex[63:32]*scale];

_mm256_i32gather_epi64():
result[63:0] = mem;base+vindex[31:0]*scale];
result[127:64] = mem;base+vindex[63:32]*scale];
result[191:128] = mem;base+vindex[95:64]*scale];
result[255:192] = mem;base+vindex[127:96]*scale];

Returns
A 128/256-bit vector with unconditionally gathered integer64 values.
_mm_mask_i64gather_epi32, _mm256_mask_i64gather_epi32
Gathers 2/4 doubleword values from memory referenced by the given base address, qword indices and scale, and using the given dword mask values. The corresponding Intel® AVX2 instruction is VPGATHERQD.

Syntax

extern __m128i _mm_mask_i64gather_epi32(__m128i def_vals, int const * base, __m128i vindex, __m128i vmask, const int scale);

extern __m256i _mm256_mask_i64gather_epi32(__m128i def_vals, int const * base, __m256i vindex, __m128i vmask, const int scale);

Arguments

def_val
the vector of dword values copied to the destination when the corresponding element of the vector mask is '0'.

base
the base address used to reference the loaded dword elements.

vindex
the vector of qword indices used to reference the loaded dword elements.

vmask
the vector of dword elements used as a vector mask; only the most significant bit of each dword is used as a mask.

scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 doubleword values from memory using the base address, qword indices and 32-bit scale. The intrinsic _mm_mask_i64gather_epi32() also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

```c
_mm_mask_i64gather_epi32():
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[127:64] = 0;

_mm256_mask_i64gather_epi32():
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[127:96]);
```

Returns

A 128/256-bit vector with conditionally gathered integer32 values.

_**mm_i64gather_epi32, _mm256_i64gather_epi32**
Gathers 2/4 doubleword values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is VPGATHERQD.
Syntax
extern __m128i _mm_i64gather_epi32(int const * base, __m128i vindex, const int scale);
extern __m128i _mm256_i64gather_epi32(int const * base, __m256i vindex, const int scale);

Arguments
base
the base address used to reference the loaded dword elements.
vindex
the vector of qword indices used to reference the loaded dword elements.
scale
The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description
The intrinsics load 2/4 doubleword values from memory using the base address, qword indices, and 32-bit scale. The intrinsic _mm_i64gather_epi32() also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

_mm_i64gather_epi32():
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[127:64] = 0;

_mm256_i64gather_epi32():
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[95:64] = mem[base+vindex[191:128]*scale];
result[127:96] = mem[base+vindex[255:192]*scale];

Returns
A 128/256-bit vector with unconditionally gathered integer32 values.

_mm_mask_i64gather_epi64, _mm256_mask_i64gather_epi64
Gathers 2/4 quadword values from memory referenced by the given base address, qword indices and scale, and using the given qword mask values. The corresponding Intel® AVX2 instruction is VPGATHERQQ.

Syntax
extern __m128i _mm_mask_i64gather_epi64(__m128i def_vals, __int64 const * base, __m128i vindex, __m128i vmask, const int scale);
extern __m256i _mm256_mask_i64gather_epi64(__m128i def_vals, __int64 const * base, __m256i vindex, __m256i vmask, const int scale);

Arguments
def_val
the vector of qword values copied to the destination when the corresponding element of the vector mask is '0'.
base
the base address used to reference the loaded qword elements.
"vindex" the vector of qword indices used to reference the loaded qword elements.

"vmask" the vector of qword elements used as a vector mask; only the most significant bit of each qword is used as a mask.

"scale" The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

**Description**
The intrinsics conditionally load 2/4 quadword values from memory using the base address, qword indices, and 64-bit scale.

Below is the pseudo-code for the intrinsics:

```c
_mm_mask_i64gather_epi64()

result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);

_mm256_mask_i64gather_epi64()

result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
```

**Returns**
A 128/256-bit vector with conditionally gathered integer64 values.

**_mm_i64gather_epi64, _mm256_i64gather_epi64**
Gathers 2/4 quadword values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is VPGATHERQQ.

**Syntax**
```c
extern __m128i _mm_i64gather_epi64(__int64 const * base, __m128i vindex, const int scale);
extern __m128i _mm256_i64gather_epi64(__int64 const * base, __m256i vindex, const int scale);
```

**Arguments**

- **base** the base address used to reference the loaded qword elements.
- **vindex** the vector of qword indices used to reference the loaded qword elements.
- **scale** The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

**Description**
The intrinsics load 2/4 quadword values from memory using the base address, qword indices, and 64-bit scale.

Below is the pseudo-code for the intrinsics:
_mm_i64gather_epi64():
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];

_mm256_i64gather_epi64():
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
result[191:128] = mem[base+vindex[191:128]*scale];
result[255:192] = mem[base+vindex[255:192]*scale];

Returns
A 128/256-bit vector with unconditionally gathered integer64 values.

Intrinsics for Logical Shift Operations

_mm256_sll_epi16/32/64
Logical shift of word/doubleword/quadword elements to left according to specified number. The corresponding Intel® AVX2 instruction is VPSLLW, VPSLLD, or VPSLLQ.

Syntax
extern __m256i _mm256_sll_epi16(__m256i s1, __m128i count);
extern __m256i _mm256_sll_epi32(__m256i s1, __m128i count);
extern __m256i _mm256_sll_epi64(__m256i s1, __m128i count);

Arguments
s1 integer source vector used for the operation
count 128-bit memory location used for the operation

Description
Performs logical shift of bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector s1 to the left by the number of bits specified in count. The empty low-order bytes are cleared (set to all '0'). If the value specified by count is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'.

The count argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

Returns
Result of the left-shift operation.

_mm256_slli_epi16/32/64
Logical shift of word/doubleword/quadword elements to left according to specified number. The corresponding Intel® AVX2 instruction is VPSLLW, VPSLLD, or VPSLLQ.

Syntax
extern __m256i _mm256_slli_epi16(__m256i s1, int count);
extern __m256i _mm256_slli_epi32(__m256i s1, int count);
extern __m256i _mm256_slli_epi64(__m256i s1, int count);

Arguments

- **s1**: integer source vector used for the operation
- **count**: 8-bit immediate used for the operation

Description

Performs a logical shift of bits in the individual data elements (words, doublewords, or quadword) in source vector `s1` to the left by the number of bits specified in `count`. The empty low-order bytes are cleared (set to all '0'). If the value specified by `count` is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all 0s. The `count` argument is an 8-bit immediate.

Returns

Result of the left-shift operation.

_mm256_sllv_epi32/64

Logical shift of doubleword/quadword elements to left according variable values. The corresponding Intel® AVX2 instruction is **VPSLLVD** or **VPSLLVQ**.

Syntax

extern __m256i _mm256_sllv_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_sllv_epi64(__m256i s1, __m256i s2);

Arguments

- **s1**: integer source vector used for the operation
- **s2**: integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector `s1` to the left by the count value of corresponding data elements in source vector `s2`. As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

Returns

Result of the left-shift operation.

_mm_sllv_epi32/64

Logical shift of word/doubleword elements in a 128-bit vector to left according variable values. The corresponding Intel® AVX2 instruction is **VPSLLVD** or **VPSLLVQ**.

Syntax

extern __m128i _mm_sllv_epi32(__m128i s1, __m128i s2);
extern __m128i _mm_sllv_epi64(__m128i s1, __m128i s2);

**Arguments**

- **s1**: 128-bit integer source vector used for the operation
- **s2**: 128-bit integer source vector providing variable values for shift operation

**Description**

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector `s1` to the left by the count value of corresponding data elements in source vector `s2`. As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

**Returns**

Result of the left-shift operation.

---

```c
extern __m256i _mm256_slli_si256(__m256i s1, const int count);
```

**Arguments**

- **s1**: integer source vector used for the operation
- **count**: 8-bit immediate used for the operation

**Description**

Performs a logical shift of 8-bit [byte] elements within a 128-bit lane of the source vector `s1` to the left by the number of bytes specified in `count`. The empty low-order bytes are cleared (set to all '0'). If the value specified by `count` is greater than 15, the destination vector is set to all 0s. The `count` argument is an 8-bit immediate.

**Returns**

Result of the left-shift operation.

---

```c
extern __m256i _mm256_srli_si256(__m256i s1, const int count);
```

**Arguments**

- **s1**: integer source vector used for the operation
- **count**: 8-bit immediate used for the operation

**Description**

Performs a logical shift of 8-bit [byte] elements to right according to specified number. The corresponding Intel® AVX2 instruction is `vpsrlq`.

**Syntax**

```c
extern __m256i _mm256_srli_si256(__m256i s1, const int count);
```
Arguments

$s1$  
integer source vector used for the operation

count  
8-bit immediate used for the operation

Description

Performs a logical shift of 8-bit [byte] elements within a 128-bit lane of source vector $s1$ to the right by the number of bytes specified in $count$. The empty low-order bytes are cleared (set to all '0'). If the value specified by $count$ is greater than 15, the destination vector is set to all '0'. The $count$ argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srl_epi16/32/64

Logical shift of word/doubleword/quadword elements to right according to specified number. The corresponding Intel® AVX2 instruction is VPSRLW, VPSRLD, or VPSRLQ.

Syntax

extern __m256i _mm256_srl_epi16(__m256i s1, __m128i count);
extern __m256i _mm256_srl_epi32(__m256i s1, __m128i count);
extern __m256i _mm256_srl_epi64(__m256i s1, __m128i count);

Arguments

$s1$  
integer source vector used for the operation

count  
128-bit memory location used for the operation

Description

Performs a logical shift of the bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector $s1$ to the right by the number of bits specified in $count$. The empty low-order bytes are cleared (set to all '0'). If the value specified by $count$ is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'.

The $count$ argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

Returns

Result of the right-shift operation.

_mm256_srli_epi16/32/64

Logical shift of word/doubleword/quadword elements to right according to specified number. The corresponding Intel® AVX2 instruction is VPSRLW, VPSRLD, or VPSRLQ.

Syntax

extern __m256i _mm256_srli_epi16(__m256i s1, int count);
extern _m256i _mm256_srlv_epi32(_m256i s1, int count);
extern _m256i _mm256_srlv_epi64(_m256i s1, int count);

Arguments

s1  integer source vector used for the operation
count  8-bit immediate used for the operation

Description

Performs a logical shift of bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector s1 to the right by the number of bits specified in count. The empty low-order bytes are cleared (set to all '0'). If the value specified by count is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'. The count argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srlv_epi32/64

Logical shift of doubleword/quadword elements to right according variable values. The corresponding Intel® AVX2 instruction is VPSRLVD or VPSRLVQ.

Syntax

extern _m256i _mm256_srlv_epi32(_m256i s1, __m256i s2);
extern _m256i _mm256_srlv_epi64(_m256i s1, __m256i s2);

Arguments

s1  integer source vector used for the operation
s2  integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector s1 to the right by the count value of corresponding data elements in source vector s2. As the bits in the data elements are shifted right, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

Returns

Result of the right-shift operation.

_mm_srlv_epi32/64

Logical shift of word/doubleword elements in a 128-bit vector to right according variable values. The corresponding Intel® AVX2 instruction is VPSRLVD or VPSRLVQ.

Syntax

extern __m128i _mm_srlv_epi32(__m128i s1, __m128i s2);
extern __m128i _mm_srlv_epi64(__m128i s1, __m128i s2);

**Arguments**

- **s1**: 128-bit integer source vector used for the operation
- **s2**: 128-bit integer source vector providing variable values for shift operation

**Description**

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector `s1` to the right by the count value of corresponding data elements in the source vector `s2`. As the bits in the data elements are shifted right, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data element are set to '0'.

**Returns**

Result of the right-shift operation.

**Intrinsics for Insert/Extract Operations**

__m256i _mm256_inserti128_si256

Inserts 128-bits of packed integer data of the second source vector into the destination vector at a 128-bit offset from imm8[0]. The corresponding Intel® AVX2 instruction is VINSERTI128.

**Syntax**

extern __m256i _mm256_inserti128_si256(__m256i a, __m128i b, const int mask);

**Arguments**

- **a**: integer source vector
- **b**: integer source vector
- **mask**: integer constant specifying offset

**Description**

Inserts 128-bits of packed integer data from the second source operand (third operand) into the destination operand (first operand) at a 128-bit offset from imm8[0]. The remaining portions of the destination are written by the corresponding fields of the first source operand (second operand). The high 7 bits of the immediate are ignored.

**Returns**

_mm256_extracti128_si256

Extracts 128-bits of packed integer data of the second source vector into the destination vector at a 128-bit offset from imm8[0]. The corresponding Intel® AVX2 instruction is VEXTRACTI128.
Syntax

extern __m128i _mm256_extracti128_si256(__m256i a, int offset);

Arguments

\( a \)  
integer source vector

\( offset \)  
integer constant specifying offset

Description

Extract 128 bits (composed of integer data) from \( a \), selected with imm, and store the result in dst.

Extracts 128-bits of packed integer data from source vector \( a \) with \( offset \). The remaining portions of the destination are written by the corresponding fields of the source vector. The destination may be either an XMM register or a 128-bit memory location. The high 7 bits of the immediate are ignored.

Returns

\_mm256_insert_epi8/16/32/64

Insert 8/16/32/64-bit integer into a vector of integers at the position specified by index.

Syntax

extern __m256i _mm256_insert_epi8(__m256i a, int8 i, const int index);
extern __m256i _mm256_insert_epi16(__m256i a, int16 i, const int index);
extern __m256i _mm256_insert_epi32(__m256i a, int32 i, const int index);
extern __m256i _mm256_insert_epi64(__m256i a, int64 i, const int index);

Arguments

\( a \)  
integer source vector

\( i \)  
integer value to insert

\( offset \)  
integer constant specifying offset

Description

Insert an integer value, \( i \) into the corresponding position of an integer source vector, \( a \), and return the resulting vector.

\_mm256_extract_epi8/16/32/64

Extract integer byte or word from packed integer array element selected by index.

Syntax

extern int _mm256_extract_epi8(__m256i a, int offset);
extern int _mm256_extract_epi16(__m256i a, int offset);
extern int _mm256_extract_epi32(__m256i a, int offset);
extern int _mm256_extract_epi64(__m256i a, int offset);
Arguments

\texttt{a} \quad \text{integer source vector}

\texttt{offset} \quad \text{integer constant specifying offset}

Description

Returns extracted 8/16/32/64 bits of data of the source vector at offset position. Offset counts with element size granularity.

Upper bits of returned integer value are cleared.

Intrinsics for Masked Load/Store Operations

\_\texttt{mm\_maskload\_epi32/64, mm256\_maskload\_epi32/64}

\textit{Conditionally loads dwords/qwords from the specified memory location, depending on the mask bits associated with each data element. The corresponding Intel® AVX2 instruction is \texttt{VPMASKMOVD or VPMASKMOVQ.}}

Syntax

\begin{verbatim}
extern __m128i _mm_maskload_epi32(int const * addr, __m128i mask);
extern __m256i _mm256_maskload_epi32(int const * addr, __m256i mask);
extern __m128i _mm_maskload_epi64(__int64 const * addr, __m128i mask);
extern __m256i _mm256_maskload_epi64(__int64 const * addr, __m256i mask);
\end{verbatim}

Arguments

\texttt{addr} \quad \text{pointer to data to be loaded}

\texttt{mask} \quad \text{integer source vector}

Description

Conditionally loads 32/64-bit data elements from the memory referenced by the \texttt{addr} and stores it into the corresponding data element of the result vector. If an element of mask is 0, the 32/64-bit zero is written to the corresponding element of the result vector. The mask bit for each data element is the most significant bit of that element in mask.

Returns

Result of the masked load operation.

\_\texttt{mm\_maskstore\_epi32/64, mm256\_maskstore\_epi32/64}

\textit{Conditionally stores dwords/qwords from the source vector to the specified memory location, depending on the given mask bits associated with each data element. The corresponding Intel® AVX2 instruction is \texttt{VPMASKMOVD or VPMASKMOVQ.}}

Syntax

\begin{verbatim}
extern void _mm_maskstore_epi32(int * addr, __m128i vmask, __m128i val);
\end{verbatim}
extern void _mm256_maskstore_epi32(int * addr, __m256i vmask, __m256i val);
extern void _mm_maskstore_epi64(__int64 * addr, __m128i vmask, __m128i val);
extern void _mm256_maskstore_epi64(__int64 * addr, __m256i vmask, __m256i val);

**Arguments**

- **addr**: pointer to data to be loaded
- **vmask**: vector mask. If element of vmask is 0, then the value in the memory is unchanged
- **val**: location from where the elements are written to vector located in memory and referenced by "addr"

**Description**

Conditionally stores 32/64-bit data elements from the source vector into the corresponding elements of the vector in memory referenced by addr. If an element of mask is 0, corresponding element of the result vector in memory stays unchanged. Only the most significant bit of each element in the vector mask is used.

**Returns**

Result of the masked store operation.

**Intrinsics for Miscellaneous Operations**

**_mm256_alignr_epi8**

Aligns elements of two source vectors depending on bits in a mask. The corresponding Intel® AVX2 instruction is VPALIGNR.

**Syntax**

```c
extern __m256i _mm256_alignr_epi8(__m256i s1, __m256i s2, const int mask);
```

**Arguments**

- **s1**: integer source vector used for the operation
- **s2**: integer source vector used for the operation
- **mask**: 8-bit immediate bits used for the operation

**Description**

Performs an alignment operation by concatenating two blocks of 16-byte data from the first and second source vectors, s1 and s2, into an intermediate 32-byte composite, shifting the composite at byte granularity to the right by a constant immediate specified by mask, and extracting the right-aligned 16-byte result into the destination vector. The immediate value is considered unsigned.
Returns

Result of the alignment operation.

__mm256_movemask_epi8

Moves byte mask from source vector. The corresponding Intel® AVX2 instruction is VPMOVMSKB.

Syntax

extern int _mm256_movemask_epi8(__m256i s1);

Arguments

s1  integer source vector used for the operation.

Description

Creates a mask from the most significant bit of each byte of source vector s1 and stores the result in the in the returned doubleword value/mask.

Returns

Result of the move mask operation.

__mm256_stream_load_si256

Loads 256-bit data from memory using non-temporal aligned hint. The corresponding Intel® AVX2 instruction is VMOVNTDQA.

Syntax

extern __m256i _mm256_stream_load_si256(__m256i const *);

Arguments

s1  integer source vector used for the operation.
Description
Loads 256-bit data from the source operand to the destination operand using a non-temporal hint if the memory source is write combining memory type.

Intrinsics for Operations to Manipulate Integer Data at Bit-Granularity

_bextr_u32/64
Extracts contiguous bits from the first source operand to the destination using an index value and length value specified in the second source operand. The corresponding Intel® AVX2 instruction is BEXTR.

Syntax
extern unsigned int _bextr_u32(unsigned int source, unsigned int sb, unsigned int bl);
extern unsigned __int64 _bextr_u64(unsigned __int64 s1, unsigned int sb, unsigned int bl);

Arguments

source  the source from where the bits are extracted
sb  start bit, the number of the bit from where the contiguous bits are extracted
bl  bit length, the number of bits to be extracted

Description
Extracts contiguous bits from the first source operand to the destination using an index value and length value specified in the second source operand. The extracted bits are written to the destination starting from the least significant bit. All higher order bits in the destination starting at bit position bl are zeroed. The destination is cleared if no bits are extracted.

Returns
Result of the operation.

_blsi_u32/64
Extracts the lowest set bit from the source operand and set the corresponding bit in the destination. The corresponding Intel® AVX2 instruction is BLSI.

Syntax
extern unsigned int _blsi_u32(unsigned int source);
extern unsigned __int64 _blsi_u64(unsigned __int64 source);

Arguments

source  the source from where the bits are extracted
Description

Extracts the lowest set bit from the source operand and sets the corresponding bit in the destination. All other bits in the destination are set to 0. If no bits are set in the source operand, all the bits in the destination are set to 0.

Returns

Result of the operation.

_blsmsk_u32/64

Sets all the lower bits of the destination to "1" up to and including lowest set bit (=1) in the source operand. The corresponding Intel® AVX2 instruction is BLSM.

Syntax

extern unsigned int _blsmsk_u32(unsigned int s1);
extern unsigned __int64 _blsmsk_u64(unsigned __int64 s1);

Arguments

s1 the source operand used for the operation

Description

Sets all the lower bits of the destination to “1” up to and including lowest set bit (=1) in the source operand. If source operand is 0, all bits of the destination are set to 1.

Returns

Result of the operation

_blsr_u32/64

Copies all bits from the source operand to the destination and resets (=0) the bit position in the destination that corresponds to the lowest set bit of the source operand. The corresponding Intel® AVX2 instruction is BLSR.

Syntax

extern unsigned int _blsr_u32(unsigned int s1);
extern unsigned __int64 _blsr_u64(unsigned __int64 s1);

Arguments

s1 the source operand from where the bits are copied

Description

Copies all bits from the source operand to the destination and resets (=0) the bit position in the destination that corresponds to the lowest set bit of the source operand.

Returns

Result of the operation
_bzhi_u32/64
Copies the bits of the first source operand into the destination and clears the higher bits in the destination according to the index value specified by the second source operand. The corresponding Intel® AVX2 instruction is BZHI.

Syntax
extern unsigned int _bzhi_u32(unsigned int source, unsigned int index);
extern unsigned __int64 _bzhi_u64(unsigned __int64 source, unsigned int index);

Arguments
- source: the source operand from where the bits are copied
- index: index value according to which the bits are copied

Description
Copies the bits of the first source operand into the destination and clears the higher bits in the destination according to the index value. The index value is specified by bits 7:0 of the second source operand.

Returns
Result of the operation.

_pext_u32/64
Transfer either contiguous or non-contiguous bits in the first source operand to contiguous low order bit positions in the destination according to the mask values. The corresponding Intel® AVX2 instruction is PEXT.

Syntax
extern unsigned int _pext_u32(unsigned int source, unsigned int mask);
extern unsigned __int64 _pext_u64(unsigned __int64 s1, unsigned __int64 mask);

Arguments
- source: the source operand from where the bits are transferred
- mask: mask value according to which the bits are transferred

Description
The intrinsics use a mask in the second source operand to transfer either contiguous or non-contiguous bits in the first source operand to contiguous, low-order bit positions in the destination. For each bit set in the mask, the intrinsic extracts the corresponding bits from the first source operand and writes them into contiguous lower bits of the destination. The remaining upper bits of the destination are set to 0.

Returns
Result of the operation
_pdep_u32/64
Transfer/scatter contiguous low order bits in the first source operand into the destination according to the mask in the second source operand. The corresponding Intel® AVX2 instruction is PDEP.

Syntax
extern unsigned int _pdep_u32(unsigned int source, unsigned int mask);
extern unsigned __int64 _pdep_u64(unsigned __int64 source, unsigned __int64 mask);

Arguments
source the source operand from where the bits are transferred
mask the mask value according to which the bits are transferred

Description
The intrinsics use a mask in the second source operand to transfer/scatter contiguous, low-order bits in the first source operand into the destination. It takes the low bits from the first source operand and deposit them in the destination at the corresponding bit locations that are set in the mask. All other bits (bits not set in mask) in the destination are set to 0.

Returns
Result of the operation

_lzcnt_u32/64
Counts the number of leading zero bits in a source operand. Returns operand size as output when source operand is zero. The corresponding Intel® AVX2 instruction is LZCNT.

Syntax
extern unsigned int _lzcnt_u32(unsigned int source);
extern unsigned __int64 _lzcnt_u64(unsigned __int64 source);

Arguments
source the source operand used for the operation

Description
Counts the number of leading most significant zero bits in a source operand returning the result into a destination when source operand is 0.

Returns
Result of the operation.
_tzcnt_u32/64
Counts the number of trailing least significant zero bits in source operand and returns the result in destination. When source operand is 0, it returns its size in bits. The corresponding Intel® AVX2 instruction is T2CNT.

Syntax
extern unsigned int _tzcnt_u32(unsigned int source);
extern unsigned __int64 _tzcnt_u64(unsigned __int64 source);

Arguments
source
the source operand used for the operation

Description
Searches the source operand for the least significant set bit. If a least significant 1 bit is found, its bit index is returned, otherwise the result is the number of bits in the operand size.

Returns
Result of the operation.

Intrinsics for Pack/Unpack Operations

_mm256_packs_epi16/32
Pack signed word/doubleword integers to signed byte/words integers and saturates. The corresponding Intel® AVX2 instruction is VPACKSSWB or VPACKSSDW.

Syntax
extern __m256i _mm256_packs_epi16(__m256i a, __m256i b);
extern __m256i _mm256_packs_epi32(__m256i a, __m256i b);

Arguments
a
integer source vector used for the operation
b
integer source vector used for the operation

Description
The _mm256_packs_epi16 intrinsic converts 16 packed signed word integers from the first and the second source operands into 32 packed signed byte integers. The _mm256_packs_epi32 intrinsic converts eight packed signed doubleword integers from the first and the second source operands into 16 packed signed word integers.

Returns
Result of the pack operation.
_mm256_packus_epi16/32
Pack signed word/doubleword integers to unsigned byte/word integers and saturates. The corresponding Intel® AVX2 instruction is _VPACKUSWB or _VPACKUSDW.

Syntax
extern __m256i _mm256_packus_epi16(__m256i a, __m256i b);
extern __m256i _mm256_packus_epi32(__m256i a, __m256i b);

Arguments

\(a\)  
integer source operand used for the operation

\(b\)  
integer source operand used for the operation

Description
The _mm256_packus_epi16 intrinsic converts 16 packed signed word integers from source operands \(a\) and \(b\) into 32 packed unsigned byte integers. The _mm256_packus_epi32 intrinsic converts eight packed signed doubleword integers from the source operands \(a\) and \(b\) into 16 packed unsigned word integers.

Returns
Result of the pack operation.

_mm256_unpackhi_epi8/16/32/64
Unpacks and interleaves the high-order data elements of the source vector with the high-order data elements in the destination vector. The corresponding Intel® AVX2 instruction is _VPUNPCKHBW, _VPUNPCKHWD, _VPUNPCKHDQ, or _VPUNPCKHQB.

Syntax
extern __m256i _mm256_unpackhi_epi8(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi16(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi32(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi64(__m256i a, __m256i b);

Arguments

\(a\)  
integer source operand used for the operation

\(b\)  
integer source operand used for the operation

Description
Unpacks and interleaves the high-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) of the source vector and the high-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) in the destination vector. The low-order data elements are ignored.

Returns
Result of the interleave operation
_mm256_unpacklo_epi8/16/32/64
Unpacks and interleaves the low-order data elements of the source vector with the low-order data elements in the destination vector. The corresponding Intel® AVX2 instruction is VPUNPCKLBW, VPUNPCKLWD, VPUNPCKLDQ, or VPUNPCKLQDQ.

Syntax
extern __m256i _mm256_unpacklo_epi8(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi16(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi32(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi64(__m256i a, __m256i b);

Arguments
a
integer source vector used for the operation
b
integer source vector used for the operation

Description
Unpacks and interleaves the low-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) of the source vector and the low-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) in the destination operand. The high-order data elements are ignored.

Returns
Result of the interleave operation

Intrinsics for Packed Move with Extend Operations

_mm256_cvtepi8_epi16/32/64
Performs packed move with sign-extend on 8-bit signed integers to 16/32/64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVSX BW, VPMOVSX BD, or VPMOVSX QD.

Syntax
extern __m256i _mm256_cvtepi8_epi16(__m128i s1);
extern __m256i _mm256_cvtepi8_epi32(__m128i s1);
extern __m256i _mm256_cvtepi8_epi64(__m128i s1);

Arguments
s1
128-bit integer source vector used for the operation

Description
Performs a packed move with sign-extend operation to convert 8-bit [byte] integers in the low bytes of the source vector, s1, to 16-bit [word], 32-bit [doubleword], or 64-bit [quadword] integers, which are stored as packed signed word/doubleword/quadword integers in the destination vector.
Returns
Result of the sign-extend operation.

_mm256_cvtepi16_epi32/64
Performs packed move with sign-extend on 16-bit signed integers to 32/64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVSXWD or VPMOVSXWQ.

Syntax
extern __m256i _mm256_cvtepi16_epi32(__m128i s1);
extern __m256i _mm256_cvtepi16_epi64(__m128i s1);

Arguments
s1  128-bit integer source vector used for the operation

Description
Performs a packed move with sign-extend operation to convert 16-bit [word] integers in the low bytes of the source vector, s1, to 32-bit [doubleword] or 64-bit [quadword] integers and stored as packed signed doubleword/quadword integers in the destination vector.

Returns
Result of the sign-extend operation.

_mm256_cvtepi32_epi64
Performs packed move with sign-extend on 32-bit signed integers to 64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVSXDQ.

Syntax
extern __m256i _mm256_cvtepi32_epi64(__m128i s1);

Arguments
s1  128-bit integer source vector used for the operation

Description
Performs a packed move with sign-extend operation to convert 32-bit [doubleword] integers in the low bytes of the source vector, s1, to 64-bit [quadword] integers and stored as packed signed quadword integers in the destination vector.

Returns
Result of the sign-extend operation.
**_mm256_cvtepu8_epi16/32/64_**
Performs packed move with zero-extend on 8-bit unsigned integers to 16/32/64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVZXBW, VPMOVZXBD, or VPMOVZXBQ.

**Syntax**
`extern __m256i _mm256_cvtepu8_epi16(__m128i s1);`
`extern __m256i _mm256_cvtepu8_epi32(__m128i s1);`
`extern __m256i _mm256_cvtepu8_epi64(__m128i s1);`

**Arguments**
`s1` 128-bit integer source vector used for the operation

**Description**
Performs a packed move with zero-extend operation to convert 8-bit [byte] integers in the low bytes of the source vector, `s1`, to 16-bit [word], 32-bit [doubleword], or 64-bit [quadword] integers and stored as packed unsigned word/doubleword/quadword integers in the destination vector.

**Returns**
Result of the zero-extend operation.

**_mm256_cvtepu16_epi32/64_**
Performs packed move with zero-extend on 16-bit unsigned integers to 32/64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVZXWD or VPMOVZXWQ.

**Syntax**
`extern __m256i _mm256_cvtepu16_epi32(__m128i s1);`
`extern __m256i _mm256_cvtepu16_epi64(__m128i s1);`

**Arguments**
`s1` 128-bit integer source vector used for the operation

**Description**
Performs a packed move with zero-extend operation to convert 16-bit [word] integers in the low bytes of the source vector, `s1`, to 32-bit [doubleword] or 64-bit [quadword] integers and stored as packed signed doubleword/quadword integers in the destination vector.

**Returns**
Result of the zero-extend operation.

**_mm256_cvtepu32_epi64_**
Performs packed move with zero-extend on 32-bit unsigned integers to 64-bit integers. The corresponding Intel® AVX2 instruction is VPMOVZXDQ.

1476
**Syntax**

extern __m256i _mm256_cvtepu32_epi64(__m128i s1);

**Arguments**

\( s1 \)

128-bit integer source vector used for the operation

**Description**

 Performs a packed move with zero-extend operation to convert 32-bit [doubleword] integers in the low bytes of the source vector, \( s1 \), to 64-bit [quadword] integers and stored as packed signed quadword integers in the destination vector.

**Returns**

Result of the zero-extend operation.

---

**Intrinsics for Permute Operations**

**_mm256_permutevar8x32_epi32**

Permutates doubleword elements of the source vector into the destination vector. The corresponding Intel\textsuperscript{®} AVX2 instruction is VPERMD.

**Syntax**

extern __m256i _mm256_permutevar8x32_epi32(__m256i val, __m256i offsets);

**Arguments**

\( val \)

the vector of 32-bit integer elements to be permuted

\( offsets \)

the vector of eight 3-bit offsets (specifying values in range [0 - 7]) for the permuted elements of 256-bit vector

**Description**

Use the offset values in each dword element of the vector \( offsets \) to select a dword element from the source vector \( val \). The result element is copied to the corresponding element of destination vector. The intrinsic does NOT allow to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

\[
\begin{align*}
\text{RESULT}[31:0] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[2:0] \times 32))[31:0]; \\
\text{RESULT}[63:32] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[34:32] \times 32))[31:0]; \\
\text{RESULT}[95:64] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[66:64] \times 32))[31:0]; \\
\text{RESULT}[127:96] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[98:96] \times 32))[31:0]; \\
\text{RESULT}[159:128] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[130:128] \times 32))[31:0]; \\
\text{RESULT}[191:160] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[162:160] \times 32))[31:0]; \\
\text{RESULT}[223:192] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[194:192] \times 32))[31:0]; \\
\text{RESULT}[255:224] & \leftarrow (\text{VAL}[255:0] >> (\text{OFFSETS}[226:224] \times 32))[31:0];
\end{align*}
\]

**Returns**

Result of the permute operation.
_mm256_permutevar8x32_ps
Permutes single-precision floating-point elements of the source vector into the destination vector. The corresponding Intel® AVX2 instruction is VPERMPS.

Syntax
extern __m256i _mm256_permutevar8x32_ps(__m256 val, __m256i offsets);

Arguments
val
the vector of 32-bit single-precision floating-point elements to be permuted

offsets
the vector of eight 3-bit offsets (specifying values in range [0 - 7]) for the permuted elements of 256-bit vector

Description
Use the offset values in each dword element of the vector offsets to select a single-precision floating-point element from the source vector val. The result element is copied to the corresponding element of destination vector. The intrinsic does NOT allow to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[31:0] <- (VAL[255:0] >> (OFFSETS[2:0] * 32))[31:0];
RESULT[63:32] <- (VAL[255:0] >> (OFFSETS[34:32] * 32))[31:0];
RESULT[95:64] <- (VAL[255:0] >> (OFFSETS[66:64] * 32))[31:0];
RESULT[127:96] <- (VAL[255:0] >> (OFFSETS[98:96] * 32))[31:0];
```

Returns
Result of the permute operation.

_mm256_permute4x64_epi64
Permutes quadword integer values of the source vector into the destination vector. The corresponding Intel® AVX2 instruction is VPERMQ.

Syntax
extern __m256i _mm256_permute4x64_epi64(__m256i val, const int control);

Arguments
val
the vector of 64-bit quadword integer elements to be permuted

control
an integer specified as an 8-bit immediate

Description
Use two-bit index values in the immediate byte to select a qword integer element from the source vector val. The result element is copied to the corresponding element of destination vector. The intrinsic allows to copy the same element of the source vector to more than one element of the destination vector.
Below is the pseudo-code for the intrinsic:

```
RESULT[63:0] <- (VAL[255:0] >> (CONTROL[1:0] * 64))[63:0];
RESULT[127:64] <- (VAL[255:0] >> (CONTROL[3:2] * 64))[63:0];
```

**Returns**

Result of the permute operation.

**_mm256_permute4x64_pd**

Permutes quadword double-precision floating-point values of the source vector into the destination vector. The corresponding Intel® AVX2 instruction is VPERMPD.

**Syntax**

```
extern __m256i _mm256_permute4x64_epi64(__m256d val, const int control);
```

**Arguments**

- **val** the vector of 64-bit qword double-precision floating-point elements to be permuted
- **control** an integer specified as an 8-bit immediate

**Description**

Use two-bit index values in the immediate byte to select a qword double-precision floating-point element from the source vector val. The result element is copied to the corresponding element of destination vector. The intrinsic allows to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[63:0] <- (VAL[255:0] >> (CONTROL[1:0] * 64))[63:0];
RESULT[127:64] <- (VAL[255:0] >> (CONTROL[3:2] * 64))[63:0];
```

**Returns**

Result of the permute operation.

**_mm256_permute2x128_si256**

Permutes 128-bit integer data from the first source vector and the second source vector in the destination vector. The corresponding Intel® AVX2 instruction is VPERM2I128.

**Syntax**

```
extern __m256i _mm256_permute2x128_si256(__m256i a, __m256i b, int control);
```

**Arguments**

- **a** integer source vector
**Description**

Permutates 128-bit integer data from source vector `a` and source vector `b` using bits in the 8-bit immediate and stores results in the destination vector.

**Returns**

Result of the permute operation.

**Intrinsics for Shuffle Operations**

`_mm256_shuffle_epi8`

Shuffles bytes in the first source vector according to the shuffle control mask in the second source vector. The corresponding Intel® AVX2 instruction is `VPSHUFB`.

**Syntax**

```cpp
extern __m256i _mm256_shuffle_epi8(__m256i a, __m256i b);      
```

**Arguments**

- `a` integer source vector
- `b` integer source vector

**Description**

Performs shuffle operations of the signed or unsigned 8-bit integers in the source vector as specified by the shuffle control mask in the second source operand.

Below is the pseudocode interpreting `a`, `b`, and `r` as arrays of unsigned 8-bit integers:

```cpp
for (i = 0; i < 16; i++){
    if (b[i] & 0x80){
        r[i] = 0;
    }else{
        r[i] = a[b[i] & 0x0F];
    }
}
```
if (b[16+i] & 0x80){
    r[16+i] = 0;
} else{
    r[16+i] = a[16+(b[16+i] & 0x0F)];
}

Returns
Result of the shuffle operation.

_mm256_shuffle_epi32
Conditionally shuffles doublewords of the source vector in the destination vector at the locations selected with the immediate control operand. The corresponding Intel® AVX2 instruction is VPSHUFD.

Syntax
extern __m256i _mm256_shuffle_epi32(__m256i val, const int control);

Arguments
val integer source vector
control immediate control operand

Description
Performs shuffle operations of the signed or unsigned 32-bit integers in the source vector as specified by the control operand. The shuffle value must be an immediate.

Returns
Result of the shuffle operation.

_mm256_shufflehi_epi16
Shuffles the upper 4 high signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The low qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding low qwords of the result value. The corresponding Intel® AVX 2 instruction is VPSHUFW.

Syntax
extern __m256i _mm256_shufflehi_epi16(__m256i val, const int control);

Arguments
val integer source operand
control immediate control mask
**Description**

Shuffles the upper four high signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The low qwords in each of two 128-bit lanes of the source operand are copied to the corresponding low qwords of the result value. The shuffle control operand must be an immediate.

Below is the pseudo-code for the intrinsic:

```c
RESULT[63:0] <- VAL[63:0]
RESULT[79:64] <- (VAL >> (CONTROL[1:0] *16))[79:64]
```

**Returns**

Result of the shuffle operation.

**_mm256_shufflelo_epi16**

*Shuffles the low 4 signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The high qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding high qwords of the result value. The corresponding Intel® AVX 2 instruction is VFSHUFLW.*

**Syntax**

```c
extern __m256i _mm256_shufflelo_epi16(__m256i val, const int control);
```

**Arguments**

- **val**: integer source vector
- **control**: immediate control operand

**Description**

Shuffles the low four signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The high qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding high qwords of the result value. The shuffle value must be an immediate.

Below is the pseudo-code for the intrinsic:

```c
RESULT[15:0] <- (VAL >> (CONTROL[1:0] *16))[15:0]
RESULT[127:64] <- VAL[127:64]
RESULT[143:128] <- (VAL >> (CONTROL[1:0] *16))[143:128]
```
Returns
Result of the shuffle operation.

Intrinsics for Intel® Transactional Synchronization Extensions (Intel® TSX)

Intel® Transactional Synchronization Extensions (Intel® TSX) Overview

Intel® transactional synchronization extensions (Intel® TSX) allow the processor to determine dynamically whether threads need to serialize through lock-protected critical sections, and to perform serialization only when required. This lets the processor expose and exploit concurrency hidden in an application due to dynamically unnecessary synchronization.

With Intel® TSX, programmer-specified code regions (also referred to as transactional regions) are executed transactionally. If the transactional execution completes successfully, then all memory operations performed within the transactional region will appear to have occurred instantaneously when viewed from other logical processors. A processor makes architectural updates performed within the region visible to other logical processors only on a successful commit, a process referred to as an atomic commit.

Intel® TSX also provides an XTEST instruction, allowing software to query whether the logical processor is transactionally executing in a transactional region identified by either Hardware Lock Elision (HLE) or Restricted Transactional Memory (RTM).

Since a successful transactional execution ensures an atomic commit, the processor executes the code region optimistically without explicit synchronization. If synchronization was unnecessary for that specific execution, execution can commit without any cross-thread serialization. If the processor cannot commit atomically, the optimistic execution fails. When this happens, the processor will roll back the execution, a process referred to as a transactional abort. On a transactional abort, the processor will discard all updates performed in the region, restore architectural state to appear as if the optimistic execution never occurred, and resume execution non-transactionally.

A processor can perform a transactional abort for numerous reasons. A primary cause is due to conflicting accesses between the transactionally executing logical processor and another logical processor. Such conflicting accesses may prevent a successful transactional execution. Memory addresses read from within a transactional region constitute the read-set of the transactional region and addresses written to within the transactional region constitute the write-set of the transactional region. Intel® TSX maintains the read- and write-sets at the granularity of a cache line. A conflicting access occurs if another logical processor either reads a location that is part of the transactional region’s write-set or writes a location that is a part of either the read- or write-set of the transactional region.

Conflicting access typically means serialization is required for this code region. Intel® TSX detects data conflicts at the granularity of a cache line, so unrelated data locations placed in the same cache line will be detected as conflicts. Transactional aborts may also occur due to limited transactional resources. The amount of data accessed in the region may exceed an implementation-specific capacity. Some instructions and system events may also cause transactional aborts. Frequent transactional aborts cause wasted cycles.

Intel® TSX provide two software interfaces to specify regions of code for transactional execution.

Hardware Lock Elision (HLE)

HLE is a legacy-compatible instruction set extension (comprising the XACQUIRE and XRELEASE prefixes) to specify transactional regions. HLE is for programmers who prefer the backward compatibility of the conventional mutual-exclusion programming model and would like to run HLE-enabled software on legacy hardware, but would like to take advantage of new lock elision capabilities on hardware with HLE support.

NOTE
Hardware Lock Elision (HLE) intrinsic functions apply to C/C++ applications for Windows* only.

Restricted Transactional Memory (RTM)

RTM is a new instruction set interface (comprising the XBEGIN, XEND, and XABORT instructions) for programmers to define transactional regions in a more flexible manner than that possible with HLE.
RTM is for programmers who prefer a flexible interface to the transactional execution hardware.

**Intel® Transactional Synchronization Extensions (Intel® TSX) Programming Considerations**

Typical programmer-identified regions are expected to transactionally execute and commit successfully. However, Intel® Transactional Synchronization Extensions (Intel® TSX) does not provide any such guarantee. A transactional execution may abort for many reasons. To take full advantage of the transactional capabilities, programmers should take into account programming considerations to increase the probability of their transactional execution committing successfully.

This section discusses various events that may cause transactional aborts. The architecture ensures that updates performed within a transaction that subsequently aborts execution will not become visible: Only a committed transactional execution updates architectural state. Transactional aborts never cause functional failures and only affect performance.

**Instruction Based Considerations**

Programmers can use any instruction safely inside a transaction, Hardware Lock Elision (HLE) or Restricted Transactional Memory (RTM) and can use transactions at any privilege level. Some instructions will always abort the transactional execution and cause execution to seamlessly and safely transition to a non-transactional path.

Intel® TSX allows for most common instructions to be used inside transactions without causing aborts. The following operations inside a transaction do not typically cause an abort:

- Operations on the instruction pointer register.
- Operations on general purpose registers (GPRs).
- Operations on the status flags (CF, OF, SF, PF, AF, and ZF).
- Operations on XMM and YMM registers.
- Operations on the MXCSR register.

**NOTE**

Programmers must be careful when intermixing Intel® Supplemental Streaming Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) operations inside a transactional region. Intermixing Intel® SSE instructions accessing XMM registers and Intel® AVX instructions accessing YMM registers may cause transactions to abort.

Programmers may use `REP/REPNE` prefixed string operations inside transactions. However, long strings may cause aborts. Further, the use of `CLD` and `STD` instructions may cause aborts if they change the value of the DF flag. If DF is '1', the `STD` instruction will not cause an abort. Similarly, if DF is '0', the `CLD` instruction will not cause an abort.

Instructions not enumerated here as causing abort when used inside a transaction will typically not cause a transaction to abort (examples include but are not limited to `MFENCE`, `LFENCE`, `SFENCE`, `RDTSC`, `RDTSCP`, etc.).

The following instructions will abort transactional execution on any implementation:

- `XABORT`
- `CPUID`
- `PAUSE`

In some implementations, the following instructions may always cause transactional aborts. These instructions are not expected to be commonly used inside typical transactional regions. Programmers must not rely on these instructions to force a transactional abort, since whether they cause transactional aborts is implementation dependent.

- Operations on X87 and MMX™ architecture state. This includes all MMX™ and X87 instructions, including the `FXRSTOR` and `FXSAVE` instructions.
• Update to non-status portion of EFLAGS: CLI, STI, POPFD, POPFQ, CLTS.
• Instructions that update segment registers, debug registers and/or control registers: MOV to DS/ES/FS/SS, POPDS/ES/FS/SS, LDS, LES, LFS, LGS, LSS, SWAPGS, WRFSBASE, NRGSBASE, LGDT, SGDT, LIDT, SIDT, LLDT, SLDT, LTR, STR, Far CALL, Far JMP, Far RET, IRET, MOV to DRx, MOV to CR0/CR2/CR3/CR4/CR8, and LMSW.
• Ring transitions: SYSENTER, SYSCALL, SYSEXIT, and SYSRET.
• TLB and Cacheability control: CLFLUSH, INVD, WBINVD, INVLPF, INVPCID, and memory instructions with a non-temporal hint (MOVNTDQA, MOVNTDQ, MOVNTI, MOVNTPD, MOVNTPS, and MOVNTQ).
• Processor state save: XSAVE, XSAVEOPT, and XRSTOR.
• Interrupts: INTn, INTO.
• IO: IN, INS, REP INS, OUT, OUTS, REP OUTS and their variants.
• VMX: VMPOTRLD, VMPPTRST, VMREAD, VMWRITE, VMCALL, VMLAUNCH, VMRESUME, VMXOFF, VMXON, INVEPT, and INVPCID.
• SMX: GETSEC, UD2, RSM, RDSMR, WRMSR, HLT, MONITOR, MWAIT, XSETBV, VZEROUPPER, MASKMOVQ, and V/MASKMOVQDQU.

Runtime Considerations

In addition to instruction-based considerations, runtime events may cause transactional execution to abort. These may be due to data access patterns or micro-architectural implementation causes. The following list is not a comprehensive discussion of all abort causes:

Any fault or trap in a transaction that must be exposed to software will be suppressed. Transactional execution will abort and execution will transition to a nontransactional execution as if the fault or trap had never occurred. If any exception is not masked, that will result in a transactional abort and it will be as if the exception had never occurred.

Synchronous exception events (#DE, #OF, #SS, #GP, #BR, #UD, #AC, #XF, #PF, #NM, #TS, #MF, #DB, #BP/INT3) that occur during transactional execution may cause an execution not to commit transactionally, and require a non-transactional execution. These events are suppressed as if they had never occurred. With HLE, since the non-transactional code path is identical to the transactional code path, these events will typically re-appear when the instruction that caused the exception is re-executed non-transactionally, causing the associated synchronous events to be delivered appropriately in the non-transactional execution.

Asynchronous events (NMI, SMI, INTR, IPI, PMI, etc.) occurring during transactional execution may cause the transactional execution to abort and transition to nontransactional execution. The asynchronous events will be queued and handled after the transactional abort is processed.

Transactions only support write-back cacheable memory type operations. A transaction may always abort if it includes operations on any other memory type. This includes instruction fetches to UC memory type.

Memory accesses within a transactional region may require the processor to set the Accessed and Dirty flags of the referenced page table entry. The behavior of how the processor handles this is implementation specific. Some implementations may allow the updates to these flags to become externally visible even if the transactional region subsequently aborts. Some Intel® TSX implementations may choose to abort the transactional execution if these flags need to be updated. Further, a processor’s page-table walk may generate accesses to its own transactionally written but uncommitted state. Some Intel® TSX implementations may choose to abort the execution of a transactional region in such situations. The architecture ensures that if the transactional region aborts, the transactionally written state will not be made architecturally visible through the behavior of structures such as TLBs.

Executing self-modifying code transactionally may also cause transactional aborts. Programmers must continue to follow Intel recommended guidelines for writing self-modifying and cross-modifying code even when employing HLE and RTM.
While an implementation of RTM and HLE will typically provide sufficient resources for executing common transactional regions, implementation constraints and excessive sizes for transactional regions may cause a transactional execution to abort and transition to a non-transactional execution. The architecture provides no guarantee of the amount of resources available to do transactional execution and does not guarantee that a transactional execution will ever succeed.

Conflicting requests to a cache line accessed within a transactional region may prevent the transaction from executing successfully. For example, if logical processor P0 reads line A in a transactional region and another logical processor P1 writes A (either inside or outside a transactional region) then logical processor P0 may abort if logical processor P1's write interferes with processor P0's ability to execute transactionally.

Similarly, if P0 writes line A in a transactional region and P1 reads or writes A (either inside or outside a transactional region), then P0 may abort if P1's access to A interferes with P0's ability to execute transactionally. Other coherence traffic may at times appear as conflicting requests and may cause aborts. While these false conflicts may happen, they are expected to be uncommon. The conflict resolution policy to determine whether P0 or P1 aborts in the above scenarios implementation specific.

Intrinsics for Restricted Transactional Memory Operations

Restricted Transactional Memory Overview

Restricted Transactional Memory (RTM) provides a software interface for transactional execution. RTM provides three new instructions—XBEGIN, XEND, and XABORT—for programmers to start, commit, and abort transactional execution.

The programmer uses the XBEGIN instruction to specify the start of the transactional code region and the XEND instruction to specify the end of the transactional code region. The XBEGIN instruction takes an operand that provides a relative offset to the fallback instruction address if the RTM region could not be successfully executed transactionally.

A processor may abort RTM transactional execution for many reasons. The hardware automatically detects transactional abort conditions and restarts execution from the fallback instruction address with the architectural state corresponding to that at the start of the XBEGIN instruction and the EAX register updated to describe the abort status.

The XABORT instruction allows programmers to abort the execution of an RTM region explicitly. The XABORT instruction takes an 8-bit immediate argument that is loaded into the EAX register becoming available to software following an RTM abort.

RTM instructions do not have any data memory location associated with them. While the hardware provides no guarantees as to whether an RTM region will ever successfully commit transactionally, most transactions that follow the recommended guidelines are expected to successfully commit transactionally.

Programmers must always provide an alternative code sequence in the fallback path to guarantee the code completes execution. This may be as simple as acquiring a lock and executing the specified code region non-transactionally. Further, a transaction that always aborts on a given implementation may complete transactionally on a future implementation. Therefore, programmers must ensure the code paths for the transactional region and the alternative code sequence are functionally tested.

Detection of RTM Support

A processor supports RTM execution if CPUID.07H.EBX.RTM [bit 11] = 1. An application must check if the processor supports RTM before it uses the RTM instructions (XBEGIN, XEND, XABORT). These instructions will generate a #UD exception when used on a processor that does not support RTM.

RTM Abort Status Definition

RTM uses the EAX register to communicate abort status to software. Following an RTM abort the EAX register has the following definition.
### EAX register bit position

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Set if abort caused by XABORT instruction.</td>
</tr>
<tr>
<td>1</td>
<td>If set, the transaction may succeed on a retry. This bit is always clear if bit '0' is set.</td>
</tr>
<tr>
<td>2</td>
<td>Set if another logical processor conflicted with a memory address that was part of the transaction that aborted.</td>
</tr>
<tr>
<td>3</td>
<td>Set if an internal buffer overflowed.</td>
</tr>
<tr>
<td>4</td>
<td>Set if a debug breakpoint was hit.</td>
</tr>
<tr>
<td>5</td>
<td>Set if an abort occurred during execution of a nested transaction.</td>
</tr>
<tr>
<td>23:6</td>
<td>Reserved.</td>
</tr>
<tr>
<td>31:24</td>
<td>XABORT argument (only valid if bit '0' set, otherwise reserved).</td>
</tr>
</tbody>
</table>

The EAX abort status for RTM only provides the cause for aborts. It does not by itself encode whether an abort or commit occurred for the RTM region. The value of EAX can be '0' following an RTM abort. For example, a CPUID instruction when used inside an RTM region causes a transactional abort and may not satisfy the requirements for setting any of the EAX bits. This may result in an EAX value of '0'.

### RTM Memory Ordering

A successful RTM commit causes all memory operations in the RTM region to appear to execute atomically. A successfully committed RTM region consisting of an XBEGIN followed by an XEND, even with no memory operations in the RTM region, has the same ordering semantics as a LOCK prefixed instruction. The XBEGIN instruction does not have fencing semantics. However, if an RTM execution aborts, all memory updates from within the RTM region are discarded and never made visible to any other logical processor.

Intel® Transactional Synchronization Extensions Programming Considerations

_xtest

Queries whether the processor is executing in a transactional region identified by restricted transactional memory (RTM) or hardware lock elision (HLE). The corresponding Intel® AVX2 instruction is XTEST.

**Syntax**

```c
unsigned char _xtest(void);
```

**Arguments**

None.

**Description**

Queries the RTM or HLE execution status. If the xtest function is called inside an RTM or an active HLE region, then the ZF flag is cleared, else it is set.
NOTE
A processor supports the `xtest` instruction if it supports either HLE or RTM. An application must check either of these feature flags before using the `xtest` instruction. While the HLE prefixes are ignored on processors that do not support HLE, this instruction will generate a #UD exception when used on a processor that does not support either HLE or RTM.

Returns
Result of the query.

_xbegin
Specifies the start of a restricted transactional memory (RTM) code region and returns a value indicating status. The corresponding Intel® AVX2 instruction is `XBEGIN`.

Syntax
```c
unsigned int _xbegin(void);
```

Arguments
None.

Description
Starts a RTM code region and returns a value indicating transaction successfully started or status from a transaction abort.

If the logical processor was not already in transactional execution, then the `xbegin` instruction causes the logical processor to start transactional execution. The `xbegin` instruction that transitions the logical processor into transactional execution is referred to as the outermost `xbegin` instruction.

The `xbegin` instruction specifies a relative offset to the fallback code path executed following a transactional abort. To promote proper program structure, this is not exposed in C++ code and the intrinsic function operates as if it invoked the following model code:

```c
__inline unsigned int _xbegin() {  
    unsigned status;
    __asm {
        move   eax, 0xFFFFFFFF
        xbegin _txnL1
        _txnL1:
        move   status, eax
    }
    return status;
}
```

When a transaction is successfully created the function will return 0xFFFFFFFF, which is never a valid status code for an aborted transaction. If the transaction aborts for any reason, the logical processor discards all architectural register and memory updates performed during the transaction execution and restores the architectural state to that corresponding to the outermost `xbegin` instruction. The EAX register is then updated with the status code of the aborted transaction, which can be used to transfer control to a fallback handler.
The instruction also specifies a relative offset to compute the address of the fallback code path following a transactional abort. On an RTM abort, the logical processor discards all architectural register and memory updates performed during the RTM execution and restores architectural state to that corresponding to the outermost `xbegin` instruction. The abort destination operand of the `xbegin` instruction is targeted to the following instruction so that there is no change in control flow whether the transaction aborts or not.

**Returns**

Returns value indicating transaction successfully started or status from a transaction abort.

### _xend

*Specifies the end of a restricted transactional memory (RTM) code region. The corresponding Intel® AVX2 instruction is XEND.*

**Syntax**

```c
void _xend(void);
```

**Arguments**

None.

**Description**

Specifies the end of restricted transactional memory code region. If this is the outermost transaction (including this `xend` instruction, the number of `xbegin` matches the number of `xend` instructions) then the processor will attempt to commit processor state automatically.

If the commit fails, the processor will rollback all register and memory updates performed during the RTM execution.

The logical processor will resume execution at the fallback address computed from the outermost `xbegin` instruction. The EAX register is updated to reflect RTM abort information. When `xend` is executed outside a transaction will cause a general protection fault (#GP).

The model instruction sequence for `xend` support is:

```c
__inline void _xend() {
    __asm { xend }
}
```

**Returns**

Result of the query.

### _xabort

*Forces a restricted transactional memory (RTM) region to abort. The corresponding Intel® AVX2 instruction is XABORT.*

**Syntax**

```c
void _xabort(const unsigned int imm);
```

**Arguments**

None.
Description

Forces a RTM region to abort. All outstanding transactions are aborted and the logical processor resumes execution at the fallback address computed through the outermost xbegin transaction.

The EAX register is updated to reflect an xabort instruction caused the abort, and the imm8 argument will be provided in the upper eight bits of the return value (EAX register bits 31:24) containing the indicated immediate value. The argument of xabort function must be a compile time constant.

The model instruction sequence for xabort support is:

```c
_inline void _xabort() { __asm { xabort } }
```

Returns

Result of the query.

Intrinsics for Hardware Lock Elision Operations

Hardware Lock Elision Overview

NOTE

Hardware Lock Elision (HLE) intrinsic functions apply to C/C++ applications for Windows* only.

Hardware Lock Elision (HLE) provides a legacy compatible instruction set interface for transactional execution. HLE provides two new instruction prefix hints: XACQUIRE and XRELEASE.

The programmer uses the XACQUIRE prefix in front of the instruction that is used to acquire the lock that is protecting the critical section. The processor treats the indication as a hint to elide the write associated with the lock acquire operation. Even though the lock acquire has an associated write operation to the lock, the processor does not add the address of the lock to the transactional region's write-set nor does it issue any write requests to the lock. Instead, the address of the lock is added to the read-set and the logical processor enters transactional execution. If the lock was available before the XACQUIRE prefixed instruction, all other processors will continue to see it as available afterwards. Since the transactionally executing logical processor neither added the address of the lock to its write-set, nor performed externally visible write operations to it, other logical processors can read the lock without causing a data conflict. This allows other logical processors to enter and concurrently execute the lock-protected section. The processor automatically detects data conflicts that occur during the transactional execution and will perform a transactional abort if necessary.

The hardware ensures program order of operations on the lock, even though the eliding processor did not perform external write operations to the lock. If the eliding processor itself reads the value of the lock in the critical section, it will appear as if the processor had acquired the lock (the read will return the non-elided value). This behavior makes an HLE execution functionally equivalent to an execution without the HLE prefixes.

The programmer uses the XRELEASE prefix in front of the instruction that is used to release the lock protecting the critical section. This involves a write to the lock. If the instruction is restoring the value of the lock to the value it had prior to the XACQUIRE prefixed lock-acquire operation on the same lock, the processor elides the external write request associated with the release of the lock and does not add the address of the lock to the write-set. The processor then attempts to commit the transactional execution.

If multiple threads execute critical sections protected by the same lock, but they do not perform conflicting data operations, the threads can execute concurrently and without serialization. Even though the software uses lock acquisition operations on a common lock, the hardware recognizes this, elides the lock, and executes the critical sections on the two threads without requiring any communication through the lock — if such communication was dynamically unnecessary.

If the processor is unable to execute the region transactionally, it will execute the region non-transactionally and without elision. HLE-enabled software has the same forward progress guarantees as the underlying non-HLE lock-based execution. For successful HLE execution, the lock and the critical section code must follow certain guidelines. These guidelines only affect performance; not following these guidelines will not cause functional failure.
Hardware without HLE support will ignore the XACQUIRE and XRELEASE prefix hints and will not perform any elision. These prefixes correspond to the REPNE/REPE IA-32 architecture prefixes ignored on the instructions where XACQUIRE and XRELEASE are valid. Importantly, HLE is compatible with the existing lock-based programming model. Improper use of hints will not cause functional bugs though it may expose latent bugs already in the code.

Intel® Transactional Synchronization Extensions Programming Considerations

HLE Acquire _InterlockedCompareExchange Functions
Performs an atomic compare-and-exchange operation on the specified values and attempts to begin a HLE transaction if supported by the executing platform. This intrinsic function applies to C/C++ applications for Windows* only.

Syntax
long _InterlockedCompareExchange_HLEAcquire(long volatile *Destination, long Exchange, long Comparand);
__int64 _InterlockedCompareExchange64_HLEAcquire(__int64 volatile *Destination, __int64 Exchange, __int64 Comparand);
void * _InterlockedCompareExchangePointer_HLEAcquire(void * volatile *Destination, void * Exchange, void * Comparand);

Parameters
Destination [in, out] pointer to the destination value
Exchange [in] value which will be written at Destination if the comparison matches.
Comparand [in] value to compare to the value referenced by Destination.

Description
Performs an atomic compare-and-exchange operation on the specified values, and also attempts to begin a HLE transaction if the executing platform supports it.
These functions compare two specified values and replaces one of them with a third value if the compared values are equal.

Returns
Returns the initial value referenced by the Destination parameter.

HLE Acquire _InterlockedExchangeAdd Functions
Performs an atomic addition of two values and attempts to begin a HLE transaction if supported by the executing platform. This intrinsic function applies to C/C++ applications for Windows* only.

Syntax
long _InterlockedExchangeAdd_HLEAcquire(long volatile *Addend, long Value);
__int64 _InterlockedExchangeAdd64_HLEAcquire(__int64 volatile *Addend, __int64 Value);
Parameters
Addend [in, out] pointer to the addend which will be replaced with the result of the addition
Value [in] value to be added to the value referenced by the Addend parameter

Description
Performs an atomic addition of two values, and also attempts to begin a HLE transaction if the executing platform supports it.

Returns
The function returns the initial value referenced by the Addend parameter.

HLE Release _InterlockedCompareExchange Functions
Performs an atomic compare-and-exchange operation on the specified values and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows* only.

Syntax
long _InterlockedCompareExchange_HLERelease(long volatile *Destination, long Exchange, long Comparand);
__int64 _InterlockedCompareExchange64_HLERelease(__int64 volatile *Destination, __int64 Exchange, __int64 Comparand);
void * _InterlockedCompareExchangePointer_HLERelease(void * volatile *Destination, void * Exchange, void * Comparand);

Parameters
Destination [in, out] pointer to the destination value
Exchange [in] value which will be written at Destination if the comparison matches.
Comparand [in] value to compare to the value referenced by Destination.

Description
Performs an atomic compare-and-exchange operation on the specified values and releases a pending HLE transaction (if one is active).
The function compares two specified values and replaces one of them with a third value if the compared values are equal.

Returns
Returns the initial value referenced by the Destination parameter.

HLE Release _InterlockedExchangeAdd Functions
Performs an atomic addition of two values and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows* only.

Syntax
long _InterlockedExchangeAdd_HLERelease(long volatile *Addend, long Value);
__int64 __InterlockedExchangeAdd64_HLERelease(__int64 volatile *Addend, __int64 Value);

**Parameters**

Addend [in, out]
pointer to the addend which will be replaced with the result of the addition

Value [in]
value to be added to the value referenced by the Addend parameter

**Description**

Performs an atomic addition of two values and releases a pending HLE transaction (if one is active).

**Returns**

Returns the initial value referenced by the Addend parameter.

**HLE Release_Store Functions**

Stores the specified value at the specified address and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows* only.

**Syntax**

void _Store_HLERelease(long volatile *Destination, long Value);
void _Store64_HLERelease(__int64 volatile *Destination, __int64 Value);
void _StorePointer_HLERelease(void * volatile *Destination, void * Value);

**Parameters**

Destination[out]
pointer to the destination value

Value [in]
value to store at Destination.

**Description**

Stores the specified value at the specified address and releases a pending HLE transaction if one is active.

**Returns**

Nothing.

**Function Prototype and Macro Definitions**

To use the prototypes and macro definitions shown in Group 1, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

**Group 1: Function Prototypes:**

```c
unsigned int _xbegin(void);
void _xend(void);
void _xabort(const unsigned int imm);
unsigned char _xtest(void);
```

The following macro definitions are included in the immintrin.h header file:

**Group 1: Macro Definitions:**

```c
#define XBEGIN_STARTED (~0u)
#define XABORT_EXPLICIT (1 << 0)
#define XABORT_RETRY (1 << 1)
```
#define _XABORT_CONFLICT (1 << 2)
#define _XABORT_CAPACITY (1 << 3)
#define _XABORT_DEBUG (1 << 4)
#define _XABORT_NESTED (1 << 5)

Group 2: Function Macros

The following function Macros are not included in immintrin.h header file. If you want to use them, you need to define them in your applications.

**For the HW with RTM support**

```c
#define __try_transaction(x) if ((x = _xbegin()) == _XBEGIN_STARTED)
#define __try_else _xend() } else
#define __transaction_abort(c) _xabort(c)
```

**For the HW with no RTM support**

```c
#define __try_transaction(x) if (0) {
#define __try_else } else
#define __transaction_abort(c)
```

`x` is an unsigned integer type local variable for programmers to access RTM transaction abort code and holds the return value of `_xbegin()`. `c` is an unsigned integer compile-time constant value that is returned in the upper bits of `x` when `_xabort(c)` is executed.

A usage sample code of macros

```c
foo() { // user macros
int status;
__try_transaction (status) {

... // transaction code ...
}
__try_else {
if (status & _XABORT_CONFLICT) {
... code
}
}
}
```

**Pseudo-ASM code**

```asm
foo() { or eax 0xffffffff
_xbegin L1 L1: mov status, eax
cmp eax 0xffffffff jnz
L2 transaction code

// when abort happens, HW restarts from L1
_xend jmp L3 L2: abort
handler_code L3: ret
}
```

The compiler will convert the macros to the instruction sequence with a proper branching for speculative execution path and alternative execution path.

The above example is similar to the usage example, except `__try_transaction` and `__try_else` macros are used instead of RTM intrinsic functions.
Intrinsics for Intel® Advanced Vector Extensions

Overview: Intrinsics for Intel® Advanced Vector Extensions Instructions

Intel® Advanced Vector Extensions (Intel® AVX) intrinsics are assembly-coded functions that call on Intel® AVX instructions, which are new vector SIMD instruction extensions for IA-32 and Intel® 64 architectures. Intel® AVX intrinsics are architecturally similar to Intel® Streaming SIMD Extensions (Intel® SSE) and double-precision floating-point portions of Intel® Streaming SIMD Extensions 2 (Intel® SSE2).

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

Intel® AVX intrinsics introduce 256-bit vector processing capability, and are supported on the IA-32 and Intel® 64 architectures built from 32nm process technology and beyond. They map directly to Intel® AVX new instructions and other enhanced 128-bit SIMD instructions.

The first generation Intel® AVX provides 256-bit SIMD register support, 256-bit vector floating-point instructions, enhancements to 128-bit SIMD instructions, and support for three and four operand syntax.

Functional Overview

Intel® AVX provide comprehensive functional improvements over previous generations of SIMD instruction extensions. The functional improvements include:

- **256-bit floating-point arithmetic primitives:** Intel® AVX enhances existing 128-bit floating-point arithmetic instructions with 256-bit capabilities for floating-point processing.
- **Enhancements for flexible SIMD data movements:** Intel® AVX provides a number of new data movement primitives to enable efficient SIMD programming in relation to loading non-unit-strided data into SIMD registers, intra-register SIMD data manipulation, conditional expression and branch handling, etc. Enhancements for SIMD data movement primitives cover 256-bit and 128-bit vector floating-point data, and across 128-bit integer SIMD data processing using VEX-encoded instructions.

Details about the Intel® AVX Intrinsics

Details of Intel® Advanced Vector Extensions Intrinsics

Intel® Advanced Vector Extensions (Intel® AVX) intrinsics map directly to Intel® AVX instructions and other enhanced 128-bit single-instruction multiple data processing (SIMD) instructions. Intel® AVX instructions are architecturally similar to extensions of the existing Intel® 64 architecture-based vector streaming SIMD portions of Intel® Streaming SIMD Extensions (Intel® SSE) instructions, and double-precision floating-point portions of Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions. However, Intel® AVX introduces the following architectural enhancements:

- Support for 256-bit wide vectors and SIMD register set.
- Instruction syntax support three and four operand syntax, to improve instruction programming flexibility and efficiency for new instruction extensions.
- Enhancement of legacy 128-bit SIMD instruction extensions to support three-operand syntax and to simplify compiler vectorization of high-level language expressions.
- Instruction encoding format using a new prefix (referred to as VEX) to provide compact, efficient encoding for three-operand syntax, vector lengths, compaction of legacy SIMD prefixes and REX functionality.
- Intel® AVX data types allow packing of up to 32 elements in a register if bytes are used. The number of elements depends upon the element type: eight single-precision floating point types or four double-precision floating point types.
Intel® Advanced Vector Extensions Registers

Intel® AVX adds 16 registers (YMM0–YMM15), each 256 bits wide, aliased onto the 16 SIMD (XMM0–XMM15) registers. The Intel® AVX new instructions operate on the YMM registers. Intel® AVX extends certain existing instructions to operate on the YMM registers, defining a new way of encoding up to three sources and one destination in a single instruction.

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data processing (SIMD).

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

Intel® Advanced Vector Extensions Types

The Intel® AVX intrinsic functions use three new C data types as operands, representing the new registers used as operands to the intrinsic functions. These are __m256, __m256d, and __m256i data types.

The __m256 data type is used to represent the contents of the extended SSE register, the YMM register, used by the Intel® AVX intrinsics. The __m256 data type can hold eight 32-bit floating-point values.

The __m256d data type can hold four 64-bit double precision floating-point values.

The __m256i data type can hold thirty-two 8-bit, sixteen 16-bit, eight 32-bit, or four 64-bit integer values.

The compiler aligns the __m256, __m256d, and __m256i local and global data to 32-byte boundaries on the stack. To align integer, float, or double arrays, use the __declspec(align) statement.

The Intel® AVX intrinsics also use Intel® SSE2 data types like __m128, __m128d, and __m128i for some operations. See Details of Intrinsics topic for more information.

VEX Prefix Instruction Encoding Support for Intel® AVX

Intel® AVX introduces a new prefix, referred to as VEX, in the Intel® 64 and IA-32 instruction encoding format. Instruction encoding using the VEX prefix provides several capabilities:
• direct encoding of a register operand within the VEX prefix.
• efficient encoding of instruction syntax operating on 128-bit and 256-bit register sets.
• compaction of REX prefix functionality.
• compaction of SIMD prefix functionality and escape byte encoding.
• providing relaxed memory alignment requirements for most VEX-encoded SIMD numeric and data
  processing instruction semantics with memory operand as compared to instructions encoded using SIMD
  prefixes.

The VEX prefix encoding applies to SIMD instructions operating on YMM registers, XMM registers, and in
some cases with a general-purpose register as one of the operands. The VEX prefix is not supported for
instructions operating on MMX™ or x87 registers.

It is recommended to use Intel® AVX intrinsics with option [Q]xAVX, because their corresponding instructions
are encoded with the VEX-prefix. The [Q]xAVX option forces other packed instructions to be encoded with
VEX too. As a result there are fewer performance stalls due to Intel® AVX to legacy Intel® SSE code
transitions.

Naming and Usage Syntax

Most Intel® AVX intrinsic names use the following notational convention:

```
_mm256_<intrin_op>_suffix(<data type> <parameter1>, <data type> <parameter2>, <data type>
<parameter3>)
```

The following table explains each item in the syntax.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm256/</td>
<td>Prefix representing the size of the result. Usually, this corresponds to the Intel® AVX vector register</td>
</tr>
<tr>
<td>_mm128</td>
<td>size of 256 bits, but certain comparison and conversion intrinsics yield a 128-bit result.</td>
</tr>
<tr>
<td>&lt;intrin_op&gt;</td>
<td>Indicates the basic operation of the intrinsic; for example, add for addition and sub for subtraction.</td>
</tr>
<tr>
<td>&lt;suffix&gt;</td>
<td>Denotes the type of data the instruction operates on. The first one or two letters of each suffix</td>
</tr>
<tr>
<td></td>
<td>denote whether the data is packed (p), extended packed (ep), or scalar (s). The remaining letters</td>
</tr>
<tr>
<td></td>
<td>and numbers denote the type, with notation as follows:</td>
</tr>
<tr>
<td></td>
<td>• s: single-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• d: double-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• i128: signed 128-bit integer</td>
</tr>
<tr>
<td></td>
<td>• i64: signed 64-bit integer</td>
</tr>
<tr>
<td></td>
<td>• u64: unsigned 64-bit integer</td>
</tr>
<tr>
<td></td>
<td>• i32: signed 32-bit integer</td>
</tr>
<tr>
<td></td>
<td>• u32: unsigned 32-bit integer</td>
</tr>
<tr>
<td></td>
<td>• i16: signed 16-bit integer</td>
</tr>
<tr>
<td></td>
<td>• u16: unsigned 16-bit integer</td>
</tr>
<tr>
<td></td>
<td>• i8: signed 8-bit integer</td>
</tr>
<tr>
<td></td>
<td>• u8: unsigned 8-bit integer</td>
</tr>
<tr>
<td></td>
<td>• ps: packed single-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• pd: packed double-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• sd: scalar double-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• epi32: extended packed 32-bit integer</td>
</tr>
<tr>
<td></td>
<td>• si256: scalar 256-bit integer</td>
</tr>
<tr>
<td>&lt;data type&gt;</td>
<td>Parameter data types: __m256, __m256d, __m256i, __m128, __m128d, __m128i, const, int, etc.</td>
</tr>
<tr>
<td>&lt;parameter1&gt;</td>
<td>Represents a source vector register: m1/s1/a</td>
</tr>
</tbody>
</table>
<parameter2> Represents another source vector register: m2/s2/b
</parameter2>

<parameter3> Represents an integer value: mask/select/offset

The third parameter is an integer value whose bits represent a conditionality based on which the intrinsic performs an operation.

**Example Usage**

```c
extern __m256d _mm256_add_pd(__m256d m1, __m256d m2);
```

where,

- `add` indicates that an addition operation must be performed
- `pd` indicates packed double-precision floating-point value

The packed values are represented in right-to-left order, with the lowest value used for scalar operations. Consider the following example operation:

```c
double a[4] = {1.0, 2.0, 3.0, 4.0};
__m256d t = _mm256_load_pd(a);
```

The result is the following:

```c
__m256d t = _mm256_set_pd(4.0, 3.0, 2.0, 1.0);
```

In other words, the YMM register that holds the value `t` appears as follows:

![YMM register diagram]

The " scalar " element is 1.0. Due to the nature of the instruction, some intrinsics require their arguments to be immediates (constant integer literals).

__declspec(align) declaration

Details of Intrinsics (general)

**Intrinsics for Arithmetic Operations**

**_mm256_add_pd**

*Adds float64 vectors. The corresponding Intel® AVX instruction is VADDPD.*

**Syntax**

```c
extern __m256d _mm256_add_pd(__m256d m1, __m256d m2);
```

**Arguments**

- `m1` float64 vector used for the operation
Description
Performs a SIMD addition of four packed double-precision floating-point elements (float64 elements) in the first source vector \( m1 \) with four float64 elements in the second source vector \( m2 \).

Returns
Result of the addition operation.

_mm256_add_ps
Adds float32 vectors. The corresponding Intel® AVX instruction is VADDPS.

Syntax
extern __m256 _mm256_add_ps(__m256 m1, __m256 m2);

Arguments
\( m1 \)
float32 vector used for the operation
\( m2 \)
float32 vector also used for the operation

Description
Performs a SIMD addition of eight packed single-precision floating-point elements (float32 elements) in the first source vector \( m1 \) with eight float32 elements in the second source vector \( m2 \).

Returns
Result of the addition operation.

_mm256_addsub_pd
Adds odd float64 elements and subtracts even float64 elements of vectors. The corresponding Intel® AVX instruction is VADDSUBPD.

Syntax
extern __m256d _mm256_addsub_pd(__m256d m1, __m256d m2);

Arguments
\( m1 \)
float64 vector used for the operation
\( m2 \)
float64 vector also used for the operation

Description
Performs a SIMD addition of the odd packed double-precision floating-point elements (float64 elements) from the first source vector \( m1 \) to the odd float64 elements of the second source vector \( m2 \). Simultaneously, the intrinsic performs subtraction of the even double-precision floating-point elements of the second source vector \( m2 \) from the even float64 elements of the first source vector \( m1 \).

Returns
Result of the operation is stored in the result vector, which is returned by the intrinsic.
**_mm256_addsub_ps_**
*Adds odd float32 elements and subtracts even float32 elements of vectors. The corresponding Intel® AVX instruction is **VADDSUBPS.***

**Syntax**

```c
extern __m256 _mm256_addsub_ps(__m256 m1, __m256 m2);
```

**Arguments**

- `m1` float32 vector used for the operation
- `m2` float32 vector also used for the operation

**Description**

Performs a SIMD addition of the odd single-precision floating-point elements (float32 elements) in the first source vector `m1` with the odd float32 elements in the second source vector `m2`.

Simultaneously, the intrinsic performs subtraction of the even single-precision floating-point elements (float32 elements) in the second source vector, `m2`, from the even float32 elements in the first source vector, `m1`.

**Returns**

Result of the operation stored in the result vector.

**_mm256_hadd_pd_**
*Adds horizontal pairs of float64 elements of two vectors. The corresponding Intel® AVX instruction is **VHADDPD.***

**Syntax**

```c
extern __m256d _mm256_hadd_pd(__m256d m1, __m256d m2);
```

**Arguments**

- `m1` float64 vector used for the operation
- `m2` float64 vector also used for the operation

**Description**

Performs a SIMD addition of adjacent (horizontal) pairs of double-precision floating-point elements (float64 elements) in the first source vector `m1` with adjacent pairs of float64 elements in the second source vector `m2`.

**Returns**

Result of the addition operation.

**_mm256_hadd_ps_**
*Adds horizontal pairs of float32 elements of two vectors. The corresponding Intel® AVX instruction is **VHADDPD.***
Syntax

```
extern __m256 _mm256_hadd_ps(__m256 m1, __m256 m2);
```

Arguments

- `m1`: float32 vector used for the operation
- `m2`: float32 vector also used for the operation

Description

Performs a SIMD addition of adjacent (horizontal) pairs of single-precision floating-point elements (float32 elements) in the first source vector `m1` with adjacent pairs of float32 elements in the second source vector `m2`.

Returns

Returns the result of the addition operation.

_mm256_sub_pd

Subtracts float64 vectors. The corresponding Intel® AVX instruction is VSUBPD.

Syntax

```
extern __m256d _mm256_sub_pd(__m256d m1, __m256d m2);
```

Arguments

- `m1`: float64 vector used for the operation
- `m2`: float64 vector also used for the operation

Description

Performs a SIMD subtraction of four packed double-precision floating-point elements (float64 elements) of the second source vector `m2` from the first source vector `m1`.

Returns

Returns the result of the subtraction operation.

_mm256_sub_ps

Subtracts float32 vectors. The corresponding Intel® AVX instruction is VSUBPS.

Syntax

```
extern __m256 _mm256_sub_ps(__m256 m1, __m256 m2);
```

Arguments

- `m1`: float32 vector used for the operation
- `m2`: float32 vector also used for the operation
Description
Performs a SIMD subtraction of eight packed single-precision floating-point elements (float32 elements) of the second source vector \( m2 \) from the first source vector \( m1 \).

Returns
Returns the result of the subtraction operation.

_mm256_hsub_pd
Subtracts horizontal pairs of float64 elements of two vectors. The corresponding Intel® AVX instruction is VHSUBPD.

Syntax
extern __m256d _mm256_hsub_pd(__m256d m1, __m256d m2);

Arguments
\( m1 \) 
float64 vector used for the operation

\( m2 \) 
float64 vector also used for the operation

Description
Performs a SIMD subtraction of adjacent (horizontal) pairs of double-precision floating-point elements (float64 elements) in the second source vector \( m2 \) from adjacent pairs of float64 elements in the first source vector \( m1 \).

Returns
Result of the subtraction operation.

_mm256_hsub_ps
Subtracts horizontal pairs of float32 elements of two vectors. The corresponding Intel® AVX instruction is VHSUBPS.

Syntax
extern __m256 _mm256_hsub_ps(__m256 m1, __m256 m2);

Arguments
\( m1 \) 
float32 vector used for the operation

\( m2 \) 
float32 vector also used for the operation

Description
Performs a SIMD subtraction of adjacent (horizontal) pairs of single-precision floating-point elements (float32 elements) in the second source vector \( m2 \) from adjacent pairs of float32 elements in the first source vector \( m1 \).

Returns
Returns the result of the subtraction operation.
**_mm256_mul_pd_**

Multiplies float64 vectors. The corresponding Intel® AVX instruction is **VMULPD**.

**Syntax**

extern __m256d _mm256_mul_pd(__m256d m1, __m256d m2);

**Arguments**

- **m1** float64 vector used for the operation
- **m2** float64 vector also used for the operation

**Description**

Performs a SIMD multiplication of four packed double-precision floating-point elements (float64 elements) in the first source vector, *m1*, with four float64 elements in the second source vector, *m2*.

**Returns**

Result of the multiplication operation.

**_mm256_mul_ps_**

Multiplies float32 vectors. The corresponding Intel® AVX instruction is **VMULPS**.

**Syntax**

extern __m256 _mm256_mul_ps(__m256 m1, __m256 m2);

**Arguments**

- **m1** float32 vector used for the operation
- **m2** float32 vector also used for the operation

**Description**

Performs a SIMD multiplication of eight packed single-precision floating-point elements (float32 elements) in the first source vector *m1* with eight float32 elements in the second source vector *m2*.

**Returns**

Result of the multiplication operation.

**_mm256_div_pd_**

Divides float64 vectors. The corresponding Intel® AVX instruction is **VDIVPD**.

**Syntax**

extern __m256d _mm256_div_pd(__m256d m1, __m256d m2);

**Arguments**

- **m1** float64 vector used for the operation
**m2**

float64 vector also used for the operation

**Description**

Performs a SIMD division of four packed double-precision floating-point elements (float64 elements) in the first source vector \( m1 \) with four float64 elements in the second source vector \( m2 \).

**Returns**

Result of the division operation.

**_mm256_div_ps**

*Divides* float32 vectors. The corresponding Intel® AVX instruction is `VDIVPS`.

**Syntax**

```c
extern __m256 _mm256_div_ps(__m256 m1, __m256 m2);
```

**Arguments**

- \( m1 \) float32 vector used for the operation
- \( m2 \) float32 vector also used for the operation

**Description**

Performs a SIMD division of eight packed single-precision floating-point elements (float32 elements) in the first source vector \( m1 \) with eight float32 elements in the second source vector \( m2 \).

**Returns**

Result of the division operation.

**_mm256_dp_ps**

*Calculates the dot product* of float32 vectors. The corresponding Intel® AVX instruction is `VDPPS`.

**Syntax**

```c
extern __m256 _mm256_dp_ps(__m256 m1, __m256 m2, const int mask);
```

**Arguments**

- \( m1 \) float32 vector used for the operation
- \( m2 \) float32 vector also used for the operation
- \( mask \) a constant of integer type where the high four bits of the mask determine how the resultant elements are summed and the low four bits determine whether the summed resultant value is to be broadcast to the destination vector or not

**Description**

First performs a SIMD multiplication of the lower four packed single-precision floating-point elements (float32 elements) from the first source vector \( m1 \) with corresponding elements in the second source vector \( m2 \).

Each of the four resulting single-precision elements is conditionally summed depending on the high four bits in the \( mask \) parameter.
The resulting summed value is broadcast to each of the lower 4 positions in the destination vector, if the corresponding lower bit of the mask is "1". If the corresponding lower bit of the mask is zero, the corresponding lower element in the destination vector is set to zero.

The process is then replicated with the high elements of the source vectors.

**Returns**

Result of the operation.

___mm256_sqrt_pd

*Computes the square root of double-precision floating point values. The corresponding Intel® AVX instruction is VSQRTPD.*

**Syntax**

```c
extern __m256d __mm256_sqrt_pd(__m256d a);
```

**Arguments**

- `a` float64 source vector

**Description**

Performs a SIMD computation of the square roots of the two or four packed double-precision floating-point values (float64 values) in the source vector and returns the result of the square root operation.

**Returns**

Result of the square root operation.

___mm256_sqrt_ps

*Computes the square root of single-precision floating point values. The corresponding Intel® AVX instruction is VSQRTPS.*

**Syntax**

```c
extern __m256 __mm256_sqrt_ps(__m256 a);
```

**Arguments**

- `a` float32 source vector

**Description**

Performs a SIMD computation of the square roots of the eight packed single-precision floating-point values (float32 values) in the source vector and returns the result of the square root operation.

**Returns**

Result of the square root operation.

___mm256_rsqrt_ps

*Computes approximate reciprocals of square roots of float32 values. The corresponding Intel® AVX instruction is VRSQRTPS.*
Syntax
extern __m256 _mm256_rsqrt_ps(__m256 a);

Arguments
a float32 source vector

Description
Performs a computation of the reciprocal of the square roots of eight single-precision floating point elements of the source vector a and returns the result as a vector.

Returns
Result of the reciprocal square root operation.

__mm256_rcp_ps
Computes approximate reciprocals of float32 values. The corresponding Intel® AVX instruction is VRCPPS.

Syntax
extern __m256 _mm256_rcp_ps(__m256 a);

Arguments
a float32 source vector

Description
Performs a computation of the reciprocal of eight single-precision floating point elements of the source vector a and returns the result as a vector.

Returns
Result of the reciprocal operation.

Intrinsics for Bitwise Operations

__mm256_and_pd
Performs bitwise logical AND operation on float64 vectors. The corresponding Intel® AVX instruction is VANDPD.

Syntax
extern __m256d _mm256_and_pd(__m256d m1, __m256d m2);

Arguments
m1 float64 vector used for the operation
m2 float64 vector also used for the operation
Description
Performs a bitwise logical AND of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns
Result of the bitwise operation.

_mm256_and_ps
Performs bitwise logical AND operation on float32 vectors. The corresponding Intel® AVX instruction is VANDPS.

Syntax
extern __m256 _mm256_and_ps(__m256 m1, __m256 m2);

Arguments

*m1*  
float32 vector used for the operation

*m2*  
float32 vector also used for the operation

Description
Performs a bitwise logical AND of the eight packed single-precision floating-point elements (float32 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns
Result of the bitwise operation.

_mm256_andnot_pd
Performs bitwise logical AND NOT operation on float64 vectors. The corresponding Intel® AVX instruction is VANDNPD.

Syntax
extern __m256d _mm256_andnot_pd(__m256d m1, __m256d m2);

Arguments

*m1*  
float64 vector used for the operation

*m2*  
float64 vector also used for the operation

Description
Performs a bitwise logical AND NOT of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns
Result of the bitwise operation.
**_mm256_andnot_ps_**
**Performs bitwise logical AND NOT operation on float32 vectors. The corresponding Intel® AVX instruction is VANDNPS.**

**Syntax**
```c
extern __m256 _mm256_andnot_ps(__m256 m1, __m256 m2);
```

**Arguments**
- `m1` float32 vector used for the operation
- `m2` float32 vector also used for the operation

**Description**
Performs a bitwise logical AND NOT of the eight packed single-precision floating-point elements (float32 elements) of the first source vector `m1`, and corresponding elements in the second source vector `m2`.

**Returns**
Result of the bitwise operation.

**_mm256_or_pd_**
**Performs bitwise logical OR operation on float64 vectors. The corresponding Intel® AVX instruction is VORPD.**

**Syntax**
```c
extern __m256d _mm256_or_pd(__m256d m1, __m256d m2);
```

**Arguments**
- `m1` float64 vector used for the operation
- `m2` float64 vector also used for the operation

**Description**
Performs a bitwise logical OR of the four packed double-precision floating-point elements (float64 elements) of the first source vector `m1`, and corresponding elements in the second source vector `m2`.

**Returns**
Result of the bitwise operation.

**_mm256_or_ps_**
**Performs bitwise logical OR operation on float32 vectors. The corresponding Intel® AVX instruction is VORPS.**

**Syntax**
```c
extern __m256 _mm256_or_ps(__m256 m1, __m256 m2);
```
Arguments

\(m1\)  
float32 vector used for the operation

\(m2\)  
float32 vector also used for the operation

Description

Performs a bitwise logical OR of the eight packed single-precision floating-point elements (float32 elements) of the first source vector \(m1\), and corresponding elements in the second source vector \(m2\).

Returns

Result of the bitwise operation.

_mm256_xor_pd

Performs bitwise logical XOR operation on float64 vectors. The corresponding Intel® AVX instruction is VXORPD.

Syntax

extern __m256d _mm256_xor_pd(__m256d m1, __m256d m2);

Arguments

\(m1\)  
float64 vector used for the operation

\(m2\)  
float64 vector also used for the operation

Description

Performs a bitwise logical XOR of the four packed double-precision floating-point elements (float64 elements) of the first source vector \(m1\), and corresponding elements in the second source vector \(m2\).

Returns

Result of the bitwise operation.

_mm256_xor_ps

Performs bitwise logical XOR operation on float32 vectors. The corresponding Intel® AVX instruction is VXORPS.

Syntax

extern __m256 _mm256_xor_ps(__m256 m1, __m256 m2);

Arguments

\(m1\)  
float32 vector used for the operation

\(m2\)  
float32 vector also used for the operation

Description

Performs a bitwise logical XOR of the eight packed single-precision floating-point elements (float32 elements) of the first source vector \(m1\), and corresponding elements in the second source vector, \(m2\).
Returns
Result of the bitwise operation.

Intrinsics for Blend and Conditional Merge Operations

_mm256_blend_pd
Performs a conditional blend/merge of float64 vectors. The corresponding Intel® AVX instruction is VBLENDPD.

Syntax
extern __m256d _mm256_blend_pd(__m256d m1, __m256d m2, const int mask);

Arguments
m1 float64 vector used for the operation
m2 float64 vector also used for the operation
mask a constant of integer type that is the mask for the operation

Description
Performs a conditional merge of four packed double-precision floating point elements (float64 elements) of two vectors according to the immediate bits of the mask parameter.

The mask parameter defines a constant integer. The immediate bits [3:0] in the mask determine from which source vector elements are copied into the resulting vector.

If the bits in mask are "1" then the corresponding elements of the second source vector are copied into the resulting vector. If the bits are "0" then the corresponding elements of the first source vector are copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns
Result of the merge/blend operation.

_mm256_blend_ps
Performs a conditional blend/merge of float32 vectors. The corresponding Intel® AVX instruction is VBLENDPS.

Syntax
extern __m256 _mm256_blend_ps(__m256 m1, __m256 m2, const int mask);

Arguments
m1 float32 vector used for the operation
m2 float32 vector also used for the operation
mask a constant of integer type that is the mask for the operation

Description
Performs a conditional merge of eight packed single-precision floating point elements (float32 elements) of two vectors according to the immediate bits of the mask parameter.
The `mask` parameter defines a constant integer. The immediate bits [7:0] in the mask determine from which source vector elements are copied into the resulting vector.

If the bits in `mask` are "1" then the corresponding elements of the second source vector are copied into the resulting vector. If the bits are "0" then the corresponding elements of the first source vector are copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns
Result of the merge/blend operation.

`_mm256_blendv_pd`
Performs conditional blend/merge of float64 vectors.
The corresponding Intel® AVX instruction is 
VBLENDVPD.

Syntax
`extern __m256d _mm256_blendv_pd(__m256d m1, __m256d m2, __m256d mask);`

Arguments
- `m1` float64 vector used for the operation
- `m2` float64 vector also used for the operation
- `mask` float64 vector with mask for the operation

Description
Performs a conditional merge of four packed double-precision floating point elements (float64 elements) of two vectors according to the most significant bits of the `mask` parameter elements.

The `mask` parameter defines a mask for the operation. The most significant bit of the corresponding double-precision floating-point elements in the `mask` determines whether the corresponding double-precision floating-point element in the resulting vector is copied from the second source or first source.

If the bit in the `mask` is “1” then the corresponding element of the second source vector is copied into the resulting vector. If the bit is “0” then the corresponding element of the first source vector is copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns
Result of the blend operation.

`_mm256_blendv_ps`
Performs conditional blend/merge of float32 vectors.
The corresponding Intel® AVX instruction is 
VBLENDVPS.

Syntax
`extern __m256 _mm256_blendv_ps(__m256 m1, __m256 m2, __m256 mask);`

Arguments
- `m1` float32 vector used for the operation
Description
Performs a conditional merge of eight packed single-precision floating point elements (float32 elements) of two vectors according to the most significant bits of the mask parameter.

The mask parameter defines a mask for the operation. The most significant bit of the corresponding single-precision floating-point elements in the mask determines whether the corresponding single-precision floating-point element in the resulting vector is copied from the second source or first source.

If the bit in the mask is “1” then the corresponding element of the second source vector is copied into the resulting vector. If the bit is “0” then the corresponding element of the first source vector is copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns
Result of the blend operation.

Intrinsics for Compare Operations

_mm_cmp_pd, _mm256_cmp_pd
Compares packed 128-bit and 256-bit float64 vector elements. The corresponding Intel® AVX instruction is VCMPPD.

Syntax
extern __m128d _mm_cmp_pd(__m128d m1, __m128d m2, const int predicate);
extern __m256d _mm256_cmp_pd(__m256d m1, __m256d m2, const int predicate);

Arguments
m1
float64 vector used for the operation
m2
float64 vector also used for the operation
predicate
an immediate operand that specifies the type of comparison to be performed of the packed values; see immintrin.h file for the values to specify the type of comparison

Description
Performs a SIMD compare of the four packed double-precision floating-point (float64) values in the first source operand, m1, and the second source operand, m2, and returns the results of the comparison.

The _mm_cmp_pd intrinsic is used for comparing 128-bit float64 values while the _mm256_cmp_pd intrinsic is used for comparing 256-bit float64 values.

The comparison predicate parameter (immediate) specifies the type of comparison performed on each of the pairs of packed values.
Returns
Result of the compare operation.

_mm_cmp_ps, _mm256_cmp_ps
Compares packed float32 elements of two vectors. 
The corresponding Intel® AVX instruction is VCMPPS.

Syntax
extern __m128 _mm_cmp_ps(__m128 m1, __m128 m2, const int predicate);
extern __m256 _mm256_cmp_ps(__m256 m1, __m256 m2, const int predicate);

Arguments
m1 float32 vector used for the operation
m2 float32 vector also used for the operation
predicate an immediate operand that specifies the type of comparison to be performed of the packed values; see immintrin.h file for the values to specify the type of comparison

Description
Performs a SIMD compare of the eight packed single-precision floating-point (float32) values in the first source operand, m1, and the second source operand, m2, and returns the results of the comparison.

The _mm_cmp_ps intrinsic is used for comparing 128-bit float32 values while the _mm256_cmp_ps intrinsic is used for comparing 256-bit float32 values.

The comparison predicate parameter (immediate) specifies the type of comparison performed on each of the pairs of packed values.

Returns
Result of the compare operation.

_mm_cmp_sd
Compares scalar float64 vectors. The corresponding Intel® AVX instruction is VCMPSD.

Syntax
extern __m128d _mm_cmp_sd(__m128d m1, __m128d m2, const int predicate);

Arguments
m1 float64 vector used for the operation
m2 float64 vector also used for the operation
predicate an immediate operand that specifies the type of comparison to be performed of the packed values; see immintrin.h file for the values to specify the type of comparison
Description
Performs a compare operation of the low double-precision floating-point values (float64 values) in the first source operand, \( m1 \), and the second source operand, \( m2 \), and returns the result.
The comparison \textit{predicate} parameter (immediate operand) specifies the type of comparison performed on each of the pairs of values.

Returns
Result of the compare operation.

\texttt{\_mm\_cmp\_ss}

\textit{Compares scalar float32 values. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VCMPPSS.}

Syntax
\begin{verbatim}
extern __m128 \_mm\_cmp\_ss(__m128 m1, __m128 m2, const int predicate);
\end{verbatim}

Arguments
\begin{itemize}
\item \textit{m1} \hspace{2cm} float32 vector used for the operation
\item \textit{m2} \hspace{2cm} float32 vector also used for the operation
\item \textit{predicate} \hspace{2cm} an immediate operand that specifies the type of comparison to be performed of the packed values; see \texttt{immintrin.h} file for the values to specify the type of comparison
\end{itemize}

Description
Performs a compare operation of the low single-precision floating-point values (float32 values) in the first source operand, \( m1 \), and the second source operand, \( m2 \), and returns the results.
The comparison \textit{predicate} parameter (immediate) specifies the type of comparison performed.

Returns
Result of the compare operation.

Intrinsics for Conversion Operations

\texttt{\_mm256\_cvtepi32\_pd}

\textit{Converts extended packed 32-bit integer values to packed double-precision floating point values. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VCVTQ2PD.}

Syntax
\begin{verbatim}
extern __m256 \_mm256\_cvtepi32\_pd(__m128i m1);
\end{verbatim}

Arguments
\begin{itemize}
\item \textit{m1} \hspace{2cm} integer source vector/operand
\end{itemize}
**Description**
Converting four packed signed doubleword integers in the source vector \textit{m1} into four packed double-precision floating-point values.

**Returns**
Result of the conversion operation.

\_\_mm256\_cvtepi32\_ps
Converts extended packed 32-bit integer values to packed single-precision floating point values. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VCVTQ2PS.

**Syntax**

\begin{verbatim}
extern __m256 \_mm256\_cvtepi32\_ps(__m256i m1);
\end{verbatim}

**Arguments**

\textit{m1} \\ integer source vector / operand

**Description**
Converts eight packed signed doubleword integers in the source vector \textit{m1} to eight packed single-precision floating-point values.

**Returns**
Result of the conversion operation.

\_\_mm256\_cvtpd\_epi32
Converts packed double-precision float values to extended 32-bit integer values. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VCVTPD2IQ.

**Syntax**

\begin{verbatim}
extern __m128i \_mm256\_cvtpd\_epi32(__m256d m1);
\end{verbatim}

**Arguments**

\textit{m1} \\ float64 source vector

**Description**
Converts four packed double-precision floating-point values in the source vector \textit{m1} to four packed signed doubleword integer (extended 32-bit integer) values in the destination.

**Returns**
Result of the conversion operation.

\_\_mm256\_cvtps\_epi32
Converts packed single-precision float values to extended 32-bit integer values. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VCVTPS2IQ.
Syntax

extern __m256i _mm256_cvtps_epi32(__m256 m1);

Arguments

m1 float32 source vector

Description

Converts eight packed single-precision floating point values in the source vector m1 to eight signed doubleword integer (extended 32-bit integer) values.

Returns

Result of the conversion operation.

_mm256_cvtpd_ps

Converts packed float64 values to packed float32 values. The corresponding Intel® AVX instruction is VCVTPD2PS.

Syntax

extern __m128 _mm256_cvtpd_ps(__m256d m1);

Arguments

m1 float64 source vector

Description

Converts four packed double-precision floating point values (float64 values) in the source vector m1 to eight packed single-precision floating-point values (float32 values).

Returns

Result of the conversion operation.

_mm256_cvtps_pd

Converts packed float32 values to packed float64 values. The corresponding Intel® AVX instruction is VCVTPS2PD.

Syntax

extern __m256d _mm256_cvtps_pd(__m128 m1);

Arguments

m1 128-bit float32 source vector

Description

Converts four packed single-precision floating point values (float32 values) in the source vector m1 to four packed double-precision floating-point values (float64 values).
Returns
Result of the conversion operation.

_mm256_cvtp_epi32
Converts packed float64 values to truncated extended 32-bit integer values. The corresponding Intel® AVX instruction is VCVTTPD2DQ.

Syntax
extern __m128i _mm256_cvtpd_epi32(__m256d m1);

Arguments
m1
float64 source vector

Description
Converts four packed double-precision floating-point values (float64 values) in the source vector to four packed signed doubleword integer (extended 32-bit integer) values in the destination.

When a conversion is inexact, a truncated (round towards zero) value is returned. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised. If this exception is masked, the indefinite integer value (80000000H) is returned.

Returns
Result of the conversion operation.

_mm256_cvtps_epi32
Converts packed float32 values to truncated extended 32-bit integer values. The corresponding Intel® AVX instruction is VCVTTPS2DQ.

Syntax
extern __m256i _mm256_cvtps_epi32(__m256 m1);

Arguments
m1
float32 source vector

Description
Converts eight packed single-precision floating-point values (float32 values) in the source vector to eight packed signed doubleword integer (extended 32-bit integer) values in the destination.

When a conversion is inexact, a truncated (round towards zero) value is returned. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised; if this exception is masked, the indefinite integer value (80000000H) is returned.

Returns
Result of the conversion operation.

_mm256_cvtsi256_si32
Extracts a 32-bit integer value.
Syntax

```cpp
int _mm256_cvtsi256_si32(__m256i a);
```

**Arguments**

- `a`  
  256-bit integer source vector

**Description**

Copies the least significant 32 bits of `a` to a 32-bit integer.

**Returns**

Result of the conversion operation.

---

`_mm256_cvtsd_f64`

*Extracts a double precision floating point value.*

**Syntax**

```cpp
double _mm256_cvtsd_f64(__m256d a);
```

**Arguments**

- `a`  
  float64 source vector

**Description**

This intrinsic extracts a double precision floating point value from the first vector element of an `__m256d`. It does so in the most efficient manner possible in the context used.

**Returns**

Result of the conversion operation.

---

`_mm256_cvtss_f32`

*Extracts a single precision floating point value.*

**Syntax**

```cpp
float _mm256_cvtsf32(__m256 a);
```

**Arguments**

- `a`  
  float32 source vector

**Description**

Extracts a single precision floating point value from the first vector element of an `__m256`. It does so in the most efficient manner possible in the context used.

**Returns**

Result of the conversion operation.

---

**Intrinsics to Determine Minimum and Maximum Values**
_mm256_max_pd
Determines the maximum of float64 vectors. The corresponding Intel® AVX instruction is VMAXPD.

Syntax
extern __m256d _mm256_max_pd(__m256d m1, __m256d m2);

Arguments
m1 float64 vector used for the operation
m2 float64 vector also used for the operation

Description
Performs a SIMD compare of the packed double-precision floating-point (float64) elements in the first source vector m1 and the second source vector m2, and returns the maximum value for each pair.

Returns
Maximum value of the compare operation.

_mm256_max_ps
Determines the maximum of float32 vectors. The corresponding Intel® AVX instruction is VMAXPS.

Syntax
extern __m256 _mm256_max_ps(__m256 m1, __m256 m2);

Arguments
m1 float32 vector used for the operation
m2 float32 vector also used for the operation

Description
Performs a SIMD compare of the packed single-precision floating-point (float32) elements in the first source vector m1 and the second source vector m2, and returns the maximum value for each pair.

Returns
Maximum value of the compare operation.

_mm256_min_pd
Determines the minimum of float64 vectors. The corresponding Intel® AVX instruction is VMINPD.

Syntax
extern __m256d _mm256_min_pd(__m256d m1, __m256d m2);

Arguments
m1 float64 vector used for the operation
Description
Performs a SIMD compare of the packed double-precision floating-point (float64) elements in the first source vector \( m1 \) and the second source vector \( m2 \), and returns the minimum value for each pair.

Returns
Minimum value of the compare operation.

\_mm256\_min\_ps
Determines the minimum of float32 vectors. The corresponding Intel\textsuperscript{®} AVX instruction is VMINPS.

Syntax
extern __m256 \_mm256\_min\_ps(__m256 m1, __m256 m2);

Arguments

\( m1 \)
float32 vector used for the operation

\( m2 \)
float32 vector also used for the operation

Description
Performs a SIMD compare of the packed single-precision floating-point (float32) elements in the first source vector \( m1 \) and the second source vector \( m2 \), and returns the minimum value for each pair.

Returns
Minimum value of the compare operation.

Intrinsics for Load and Store Operations

\_mm256\_broadcast\_pd
Loads and broadcasts packed double-precision floating point values. The corresponding Intel\textsuperscript{®} AVX instruction is VBROADCASTF128.

Syntax
extern __m256d \_mm256\_broadcast\_pd(__m128d const *a);

Arguments

\*a
pointer to a memory location that can hold constant float64 values

Description
Loads 128-bit float64 values from the specified address pointed to by \( a \), and broadcasts it to two elements in the destination 256-bit vector.

Returns
Result of the load and broadcast operation.
_mm256_broadcast_ps

Loads and broadcasts packed single-precision floating point values. The corresponding Intel® AVX instruction is VBROADCASTF128.

Syntax
extern __m256 _mm256_broadcast_ps(__m128 const *a);

Arguments
*a
pointer to a memory location that can hold constant 128-bit float32 values

Description
Loads 128-bit float32 values from the specified address pointed to by a, and broadcasts it to all elements in the destination 256-bit vector.

Returns
Result of the load and broadcast operation.

_mm256_broadcast_sd

Loads and broadcasts scalar double-precision floating point values to a 256-bit destination operand. The corresponding Intel® AVX instruction is VBROADCASTSD.

Syntax
extern __m256d _mm256_broadcast_sd(double const *a);

Arguments
*a
pointer to a memory location that can hold constant scalar float64 values

Description
Loads scalar double-precision floating-point values from the specified address a, and broadcasts it to all four elements in the destination vector.

Returns
Result of the load and broadcast operation.

_mm256_broadcast_ss, _mm_broadcast_ss

Loads and broadcasts 256/128-bit scalar single-precision floating point values to a 256/128-bit destination operand. The corresponding Intel® AVX instruction is VBROADCASTSS.

Syntax
extern __m256 _mm256_broadcast_ss(float const *a);
extern __m128 _mm_broadcast_ss(float const *a);
Arguments
*a pointer to a memory location that can hold constant 256-bit or 128-bit float32 values

Description
Loads scalar single-precision floating-point values from the specified address pointed to by a, and broadcasts it to elements in the destination vector.

The _m256_broadcast_ss intrinsic broadcasts the loaded values to all eight elements in the 256-bit destination vector.

The _mm_broadcast_ss intrinsic broadcasts the loaded values to all four elements in the 128-bit destination vector.

Returns
Result of the load and broadcast operation.

_mm256_load_pd
Moves packed double-precision floating point values from aligned memory location to a destination vector. The corresponding Intel® AVX instruction isVMOVAPD.

Syntax
extern __m256d _mm256_load_pd(double const *a);

Arguments
*a pointer to a memory location that can hold constant float64 values; the address must be 32-byte aligned

Description
Loads packed double-precision floating point values (float64 values) from the 256-bit aligned memory location pointed to by a, into a destination float64 vector, which is retured by the intrinsic.

Returns
A 256-bit vector with float64 values.

_mm256_load_ps
Moves packed single-precision floating point values from aligned memory location to a destination vector. The corresponding Intel® AVX instruction isVMOVAPS.

Syntax
extern __m256 _mm256_load_ps(float const *a);

Arguments
*a pointer to a memory location that can hold constant float32 values; the address must be 32-byte aligned
Description
Loads packed single-precision floating point values (float32 values) from the 256-bit aligned memory location pointed to by a, into a destination float32 vector, which is returned by the intrinsic.

Returns
A 256-bit vector with float32 values.

_mm256_load_si256
Moves integer values from aligned memory location to a destination vector. The corresponding Intel® AVX instruction is VMOVQDQA.

Syntax
extern __m256i _mm256_load_si256(__m256i const *a);

Arguments
*a
        pointer to a memory location that can hold constant integer values; the address must be 32-byte aligned

Description
Loads integer values from the 256-bit aligned memory location pointed to by *a, into a destination integer vector, which is returned by the intrinsic.

Returns
A 256-bit vector with integer values.

_mm256_loadu_pd
Moves packed double-precision floating point values from unaligned memory location to a destination vector. The corresponding Intel® AVX instruction is VMOVUPD.

Syntax
extern __m256d _mm256_loadu_pd(double const *a);

Arguments
*a
        pointer to a memory location that can hold constant float64 values;

Description
Loads packed double-precision floating point values (float64 values) from the 256-bit unaligned memory location pointed to by a, into a destination float64 vector, which is returned by the intrinsic.

Returns
A 256-bit vector with float64 values.
**_mm256_loadu_ps**

Moves packed single-precision floating point values from unaligned memory location to a destination vector. The corresponding Intel® AVX instruction is VMOVUPS.

**Syntax**

```c
extern __m256 _mm256_loadu_ps(float const *a);
```

**Arguments**

*a*

pointer to a memory location that can hold constant float32 values

**Description**

Loads packed single-precision floating point values (float32 values) from the 256-bit unaligned memory location pointed to by `a`, into a destination float32 vector, which is returned by the intrinsic.

**Returns**

A 256-bit vector with float32 values.

**_mm256_loadu_si256**

Moves integer values from unaligned memory location to a destination vector. The corresponding Intel® AVX instruction is VMOVQDQU.

**Syntax**

```c
extern __m256i _mm256_loadu_si256(__m256i const *a);
```

**Arguments**

*a*

pointer to a memory location that can hold constant integer values

**Description**

Loads integer values from the 256-bit unaligned memory location pointed to by `*a`, into a destination integer vector, which is returned by the intrinsic.

**Returns**

A 256-bit vector with integer values.

**_mm256_maskload_pd, _mm_maskload_pd**

Loads packed double-precision floating point values according to mask values. The corresponding Intel® AVX instruction is VMASKMOVPD.

**Syntax**

```c
extern __m256d _mm256_maskload_pd(double const *a, __m256i mask);
extern __m128d _mm_maskload_pd(double const *a, __m128i mask);
```
Arguments

*a
pointer to a 256/128-bit memory location that can hold constant float64 values

mask
integer value calculated based on the most-significant-bit of each quadword of a mask register

Description

Loads packed double-precision floating point (float64) values from the 256/128-bit memory location pointed to by a, into a destination register using the mask value.

The mask is calculated from the most significant bit of each qword of the mask register. If any of the bits of the mask is set to zero, the corresponding value from the memory location is not loaded, and the corresponding field of the destination vector is set to zero.

Returns

A 256/128-bit register with float64 values.

_mm256_maskload_ps, _mm_maskload_ps

Loads packed single-precision floating point values according to mask values. The corresponding Intel® AVX instruction is VMASKMOVPS.

Syntax

extern __m256 _mm256_maskload_ps(float const *a, __m256i mask);
extern __m128 _mm_maskload_ps(float const *a, __m128i mask);

Arguments

*a
pointer to a 256/128-bit memory location that can hold constant float32 values

mask
integer value calculated based on the most-significant-bit of each doubleword of a mask register

Description

Loads packed single-precision floating point (float32) values from the 256/128-bit memory location pointed to by a, into a destination register using the mask value.

The mask is calculated from the most significant bit of each dword of the mask register. If any of the bits of the mask is set to zero, the corresponding value from the memory location is not loaded, and the corresponding field of the destination vector is set to zero.

Returns

A 256/128-bit register with float32 values.

_mm256_store_pd

Moves packed double-precision floating point values from a float64 vector to an aligned memory location. The corresponding Intel® AVX instruction is VMOVAEPD.
extern void _mm256_store_pd(double *a, __m256d b);

**Arguments**

*a*  
pointer to a memory location that can hold double-precision floating point (float64) values; the address must be 32-byte aligned

*b*  
float64 vector

**Description**

Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, *b*, to a 256-bit aligned memory location, pointed to by *a*.

**Returns**

Nothing

---

extern void _mm256_store_ps(float *a, __m256 b);

**Arguments**

*a*  
pointer to a memory location that can hold single-precision floating point (float32) values; the address must be 32-byte aligned

*b*  
float32 vector

**Description**

Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, *b*, to a 256-bit aligned memory location, pointed to by *a*.

**Returns**

Nothing.

---

extern void _mm256_store_si256(__m256i *a, __m256i b);

**Arguments**

*a*  
pointer to a memory location that can hold scalar integer values; the address must be 32-byte aligned.
b integer vector

Description
Performs a store operation by moving integer values from a 256-bit integer vector, \( b \), to a 256-bit aligned memory location, pointed to by \( a \).

Returns
Nothing.

_mm256_storeu_pd

Moves packed double-precision floating point values from a float64 vector to an unaligned memory location. The corresponding Intel® AVX instruction is VMOVUPD.

Syntax
extern void _mm256_storeu_pd(double *a, __m256d b);

Arguments
*a pointer to a memory location that can hold double-precision floating point (float64) values

b float64 vector

Description
Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, \( b \), to a 256-bit unaligned memory location, pointed to by \( a \).

Returns
Nothing.

_mm256_storeu_ps

Moves packed single-precision floating point values from a float32 vector to an unaligned memory location. The corresponding Intel® AVX instruction is VMOVUPS.

Syntax
extern void _mm256_storeu_ps(float *a, __m256 b);

Arguments
*a pointer to a memory location that can hold single-precision floating point (float32) values

b float32 vector

Description
Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, \( b \), to a 256-bit unaligned memory location, pointed to by \( a \).
Returns
Nothing.

_mm256_storeu_si256
Moves values from a integer vector to an unaligned memory location. The corresponding Intel® AVX instruction is VMOVDQU.

Syntax
extern void _mm256_storeu_si256(__m256i *a, __m256i b);

Arguments
*a pointer to a memory location that can hold scalar integer values
b integer vector

Description
Performs a store operation by moving integer values from a 256-bit integer vector, b, to a 256-bit unaligned memory location, pointed to by a.

Returns
Nothing.

_mm256_stream_pd
Moves packed double-precision floating-point values using non-temporal hint. The corresponding Intel® AVX instruction is VMOVNTPD.

Syntax
extern void _mm256_stream_pd(double *p, __m256d a);

Arguments
*p pointer to a memory location that can hold double-precision floating point (float64) values; the address must be 32-byte aligned
a float64 vector

Description
Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, a, to a 256-bit aligned memory location, pointed to by p, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns
Result of the streaming/store operation.
__mm256_stream_ps
Moves packed single-precision floating-point values using non-temporal hint. The corresponding Intel® AVX instruction is VMOVNTPS.

Syntax
extern void __mm256_stream_ps(float *p, __m256 a);

Arguments
*p pointer to a memory location that can hold single-precision floating point (float32) values; the address must be 32-byte aligned

a float32 vector

Description
Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, a, to a 256-bit aligned memory location, pointed to by p, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns
Result of the streaming/store operation.

__mm256_stream_si256
Moves packed integer values using non-temporal hint. The corresponding Intel® AVX instruction is VMOVNTDQ.

Syntax
extern void __mm256_stream_si256(__m256i *p, __m256i a);

Arguments
*p pointer to a memory location that can hold scalar integer values; the address must be 32-byte aligned

a integer vector

Description
Performs a store operation by moving scalar integer values from an integer vector a, to a 256-bit aligned memory location, pointed to by p, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns
Result of the streaming/store operation.

__mm256_maskstore_pd, __mm_maskstore_pd
Stores packed double-precision floating point values according to mask values. The corresponding Intel® AVX instruction is VMASKMOVPD.
Syntax

extern void _mm256_maskstore_pd(double *a, __m256i mask, __m256 d b);
extern void _mm_maskstore_pd(double *a, __m128i mask, __m128 d b);

Arguments

*a          pointer to a 256/128-bit memory location that can hold constant double-
precision floating point (float64) values

mask        integer value calculated based on the most-significant-bit of each quadword
            of a mask register

b            a 256/128-bit float64 vector

Description

Performs a store operation by moving packed double-precision floating point (float64) values from a vector, b, to a 256/128-bit memory location, pointed to by a, using a mask.

The mask is calculated from the most significant bit of each qword of the mask register. If any of the bits of the mask are set to zero, the corresponding value from the float64 vector is not loaded, and the corresponding field of the destination memory location is left unchanged.

NOTE
Stores are atomic. Faults do not occur for memory locations for which all corresponding mask bits are set to zero.

Returns

Nothing.

_mm256_maskstore_ps, _mm_maskstore_ps
Stores packed single-precision floating point values according to mask values. The corresponding Intel® AVX instruction is VMASKMOVPS.

Syntax

extern void _mm256_maskstore_ps(float *a, __m256i mask, __m256 b);
extern void _mm_maskstore_ps(float *a, __m128i mask, __m128 b);

Arguments

*a          pointer to a 256/128-bit memory location that can hold constant single-
precision floating point (float32) values

mask        integer value calculated based on the most-significant-bit of each quadword
            of a mask register

b            a 256/128-bit float32 vector

Description

Performs a store operation by moving packed single-precision floating point (float32) values from a vector, b, to a 256/128-bit memory location, pointed to by a, using a mask.
The mask is calculated from the most significant bit of each qword of the mask register. If any of the bits of the mask are set to zero, the corresponding value from the float32 vector is not loaded, and the corresponding field of the destination memory location is left unchanged.

**NOTE**
Stores are atomic. Faults do not occur for memory locations for which all corresponding mask bits are set to zero.

**Returns**
Nothing.

**Intrinsics for Miscellaneous Operations**

_**mm256_extractf128_pd**_

Extracts 128-bit packed float64 values. The corresponding Intel® AVX instruction is VEXTRACTF128.

**Syntax**

extern __m128d _mm256_extractf128_pd(__m256d m1, const int offset);

**Arguments**

- \( m1 \) : float64 source vector
- \( offset \) : a constant integer value that represents the 128-bit offset from where extraction must start

**Description**

Extracts 128-bit packed double-precision floating point values (float64 values) from the source vector \( m1 \), starting from the location specified by the value in the \( offset \) parameter.

**Returns**

Result of the extraction operation.

_**mm256_extractf128_ps**_

Extracts 128-bit float32 values. The corresponding Intel® AVX instruction is VEXTRACTF128.

**Syntax**

extern __m128 _mm256_extractf128_ps(__m256 m1, const int offset);

**Arguments**

- \( m1 \) : float32 source vector
- \( offset \) : a constant integer value that represents the 128-bit offset from where extraction must start
Description

Extracts 128-bit packed single-precision floating point values (float32 values) from the source vector \( m1 \), starting from the location specified by the value in the \( \text{offset} \) parameter.

Returns

Result of the extraction operation.

_mm256_extractf128_si256

Extracts 128-bit scalar integer values. The corresponding Intel\textsuperscript{®} AVX instruction is VEXTRACTF128.

Syntax

extern __m128i _mm256_extractf128_si256(__m256i m1, const int offset);

Arguments

- \( m1 \) integer source vector
- \( \text{offset} \) a constant integer value that represents the offset from where extraction must start

Description

Extracts 128-bit scalar integer values from the source vector \( m1 \), starting from the location specified by the value in the \( \text{offset} \) parameter.

Returns

Result of the extraction operation.

_mm256_insertf128_pd

Inserts 128 bits of packed float64 values. The corresponding Intel\textsuperscript{®} AVX instruction is VINSERTF128.

Syntax

extern __m256d _mm256_insertf128_pd(__m256d a, __m128d b, int offset);

Arguments

- \( a \) 256-bit float64 source vector
- \( b \) 128-bit float64 source vector
- \( \text{offset} \) an integer value that represents the 128-bit offset where the insertion must start

Description

Performs an insertion of 128 bits of packed double-precision floating-point values (float64 values) from the second source vector \( b \) into a destination at a 128-bit offset specified by the \( \text{offset} \) parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector \( a \).

Returns

Result of the insertion operation.
__mm256_insertf128_ps

*Inserts 128 bits of packed float32 values. The corresponding Intel® AVX instruction is VINSERTF128.*

**Syntax**

```c
extern __m256 __mm256_insertf128_ps(__m256 a, __m128 b, int offset);
```

**Arguments**

- `a`: 256-bit float32 source vector
- `b`: 128-bit float32 source vector
- `offset`: an integer value that represents the 128-bit offset where the insertion must start

**Description**

Performs an insertion of 128 bits of packed single-precision floating-point values (float32 values) from the second source vector `b`, into a destination at a 128-bit offset specified by the `offset` parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector `a`.

**Returns**

Result of the insertion operation.

__mm256_insertf128_si256

*Inserts 128 bits of packed scalar integer values. The corresponding Intel® AVX instruction is VINSERTF128.*

**Syntax**

```c
extern __m256i __mm256_insertf128_si256(__m256i a, __m128i b, int offset);
```

**Arguments**

- `a`: 256-bit integer source vector
- `b`: 128-bit integer source vector
- `offset`: an integer value that represents the 128-bit offset where the insertion must start

**Description**

Performs an insertion of 128 bits of packed scalar integer values from the second source vector `b`, into a destination at a 128-bit offset specified by the `offset` parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector `a`.

**Returns**

Result of the insertion operation.

__mm256_lddqu_si256

*Moves unaligned integer from memory. The corresponding Intel® AVX instruction is VLDDQU.*
Syntax
extern __m256i _mm256_lddqu_si256(__m256i const *a);

Arguments
*a  
points to a memory location from where unaligned integer value must be moved

Description
Fetches 32 bytes of data, starting at a memory address specified by the a parameter, and places them in a destination. This intrinsic calls the corresponding instruction VLDDQU, which performs an operation functionally similar to the VMOVQ instruction.

Returns
Result of the move operation.

_mm256 Movedup_pd
Duplicates even-indexed double-precision floating point values. The corresponding Intel® AVX instruction is VMOVDDUP.

Syntax
extern __m256d _mm256_movedup_pd(__m256d a);

Arguments
a  
float64 source vector

Description
Performs a duplication of even-indexed double-precision floating-point values (float64 values) in the source vector a, and returns the result.

Returns
Result of the duplication operation.

_mm256 Movehdup_ps
Duplicates odd-indexed single-precision floating point values. The corresponding Intel® AVX instruction is VMOVSSDUP.

Syntax
extern __m256 _mm256_movehdup_ps(__m256 a);

Arguments
a  
float32 source vector

Description
Performs a duplication of odd-indexed single-precision floating-point values (float32 values) in the source vector a, and returns the result.
Returns
Result of the duplication operation.

_mm256_moveldup_ps
Duplicates even-indexed single-precision floating point values. The corresponding Intel® AVX instruction is VMOVSLDUP.

Syntax
extern __m256 _mm256_moveldup_ps(__m256 a);

Arguments
a float32 source vector

Description
Performs a duplication of even-indexed single-precision floating-point values (float32 values) in the source vector a, and returns the result.

Returns
Result of the duplication operation.

_mm256_movemask_pd
Extracts float64 sign mask. The corresponding Intel® AVX instruction is VMOVMSKPD.

Syntax
extern int _mm256_movemask_pd(__m256d a);

Arguments
a float64 source vector

Description
Performs an extract operation of sign bits from four double-precision floating point elements (float64 elements) of the source vector a, and composes them into bitmasks.

Returns
An integer bitmask of four meaningful bits.

_mm256_movemask_ps
Extracts float32 sign mask. The corresponding Intel® AVX instruction is VMOVMSKPS.

Syntax
extern int _mm256_movemask_ps(__m256 a);
Arguments

\( a \)  
float32 source vector

Description

Performs an extract operation of sign bits from eight single-precision floating point elements (float32 elements) of the source vector \( a \), and composes them into bitmasks.

Returns

An integer bitmask of eight meaningful bits.

_\text{mm256\_round\_pd}_

Rounds off double-precision floating point values to nearest upper/lower integer depending on rounding mode. The corresponding Intel® AVX instruction is _VROUNPD_.

Syntax

extern __m256d _mm256_round_pd(__m256d a, int iRoundMode);

Arguments

\( a \)  
float64 vector

\( \text{iRoundMode} \)  
A hexadecimal value dependent on rounding mode:

- For rounding off to upper integer, the value is 0x0A
- For rounding off to lower integer, the value is 0x09

Description

Rounds off the elements of a float64 vector \( a \) to the nearest upper/lower integer value. Two shortcuts, in the form of `#defines`, are used to achieve these two separate operations:

```
#define _mm256_ceil_pd(a)   _mm256_round_pd((a), 0x0A)
#define _mm256_floor_pd(a)  _mm256_round_pd((a), 0x09)
```

These `#defines` tell the preprocessor to replace all instances of `_mm256_ceil_pd(a)` with `_mm256_round_pd((a), 0x0A)` and all instances of `_mm256_floor_pd(a)` with `_mm256_round_pd((a), 0x09)`.  

For example, if you write the following:

```c
__m256 a, b;
a = _mm256_ceil_pd(b);
```

the preprocessor will modify it to:

```c
a = _mm256_round_pd(b, 0xA);
```

The Precision Floating Point Exception is signaled according to the (immediate operand) \( \text{iRoundMode} \) value.

Returns

Result of the rounding off operation as a vector with double-precision floating point values.
_mm256_round_ps
Rounds off single-precision floating point values to nearest upper/lower integer depending on rounding mode. The corresponding Intel® AVX instruction is VROUNDPS.

Syntax
extern __m256 _mm256_round_ps(__m256 a, int iRoundMode);

Arguments
a float32 vector
iRoundMode A hexadecimal value dependent on rounding mode:
• For rounding off to upper integer, the value is 0x0A
• For rounding off to lower integer, the value is 0x09

Description
Rounds off the elements of a float32 vector a to the nearest upper/lower integer value. Two shortcuts, in the form of #defines, are used to achieve these two separate operations:

#define _mm256_ceil_ps(a)   _mm256_round_ps((a), 0x0A)
#define _mm256_floor_ps(a)  _mm256_round_ps((a), 0x09)

These #defines tells the preprocessor to replace all instances of _mm256_ceil_ps(a) with _mm256_round_ps((a), 0x0A) and all instances of _mm256_floor_ps(a) with _mm256_round_ps((a), 0x09).

For example, if you write the following:

__m256 a, b;
a = _mm256_ceil_ps(b);

the preprocessor will modify it to:

a = _mm256_round_ps(b, 0x0A);

The Precision Floating Point Exception is signaled according to the (immediate operand) iRoundMode value.

Returns
Result of the rounding off operation as a vector with single-precision floating point values.

_mm256_set_pd
Initializes 256-bit vector with float64 values. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_set_pd(double, double, double, double);

Arguments
double a float64 value to be initialized into the 256-bit vector; there are four double parameters, one for each float64 vector element
Description

Initializes a 256-bit vector with double-precision floating point values (float64 values) as specified by the `double` parameter.

Returns

A float64 vector initialized with specified double-precision floating point values.

_mm256_set_ps

Initializes 256-bit vector with float32 values. No corresponding Intel® AVX instruction.

Syntax

```c
extern __m256 _mm256_set_ps(float, float, float, float, float, float, float, float);
```

Arguments

- `float` a float32 value to be initialized into the 256-bit vector; there are eight float parameters, one for each float32 vector element.

Description

Initializes a 256-bit vector with single-precision floating point values (float32 values) as specified by the `float` parameter.

Returns

A float32 vector initialized with specified single-precision floating point values.

_mm256_set_epi8/16/32/64x

Initializes 256-bit vector with integer values. No corresponding Intel® AVX instruction.

Syntax

```c
extern __m256i _mm256_set_epi8(char e31, char e30, char e29, char e28, char e27, char e26, char e25, char e24, char e23, char e22, char e21, char e20, char e19, char e18, char e17, char e16, char e15, char e14, char e13, char e12, char e11, char e10, char e9, char e8, char e7, char e6, char e5, char e4, char e3, char e2, char e1, char e0);
extern __m256i _mm256_set_epi16(short e15, short e14, short e13, short e12, short e11, short e10, short e9, short e8, short e7, short e6, short e5, short e4, short e3, short e2, short e1, short e0);
extern __m256i _mm256_set_epi32(int e7, int e6, int e5, int e4, int e3, int e2, int e1, int e0);
extern __m256i _mm256_set_epi64x(__int64 e3, __int64 e2, __int64 e1, __int64 e0);
```

Arguments

- `e_n` An 8/16/32/64-bit integer value to be initialized into the 256-bit vector. For each variant, there is one integer parameter for each 8/16/32/64-bit integer vector element.
Description
Initializes a 256-bit vector with extended packed integer values (8/16/32/64-bit values) as specified by the e_n parameter.

Returns
An 8/16/32/64-bit integer vector initialized with specified extended packed integer values.

_mm256_setr_pd
Initializes 256-bit vector with float64 values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_setr_pd(double, double, double, double);

Arguments
double a float64 value to be initialized into the 256-bit vector; there are four double parameters, one for each float64 vector element

Description
Initializes a 256-bit vector with double-precision floating point values (float64 values) in reverse order as specified by the double parameter.

Returns
A float64 vector initialized with specified double-precision floating point values in reverse.

_mm256_setr_ps
Initializes 256-bit vector with float32 values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax
extern __m256 _mm256_setr_ps(float, float, float, float, float, float, float, float);

Arguments
float a float32 value to be initialized into the 256-bit vector; there are eight float parameters, one for each float32 vector element

Description
Initializes a 256-bit vector with single-precision floating point values (float32 values) in reverse order as specified by the float parameter.

Returns
A float32 vector initialized with specified single-precision floating point values in reverse.
_mm256_setr_epi32
Initializes 256-bit vector with integer values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_setr_epi32(int, int, int, int, int, int, int, int);
extern __m256i _mm256_setr_epi8(char e31, char e30, char e29, char e28, char e27, char e26, char e25, char e24, char e23, char e22, char e21, char e20, char e19, char e18, char e17, char e16, char e15, char e14, char e13, char e12, char e11, char e10, char e9, char e8, char e7, char e6, char e5, char e4, char e3, char e2, char e1, char e0);
extern __m256i _mm256_setr_epi316(short e15, short e14, short e13, short e12, short e11, short e10, short e9, short e8, short e7, short e6, short e5, short e4, short e3, short e2, short e1, short e0);
extern __m256i _mm256_setr_epi32(int e7, int e6, int e5, int e4, int e3, int e2, int e1, int e0);
extern __m256i _mm256_setr_epi64x(__int64 e3, __int64 e2, __int64 e1, __int64 e0);

Arguments
e_n An 8/16/32/64-bit integer value to be initialized into the 256-bit vector. For each variant, there is one integer parameter for each 8/16/32/64-bit integer vector element.

Description
Initializes a 256-bit vector with extended packed integer values (8/16/32/64-bit values), in reverse order, as specified by the e_n parameter.

Returns
An 8/16/32/64-bit integer vector initialized with specified extended packed integer values in reverse.

_mm256_set1_pd
Initializes 256-bit vector with scalar double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_set1_pd(double);

Arguments
double a float64 value to be initialized into the 256-bit vector; there is one double parameter to initialize each float64 vector element

Description
Initializes a 256-bit vector with scalar double-precision floating point values (float64 values) as specified by the double parameter.

Returns
A float64 vector with all elements set to the specified scalar double-precision floating point value.
__mm256_set1_ps

Initializes 256-bit vector with scalar single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m256 __mm256_set1_ps(float);

Arguments
float

Description
Initializes a 256-bit vector with scalar single-precision floating point values (float32 values) as specified by the float parameter.

Returns
A float32 vector with all elements set to the specified scalar single-precision floating point value.

__mm256_set1_epi32

Initializes 256-bit vector with scalar integer values. No corresponding Intel® AVX instruction.

Syntax
extern __m256i __mm256_set1_epi8(char a);
extern __m256i __mm256_set1_epi16(short a);
extern __m256i __mm256_set1_epi32(int a);
extern __m256i __mm256_set1_epi64x(long long a);

Arguments
a

Description
Initializes a 256-bit vector with scalar integer values (8/16/32/64-bit values) as specified by the a parameter.

Returns
An 8/16/32/64-bit integer vector with all elements set to the specified scalar integer value.

__mm256_setzero_pd

Sets float64 YMM registers to zero. No corresponding Intel® AVX instruction.

Syntax
extern __m256d __mm256_setzero_pd(void);
Arguments
None

Description
Sets all the elements of a float64 vector to zero and returns the float64 vector. This is a utility intrinsic that helps during programming.

Returns
A float64 vector with all elements set to zero.

_mm256_setzero_ps
Sets float32 YMM registers to zero. No corresponding Intel® AVX instruction.

Syntax
extern __m256 _mm256_setzero_ps(void);

Arguments
None

Description
Sets all the elements of a float32 vector to zero and returns the float32 vector. This is a utility intrinsic that helps during programming.

Returns
A float32 vector with all elements set to zero.

_mm256_setzero_si256
Sets integer YMM registers to zero. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_setzero_si256(void);

Arguments
None

Description
Sets all the elements of an integer vector to zero and returns the integer vector. This is a utility intrinsic that helps during programming.

Returns
An integer vector with all elements set to zero.

_mm256_zeroall
Zeroes all YMM registers. The corresponding Intel® AVX instruction is VZEROALL.
Syntax

extern void _mm256_zeroall(void);

Arguments
None

Description
Zeroes all YMM registers. This intrinsic is useful to clear all the YMM registers when transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

There is no transition penalty if an application clears the bits of all YMM registers (sets to '0') via VZEROALL, the corresponding instruction for this intrinsic, before transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

Returns
Nothing

_mm256_zeroupper
Zeroes the upper bits of the YMM registers. The corresponding Intel® AVX instruction is VZEROUPPER.

Syntax
extern void _mm256_zeroupper(void);

Arguments
None

Description
Zeroes the upper 128 bits of all YMM registers. The lower 128 bits that correspond to the XMM registers are left unmodified.

This intrinsic is useful to clear the upper bits of the YMM registers when transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions. There is no transition penalty if an application clears the upper bits of all YMM registers (sets to '0') via VZEROUPPER, the corresponding instruction for this intrinsic, before transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

Returns
Result of the operation.

Intrinsics for Packed Test Operations

_mm256_testz_si256
Performs a packed bit test of two integer vectors to set the ZF flag. The corresponding Intel® AVX instruction is VPTEST.
**Syntax**

`extern int _mm256_testz_si256(__m256i s1, __m256i s2);`

**Arguments**

- `s1` first source integer vector
- `s2` second source integer vector

**Description**

Allows setting of the ZF flag. The ZF flag is set based on the result of a bitwise AND operation between the first and second source vectors. The corresponding instruction `vpTest` sets the ZF flag if all the resulting bits are 0. If the resulting bits are non-zeros, the instruction clears the ZF flag.

**Returns**

- Non-zero if ZF flag is set
- Zero if the ZF flag is not set

---

**_mm256_testc_si256**

*Performs a packed bit test of two integer vectors to set the CF flag. The corresponding Intel® AVX instruction is vpTest.*

**Syntax**

`extern int _mm256_testc_si256(__m256i s1, __m256i s2);`

**Arguments**

- `s1` first source integer vector
- `s2` second source integer vector

**Description**

Allows setting of the CF flag. The CF flag is set based on the result of a bitwise AND and logical NOT operation between the first and second source vectors. The corresponding instruction, `vpTest`, sets the CF flag if all the resulting bits are 0. If the resulting bits are non-zeros, the instruction clears the CF flag.

**Returns**

- Non-zero if CF flag is set
- Zero if the CF flag is not set

---

**_mm256_testnzc_si256**

*Performs a packed bit test of two integer vectors to set ZF and CF flags. The corresponding Intel® AVX instruction is vpTest.*

**Syntax**

`extern int _mm256_testnzc_si256(__m256i s1, __m256i s2);`
Arguments

s1  
first source integer vector

s2  
second source integer vector

Description

Performs a packed bit test of s1 and s2 vectors using VTESTPD, s1, s2 instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set).

The VTESTPD instruction performs a bitwise comparison of all the sign bits of the integer elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

Returns

1: indicates that both ZF and CF flags are clear
0: indicates that either ZF or CF flag is set

_mm256_testz_pd, _mm_testz_pd
Performs a packed bit test of two float64 256-bit or 128-bit vectors to set the ZF flag. The corresponding Intel® AVX instruction is VTESTPD.

Syntax

extern int _mm256_testz_pd(__m256d s1, __m256d s2);
extern int _mm_testz_pd(__m128d s1, __m128d s2);

Arguments

s1  
first float64 source vector

s2  
second float64 source vector

Description

Compute the bitwise AND of the two vectors s1 and s2, representing double-precision (64-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

NOTE

Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

Non-zero if ZF flag is set
Zero if the ZF flag is not set

_mm256_testz_ps, _mm_testz_ps
Performs a packed bit test of two float32 256-bit or 128-bit vectors to set the ZF flag. The corresponding Intel® AVX instruction is VTESTPS.

Syntax
extern int _mm256_testz_ps(__m256 s1, __m256 s2);
extern int _mm_testz_ps(__m128 s1, __m128 s2);

Arguments
s1 first source float32 vector
s2 second source float32 vector

Description
Compute the bitwise AND of the two vectors s1 and s2, representing single-precision (32-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns
Non-zero if ZF flag is set
Zero if the ZF flag is not set

_mm256_testc_pd, _mm_testc_pd
Performs a packed bit test of two 256-bit or 128-bit float64 vectors to set the CF flag. The corresponding Intel® AVX instruction is VTESTPD.

Syntax
extern int _mm256_testc_pd(__m256d s1, __m256d s2);
extern int _mm_testc_pd(__m128d s1, __m128d s2);

Arguments
s1 first source float64 vector
s2 second source float64 vector
Description
Compute the bitwise AND of the two vectors s1 and s2, representing double-precision (64-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set CF to 0. Return the CF value.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns
Non-zero if CF flag is set
Zero if the CF flag is not set

_mm256_testc_ps, _mm_testc_ps
Performs a packed bit test of two 256-bit or 128-bit float32 vectors to set the CF flag. The corresponding Intel® AVX instruction is VTESTPS.

Syntax
extern int _mm256_testc_ps(__m256 s1, __m256 s2);
extern int _mm_testc_ps(__m128 s1, __m128 s2);

Arguments
s1 first source float32 vector
s2 second source float32 vector

Description
Compute the bitwise AND of the two vectors s1 and s2, representing single-precision (32-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns
Non-zero if CF flag is set
Zero if the CF flag is not set
_mm256_testnzc_pd, _mm_testnzc_pd
Performs a packed bit test of two 256-bit float64 or 128-bit float64 vectors to check ZF and CF flag settings. The corresponding Intel® AVX instruction is VTESTPD.

Syntax
extern int _mm256_testnzc_pd(__m256d s1, __m256d s2);
extern int _mm_testnzc_pd(__m128d s1, __m256d s2);

Arguments
s1 first source float64 vector
s2 second source float64 vector

Description
Performs a packed bit test of s1 and s2 vectors using VTESTPD, s2 instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set).

The VTESTPD instruction performs a bitwise comparison of all the sign bits of the double-precision elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

The _mm_testnzc_pd intrinsic checks the ZF and CF flags according to results of the 128-bit float64 source vectors. The _m256_testnzc_pd intrinsic checks the ZF and CF flags according to the results of the 256-bit float64 source vectors.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns
1: indicates that both ZF and CF flags are clear
0: indicates that either ZF or CF flag is set

_mm256_testnzc_ps, _mm_testnzc_ps
Performs a packed bit test of two 256-bit or 128-bit float32 vectors to check ZF and CF flag settings. The corresponding Intel® AVX instruction is VTESTPS.

Syntax
extern int _mm256_testnzc_ps(__m256 s1, __m256 s2);
extern int _mm_testnzc_ps(__m128 s1, __m128 s2);
Arguments

s1  first source float32 vector
s2  second source float32 vector

Description

Performs a packed bit test of s1 and s2 vectors using VTESTPDS1, s2 instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set).

The VTESTPD instruction performs a bitwise comparison of all the sign bits of the single-precision elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

The _mm256_testnzc_ps intrinsic checks the ZF and CF flags according to results of the 128-bit float32 source vectors. The _m256_testnzc_ps intrinsic checks the ZF and CF flags according to the results of the 256-bit float32 source vectors.

NOTE

Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

1: indicates that both ZF and CF flags are clear
0: indicates that either ZF or CF flag is set

Intrinsics for Permute Operations

_mm256_permute_pd, _mm_permute_pd

Permutates 256-bit or 128-bit float64 values into a 256-bit or 128-bit destination vector. The corresponding Intel® AVX instruction is VPERMILPD.

Syntax

extern __m256d _mm256_permute_pd(__m256d m1, int control);
extern __m128d _mm_permute_pd(__m128d m1, int control);

Arguments

m1  a 256-bit or 128-bit float64 vector
control  an integer specified as an 8-bit immediate;
• for the 256-bit m1 vector this integer contains four 1-bit control fields in the low 4 bits of the immediate
• for the 128-bit \( m1 \) vector this integer contains two 1-bit control fields in the low 2 bits of the immediate

**Description**

The \_mm256\_permute\_pd intrinsic permutes double-precision floating point elements (float64 elements) in the 256-bit source vector \( m1 \), according to a specified 1-bit control field, \( control \), and stores the result in a destination vector.

The \_mm\_permute\_pd intrinsic permutes double-precision floating point elements (float64 elements) in the 128-bit source vector \( m1 \), according to a specified 1-bit control field, \( control \), and stores the result in a destination vector.

**Returns**

A 256-bit or 128-bit float64 vector with permuted values.

\_mm256\_permute\_ps, \_mm\_permute\_ps

Permutes 256-bit or 128-bit float32 values into a 256-bit or 128-bit destination vector. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VPERMILPS.

**Syntax**

extern \_m256 \_mm256\_permute\_ps(\_m256 \( m1 \), int \( control \));

extern \_m128 \_mm\_permute\_ps(\_m128 \( m1 \), int \( control \));

**Arguments**

- \( m1 \) a 256-bit or 128-bit float32 vector
- \( control \) an integer specified as an 8-bit immediate;
  - for the 256-bit \( m1 \) vector this integer contains four 2-bit control fields in the low 8 bits of the immediate
  - for the 128-bit \( m1 \) vector this integer contains two 2-bit control fields in the low 4 bits of the immediate

**Description**

The \_mm256\_permute\_ps intrinsic permutes single-precision floating point elements (float32 elements) in the 256-bit source vector \( m1 \), according to a specified 2-bit control field, \( control \), and stores the result in a destination vector.

The \_mm\_permute\_ps intrinsic permutes single-precision floating point elements (float32 elements) in the 128-bit source vector \( m1 \), according to a specified 2-bit control field, \( control \), and stores the result in a destination vector.

**Returns**

A 256-bit or 128-bit float32 vector with permuted values.

\_mm256\_permutevar\_pd, \_mm\_permutevar\_pd

Permutes float64 values into a 256-bit or 128-bit destination vector. The corresponding Intel\textsuperscript{\textregistered} AVX instruction is VPERMILPD.
**Syntax**

extern __m256d _mm256_permutevar_pd(__m256d m1, __m256i control);
extern __m128d _mm_permutevar_pd(__m128d m1, __m128i control);

**Arguments**

- \( m1 \)  
  a 256-bit or 128-bit float64 vector

- \( control \)  
  a vector with 1-bit control fields, one for each corresponding element of the source vector
  
  - for the 256-bit \( m1 \) source vector this \( control \) vector contains four 1-bit control fields in the low 4 bits of the immediate
  
  - for the 128-bit \( m1 \) source vector this \( control \) vector contains two 1-bit control fields in the low 2 bits of the immediate

**Description**

Permutes double-precision floating-point values in the source vector, \( m1 \), according to the the 1-bit control fields in the low bytes of corresponding elements of a shuffle control. The result is stored in a destination vector.

**Returns**

A 256-bit or 128-bit float64 vector with permuted values.

---

**_mm_permutevar_ps, _mm256_permutevar_ps**

Permutates float32 values into a 256-bit or 128-bit destination vector. The corresponding Intel\textsuperscript{®} AVX instruction is VPERMILPS.

**Syntax**

extern __m256 _mm256_permutevar_ps(__m256 m1, __m256i control);
extern __m128 _mm_permutevar_ps(__m128 m1, __m128i control);

**Arguments**

- \( m1 \)  
  a 256-bit or 128-bit float32 vector

- \( control \)  
  a vector with 2-bit control fields, one for each corresponding element of the source vector
  
  - for the 256-bit \( m1 \) source vector this \( control \) vector contains eight 2-bit control fields
  
  - for the 128-bit \( m1 \) source vector this \( control \) vector contains four 2-bit control fields

**Description**

Permutes single-precision floating-point values in the source vector, \( m1 \), according to the the 2-bit control fields in the low bytes of corresponding elements of a shuffle control. The result is stored in a destination vector.

**Returns**

A 256-bit or 128-bit float32 vector with permuted values.
_mm256_permute2f128_pd

Permutes 128-bit double-precision floating point containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is VPERM2F128.

Syntax

extern __m256d _mm256_permute2f128_pd(__m256d m1, __m256d m2, int control);

Arguments

- **m1** a 256-bit float64 source vector
- **m2** a 256-bit float64 source vector
- **control** an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description

Permutes 128-bit floating-point-containing fields from the first source vector **m1** and second source vector **m2**, by using bits in the 8-bit **control** argument.

Returns

A 256-bit float64 vector with permuted values.

__mm256_permute2f128_ps

Permutes 128-bit single-precision floating point containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is VPERM2F128.

Syntax

extern __m256 _mm256_permute2f128_ps(__m256 m1, __m256 m2, int control);

Arguments

- **m1** a 256-bit float32 source vector
- **m2** a 256-bit float32 source vector
- **control** an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description

Permutes 128-bit floating-point-containing fields from the first source vector **m1** and second source vector **m2**, by using bits in the 8-bit **control** argument.

Returns

A 256-bit float32 vector with permuted values.

__mm256_permute2f128_si256

Permutes 128-bit integer containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is VPERM2F128.
Syntax
extern __m256i _mm256_permute2f128_si256(__m256i m1, __m256i m2, int control);

Arguments

m1          a 256-bit integer source vector
m2          a 256-bit integer source vector
control     an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description
Permutes 128-bit integer-containing fields from the first source vector m1 and second source vector m2, by using bits in the 8-bit control argument.

Returns
A 256-bit integer vector with permuted values.

Intrinsics for Shuffle Operations

_mm256_shuffle_pd
Shuffles float64 vectors. The corresponding Intel® AVX instruction is VSHUFPD.

Syntax
extern __m256d _mm256_shuffle_pd(__m256d m1, __m256d m2, const int select);

Arguments

m1          float64 vector used for the operation
m2          float64 vector also used for the operation
select      a constant of integer type that determines which elements of the source vectors are moved to the result

Description
Moves or shuffles either of the two packed double-precision floating-point elements (float64 elements) from the double quadword in the source vectors to the low and high quadwords of the double quadword of the result.

The elements of the first source vector are moved to the low quadword while the elements of the second source vector are moved to the high quadword of the result. The constant defined by the select parameter determines which of the two elements of the source vectors are moved to the result.

Returns
Result of the shuffle operation.
**_mm256_shuffle_ps_**

*Shuffles float32 vectors. The corresponding Intel® AVX instruction is VSHUFPS.*

**Syntax**

```cpp
extern __m256 _mm256_shuffle_ps(__m256 m1, __m256 m2, const int select);
```

**Arguments**

- **m1**: float32 vector used for the operation
- **m2**: float32 vector also used for the operation
- **select**: a constant of integer type which determines which elements of the source vectors move to the result

**Description**

Moves or shuffles two of the packed single-precision floating-point elements (float32 elements) from the double quadword in the source vectors to the low and high quadwords of the double quadword of the result.

The elements of the first source vector are moved to the low quadword while the elements of the second source vector are moved to the high quadword of the result. The constant defined by the `select` parameter determines which of the two elements of the source vectors are moved to the result.

**Returns**

Result of the shuffle operation.

**Intrinsics for Unpack and Interleave Operations**

**_mm256_unpackhi_pd_**

*Unpacks and interleaves high packed double-precision floating point values. The corresponding Intel® AVX instruction is VUNPCKHPD.*

**Syntax**

```cpp
extern __m256d _mm256_unpackhi_pd(__m256d m1, __m256d m2);
```

**Arguments**

- **m1**: float64 source vector
- **m2**: float64 source vector

**Description**

Performs an interleaved unpack operation of high double-precision floating point values of the two source vectors `m1` and `m2`, and returns the result of the operation.

**Returns**

A vector with unpacked interleaved double-precision floating point values.
_mm256_unpackhi_ps
Unpacks and interleaves high packed single-precision floating point values. The corresponding Intel® AVX instruction is VUNPCKHPS.

Syntax
extern __m256 _mm256_unpackhi_ps(__m256 m1, __m256 m2);

Arguments
m1 float32 source vector
m2 float32 source vector

Description
Performs an interleaved unpack operation of high single-precision floating point values of the two source vectors m1 and m2, and returns the result of the operation.

Returns
A vector with unpacked interleaved single-precision floating point values.

_mm256_unpacklo_pd
Unpacks and interleaves low packed double-precision floating point values. The corresponding Intel® AVX instruction is VUNPCKLPD.

Syntax
extern __m256d _mm256_unpacklo_pd(__m256d m1, __m256d m2);

Arguments
m1 float64 source vector
m2 float64 source vector

Description
Performs an interleaved unpack operation of low double-precision floating point values of the two source vectors m1 and m2, and returns the result of the operation.

Returns
A vector with unpacked interleaved double-precision floating point values.

_mm256_unpacklo_ps
Unpacks and interleaves low packed single-precision floating point values. The corresponding Intel® AVX instruction is VUNPCKLPS.

Syntax
extern __m256 _mm256_unpacklo_ps(__m256 m1, __m256 m2);
Arguments

m1 float32 source vector
m2 float32 source vector

Description
Performs an interleaved unpack operation of low single-precision floating point values of the two source vectors m1 and m2, and returns the result of the operation.

Returns
A vector with unpacked interleaved single-precision floating point values.

Support Intrinsic for Vector Typecasting Operations

_mm256_castpd_ps
Typecasts double-precision floating point values to single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m256 _mm256_castpd_ps(__m256d a);

Arguments
a float64 source vector

Description
Performs a typecast operation from double-precision floating point values (float64 values) to single-precision floating point values (float32 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns
A vector with single-precision floating point values.

_mm256_castps_pd
Typecasts single-precision floating point values to double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_castps_pd(__m256 a);

Arguments
a float32 source vector

Description
Performs a typecast operation from single-precision floating point values (float32 values) to double-precision floating point values (float64 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.
Returns
A vector with double-precision floating point values.

_mm256_castpd_si256
Typecasts double-precision floating point values to integer values. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_castpd_si256(__m256d a);

Arguments
a float64 source vector

Description
Performs a typecast operation from double-precision floating point values (float64 values) to integer values. This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns
A vector with 256-bit integer values.

_mm256_castps_si256
Typecasts single-precision floating point values to integer values. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_castps_si256(__m256 a);

Arguments
a float32 source vector

Description
Performs a typecast operation from single-precision floating point values (float32 values) to integer values. This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns
A vector with 256-bit integer values.

_mm256_castsi256_pd
Typecasts 256-bit integer values to double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_castsi256_pd(__m256i a);
Arguments

a 256-bit integer vector

Description

Performs a typecast operation from 256-bit integer values to double-precision floating point values (float64 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with double-precision floating point values.

_mm256_castsi256_ps

Typecasts 256-bit integer values to single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

extern __m256 _mm256_castsi256_ps(__m256i a);

Arguments

a 256-bit integer source vector

Description

Performs a typecast operation from 256-bit integer values to single-precision floating point values (float32 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with single-precision floating point values.

_mm256_castpd128_pd256

Typecasts 128-bit double-precision floating point values to 256-bit double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

extern __m256d _mm256_castpd128_pd256(__m128d a);

Arguments

a 128-bit float64 vector

Description

Performs a typecast operation from 128-bit double-precision floating point values to 256-bit double-precision floating point values.

The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.
**Returns**
A vector with 256-bit double-precision floating point values. The upper bits of the resulting vector are undefined.

**_mm256_castpd256_pd128**
Typecasts 256-bit double-precision floating point values to 128-bit double-precision floating point values. No corresponding Intel® AVX instruction.

**Syntax**
```c
extern __m128d _mm256_castpd256_pd128(__m256d a);
```

**Arguments**
a
256-bit float64 source vector

**Description**
Performs a typecast operation from 256-bit double-precision floating point values to 128-bit double-precision floating point values.
The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce extra moves to the generated code.

**Returns**
A vector with 128-bit double-precision floating point values.

**_mm256_castps128_ps256**
Typecasts 128-bit single-precision floating point values to 256-bit single-precision floating point values.
No corresponding Intel® AVX instruction.

**Syntax**
```c
extern __m256 _mm256_castps128_ps256(__m128 a);
```

**Arguments**
a
128-bit float32 source vector

**Description**
Performs a typecast operation from 128-bit single-precision floating point values to 256-bit single-precision floating point values.
The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.

**Returns**
A vector with 256-bit single-precision floating point values. The upper bits of the resulting vector are undefined.
_mm256_castps256_ps128
Typecasts 256-bit single-precision floating point values to 128-bit single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax
extern __m128 _mm256_castps256_ps128(__m256 a);

Arguments

\( a \)
256-bit float32 source vector

Description
Performs a typecast operation from 256-bit single-precision floating point values to 128-bit single-precision floating point values.
The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce extra moves to the generated code.

Returns
A vector with 128-bit single-precision floating point values.

_mm256_castsi128_si256
Typecasts 128-bit integer values to 256-bit integer values. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_castsi128_si256(__m128i a);

Arguments

\( a \)
128-bit integer source vector

Description
Performs a typecast operation from 128-bit integer values to 256-bit integer values.
The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.

Returns
A vector with 256-bit integer values. The upper bits of the resulting vector are undefined.

_mm256_castsi256_si128
Typecasts 256-bit integer values to 128-bit integer values. No corresponding Intel® AVX instruction.

Syntax
extern __m128i _mm256_castsi256_si128(__m256i a);
Arguments

a  256-bit integer source vector

Description
Performs a typecast operation from 256-bit integer values to 128-bit integer values.
The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce
extra moves to the generated code.

Returns
A vector with 128-bit integer values.

Intrinsics Generating Vectors of Undefined Values

_mm256_undefined_ps()

Returns a vector of eight single precision floating point elements. No corresponding Intel® AVX instruction.

Syntax
extern __m256 _mm256_undefined_ps(void);

Description
This intrinsic returns a vector of eight single precision floating point elements. The content of the vector is
not specified. The prototype of this intrinsic is in the immintrin.h header file.

Returns
A vector of eight single precision floating point elements.

See Also
Intrinsics Returning Vectors of Undefined Values

_mm256_undefined_pd()

Returns a vector of four double precision floating point elements. No corresponding Intel® AVX instruction.

Syntax
extern __m256d _mm256_undefined_pd(void);

Description
This intrinsic returns a vector of four double precision floating point elements. The content of the vector is
not specified. The prototype of this intrinsic is in the immintrin.h header file.

Returns
A vector of four double precision floating point elements.

See Also
Intrinsics Returning Vectors of Undefined Values
_mm256_undefined_si256
Returns a vector of eight packed doubleword integer elements. No corresponding Intel® AVX instruction.

Syntax
extern __m256i _mm256_undefined_si256(void);

Description
This intrinsic returns a vector of eight packed doubleword integer elements. The content of the vector is not specified. The prototype of this intrinsic is in the immintrin.h header file.

Returns
A vector of eight packed doubleword integer elements.

Intrinsics for Intel® Streaming SIMD Extensions 4 (Intel® SSE4)

Overview: Intel® Streaming SIMD Extensions 4 (Intel® SSE4)
The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) instructions. Intel® SSE4 includes the following categories:

• Vectorizing Compiler and Media Accelerators.
• Efficient Accelerated String and Text Processing.

Efficient Accelerated String and Text Processing

Overview: Efficient Accelerated String and Text Processing
The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) Efficient Accelerated String and Text Processing instructions.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

The following topics summarize these intrinsics:

• Packed Comparison Intrinsics for Streaming SIMD Extensions 4
• Application Targeted Accelerators Intrinsics

Packed Compare Intrinsics
These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics perform packed comparisons. Some of these intrinsics could map to more than one instruction; the Intel® C++ Compiler selects the instruction to generate.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```
<table>

**_mm_cmpestri**

```c
int_mm_cmpestri(__m128i src1, int len1, __m128i src2, int len2, const int mode);
```

Performs a packed comparison of string data with explicit lengths, generating an index and storing the result in ECX.

**_mm_cmpestrm**

```c
__m128i__mm_cmpestrm(__m128i src1, int len1, __m128i src2, int len2, const int mode);
```

Performs a packed comparison of string data with explicit lengths, generating a mask and storing the result in XMM0.

**_mm_cmpestri**

```c
int_mm_cmpestri(__m128i src1, __m128i src2, const int mode);
```

Performs a packed comparison of string data with implicit lengths, generating an index and storing the result in ECX.
_mm_cmpistrm
__m128i _mm_cmpistrm(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths, generating a mask and storing the result in XMM0.

_mm_cmpestrz
int _mm_cmpestrz(__m128i src1, int len1, __m128i src2, int len2, const int mode);
Performs a packed comparison of string data with explicit lengths. Returns '1' if ZFlag == 1, otherwise '0'.

_mm_cmpestrc
int _mm_cmpestrc(__m128i src1, int len1, __m128i src2, int len2, const int mode);
Performs a packed comparison of string data with explicit lengths. Returns '1' if CFlag == 1, otherwise '0'.

_mm_cmpestrs
int _mm_cmpestrs(__m128i src1, int len1, __m128i src2, int len2, const int mode);
Performs a packed comparison of string data with explicit lengths. Returns '1' if SFlag == 1, otherwise '0'.

_mm_cmpestro
int _mm_cmpestro(__m128i src1, int len1, __m128i src2, int len2, const int mode);
Performs a packed comparison of string data with explicit lengths. Returns '1' if OFlag == 1, otherwise '0'.

_mm_cmpestra
int _mm_cmpestra(__m128i src1, int len1, __m128i src2, int len2, const int mode);
Performs a packed comparison of string data with explicit lengths. Returns '1' if CFlag == 0 and ZFlag == 0, otherwise '0'.

_mm_cmpistrz
int _mm_cmpistrz(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths. Returns '1' if (ZFlag == 1), otherwise '0'.

_mm_cmpistrc
int _mm_cmpistrc(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths. Returns '1' if (CFlag == 1), otherwise '0'.

_mm_cmpistrs
int _mm_cmpistrs(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths. Returns '1' if (SFlag == 1), otherwise '0'.
_mm_cmpistro
int _mm_cmpistro(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths. Returns '1' if (OFlag == 1), otherwise '0'.

ꦩᠮ_𝑐𝑚𝑝𝑖𝑠𝑡𝑟𝑎
int _mm_cmpista(__m128i src1, __m128i src2, const int mode);
Performs a packed comparison of string data with implicit lengths. Returns '1' if (ZFlag == 0 and CFlag == 0), otherwise '0'.

### Application Targeted Accelerators Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics extend the capabilities of Intel® architectures by adding performance-optimized, low-latency, lower power fixed-function accelerators on the processor die to benefit specific applications.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

Intrinsics marked with * are implemented only on Intel® 64 architecture. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

<table>

</tr>
</tbody>
</table>

_.mm_popcnt_u32
unsigned int _mm_popcnt_u32(unsigned int v);
Counts the number of set bits in a data operation.

_.mm_popcnt_u64
__int64 _mm_popcnt_u64(unsigned __int64 v);
Counts the number of set bits in a data operation.
NOTE
Use only on Intel® 64 architecture.

_mm_crc32_u8

unsigned int _mm_crc32_u8(unsigned int crc, unsigned char v);

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m8.

_mm_crc32_u16

unsigned int _mm_crc32_u16(unsigned int crc, unsigned short v);

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m16.

_mm_crc32_u32

unsigned int _mm_crc32_u32(unsigned int crc, unsigned int v);

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m32.

_mm_crc32_u64

unsigned __int64 _mm_crc32_u64(unsigned __int64 crc, unsigned __int64 v);

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m64.

NOTE
Use only on Intel® 64 architecture.

Vectorizing Compiler and Media Accelerators

Overview: Vectorizing Compiler and Media Accelerators

The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) Vectorizing Compiler and Media Accelerators instructions.

To use these intrinsics, include the immintrin.h file as follows:

#include <immintrin.h>

• Packed Blending Intrinsics for Streaming SIMD Extensions 4
• Floating Point Dot Product Intrinsics for Streaming SIMD Extensions 4
• Packed Format Conversion Intrinsics for Streaming SIMD Extensions 4
• Packed Integer Min/Max Intrinsics for Streaming SIMD Extensions 4
• Floating Point Rounding Intrinsics for Streaming SIMD Extensions 4
• DWORD Multiply Intrinsics for Streaming SIMD Extensions 4
• Register Insertion/Extraction Intrinsics for Streaming SIMD Extensions 4
• Test Intrinsics for Streaming SIMD Extensions 4
• Packed DWORD to Unsigned WORD Intrinsic for Streaming SIMD Extensions 4
• Packed Compare for Equal Intrinsics for Streaming SIMD Extensions 4
• Cacheability Support Intrinsic for Streaming SIMD Extension 4

**Packed Blending Intrinsics**

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics pack multiple operations in a single instruction. Blending conditionally copies one field in the source onto the corresponding field in the destination. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

**Intrinsic Syntax**

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>__m128 _mm_blend_ps(__m128 v1, __m128 v2, const int mask)</td>
<td>Selects single precision float data from two sources using constant mask</td>
<td>BLENDPS</td>

</tr>
<tr>
<td>__m128i __mm_blendv_epi8(__m128i v1, __m128i v2, __m128i mask)</td>
<td>Selects integer bytes from two sources using variable mask</td>
<td>PBLENDVB</td>
</tr>
<tr>
<td>__m128i __mm_blendv_epi16(__m128i v1, __m128i v2, __m128i mask)</td>
<td>Selects integer words from two sources using variable mask</td>
<td>PBLENDW</td>
</tr>
</tbody>
</table>

**Floating Point Dot Product Intrinsics**

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics enable floating point single-precision and double-precision dot products. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

**Intrinsic**

<table>
<thead>
<tr>
<th>Intrinsic</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_dp_pd</td>
<td>Double-precision dot product</td>
<td>DPPD</td>
</tr>
<tr>
<td>_mm_dp_ps</td>
<td>Single-precision dot product</td>
<td>DPPS</td>
</tr>
</tbody>
</table>

```c
__mm_dp_pd
__m128d _mm_dp_pd( __m128d a, __m128d b, const int mask);
```
Calculates the dot product of double-precision packed values with mask-defined summing and zeroing of the parts of the result.

```c
__m128_mm_dp_ps(__m128 a, __m128 b, const int mask);
```

Calculates the dot product of single-precision packed values with mask-defined summing and zeroing of the parts of the result.

### Packed Format Conversion Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics convert a packed integer to a zero-extended or sign-extended integer with wider type. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>

<tr>
<td>_m128i_mm_cvtepu16_epi64(__m128i a)</td>
<td>Zero extend two words into two quadwords</td>
<td>PMOVZXWXQ</td>
</tr>
</tbody>
</table>
Packed Integer Min/Max Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics compare packed integers in the destination operand and the source operand, and return the minimum or maximum for each packed operand in the destination operand. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>__m128i_mm_max_epi8(__m128i a, __m128i b)</td>
<td>Calculates maximum of signed packed integer bytes</td>
<td>PMAXSB</td>
</tr>
<tr>
<td>__m128i_mm_max_epi32(__m128i a, __m128i b)</td>
<td>Calculates maximum of signed packed integer doublewords</td>
<td>PMAXSD</td>
</tr>
<tr>
<td>__m128i_mm_max_epu32(__m128i a, __m128i b)</td>
<td>Calculates maximum of unsigned packed integer doublewords</td>
<td>PMAXUD</td>
</tr>
<tr>
<td>__m128i_mm_max_epu16(__m128i a, __m128i b)</td>
<td>Calculates maximum of unsigned packed integer words</td>
<td>PMAXUW</td>
</tr>
<tr>
<td>__m128i_mm_min_epi8(__m128i a, __m128i b)</td>
<td>Calculates minimum of signed packed integer bytes</td>
<td>PMINSB</td>
</tr>
<tr>
<td>__m128i_mm_min_epi32(__m128i a, __m128i b)</td>
<td>Calculates minimum of signed packed integer doublewords</td>
<td>PMINSD</td>
</tr>
<tr>

<td>PMINUD</td>
</tr>
<tr>
<td>__m128i_mm_min_epu16(__m128i a, __m128i b)</td>
<td>Calculates minimum of unsigned packed integer words</td>
<td>PMINUW</td>
</tr>
</tbody>
</table>

Floating Point Rounding Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) rounding intrinsics cover scalar and packed single-precision and double-precision floating-point operands. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The floor and ceil intrinsics correspond to the definitions of floor and ceil in the ISO 9899:1999 standard for the C programming language.

### DWORD Multiply Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) DWORD multiply intrinsics are designed to aid vectorization. They enable four simultaneous 32-bit by 32-bit multiplies. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```cpp
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>
</tr>

<td>FMULDQ</td>
</tr>
<tr>
<td>__m128i _mm_mullo_epi32(__m128i a, __m128i b)</td>
<td>Packed integer 32-bit multiplication with truncation of upper halves of results</td>
<td>FMULLD</td>
</tr>
</tbody>
</table>

### Register Insertion/Extraction Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics enable data insertion and extraction between general purpose registers and MMX registers. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```cpp
#include <immintrin.h>
```
Intrinsics marked with * are implemented only on Intel® 64 architectures. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

<table>

<td>PEXTRQ</td>
</tr>
</tbody>
</table>

Test Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics perform packed integer 128-bit comparisons. The prototypes for these intrinsics are in the smmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE4 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_testz_si128</td>
<td>Checks for all zeros in specified bits of a 128-bit value</td>
<td>PTEST</td>
</tr>
</tbody>
</table>
**Intrinsic Name** | **Operation** | **Corresponding Intel® SSE4 Instruction**
---|---|---
_mm_testc_si128 | Checks for all ones in specified bits of a 128-bit value | PTEST
_mm_testnzc_si128 | Checks for at least one '0' and at least one '1' in the specified bits of a 128-bit value | PTEST

### _mm_testc_si128

```c
int _mm_testc_si128(__m128i s1, __m128i s2);
```

Returns '1' if the bitwise AND operation on `s1` and `s2` results in all zeros, else returns '0'. That is,

```c
_mm_testc_si128 := ( (s1 & s2) == 0 ? 1 : 0 )
```

This intrinsic checks if the \textit{ZF} flag equals '1' as a result of the instruction \texttt{PTEST} \texttt{s1}, \texttt{s2}. For example, it allows you to check if all set bits in `s2` (mask) are zeros in `s1`.

**Corresponding instruction:** \texttt{PTEST}

### _mm_testc_si128

```c
int _mm_testc_si128(__m128i s1, __m128i s2);
```

Returns '1' if the bitwise AND operation on `s2` and logical NOT `s1` results in all zeros, else returns '0'. That is,

```c
_mm_testc_si128 := ( (~s1 & s2) == 0 ? 1 : 0 )
```

This intrinsic checks if the \textit{CF} flag equals '1' as a result of the instruction \texttt{PTEST} \texttt{s1}, \texttt{s2}. For example it allows you to check if all set bits in `s2` (mask) are also set in `s1`.

**Corresponding instruction:** \texttt{PTEST}

### _mm_testnzc_si128

```c
int _mm_testnzc_si128(__m128i s1, __m128i s2);
```

Returns '1' if the following conditions are true: bitwise operation of `s1` AND `s2` does not equal all zeros and bitwise operation of NOT `s1` AND `s2` does not equal all zeros, otherwise returns '0'. That is,

```c
_mm_testnzc_si128 := ( ( (s1 & s2) != 0 && (~s1 & s2) != 0 ) ? 1 : 0 )
```

This intrinsic checks if both the \textit{CF} and \textit{ZF} flags are not '1' as a result of the instruction \texttt{PTEST} \texttt{s1}, \texttt{s2}. For example, it allows you to check that the result has both zeros and ones in `s1` on positions specified as set bits in `s2` (mask).

**Corresponding instruction:** \texttt{PTEST}

### Packed DWORD to Unsigned WORD Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the \texttt{ammintrin.h} file. To use this intrinsic, include the \texttt{immintrin.h} file as follows:

```c
#include <immintrin.h>
```

```c
__m128i _mm_packus_epi32(__m128i m1, __m128i m2);
```
Converts eight packed signed doublewords into eight packed unsigned words, using unsigned saturation to handle overflow condition.

**Corresponding instruction:** PACKUSDW

### Packed Compare for Equal Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the smmintrin.h file. To use this intrinsic, include the immintrin.h file as follows:

```c
#include <immintrin.h>

__m128i _mm_cmpeq_epi64(__m128i a, __m128i b);
```

Performs a packed integer 64-bit comparison for equality. The intrinsic fills the corresponding parts of the result with zeroes or ones based on equality.

**Corresponding instruction:** PCMPEQQ

### Cacheability Support Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the smmintrin.h file. To use this intrinsic, include the immintrin.h file as follows:

```c
#include <immintrin.h>

extern __m128i _mm_stream_load_si128(__m128i* v1);
```

Loads __m128 data from a 16-byte aligned address, v1, to the destination operand, m128i without polluting the caches.

**Corresponding instruction:** MOVNTDQA

---

### Intrinsics for Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)

**Overview: Supplemental Streaming SIMD Extensions 3 (SSSE3)**

Intel® C++ intrinsics listed in this section correspond to the Supplemental Streaming SIMD Extensions 3 (SSSE3) instructions. The prototypes for these intrinsics are in tmmintrin.h.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The following topics summarize these intrinsics:

- Addition Intrinsics
- Subtraction Intrinsics
- Multiplication Intrinsics
- Absolute Value Intrinsics
- Shuffle Intrinsics
- Concatenate Intrinsics
- Negation Intrinsics
Addition Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for horizontal addition. The prototypes for these intrinsics are in tmmintrin.h.

To use these intrinsics, include the immintrin.h file as follows:

```cpp
#include <immintrin.h>
```

**_mm_hadd_epi16**

```cpp
extern __m128i _mm_hadd_epi16(__m128i a, __m128i b);
```

Adds horizontally packed signed words. Interpreting a, b, and r as arrays of 16-bit signed integers:

```cpp
for (i = 0; i < 4; i++) {
    r[i] = a[2*i] + a[2*i+1];
    r[i+4] = b[2*i] + b[2*i+1];
}
```

**_mm_hadd_epi32**

```cpp
extern __m128i _mm_hadd_epi32(__m128i a, __m128i b);
```

Adds horizontally packed signed doublewords. Interpreting a, b, and r as arrays of 32-bit signed integers:

```cpp
for (i = 0; i < 2; i++) {
    r[i] = a[2*i] + a[2*i+1];
    r[i+2] = b[2*i] + b[2*i+1];
}
```

**_mm_hadds_epi16**

```cpp
extern __m128i _mm_hadds_epi16(__m128i a, __m128i b);
```

Adds horizontally packed signed words with signed saturation. Interpreting a, b, and r as arrays of 16-bit signed integers:

```cpp
for (i = 0; i < 4; i++) {
    r[i] = signed_saturate_to_word(a[2*i] + a[2*i+1]);
    r[i+4] = signed_saturate_to_word(b[2*i] + b[2*i+1]);
}
```

**_mm_hadd_pi16**

```cpp
extern __m64 _mm_hadd_pi16(__m64 a, __m64 b);
```

Adds horizontally packed signed words. Interpreting a, b, and r as arrays of 16-bit signed integers:

```cpp
for (i = 0; i < 2; i++) {
    r[i] = a[2*i] + a[2*i+1];
    r[i+2] = b[2*i] + b[2*i+1];
}
```

**_mm_hadd_pi32**

```cpp
extern __m64 _mm_hadd_pi32(__m64 a, __m64 b);
```
Adds horizontally packed signed doublewords. Interpreting \(a\), \(b\), and \(r\) as arrays of 32-bit signed integers:

\[
\begin{align*}
  r[0] &= a[1] + a[0]; \\
  r[1] &= b[1] + b[0];
\end{align*}
\]

**_mm_hadds_pi16**

```c
extern __m64 _mm_hadds_pi16(__m64 a, __m64 b);
```

Adds horizontally packed signed words with signed saturation. Interpreting \(a\), \(b\), and \(r\) as arrays of 16-bit signed integers:

```c
for (i = 0; i < 2; i++) {
  r[i] = signed_saturate_to_word(a[2*i] + a[2*i+1]);
  r[i+2] = signed_saturate_to_word(b[2*i] + b[2*i+1]);
}
```

**Subtraction Intrinsics**

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for horizontal subtraction. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

**_mm_hsub_epi16**

```c
extern __m128i _mm_hsub_epi16(__m128i a, __m128i b);
```

Subtract horizontally packed signed words.

Interpreting \(a\), \(b\), and \(r\) as arrays of 16-bit signed integers:

```c
for (i = 0; i < 4; i++) {
  r[i] = a[2*i] - a[2*i+1];
  r[i+4] = b[2*i] - b[2*i+1];
}
```

**_mm_hsub_epi32**

```c
extern __m128i _mm_hsub_epi32(__m128i a, __m128i b);
```

Subtracts horizontally packed signed doublewords.

Interpreting \(a\), \(b\), and \(r\) as arrays of 32-bit signed integers:

```c
for (i = 0; i < 2; i++) {
  r[i] = a[2*i] - a[2*i+1];
  r[i+2] = b[2*i] - b[2*i+1];
}
```

**_mm_hsubs_epi16**

```c
extern __m128i _mm_hsubs_epi16(__m128i a, __m128i b);
```

Subtracts horizontally packed signed words with signed saturation.
Interpreting $a$, $b$, and $r$ as arrays of 16-bit signed integers:

```c
for (i = 0; i < 4; i++) {
    r[i] = signed_saturate_to_word(a[2*i] - a[2*i+1]);
    r[i+4] = signed_saturate_to_word(b[2*i] - b[2*i+1]);
}
```

**_mm_hsub_pi16_**

```c
extern __m64 _mm_hsub_pi16(__m64 a, __m64 b);
```
Subtracts horizontally packed signed words.

Interpreting $a$, $b$, and $r$ as arrays of 16-bit signed integers:

```c
for (i = 0; i < 2; i++) {
    r[i] = a[2*i] - a[2*i+1];
    r[i+2] = b[2*i] - b[2*i+1];
}
```

**_mm_hsub_pi32_**

```c
extern __m64 _mm_hsub_pi32(__m64 a, __m64 b);
```
Subtracts horizontally packed signed doublewords.

Interpreting $a$, $b$, and $r$ as arrays of 32-bit signed integers:

```c
r[0] = a[0] - a[1];
r[1] = b[0] - b[1];
```

**_mm_hsubs_pi16_**

```c
extern __m64 _mm_hsubs_pi16(__m64 a, __m64 b);
```
Subtracts horizontally packed signed words with signed saturation.

Interpreting $a$, $b$, and $r$ as arrays of 16-bit signed integers:

```c
for (i = 0; i < 2; i++) {
    r[i] = signed_saturate_to_word(a[2*i] - a[2*i+1]);
    r[i+2] = signed_saturate_to_word(b[2*i] - b[2*i+1]);
}
```

**Multiplication Intrinsics**

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for multiplication. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

**_mm_maddubs_epi16_**

```c
extern __m128i _mm_maddubs_epi16(__m128i a, __m128i b);
```
Multiplies signed and unsigned bytes, adds horizontal pair of signed words, and packs saturated signed words.
Interpreting $a$ as array of unsigned 8-bit integers, $b$ as arrays of signed 8-bit integers, and $r$ as arrays of 16-bit signed integers:

```c
for (i = 0; i < 8; i++) {
    r[i] = signed_saturate_to_word(a[2*i+1] * b[2*i+1] + a[2*i]*b[2*i]);
}
```

`_mm_maddubs_pi16`

```c
extern __m64 __maddubs_pi16(__m64 a, __m64 b);
```

Multiplies signed and unsigned bytes, adds horizontal pair of signed words, and packs saturated signed words.

Interpreting $a$ as array of unsigned 8-bit integers, $b$ as arrays of signed 8-bit integers, and $r$ as arrays of 16-bit signed integers:

```c
for (i = 0; i < 4; i++) {
    r[i] = signed_saturate_to_word(a[2*i+1] * b[2*i+1] + a[2*i]*b[2*i]);
}
```

`_mm_mulhrs_epi16`

```c
extern __m128i __mm_mulhrs_epi16(__m128i a, __m128i b);
```

Multiplies signed words, scales and rounds signed doublewords, and packs high 16-bits.

Interpreting $a$, $b$, and $r$ as arrays of signed 16-bit integers:

```c
for (i = 0; i < 8; i++) {
    r[i] = (( (int32)((a[i] * b[i]) >> 14) + 1) >> 1) & 0xFFFF;
}
```

`_mm_mulhrs_pi16`

```c
extern __m64 __mm_mulhrs_pi16(__m64 a, __m64 b);
```

Multiplies signed words, scales and rounds signed doublewords, and packs high 16-bits.

Interpreting $a$, $b$, and $r$ as arrays of signed 16-bit integers:

```c
for (i = 0; i < 4; i++) {
    r[i] = (( (int32)((a[i] * b[i]) >> 14) + 1) >> 1) & 0xFFFF;
}
```

**Absolute Value Intrinsics**

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used to compute absolute values. The prototypes for these intrinsics are in tmmintrin.h.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

`_mm_abs_epi8`

```c
extern __m128i __mm_abs_epi8(__m128i a);
```
Computes absolute value of signed bytes. Interpreting \(a\) and \(r\) as arrays of signed 8-bit integers:

```c
for (i = 0; i < 16; i++) {
    r[i] = abs(a[i]);
}
```

**_mm_abs_epi16**

extern __m128i _mm_abs_epi16(__m128i a);

Computes absolute value of signed words. Interpreting \(a\) and \(r\) as arrays of signed 16-bit integers:

```c
for (i = 0; i < 8; i++) {
    r[i] = abs(a[i]);
}
```

**_mm_abs_epi32**

extern __m128i _mm_abs_epi32(__m128i a);

Computes absolute value of signed doublewords. Interpreting \(a\) and \(r\) as arrays of signed 32-bit integers:

```c
for (i = 0; i < 4; i++) {
    r[i] = abs(a[i]);
}
```

**_mm_abs_pi8**

extern __m64 _mm_abs_pi8(__m64 a);

Computes absolute value of signed bytes. Interpreting \(a\) and \(r\) as arrays of signed 8-bit integers:

```c
for (i = 0; i < 8; i++) {
    r[i] = abs(a[i]);
}
```

**_mm_abs_pi16**

extern __m64 _mm_abs_pi16(__m64 a);

Computes absolute value of signed words. Interpreting \(a\) and \(r\) as arrays of signed 16-bit integers:

```c
for (i = 0; i < 4; i++) {
    r[i] = abs(a[i]);
}
```

**_mm_abs_pi32**

extern __m64 _mm_abs_pi32(__m64 a);

Computes absolute value of signed doublewords. Interpreting \(a\) and \(r\) as arrays of signed 32-bit integers:

```c
for (i = 0; i < 2; i++) {
    r[i] = abs(a[i]);
}
```

**Shuffle Intrinsics**

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used to perform shuffle operations. The prototypes for these intrinsics are in `tmmintrin.h`. 
To use these intrinsics, include the \texttt{immintrin.h} file as follows:

```c
#include <immintrin.h>
```

\texttt{\_mm\_shuffle\_epi8}

\texttt{extern \_m128i \_mm\_shuffle\_epi8(\_m128i a, \_m128i b);}

Shuffle bytes from \texttt{a} according to contents of \texttt{b}.

Interpreting \texttt{a}, \texttt{b}, and \texttt{r} as arrays of unsigned 8-bit integers:

```c
for (i = 0; i < 16; i++){
  if (b[i] & 0x80){
    r[i] = 0;
  } else {
    r[i] = a[b[i] & 0x0F];
  }
}
```

\texttt{\_mm\_shuffle\_pi8}

\texttt{extern \_m64 \_mm\_shuffle\_pi8(\_m64 a, \_m64 b);}

Shuffle bytes from \texttt{a} according to contents of \texttt{b}.

Interpreting \texttt{a}, \texttt{b}, and \texttt{r} as arrays of unsigned 8-bit integers:

```c
for (i = 0; i < 8; i++){
  if (b[i] & 0x80){
    r[i] = 0;
  } else {
    r[i] = a[b[i] & 0x07];
  }
}
```

\textbf{Concatenate Intrinsics}

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used concatenation. The prototypes for these intrinsics are in \texttt{tmmintrin.h}.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

```c
#include <immintrin.h>
```

\texttt{\_mm\_alignr\_epi8}

\texttt{extern \_m128i \_mm\_alignr\_epi8(\_m128i a, \_m128i b, int n);}

Concatenates \texttt{a} and \texttt{b}, extracts byte-aligned result shifted to the right by \texttt{n}.

Interpreting \texttt{t1} as 256-bit unsigned integer, \texttt{a}, \texttt{b}, and \texttt{r} as 128-bit unsigned integers:

```c
t1[255:128] = a;
t1[127:0] = b;
t1[255:0] = t1[255:0] >> (8 * n); // unsigned shift
r[127:0] = t1[127:0];
```
_mm_alignr_pi8

extern __m64 _mm_alignr_pi8(__m64 a, __m64 b, int n);

Concatenates a and b, extracts byte-aligned result shifted to the right by n.

Interpreting t1 as 128-bit unsigned integer, a, b, and r as 64-bit unsigned integers:

```c
    t1[127:64] = a;
    t1[63:0] = b;
    t1[127:0] = t1[127:0] >> (8 * n); // unsigned shift
    r[63:0] = t1[63:0];
```

Negation Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for negation. The prototypes for these intrinsics are in tmmintrin.h.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

_mm_sign_epi8

extern __m128i _mm_sign_epi8(__m128i a, __m128i b);

Negates packed bytes in a if corresponding sign in b is less than zero.

Interpreting a, b, and r as arrays of signed 8-bit integers:

```c
for (i = 0; i < 16; i++){
    if (b[i] < 0){
        r[i] = -a[i];
    } else
    if (b[i] == 0){
        r[i] = 0;
    } else {
        r[i] = a[i];
    }
}
```

_mm_sign_epi16

extern __m128i _mm_sign_epi16(__m128i a, __m128i b);

Negates packed words in a if corresponding sign in b is less than zero.

Interpreting a, b, and r as arrays of signed 16-bit integers:

```c
for (i = 0; i < 8; i++){
    if (b[i] < 0){
        r[i] = -a[i];
    } else
    if (b[i] == 0){
        r[i] = 0;
    } else {
        r[i] = a[i];
    }
```
\[ r[i] = a[i]; \]
\}

_\texttt{mm\_sign\_epi32} 

\texttt{extern \_m128i \_mm\_sign\_epi32(\_m128i a, \_m128i b);} 

Negates packed doublewords in \( a \) if corresponding sign in \( b \) is less than zero.

Interpreting \( a, b, \) and \( r \) as arrays of signed 32-bit integers:

\[
\begin{align*}
\text{for} & \quad (i = 0; i < 4; i++) \{} \\
& \quad \quad \text{if} (b[i] < 0) \{} \\
& \quad \quad \quad r[i] = -a[i]; \\
& \quad \quad \} \else \\
& \quad \quad \quad \text{if} (b[i] == 0) \{} \\
& \quad \quad \quad r[i] = 0; \\
& \quad \quad \} \else \\
& \quad \quad \quad r[i] = a[i]; \\
& \quad \} \\
\end{align*}
\]

_\texttt{mm\_sign\_pi8} 

\texttt{extern \_m64 \_mm\_sign\_pi8(\_m64 a, \_m64 b);} 

Negates packed bytes in \( a \) if corresponding sign in \( b \) is less than zero.

Interpreting \( a, b, \) and \( r \) as arrays of signed 8-bit integers:

\[
\begin{align*}
\text{for} & \quad (i = 0; i < 16; i++) \{} \\
& \quad \quad \text{if} (b[i] < 0) \{} \\
& \quad \quad \quad r[i] = -a[i]; \\
& \quad \quad \} \else \\
& \quad \quad \quad \text{if} (b[i] == 0) \{} \\
& \quad \quad \quad r[i] = 0; \\
& \quad \quad \} \else \\
& \quad \quad \quad r[i] = a[i]; \\
& \quad \} \\
\end{align*}
\]

_\texttt{mm\_sign\_pi16} 

\texttt{extern \_m64 \_mm\_sign\_pi16(\_m64 a, \_m64 b);} 

Negates packed words in \( a \) if corresponding sign in \( b \) is less than zero.

Interpreting \( a, b, \) and \( r \) as arrays of signed 16-bit integers:

\[
\begin{align*}
\text{for} & \quad (i = 0; i < 8; i++) \{} \\
& \quad \quad \text{if} (b[i] < 0) \{} \\
& \quad \quad \quad r[i] = -a[i]; \\
& \quad \quad \} \else \\
& \quad \quad \quad \text{if} (b[i] == 0) \{} \\
& \end{align*}
\]
# _mm_sign_pi32

extern __m64 _mm_sign_pi32(__m64 a, __m64 b);

Negates packed doublewords in `a` if corresponding sign in `b` is less than zero.

Interpreting `a`, `b`, and `r` as arrays of signed 32-bit integers:

```c
for (i = 0; i < 2; i++){
    if (b[i] < 0){
        r[i] = -a[i];
    } else
        if (b[i] == 0){
            r[i] = 0;
        } else {
            r[i] = a[i];
        }
}
```

## Intrinsics for Intel® Streaming SIMD Extensions 3 (Intel® SSE3)

### Overview: Intel® Streaming SIMD Extensions 3 (Intel® SSE3)

The Intel® C++ intrinsics listed in this section are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the `pmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The following topics summarize these intrinsics:

- Floating-point Vector Intrinsics
- Integer Vector Intrinsics
- Miscellaneous Intrinsics
- Macro Functions

### Integer Vector Intrinsic

The integer vector intrinsic listed here is designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototype for this intrinsic is in the `pmmintrin.h` header file.

To use this intrinsic, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```
\( R \) represents the register into which the returns are placed.

\texttt{\_mm\_lddqu\_si128}

\texttt{\_m128i \_mm\_lddqu\_si128(\_m128i const \*p);} 

Loads an unaligned 128-bit value. This differs from \texttt{MOVDQU} in that it can provide higher performance in some cases. However, it also may provide lower performance than \texttt{MOVDQU} if the memory value being read was just written.

\[ R \]
\[ \*p; \]

\textbf{Single-precision Floating-point Vector Intrinsics}

The single-precision floating-point vector intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the \texttt{pmmintrin.h} header file.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

\begin{verbatim}
#include <immintrin.h>
\end{verbatim}

The results of each intrinsic operation are placed in the registers \( R0, R1, R2, \) and \( R3. \)

<table>

Double-precision Floating-point Vector Intrinsics
The double-precision floating-point intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the pmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in the registers R0 and R1.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>

Miscellaneous Intrinsics

The intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the pmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```
### intrinsics for Intel® Streaming SIMD Extensions 2 (Intel® SSE2)

#### overview: Intel® Streaming SIMD Extensions 2 (Intel® SSE2)

This section describes the C++ language-level features supporting the Intel® Streaming SIMD Extensions 2 (Intel® SSE2) in the Intel® C++ Compiler. The features are divided into two categories:

- **Floating-Point Intrinsics** -- describes the arithmetic, logical, compare, conversion, memory, and initialization intrinsics for the double-precision floating-point data type (`__m128d`).
- **Integer Intrinsics** -- describes the arithmetic, logical, compare, conversion, memory, and initialization intrinsics for the extended-precision integer data type (`__m128i`).

The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

**Note**

There are no intrinsics for floating-point move operations. To move data from one register to another, a simple assignment, `A = B`, suffices, where `A` and `B` are the source and target registers for the move operation.

Some intrinsics are "composites" - they require more than one instruction to implement them. Intrinsics that require one instruction to implement them are referred to as "simple".

You should be familiar with the hardware features provided by Intel® SSE2 when writing programs with the intrinsics. The following are three important issues to keep in mind:

- Certain intrinsics, such as `_mm_loadr_pd` and `_mm_cmpgt_sd`, are not directly supported by the instruction set. While these intrinsics are convenient programming aids, be mindful of their implementation cost.
- Data loaded or stored as `__m128d` objects must be generally 16-byte-aligned.
- Some intrinsics require that their argument be immediates, that is, constant integers (literals), due to the nature of the instruction.
Macro Functions

The macro function intrinsics listed here were designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). They are also compatible with Streaming SIMD Extensions 2 (Intel® SSE2).

The prototypes for these intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

```c
_MM_SET_DENORMALS_ZERO_MODE
_MM_SET_DENORMALS_ZERO_MODE(x);
```

Macro arguments: either `_MM_DENORMALS_ZERO_ON`, `_MM_DENORMALS_ZERO_OFF`.

This macro causes "denormals are zero" mode to be turned ON or OFF by setting the appropriate bit of the control register.

```c
_MM_GET_DENORMALS_ZERO_MODE
_MM_GET_DENORMALS_ZERO_MODE();
```

No arguments.

This macro returns the current value of the denormals are zero mode bit of the control register.

Floating-point Intrinsics

Arithmetic Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point arithmetic operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R0` and `R1`, where `R0` and `R1` each represent one piece of the result register.

<table>

<td>MAXPD</td>
</tr>
</tbody>
</table>

**_mm_add_sd**

```c
__m128d _mm_add_sd(__m128d a, __m128d b);
```

Adds the lower double-precision FP (floating-point) values of a and b; the upper double-precision FP value is passed through from a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 + b0</td>
<td>a1</td>
</tr>
</tbody>
</table>

**_mm_add_pd**

```c
__m128d _mm_add_pd(__m128d a, __m128d b);
```

Adds the two DP FP values of a and b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 + b0</td>
<td>a1 + b1</td>
</tr>
</tbody>
</table>

**_mm_sub_sd**

```c
__m128d _mm_sub_sd(__m128d a, __m128d b);
```

Subtracts the lower DP FP value of b from a. The upper DP FP value is passed through from a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 - b0</td>
<td>a1</td>
</tr>
</tbody>
</table>

**_mm_sub_pd**

```c
__m128d _mm_sub_pd(__m128d a, __m128d b);
```

Subtracts the two DP FP values of b from a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 - b0</td>
<td>a1 - b1</td>
</tr>
</tbody>
</table>
_mm_mul_sd
__m128d __mm_mul_sd(__m128d a, __m128d b);
Multiplies the lower DP FP values of \(a\) and \(b\). The upper DP FP is passed through from \(a\).

\[
\begin{array}{cc}
\text{R0} & \text{R1} \\
a0 \times b0 & a1
\end{array}
\]

_mm_mul_pd
__m128d __mm_mul_pd(__m128d a, __m128d b);
Multiplies the two DP FP values of \(a\) and \(b\).

\[
\begin{array}{cc}
\text{R0} & \text{R1} \\
a0 \times b0 & a1 \times b1
\end{array}
\]

_ mm_div_sd
__m128d __mm_div_sd(__m128d a, __m128d b);
Divides the lower DP FP values of \(a\) and \(b\). The upper DP FP value is passed through from \(a\).

\[
\begin{array}{cc}
\text{R0} & \text{R1} \\
a0 \div b0 & a1
\end{array}
\]

_ mm_div_pd
__m128d __mm_div_pd(__m128d a, __m128d b);
Divides the two DP FP values of \(a\) and \(b\).

\[
\begin{array}{cc}
\text{R0} & \text{R1} \\
a0 \div b0 & a1 \div b1
\end{array}
\]

_ mm_sqrt_sd
__m128d __mm_sqrt_sd(__m128d a, __m128d b);
Computes the square root of the lower DP FP value of \(b\). The upper DP FP value is passed through from \(a\).

\[
\begin{array}{cc}
\text{R0} & \text{R1} \\
\sqrt{b0} & a1
\end{array}
\]

_ mm_sqrt_pd
__m128d __mm_sqrt_pd(__m128d a);
Computes the square root of the two DP FP values of \(a\).
Computes the minimum of the lower DP FP values of \(a\) and \(b\). The upper DP FP value is passed through from \(a\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqrt(a0)</td>
<td>sqrt(a1)</td>
</tr>
</tbody>
</table>

Computes the minima of the two DP FP values of \(a\) and \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>min (a0, b0)</td>
<td>min(a1, b1)</td>
</tr>
</tbody>
</table>

Computes the maximum of the lower DP FP values of \(a\) and \(b\). The upper DP FP value is passed through from \(a\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>max (a0, b0)</td>
<td>a1</td>
</tr>
</tbody>
</table>

Computes the maxima of the two DP FP values of \(a\) and \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>max (a0, b0)</td>
<td>max (a1, b1)</td>
</tr>
</tbody>
</table>

**Logical Intrinsics**

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point logical operations are listed in the following table. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```
The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by R0 and R1, where R0 and R1 each represent one piece of the result register.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_and_pd</td>
<td>Computes AND</td>
<td>ANDPD</td>
</tr>
<tr>
<td>_mm_andnot_pd</td>
<td>Computes AND and NOT</td>
<td>ANDNPD</td>
</tr>
<tr>
<td>_mm_or_pd</td>
<td>Computes OR</td>
<td>ORPD</td>
</tr>
<tr>
<td>_mm_xor_pd</td>
<td>Computes XOR</td>
<td>XORPD</td>
</tr>
</tbody>
</table>

_mm_and_pd
__m128d _mm_and_pd(__m128d a, __m128d b);
Computes the bitwise AND of the two DP FP values of a and b.

R0  R1
---  ---
a0 & b0  a1 & b1

_mm_andnot_pd
__m128d _mm_andnot_pd(__m128d a, __m128d b);
Computes the bitwise AND of the 128-bit value in b and the bitwise NOT of the 128-bit value in a.

R0  R1
---  ---
(~a0) & b0  (~a1) & b1

_mm_or_pd
__m128d _mm_or_pd(__m128d a, __m128d b);
Computes the bitwise OR of the two DP FP values of a and b.

R0  R1
---  ---
a0 | b0  a1 | b1

_mm_xor_pd
__m128d _mm_xor_pd(__m128d a, __m128d b);
Computes the bitwise XOR of the two DP FP values of a and b.

R0  R1
---  ---
a0 ^ b0  a1 ^ b1
Compare Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point comparison operations are listed in the following table. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

Each comparison intrinsic performs a comparison of \( a \) and \( b \). For the packed form, the two double-precision FP values of \( a \) and \( b \) are compared, and a 128-bit mask is returned. For the scalar form, the lower double-precision FP values of \( a \) and \( b \) are compared, and a 64-bit mask is returned; the upper double-precision FP value is passed through from \( a \).

The mask is set to \( 0xffffffffffffffff \) for each element where the comparison is true, and set to \( 0x0 \) where the comparison is false. The \( r \) following the instruction name indicates that the operands to the instruction are reversed in the actual implementation.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by \( R, R0, \) and \( R1 \), where \( R, R0, \) and \( R1 \) each represent one piece of the result register.

</tbody>
</table>

**_mm_cmpeq_pd**

```c
__m128d _mm_cmpeq_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of `a` and `b` for equality.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a0 == b0) ? 0xffffffffffffffff : 0x0</td>
<td>(a1 == b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmplt_pd**

```c
__m128d _mm_cmplt_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of `a` and `b` for `a` less than `b`.
\_mm\_cmple\_pd
\_m128d \_mm\_cmple\_pd(\_m128d a, \_m128d b);
Compares the two DP FP values of \(a\) and \(b\) for \(a\) less than or equal to \(b\).

\_mm\_cmpgt\_pd
\_m128d \_mm\_cmpgt\_pd(\_m128d a, \_m128d b);
Compares the two DP FP values of \(a\) and \(b\) for \(a\) greater than \(b\).

\_mm\_cmpge\_pd
\_m128d \_mm\_cmpge\_pd(\_m128d a, \_m128d b);
Compares the two DP FP values of \(a\) and \(b\) for \(a\) greater than or equal to \(b\).

\_mm\_cmpord\_pd
\_m128d \_mm\_cmpord\_pd(\_m128d a, \_m128d b);
Compares the two DP FP values of \(a\) and \(b\) for ordered.

\_mm\_cmpunord\_pd
\_m128d \_mm\_cmpunord\_pd(\_m128d a, \_m128d b);
Compares the two DP FP values of \(a\) and \(b\) for unordered.
**_mm_cmpneq_pd_**

__m128d _mm_cmpneq_pd(__m128d a, __m128d b);

Compares the two DP FP values of \(a\) and \(b\) for inequality.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a0 != b0) ? 0xffffffffffffffff : 0x0</td>
<td>(a1 != b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmpnlt_pd_**

__m128d _mm_cmpnlt_pd(__m128d a, __m128d b);

Compares the two DP FP values of \(a\) and \(b\) for \(a\) not less than \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>!(a0 &lt; b0) ? 0xffffffffffffffff : 0x0</td>
<td>!(a1 &lt; b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmpnle_pd_**

__m128d _mm_cmpnle_pd(__m128d a, __m128d b);

Compares the two DP FP values of \(a\) and \(b\) for \(a\) not less than or equal to \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>!(a0 &lt;= b0) ? 0xffffffffffffffff : 0x0</td>
<td>!(a1 &lt;= b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmpngt_pd_**

__m128d _mm_cmpngt_pd(__m128d a, __m128d b);

Compares the two DP FP values of \(a\) and \(b\) for \(a\) not greater than \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>!(a0 &gt; b0) ? 0xffffffffffffffff : 0x0</td>
<td>!(a1 &gt; b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmpnge_pd_**

__m128d _mm_cmpnge_pd(__m128d a, __m128d b);

Compares the two DP FP values of \(a\) and \(b\) for \(a\) not greater than or equal to \(b\).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>!(a0 &gt;= b0) ? 0xffffffffffffffff : 0x0</td>
<td>!(a1 &gt;= b1) ? 0xffffffffffffffff : 0x0</td>
</tr>
</tbody>
</table>

**_mm_cmpeq_sd_**

__m128d _mm_cmpeq_sd(__m128d a, __m128d b);

Compares the lower DP FP value of \(a\) and \(b\) for equality. The upper DP FP value is passed through from \(a\).
- **_mm_cmplt_sd**
  
  _m128d _mm_cmplt_sd(__m128d a, __m128d b);

  Compares the lower DP FP value of \( a \) and \( b \) for \( a \) less than \( b \). The upper DP FP value is passed through from \( a \).

- **_mm_cmple_sd**
  
  _m128d _mm_cmple_sd(__m128d a, __m128d b);

  Compares the lower DP FP value of \( a \) and \( b \) for \( a \) less than or equal to \( b \). The upper DP FP value is passed through from \( a \).

- **_mm_cmpgt_sd**
  
  _m128d _mm_cmpgt_sd(__m128d a, __m128d b);

  Compares the lower DP FP value of \( a \) and \( b \) for \( a \) greater than \( b \). The upper DP FP value is passed through from \( a \).

- **_mm_cmpge_sd**
  
  _m128d _mm_cmpge_sd(__m128d a, __m128d b);

  Compares the lower DP FP value of \( a \) and \( b \) for \( a \) greater than or equal to \( b \). The upper DP FP value is passed through from \( a \).

- **_mm_cmpord_sd**
  
  _m128d _mm_cmpord_sd(__m128d a, __m128d b);

  Compares the lower DP FP value of \( a \) and \( b \) for ordered. The upper DP FP value is passed through from \( a \).
_mm_cmpunord_sd
__m128d __m_cmpunord_sd(__m128d a, __m128d b);
Compares the lower DP FP value of \( a \) and \( b \) for unordered. The upper DP FP value is passed through from \( a \).

_R0_  _R1_
(a0 ord b0) ? 0xffffffffffffffff : 0x0  a1

_mm_cmpneq_sd
__m128d __m_cmpneq_sd(__m128d a, __m128d b);
Compares the lower DP FP value of \( a \) and \( b \) for inequality. The upper DP FP value is passed through from \( a \).

_R0_  _R1_
(a0 != b0) ? 0xffffffffffffffff : 0x0  a1

_mm_cmpnlt_sd
__m128d __m_cmpnlt_sd(__m128d a, __m128d b);
Compares the lower DP FP value of \( a \) and \( b \) for \( a \) not less than \( b \). The upper DP FP value is passed through from \( a \).

_R0_  _R1_
!(a0 < b0) ? 0xffffffffffffffff : 0x0  a1

_mm_cmpnle_sd
__m128d __m_cmpnle_sd(__m128d a, __m128d b);
Compares the lower DP FP value of \( a \) and \( b \) for \( a \) not less than or equal to \( b \). The upper DP FP value is passed through from \( a \).

_R0_  _R1_
!(a0 <= b0) ? 0xffffffffffffffff : 0x0\&#9;  a1

_mm_cmpngt_sd
__m128d __m_cmpngt_sd(__m128d a, __m128d b);
Compares the lower DP FP value of \( a \) and \( b \) for \( a \) not greater than \( b \). The upper DP FP value is passed through from \( a \).

_R0_  _R1_
!(a0 > b0) ? 0xffffffffffffffff : 0x0  a1

**_mm_cmpnge_sd_**

```c
__m128d _mm_cmpnge_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of `a` and `b` for `a` not greater than or equal to `b`. The upper DP FP value is passed through from `a`.

<table>
<thead>

\]

Conversion Intrinsics
Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point conversion operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

Each conversion intrinsic takes one data type and performs a conversion to a different type. Some conversions, such as those performed by the `_mm_cvtpd_ps` intrinsic, result in a loss of precision. The rounding mode used in such cases is determined by the value in the MXCSR register. The default rounding mode is round-to-nearest.

**NOTE**
The rounding mode used by the C and C++ languages when performing a type conversion is to truncate. The `_mm_cvtpd_epi32` and `_mm_cvttssd_si32` intrinsics use the truncate rounding mode regardless of the mode specified by the MXCSR register.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by \(R, R0, R1, R2, \text{ and } R3\), where each represent the registers in which results are placed.
<table>

### _mm_cvtps_pd

```c
__m128d _mm_cvtps(__m128 a);
```

Converts the lower two SP FP values of `a` to DP FP values.
_mm_cvtepi32_pd
__m128d _mm_cvtepi32_pd(__m128i a);
Converts the lower two signed 32-bit integer values of a to DP FP values.

_R0_  _R1_
| (double) a0 | (double) a1 |

_mm_cvtpd_epi32
__m128i _mm_cvtpd_epi32(__m128d a);
Converts the two DP FP values of a to 32-bit signed integer values.

_R0_  _R1_  _R2_  _R3_
| (int) a0 | (int) a1 | 0x0 | 0x0 |

_mm_cvtsd_si32
int _mm_cvtsd_si32(__m128d a);
Converts the lower DP FP value of a to a 32-bit signed integer value.

_R_
| (int) a0 |

_mm_cvtsd_ss
__m128 _mm_cvtsd_ss(__m128 a, __m128d b);
Converts the lower DP FP value of b to an SP FP value. The upper SP FP values in a are passed through.

_R0_  _R1_  _R2_  _R3_
| (float) b0 | a1 | a2 | a3 |

_mm_cvtsi32_sd
__m128d _mm_cvtsi32_sd(__m128d a, int b);
Converts the signed integer value in b to a DP FP value. The upper DP FP value in a is passed through.

_R0_  _R1_
| (double) b | a1 |
\textit{\_mm\_cvtss\_sd}

\_m128d \_mm\_cvtss\_sd(\_m128d \textit{a}, \_m128d \textit{b});

Converts the lower SP FP value of \textit{b} to a DP FP value. The upper value DP FP value in \textit{a} is passed through.

\begin{tabular}{ll}
\hline
R0 & R1 \\
\texttt{(double) b0} & a1 \\
\hline
\end{tabular}

\textit{\_mm\_cvttpd\_epi32}

\_m128i \_mm\_cvttpd\_epi32(\_m128d \textit{a});

Converts the two DP FP values of \textit{a} to 32-bit signed integers using truncate.

\begin{tabular}{llll}
\hline
R0 & R1 & R2 & R3 \\
\texttt{(int) a0} & \texttt{(int) a1} & 0x0 & 0x0 \\
\hline
\end{tabular}

\textit{\_mm\_cvttsd\_si32}

int \_mm\_cvttsd\_si32(\_m128d \textit{a});

Converts the lower DP FP value of \textit{a} to a 32-bit signed integer using truncate.

\begin{tabular}{l}
\hline
R \\
\texttt{(int) a0} \\
\hline
\end{tabular}

\textit{\_mm\_cvtpd\_pi32}

\_m64 \_mm\_cvtpd\_pi32(\_m128d \textit{a});

Converts the two DP FP values of \textit{a} to 32-bit signed integer values.

\begin{tabular}{ll}
\hline
R0 & R1 \\
\texttt{(int)a0} & \texttt{(int) a1} \\
\hline
\end{tabular}

\textit{\_mm\_cvtpd\_pi32}

\_m64 \_mm\_cvtpd\_pi32(\_m128d \textit{a});

Converts the two DP FP values of \textit{a} to 32-bit signed integer values using truncate.

\begin{tabular}{ll}
\hline
R0 & R1 \\
\texttt{(int)a0} & \texttt{(int) a1} \\
\hline
\end{tabular}

\textit{\_mm\_cvtpi32\_pd}

\_m128d \_mm\_cvtpi32\_pd(\_m64 \textit{a});

Converts the two 32-bit signed integer values of \textit{a} to DP FP values.
This intrinsic extracts a double precision floating point value from the first vector element of an __m128d. It does so in the most efficient manner possible in the context used.

NOTE
This intrinsic does not map to any specific Intel® SSE2 instruction.

Load Intrinsics
Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point load operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The load and set operations are similar in that both initialize __m128d data. However, the set operations take a double argument and are intended for initialization with constants, while the load operations take a double pointer argument and are intended to mimic the instructions for loading data from memory.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by R0 and R1, where R0 and R1 each represent one piece of the result register.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>__mm_load_pd</td>
<td>Loads two DP FP values</td>

<td>Loads a DP FP value as the lower DP FP value of the result</td>
<td>MOVLPD</td>
</tr>
</tbody>
</table>

__mm_load_pd
__m128d __mm_load_pd(double const*dp);
Loads two DP FP values. The address p must be 16-byte aligned.
### _mm_load1_pd

\[
\_\text{m128d } _\text{mm\_load1\_pd(}\text{double const}\ast\text{dp)};
\]

Loads a single DP FP value, copying to both elements. The address \( p \) need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>p[0]</td>
<td>p[1]</td>
</tr>
</tbody>
</table>

### _mm_loadr_pd

\[
\_\text{m128d } _\text{mm\_loadr\_pd(}\text{double const}\ast\text{dp)};
\]

Loads two DP FP values in reverse order. The address \( p \) must be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>p[1]</td>
<td>p[0]</td>
</tr>
</tbody>
</table>

### _mm_loadu_pd

\[
\_\text{m128d } _\text{mm\_loadu\_pd(}\text{double const}\ast\text{dp)};
\]

Loads two DP FP values. The address \( p \) need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>p[0]</td>
<td>p[1]</td>
</tr>
</tbody>
</table>

### _mm_load_sd

\[
\_\text{m128d } _\text{mm\_load\_sd(}\text{double const}\ast\text{dp)};
\]

Loads a DP FP value. The upper DP FP is set to zero. The address \( p \) need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>*p</td>
<td>0.0</td>
</tr>
</tbody>
</table>

### _mm_loadh_pd

\[
\_\text{m128d } _\text{mm\_loadh\_pd(}_\text{m128d } a, \text{double const}\ast\text{dp)};
\]

Loads a DP FP value as the upper DP FP value of the result. The lower DP FP value is passed through from \( a \). The address \( p \) need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>*p</td>
</tr>
</tbody>
</table>
**_mm_loadl_pd_**

```c
__m128d _mm_loadl_pd(__m128d a, double const*dp);
```

Loads a DP FP value as the lower DP FP value of the result. The upper DP FP value is passed through from `a`. The address `p` need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>*p</td>
<td>a1</td>
</tr>
</tbody>
</table>

### Set Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point set operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The load and set operations are similar in that both initialize `__m128d` data. However, the set operations take a double argument and are intended for initialization with constants, while the load operations take a double pointer argument and are intended to mimic the instructions for loading data from memory.

Some of the these intrinsics are composite intrinsics because they require more than one instruction to implement them.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R0` and `R1`, where `R0` and `R1` each represent one piece of the result register.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>

</tbody>
</table>

_mm_store_sd

```c
void _mm_store_sd(double *dp, __m128d a);
```
Stores the lower DP FP value of \( a \). The address \( dp \) needs not be 16-byte aligned.

```
  *dp
  a0
```

_mm_store1_pd

```c
void _mm_store1_pd(double *dp, __m128d a);
```
Stores the lower DP FP value of \( a \) twice. The address \( dp \) must be 16-byte aligned.

```
da[0]          dp[1]
a0             a0
```

_mm_store_pd

```c
void _mm_store_pd(double *dp, __m128d a);
```
Stores two DP FP values. The address \( dp \) must be 16-byte aligned.

```
da[0]          dp[1]
a0             a1
```

_mm_storeu_pd

```c
void _mm_storeu_pd(double *dp, __m128d a);
```
Stores two DP FP values. The address \( dp \) need not be 16-byte aligned.

<table>
<thead>
<tr>
<th>( dp[0] )</th>
<th>( dp[1] )</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
</tr>
</tbody>
</table>

_mm_storer_pd
void _mm_storer_pd(double *dp, __m128d a);

Stores two DP FP values in reverse order. The address \( dp \) must be 16-byte aligned.

<table>
<thead>
<tr>
<th>( dp[0] )</th>
<th>( dp[1] )</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1</td>
<td>a0</td>
</tr>
</tbody>
</table>

_mm_storeh_pd
void _mm_storeh_pd(double *dp, __m128d a);

Stores the upper DP FP value of \( a \).

*dp

<table>
<thead>
<tr>
<th>( dp )</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1</td>
</tr>
</tbody>
</table>

void _mm_storel_pd(double *dp, __m128d a);

Stores the lower DP FP value of \( a \).

*dp

<table>
<thead>
<tr>
<th>( dp )</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
</tr>
</tbody>
</table>

**Integer Intrinsics**

**Arithmetic Intrinsics**

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer arithmetic operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the \textit{emmintrin.h} header file.

To use these intrinsics, include the \textit{immintrin.h} file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. \( R, R0, R1, \ldots, R15 \) represent the registers in which results are placed.

<table>

<td>UnsignedSaturate (a7 + b7)</td>
</tr>
</tbody>
</table>

_mm_avg_epu8

__m128i _mm_avg_epu8(__m128i a, __m128i b);

Computes the average of the 16 unsigned 8-bit integers in `a` and the 16 unsigned 8-bit integers in `b` and rounds.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a0 + b0) / 2</td>
<td>(a1 + b1) / 2</td>
<td>...</td>
<td>(a15 + b15) / 2</td>
</tr>
</tbody>
</table>

_mm_avg_epi16

__m128i _mm_avg_epi16(__m128i a, __m128i b);

Computes the average of the eight unsigned 16-bit integers in `a` and the eight unsigned 16-bit integers in `b` and rounds.
\(\frac{a_0 + b_0}{2}\) \(\frac{a_1 + b_1}{2}\) \(\ldots\) \(\frac{a_7 + b_7}{2}\)

**_mm_madd_epi16**

\[
\_\text{mm}_\text{madd}_\text{epi16}(\text{\_m128} \ a, \text{\_m128} \ b);
\]

Multiplies the eight signed 16-bit integers from \(a\) by the eight signed 16-bit integers from \(b\). Adds the signed 32-bit integer results pairwise and packs the four signed 32-bit integer results.

\(\frac{(a_0 \times b_0)}{2}\) \(\frac{(a_1 \times b_1)}{2}\) \(\ldots\) \(\frac{(a_7 \times b_7)}{2}\)

**_mm_max_epi16**

\[
\_\text{mm}_\text{max}_\text{epi16}(\text{\_m128} \ a, \text{\_m128} \ b);
\]

Computes the pairwise maxima of the eight signed 16-bit integers from \(a\) and the eight signed 16-bit integers from \(b\).

\(\text{max}(a_0, b_0)\) \(\text{max}(a_1, b_1)\) \(\ldots\) \(\text{max}(a_7, b_7)\)

**_mm_max_epu8**

\[
\_\text{mm}_\text{max}_\text{epu8}(\text{\_m128} \ a, \text{\_m128} \ b);
\]

Computes the pairwise maxima of the 16 unsigned 8-bit integers from \(a\) and the 16 unsigned 8-bit integers from \(b\).

\(\text{max}(a_0, b_0)\) \(\text{max}(a_1, b_1)\) \(\ldots\) \(\text{max}(a_{15}, b_{15})\)

**_mm_min_epi16**

\[
\_\text{mm}_\text{min}_\text{epi16}(\text{\_m128} \ a, \text{\_m128} \ b);
\]

Computes the pairwise minima of the eight signed 16-bit integers from \(a\) and the eight signed 16-bit integers from \(b\).

\(\text{min}(a_0, b_0)\) \(\text{min}(a_1, b_1)\) \(\ldots\) \(\text{min}(a_7, b_7)\)

**_mm_min_epu8**

\[
\_\text{mm}_\text{min}_\text{epu8}(\text{\_m128} \ a, \text{\_m128} \ b);
\]

Computes the pairwise minima of the 16 unsigned 8-bit integers from \(a\) and the 16 unsigned 8-bit integers from \(b\).
<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>min(a0, b0)</td>
<td>min(a1, b1)</td>
<td>...</td>
<td>min(a15, b15)</td>
</tr>
</tbody>
</table>

_mm_mulhi_epi16

__m128i _mm_mulhi_epi16(__m128i a, __m128i b);

Multiplies the eight signed 16-bit integers from \( a \) by the eight signed 16-bit integers from \( b \). Packs the upper 16-bits of the eight signed 32-bit results.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>((a0 \times b0)[31:16])</td>
<td>((a1 \times b1)[31:16])</td>
<td>...</td>
<td>((a7 \times b7)[31:16])</td>
</tr>
</tbody>
</table>

_mm_mulhi_epu16

__m128i _mm_mulhi_epu16(__m128i a, __m128i b);

Multiplies the eight unsigned 16-bit integers from \( a \) by the eight unsigned 16-bit integers from \( b \). Packs the upper 16-bits of the eight unsigned 32-bit results.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>((a0 \times b0)[31:16])</td>
<td>((a1 \times b1)[31:16])</td>
<td>...</td>
<td>((a7 \times b7)[31:16])</td>
</tr>
</tbody>
</table>

_mm_mullo_epi16

__m128i _mm_mullo_epi16(__m128i a, __m128i b);

Multiplies the eight signed or unsigned 16-bit integers from \( a \) by the eight signed or unsigned 16-bit integers from \( b \). Packs the lower 16-bits of the eight signed or unsigned 32-bit results.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>((a0 \times b0)[15:0])</td>
<td>((a1 \times b1)[15:0])</td>
<td>...</td>
<td>((a7 \times b7)[15:0])</td>
</tr>
</tbody>
</table>

_mm_mul_su32

__m64 _mm_mul_su32(__m64 a, __m64 b);

Multiplies the lower 32-bit integer from \( a \) by the lower 32-bit integer from \( b \), and returns the 64-bit integer result.

<table>
<thead>
<tr>
<th>R0</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 \times b0</td>
</tr>
</tbody>
</table>

_mm_mul_epu32

__m128i _mm_mul_epu32(__m128i a, __m128i b);

Multiplies two unsigned 32-bit integers from \( a \) by two unsigned 32-bit integers from \( b \). Packs the two unsigned 64-bit integer results.
<table>
<thead>
<tr>
<th>R0</th>
<th>R1 to R3</th>
<th>R4</th>
<th>R5 to R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 * b0</td>
<td>a2 * b2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

_mm_sad_epu8

__m128i _mm_sad_epu8(__m128i a, __m128i b);

Computes the absolute difference of the 16 unsigned 8-bit integers from a and the 16 unsigned 8-bit integers from b. Sums the upper eight differences and lower eight differences, and packs the resulting two unsigned 16-bit integers into the upper and lower 64-bit elements.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1 to R3</th>
<th>R4</th>
<th>R5 to R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs(a0 - b0) + 0x0</td>
<td>abs(a8 - b8) + 0x0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>abs(a1 - b1) +...+</td>
<td>abs(a9 - b9) +...+</td>
<td></td>
<td></td>
</tr>
<tr>
<td>abs(a7 - b7)</td>
<td>abs(a15 - b15)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

_mm_sub_epi8

__m128i _mm_sub_epi8(__m128i a, __m128i b);

Subtracts the 16 signed or unsigned 8-bit integers of b from the 16 signed or unsigned 8-bit integers of a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 - b0</td>
<td>a1 - b1</td>
<td>...</td>
<td>a15 - b15</td>
</tr>
</tbody>
</table>

_mm_sub_epi16

__m128i _mm_sub_epi16(__m128i a, __m128i b);

Subtracts the eight signed or unsigned 16-bit integers of b from the eight signed or unsigned 16-bit integers of a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 - b0</td>
<td>a1 - b1</td>
<td>...</td>
<td>a7 - b7</td>
</tr>
</tbody>
</table>

_mm_sub_epi32

__m128i _mm_sub_epi32(__m128i a, __m128i b);

Subtracts the four signed or unsigned 32-bit integers of b from the four signed or unsigned 32-bit integers of a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0 - b0</td>
<td>a1 - b1</td>
<td>a2 - b2</td>
<td>a3 - b3</td>
</tr>
</tbody>
</table>

_mm_sub_si64

__m64 _mm_sub_si64 (__m64 a, __m64 b);

Subtracts the signed or unsigned 64-bit integer b from the signed or unsigned 64-bit integer a.
### _mm_sub_epi64

\[
\_\text{m128i } \_\text{mm\_sub\_epi64}(\_\text{m128i } a, \_\text{m128i } b);
\]

Subtracts the two signed or unsigned 64-bit integers in \( b \) from the two signed or unsigned 64-bit integers in \( a \).

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a0 - b0 )</td>
<td>( a1 - b1 )</td>
</tr>
</tbody>
</table>

### _mm_subs_epi8

\[
\_\text{m128i } \_\text{mm\_subs\_epi8}(\_\text{m128i } a, \_\text{m128i } b);
\]

Subtracts the 16 signed 8-bit integers of \( b \) from the 16 signed 8-bit integers of \( a \) using saturating arithmetic.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>SignedSaturate (a0 - b0)</td>
<td>SignedSaturate (a1 - b1)</td>
<td>...</td>
<td>SignedSaturate (a15 - b15)</td>
</tr>
</tbody>
</table>

### _mm_subs_epi16

\[
\_\text{m128i } \_\text{mm\_subs\_epi16}(\_\text{m128i } a, \_\text{m128i } b);
\]

Subtracts the eight signed 16-bit integers of \( b \) from the eight signed 16-bit integers of \( a \) using saturating arithmetic.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>SignedSaturate (a0 - b0)</td>
<td>SignedSaturate (a1 - b1)</td>
<td>...</td>
<td>SignedSaturate (a7 - b7)</td>
</tr>
</tbody>
</table>

### _mm_subs_epu8

\[
\_\text{m128i } \_\text{mm\_subs\_epu8}(\_\text{m128i } a, \_\text{m128i } b);
\]

Subtracts the 16 unsigned 8-bit integers of \( b \) from the 16 unsigned 8-bit integers of \( a \) using saturating arithmetic.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R15</th>
</tr>
</thead>
<tbody>
<tr>
<td>UnsignedSaturate (a0 - b0)</td>
<td>UnsignedSaturate (a1 - b1)</td>
<td>...</td>
<td>UnsignedSaturate (a15 - b15)</td>
</tr>
</tbody>
</table>

### _mm_subs_epu16

\[
\_\text{m128i } \_\text{mm\_subs\_epu16}(\_\text{m128i } a, \_\text{m128i } b);
\]

Subtracts the eight unsigned 16-bit integers of \( b \) from the eight unsigned 16-bit integers of \( a \) using saturating arithmetic.
Logical Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer logical operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in register R. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_and_si128</td>
<td>Computes AND</td>
<td>PAND</td>
</tr>
<tr>
<td>_mm_andnot_si128</td>
<td>Computes AND and NOT</td>
<td>PANDN</td>
</tr>
<tr>
<td>_mm_or_si128</td>
<td>Computes OR</td>
<td>POR</td>
</tr>
<tr>
<td>_mm_xor_si128</td>
<td>Computes XOR</td>
<td>PXOR</td>
</tr>
</tbody>
</table>

**_mm_and_si128**

```c
__m128i __m128i _mm_and_si128(__m128i a, __m128i b);
```

Computes the bitwise AND of the 128-bit value in a and the 128-bit value in b.

**R0**

```c
a & b
```

**_mm_andnot_si128**

```c
__m128i __m128i _mm_andnot_si128(__m128i a, __m128i b);
```

Computes the bitwise AND of the 128-bit value in b and the bitwise NOT of the 128-bit value in a.

**R0**

```c
(~a) & b
```

**_mm_or_si128**

```c
__m128i __m128i _mm_or_si128(__m128i a, __m128i b);
```

Computes the bitwise OR of the 128-bit value in a and the 128-bit value in b.

**R0**

```c
a | b
```
### _mm_xor_si128

```
_m128i _mm_xor_si128(_m128i a, _m128i b);
```

Computes the bitwise XOR of the 128-bit value in `a` and the 128-bit value in `b`.

### Shift Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer shift operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`...`R7` represent the registers in which results are placed.

#### NOTE

The `count` argument is one shift count that applies to all elements of the operand being shifted. It is not a vector shift count that shifts each element by a different amount.

Compare Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer comparison operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R, R0, R1, ..., R15 represent the registers in which results are placed.

Conversion Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer conversion operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. \(R, R0, R1, R2,\) and \(R3\) represent the registers in which results are placed.
Intrinsics marked with * are implemented only on Intel® 64 architecture. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

<table>
<thead>
<tr>

<tbody>
<tr>
<td>(double)b</td>
<td>a1</td>
</tr>
</tbody>
</table>

_mm_cvtsd_si64
__int64 _mm_cvtsd_si64(__m128d a);
Converts the lower DP FP value of a to a 64-bit signed integer value according to the current rounding mode.

**NOTE**
Use only on Intel® 64 architectures.

<table>
<thead>
<tr>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>(__int64) a0</td>
</tr>
</tbody>
</table>

_mm_cvttsd_si64
__int64 _mm_cvttsd_si64(__m128d a);
Converts the lower DP FP value of a to a 64-bit signed integer value using truncation.
**NOTE**
Use only on Intel® 64 architectures.

R

(\_\_\_int64) a0

```c
_mm_cvtepi32_ps

_m128\_mm_cvtepi32\_ps(_m128i a);
```

Converts the four signed 32-bit integer values of `a` to SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(float) a0</td>
<td>(float) a1</td>

<td>0x0</td>
</tr>
</tbody>
</table>

### _mm_cvtsi64_si128

```c
__m128i _mm_cvtsi64_si128(__int64 a);
```

Moves 64-bit integer `a` to the lower 64 bits of an `__m128i` object, zeroing the upper bits.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0x0</td>
</tr>
</tbody>
</table>

### _mm_cvtsi128_si32

```c
int _mm_cvtsi128_si32(__m128i a);
```

Moves the least significant 32 bits of `a` to a 32-bit integer.

<table>
<thead>
<tr>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
</tr>
</tbody>
</table>

### _mm_cvtsi128_si64

```c
__int64 _mm_cvtsi128_si64(__m128i a);
```

Moves the lower 64 bits of `a` to a 64-bit integer.

<table>
<thead>
<tr>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
</tr>
</tbody>
</table>

### Load Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer load operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```
The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. \( R, R_0, \) and \( R_1 \) represent the registers in which results are placed.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_load_si128</td>
<td>Load</td>
<td>MOVQ</td>
</tr>
<tr>
<td>_mm_loadu_si128</td>
<td>Load</td>
<td>MOVDQU</td>
</tr>
<tr>
<td>_mm_loadl_epi64</td>
<td>Load and zero</td>
<td>MOVQ</td>
</tr>
</tbody>
</table>

**_mm_load_si128**

\[
_mm\_load\_si128(__m128i \*p);
\]

Loads 128-bit value. Address \( p \) must be 16-byte aligned.

\[
R \rightarrow *p
\]

**_mm_loadu_si128**

\[
_mm\_loadu\_si128(__m128i \*p);
\]

Loads 128-bit value. Address \( p \) not need be 16-byte aligned.

\[
R \rightarrow *p
\]

**_mm_loadl_epi64**

\[
_mm\_loadl\_epi64(__m128i \*p);
\]

Load the lower 64 bits of the value pointed to by \( p \) into the lower 64 bits of the result, zeroing the upper 64 bits of the result.

\[
R_0 \rightarrow *p[63:0] \quad R_1 \rightarrow 0x0
\]

**Set Intrinsics**

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer set operations are listed in this topic. These intrinsics are composite intrinsics because they require more than one instruction to implement them. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. \( R, R_0, R_1...R_{15} \) represent the registers in which results are placed.

**Store Intrinsics**

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer store operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The detailed description of each intrinsic contains a table detailing the returns. In these tables, \( p \) is an access to the result.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_stream_si128</td>

<td>Conditional store</td>
<td>MASKMOVDQU</td>
</tr>
<tr>
<td>_mm_storel_epi64</td>
<td>Store lowest</td>
<td>MOVQ</td>
</tr>
</tbody>
</table>

_mm_stream_si128

void _mm_stream_si128(__m128i *p, __m128i a);
Stores the data in \( a \) to the address \( p \) without polluting the caches. If the cache line containing address \( p \) is already in the cache, the cache will be updated. Address \( p \) must be 16 byte aligned.

*p

a
_mm_stream_si32
void _mm_stream_si32(int *p, int a);
Stores the data in a to the address p without polluting the caches. If the cache line containing address p is already in the cache, the cache will be updated.

*p

a

_mm_store_si128
void _mm_store_si128(__m128i *p, __m128i b);
Stores 128-bit value. Address p must be 16 byte aligned.

*p

a

_mm_storeu_si128
void _mm_storeu_si128(__m128i *p, __m128i b);
Stores 128-bit value. Address p need not be 16-byte aligned.

*p

a

_mm_maskmoveu_si128
void _mm_maskmoveu_si128(__m128i d, __m128i n, char *p);
Conditionally store byte elements of d to address p. The high bit of each byte in the selector n determines whether the corresponding byte in d will be stored. Address p need not be 16-byte aligned.

if (n0[7])
if (n1[7])
...
if (n15[7])
p[0] := d0
p[1] := d1
...

_mm_storel_epi64
void _mm_storel_epi64(__m128i *p, __m128i a);
Stores the lower 64 bits of the value pointed to by p.

*p[63:0]
a0

Miscellaneous Functions and Intrinsics
Cacheability Support Intrinsics

The prototypes for Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for cacheability support are in the emmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE2 Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_stream_pd</td>
<td>Store</td>
<td>MOVNTPD</td>
</tr>
<tr>
<td>_mm256_stream_pd</td>
<td>Store</td>
<td>VMOVNTPD</td>
</tr>
<tr>
<td>_mm_stream_si128</td>
<td>Store</td>
<td>MOVNTDQ</td>
</tr>
<tr>
<td>_mm256_stream_si256</td>
<td>Store</td>
<td>VMOVNTDQ</td>
</tr>
<tr>
<td>_mm_stream_si32</td>
<td>Store</td>
<td>MOVNTI</td>
</tr>
<tr>

<tr>
<td>_mm_lfence</td>
<td>Guarantee visibility</td>
<td>LFENCE</td>
</tr>
<tr>
<td>_mm_mfence</td>
<td>Guarantee visibility</td>
<td>MFENCE</td>
</tr>
</tbody>
</table>

_mm_stream_pd

```c
void _mm_stream_pd(double *p, __m128d a);
```

Stores the data in `a` to the address `p` without polluting caches. The address `p` must be 16-byte (128-bit version) aligned. If the cache line containing address `p` is already in the cache, the cache will be updated.

```
P[0] := a0 P[1] := a1
```

_mm256_stream_pd

```c
void _mm256_stream_pd(double *p, __m256d a);
```

Stores the data in `a` to the address `p` without polluting caches. The address `p` must be 32-byte (VEX.256 encoded version) aligned. If the cache line containing address `p` is already in the cache, the cache will be updated.

```
P[0] := a0 P[1] := a1
```
_mm_stream_si128
void _mm_stream_si128(__m128i *p, __m128i a);
Stores the data in a to the address p without polluting the caches. If the cache line containing address p is already in the cache, the cache will be updated. Address p must be 16-byte (128-bit version) aligned.

*p

a

_mm256_stream_si256
void _mm256_stream_si256(__m256i *p, __m256i a);
Stores the data in a to the address p without polluting the caches. If the cache line containing address p is already in the cache, the cache will be updated. Address p must be 32-byte (VEX.256 encoded version) aligned.

*p

a

_mm_stream_si32
void _mm_stream_si32(int *p, int a);
Stores the 32-bit integer data in a to the address p without polluting the caches. If the cache line containing address p is already in the cache, the cache will be updated.

*p

a

_mm_stream_si64
void _mm_stream_si64(__int64 *p, __int64 a);
Stores the 64-bit integer data in a to the address p without polluting the caches. If the cache line containing address p is already in the cache, the cache is updated.

*p

a

_mm_clflush
void _mm_clflush(void const*p);
Cache line containing p is flushed and invalidated from all caches in the coherency domain.

*p

a
**_mm_clflushopt**

```c
void _mm_clflushopt(void const *p);
```

Cache line containing `p` is flushed and invalidated from all caches in the coherency domain. This optimized version of the `_mm_clflush` is available if indicated by the CPUID feature flag `CLFLUSHOPT`.

```c
*p
```

**_mm_lfence**

```c
void _mm_lfence(void);
```

Guarantees that every load instruction that precedes, in program order, the load fence instruction is globally visible before any load instruction which follows the fence in program order.

**_mm_mfence**

```c
void _mm_mfence(void);
```

Guarantees that every memory access that precedes, in program order, the memory fence instruction is globally visible before any memory instruction which follows the fence in program order.

**Miscellaneous Intrinsics**

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for miscellaneous operations are listed in the following table followed by descriptions.

The prototypes for Intel® SSE intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>

</tbody>
</table>

### _mm_packs_epi16

```c
__m128i _mm_packs_epi16(__m128i a, __m128i b);
```

Packs the 16 signed 16-bit integers from `a` and `b` into 8-bit integers and saturates.

<table>
<thead>
<tr>
<th>R0</th>
<th>...</th>
<th>R7</th>
<th>R8</th>

<td></td>
</tr>
</tbody>
</table>

### _mm_packus_epi16

```c
__m128i _mm_packus_epi16(__m128i a, __m128i b);
```

Packs the 16 signed 16-bit integers from `a` and `b` into 8-bit unsigned integers and saturates.

<table>
<thead>
<tr>
<th>R0</th>
<th>...</th>
<th>R7</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Signed</td>
<td>...</td>
<td>Signed</td>
<td>...</td>
</tr>
</tbody>
</table>
**_mm_extract_epi16_**

\[
\text{int } _\text{mm\_extract\_epi16}(\_\text{m128i } a, \text{ int } \text{imm});
\]

Extracts the selected signed or unsigned 16-bit integer from \( a \) and zero extends. The selector \( \text{imm} \) must be an immediate.

```
R0
(imm == 0) ? a0: ( (imm == 1) ? a1: ... (imm==7) ? a7)
```

**_mm_insert_epi16_**

\[
\_\text{m128i } _\text{mm\_insert\_epi16}(\_\text{m128i } a, \text{ int } b, \text{ int } \text{imm});
\]

Inserts the least significant 16 bits of \( b \) into the selected 16-bit integer of \( a \). The selector \( \text{imm} \) must be an immediate.

```
R0
R1
(imm == 0) ? b : (imm == 1) ? b : ... (imm == 7) ? b :
 a0; a1; ... a7;
```

**_mm_movemask_epi8_**

\[
\text{int } _\text{mm\_movemask\_epi8}(\_\text{m128i } a);
\]

 Creates a 16-bit mask from the most significant bits of the 16 signed or unsigned 8-bit integers in \( a \) and zero extends the upper bits.

```
R0
```

**_mm_shuffle_epi32_**

\[
\_\text{m128i } _\text{mm\_shuffle\_epi32}(\_\text{m128i } a, \text{ int } \text{imm});
\]

Shuffles the four signed or unsigned 32-bit integers in \( a \) as specified by \( \text{imm} \). The shuffle value, \( \text{imm} \), must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.

**_mm_shufflehi_epi16_**

\[
\_\text{m128i } _\text{mm\_shufflehi\_epi16}(\_\text{m128i } a, \text{ int } \text{imm});
\]

Shuffles the upper four signed or unsigned 16-bit integers in \( a \) as specified by \( \text{imm} \). The shuffle value, \( \text{imm} \), must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.
_mm_shufflelo_epi16
__m128i _mm_shufflelo_epi16(__m128i a, int imm);
Shuffles the lower four signed or unsigned 16-bit integers in a as specified by imm. The shuffle value, imm, must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.

_mm_unpackhi_epi8
__m128i _mm_unpackhi_epi8(__m128i a, __m128i b);
Interleaves the upper eight signed or unsigned 8-bit integers in a with the upper eight signed or unsigned 8-bit integers in b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
<th>...</th>
<th>R14</th>
<th>R15</th>

<td>b15</td>
</tr>
</tbody>
</table>

_mm_unpackhi_epi16
__m128i _mm_unpackhi_epi16(__m128i a, __m128i b);
Interleaves the upper four signed or unsigned 16-bit integers in a with the upper four signed or unsigned 16-bit integers in b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
<th>R4</th>
<th>R5</th>
<th>R6</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>

<td>b4</td>
<td>a5</td>
<td>b5</td>
<td>a6</td>
<td>b6</td>
<td>a7</td>
<td>b7</td>
</tr>
</tbody>
</table>

_mm_unpackhi_epi32
__m128i _mm_unpackhi_epi32(__m128i a, __m128i b);
Interleaves the upper two signed or unsigned 32-bit integers in a with the upper two signed or unsigned 32-bit integers in b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a2</td>
<td>b2</td>
<td>a3</td>
<td>b3</td>
</tr>
</tbody>
</table>

_mm_unpackhi_epi64
__m128i _mm_unpackhi_epi64(__m128i a, __m128i b);
Interleaves the upper signed or unsigned 64-bit integer in a with the upper signed or unsigned 64-bit integer in b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1</td>
<td>b1</td>
</tr>
</tbody>
</table>

_mm_unpacklo_epi8
__m128i _mm_unpacklo_epi8(__m128i a, __m128i b);
Interleaves the lower eight signed or unsigned 8-bit integers in \( a \) with the lower eight signed or unsigned 8-bit integers in \( b \).

\[
\begin{array}{cccccccc}
R0 & R1 & R2 & R3 & \ldots & R14 & R15 \\
 a0 & b0 & a1 & b1 & \ldots & a7 & b7 \\
\end{array}
\]

\textit{\_mm\_unpacklo\_epi16}

\texttt{\_m128i \_mm\_unpacklo\_epi16(\_m128i a, \_m128i b);} 

Interleaves the lower four signed or unsigned 16-bit integers in \( a \) with the lower four signed or unsigned 16-bit integers in \( b \).

\[
\begin{array}{cccccccc}
R0 & R1 & R2 & R3 & R4 & R5 & R6 & R7 \\
 a0 & b0 & a1 & b1 & a2 & b2 & a3 & b3 \\
\end{array}
\]

\textit{\_mm\_unpacklo\_epi32}

\texttt{\_m128i \_mm\_unpacklo\_epi32(\_m128i a, \_m128i b);} 

Interleaves the lower two signed or unsigned 32-bit integers in \( a \) with the lower two signed or unsigned 32-bit integers in \( b \).

\[
\begin{array}{cccc}
R0 & R1 & R2 & R3 \\
 a0 & b0 & a1 & b1 \\
\end{array}
\]

\textit{\_mm\_unpacklo\_epi64}

\texttt{\_m128i \_mm\_unpacklo\_epi64(\_m128i a, \_m128i b);} 

Interleaves the lower signed or unsigned 64-bit integer in \( a \) with the lower signed or unsigned 64-bit integer in \( b \).

\[
\begin{array}{c}
R0 & R1 \\
 a0 & b0 \\
\end{array}
\]

\textit{\_mm\_movepi64\_pi64}

\texttt{\_m64 \_mm\_movepi64\_pi64(\_m128i a);} 

Returns the lower 64 bits of \( a \) as an \_m64 type.

\[
\begin{array}{c}
R0 \\
a0 \\
\end{array}
\]

\textit{\_mm\_movpi64\_pi64}

\texttt{\_m128i \_mm\_movpi64\_pi64(\_m64 a);} 

Moves the 64 bits of \( a \) to the lower 64 bits of the result, zeroing the upper bits.
_mm_move_epi64

__m128i _mm_move_epi64(__m128i a);

Moves the lower 64 bits of a to the lower 64 bits of the result, zeroing the upper bits.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>

<td>a0</td>
<td>0X0</td>
</tr>
</tbody>
</table>

_mm_unpackhi_pd

__m128d _mm_unpackhi_pd(__m128d a, __m128d b);

Interleaves the upper DP FP values of a and b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1</td>
<td>b1</td>
</tr>
</tbody>
</table>

_mm_unpacklo_pd

__m128d _mm_unpacklo_pd(__m128d a, __m128d b);

Interleaves the lower DP FP values of a and b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>b0</td>
</tr>
</tbody>
</table>

_mm_movemask_pd

int _mm_movemask_pd(__m128d a);

Creates a two-bit mask from the sign bits of the two DP FP values of a.

<table>
<thead>
<tr>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>sign(a1) &lt;&lt; 1</td>
</tr>
</tbody>
</table>

_mm_shuffle_pd

__m128d _mm_shuffle_pd(__m128d a, __m128d b, int i)

Selects two specific DP FP values from a and b, based on the mask i. The mask must be an immediate. See Macro Function for Shuffle for a description of the shuffle semantics.

Casting Support Intrinsics

Intel® C++ Compiler supports casting between various single-precision, double-precision, and integer vector types. These intrinsics do not convert values; they change one data type to another without changing the value.
The intrinsics for casting support do not have any corresponding Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions. The syntax for the Casting Support intrinsics are as follows:

```
__m128 _mm_castpd_ps(__m128d in);
__m128i _mm_castpd_si128(__m128d in);
__m128d _mm_castps_pd(__m128 in);
__m128i _mm_castps_si128(__m128 in);
__m128 _mm_castsi128_ps(__m128i in);
__m128d _mm_castsi128_pd(__m128i in);
```

**Pause Intrinsic**

The prototype for this Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsic is in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

**PAUSE Intrinsic**

```
void _mm_pause(void);
```

The `pause` intrinsic is used in spin-wait loops with the processors implementing dynamic execution (especially out-of-order execution). In the spin-wait loop, the `pause` intrinsic improves the speed at which the code detects the release of the lock and provides especially significant performance gain.

The execution of the next instruction is delayed for an implementation-specific amount of time. The `PAUSE` instruction does not modify the architectural state. For dynamic scheduling, the `PAUSE` instruction reduces the penalty of exiting from the spin-loop.

**Example of loop with the PAUSE instruction:**

In this example, the program spins until memory location A matches the value in register eax. The code sequence that follows shows a test-and-test-and-set.

```
spin_loop:pause
cmp eax, A
jne spin_loop
```

In this example, the spin occurs only after the attempt to get a lock has failed.

```
get_lock: mov eax, 1
xchg eax, A ; Try to get lock
cmp eax, 0 ; Test if successful
jne spin_loop
```

**Critical Section**

```
// critical_section code
mov A, 0 ; Release lock
jmp continue
spin_loop: pause;
// spin-loop hint
cmp 0, A ;
// check lock availability
```
jne spin_loop
jmp get_lock
// continue: other code

NOTE
The first branch is predicted to fall-through to the critical section in anticipation of successfully gaining access to the lock. It is highly recommended that all spin-wait loops include the PAUSE instruction. Since PAUSE is backwards compatible to all existing IA-32 architecture-based processor generations, a test for processor type (a CPUID test) is not needed. All legacy processors execute PAUSE instruction as a NOP, but in processors that use the PAUSE instruction as a hint there can be significant performance benefit.

Macro Function for Shuffle
Intel® Streaming SIMD Extensions 2 (Intel® SSE2) provide a macro function to help create constants that describe shuffle operations. The macro takes two small integers (in the range of 0 to 1) and combines them into an 2-bit immediate value used by the SHUFPD instruction. See the following example.

You can view the two integers as selectors for choosing which two words from the first input operand and which two words from the second are to be put into the result word.

View of Original and Result Words with Shuffle Function Macro

Intrinsics Returning Vectors of Undefined Values
These intrinsics generate vectors of undefined values. The result of the intrinsics is usually used as an argument to another intrinsic that requires all operands to be initialized, and when the content of a particular argument does not matter.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

For example, you can use such an intrinsic when you need to calculate a sum of packed double-precision floating-point values located in the `xmm` register. To avoid unnecessary moves, you can use the following code to obtain the required result at the low 64 bits:

```c
__m128d HILO    = doSomeWork();
__m128d HI = _mm_unpackhi_pd(HILO, _mm_undefined_pd());
__m128d result = _mm_add_sd(HI, HILO);
```

### _mm_undefined_pd

```c
extern __m128d _mm_undefined_pd(void);
```

Returns a vector of two double precision floating point elements. The content of the vector is not specified.

### _mm_undefined_si128

```c
extern __m128i _mm_undefined_si128(void);
```

Returns a vector of four packed doubleword integer elements. The content of the vector is not specified.

**See Also**

- `_mm256_undefined_si128()` Returns a vector of eight packed doubleword integer elements. No corresponding Intel® AVX instruction.
- `_mm256_undefined_pd()` Returns a vector of four double precision floating point elements. No corresponding Intel® AVX instruction.

## Intrinsics for Intel® Streaming SIMD Extensions (Intel® SSE)

### Overview: Intel® Streaming SIMD Extensions (Intel® SSE)

This section describes the C++ language-level features supporting the Intel® Streaming SIMD Extensions (Intel® SSE) in the Intel® C++ Compiler. The prototypes for Intel® SSE intrinsics are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The following topics summarize these intrinsics:

- Floating Point Intrinsics
- Arithmetic Operation Intrinsics
- Logical Operation Intrinsics
- Comparison Intrinsics
- Conversion Intrinsics
- Load Operations
- Set Operations
- Store Operations
- Cacheability Support
- Integer Intrinsics
- Intrinsics to Read and Write Registers
- Miscellaneous Intrinsics
Details about Intel® Streaming SIMD Extensions Intrinsics

Intel® Streaming SIMD Extensions (Intel® SSE) instructions use the following features:

- Registers – Enable packed data of up to 128 bits in length for optimal SIMD processing
- Data Types – Enable packing of up to 16 elements of data in one register

Registers

Intel® Streaming SIMD Extensions use eight 128-bit registers (XMM0 to XMM7).

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data processing (SIMD).

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

**NOTE**
The MM and XMM registers are the SIMD registers used by the systems based on IA-32 architecture to implement MMX™ technology and Intel® SSE or Intel® Streaming SIMD Extensions 2 (Intel® SSE2).

Data Types

These intrinsic functions use four new C data types as operands, representing the new registers that are used as the operands to these intrinsic functions.

New Data Types

The following table details for which instructions each of the new data types are available.

<table>
<thead>
<tr>
<th>New Data Type</th>
<th>Intel® Streaming SIMD Extensions Intrinsics</th>

</tr>
<tr>
<td>__m128i</td>
<td>Not available</td>
<td>Available</td>
<td>Available</td>
</tr>
</tbody>
</table>

**__m128 Data Types**

The __m128 data type is used to represent the contents of a Intel® SSE register used by Intel® SSE intrinsics. The __m128 data type can hold four 32-bit floating-point values.

The __m128d data type can hold two 64-bit floating-point values.

The __m128i data type can hold sixteen 8-bit, eight 16-bit, four 32-bit, or two 64-bit integer values.

The compiler aligns __m128d and __m128i local and global data to 16-byte boundaries on the stack. To align integer, float, or double arrays, you can use the __declspec(align) statement.
Data Types Usage Guidelines

These data types are not basic ANSI C data types. You must observe the following usage restrictions:

- Use data types only on either side of an assignment, as a return value, or as a parameter. You cannot use it with other arithmetic expressions (+, -, etc).
- Use data types as objects in aggregates, such as unions, to access the byte elements and structures.
- Use data types only with the respective intrinsics described in this documentation.

Accessing __m128i Data

To access 8-bit data:

```c
#define _mm_extract_epi8(x, imm) 
    (((imm) & 0x1) == 0) ? 
      _mm_extract_epi16((x), (imm) >> 1) & 0xff : 
      _mm_extract_epi16(_mm_srli_epi16((x), 8), (imm) >> 1))
```

For 16-bit data, use the following intrinsic:

```c
int _mm_extract_epi16(__m128i a, int imm)
```

To access 32-bit data:

```c
#define _mm_extract_epi32(x, imm) 
    _mm_cvtsi128_si32(_mm_srli_epi16((x), 4 * (imm)))
```

See Also
__declspec(align) declaration

Writing Programs with Intel® Streaming SIMD Extensions (Intel® SSE) Intrinsics

You should be familiar with the hardware features provided by Intel® Streaming SIMD Extensions (Intel® SSE) when writing programs with the intrinsics. The following are four important issues to keep in mind:

- Certain intrinsics, such as _mm_loadr_ps and _mm_cmpgt_ss, are not directly supported by the instruction set. While these intrinsics are convenient programming aids, be mindful that they may consist of more than one machine-language instruction.
- Floating-point data loaded or stored as __m128 objects must be generally 16-byte-aligned.
- Some intrinsics require that their argument be immediates, that is, constant integers (literals), due to the nature of the instruction.
- The result of arithmetic operations acting on two NaN (Not a Number) arguments is undefined. Therefore, FP operations using NaN arguments will not match the expected behavior of the corresponding assembly instructions.

Arithmetic Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for arithmetic operations are in the xmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

**Compare Intrinsics**

The prototypes for Intel\(^\text{®}\) Streaming SIMD Extensions (Intel\(^\text{®}\) SSE) intrinsics for comparison operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

Each comparison intrinsic performs a comparison of \(a\) and \(b\). For the packed form, the four single-precision FP values of \(a\) and \(b\) are compared, and a 128-bit mask is returned. For the scalar form, the lower single-precision FP values of \(a\) and \(b\) are compared, and a 32-bit mask is returned; the upper three single-precision FP values are passed through from \(a\). The mask is set to \(0xffffffff\) for each element where the comparison is true and \(0x0\) where the comparison is false.

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R or R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Compares the lower SP FP value of \textit{a} and \textit{b} for \textit{a} not equal to \textit{b}. If \textit{a} and \textit{b} are not equal, 1 is returned. Otherwise, 0 is returned.

R
r := (a0 != b0) ? 0x1 : 0x0

Conversion Intrinsics
The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for conversion operations are in the \texttt{xmmintrin.h} header file.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

\texttt{
#include <immintrin.h>
}
The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R or R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Intrinsics marked with * are available only on Intel® 64 architecture. The rest of the intrinsics can be implemented on both IA-32 and Intel® 64 architectures.

### _mm_cvtpu16_ps

```c
__m128 __m128_cvtpu16_ps(__m64 a);
```

Converts the four 16-bit unsigned integer values in `a` to four SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(float)a0</td>
<td>(float)a1</td>
<td>(float)a2</td>
<td>(float)a3</td>
</tr>
</tbody>
</table>
`_mm_cvtpi8_ps`

```c
__m128 _mm_cvtpi8_ps(__m64 a);
```

Converts the lower four 8-bit signed integer values in `a` to four SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(float)a0</td>
<td>(float)a1</td>
<td>(float)a2</td>
<td>(float)a3</td>
</tr>
</tbody>
</table>

`_mm_cvtpu8_ps`

```c
__m128 _mm_cvtpu8_ps(__m64 a);
```

Converts the lower four 8-bit unsigned integer values in `a` to four SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(float)a0</td>
<td>(float)a1</td>
<td>(float)a2</td>
<td>(float)a3</td>
</tr>
</tbody>
</table>

`_mm_cvtpi32x2_ps`

```c
__m128 _mm_cvtpi32x2_ps(__m64 a, __m64 b);
```

Converts the two 32-bit signed integer values in `a` and the two 32-bit signed integer values in `b` to four SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(float)a0</td>
<td>(float)a1</td>
<td>(float)b0</td>
<td>(float)b1</td>
</tr>
</tbody>
</table>

`_mm_cvtps_pi16`

```c
__m64 _mm_cvtps_pi16(__m128 a);
```

Converts the four SP FP values in `a` to four signed 16-bit integer values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(short)a0</td>
<td>(short)a1</td>
<td>(short)a2</td>
<td>(short)a3</td>
</tr>
</tbody>
</table>

`_mm_cvtps_pi8`

```c
__m64 _mm_cvtps_pi8(__m128 a);
```

Converts the four SP FP values in `a` to the lower four signed 8-bit integer values of the result.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(char)a0</td>
<td>(char)a1</td>
<td>(char)a2</td>
<td>(char)a3</td>
</tr>
</tbody>
</table>

`_mm_cvtsf32`

```c
float _mm_cvtsf32(__m128 a);
```

Extracts a SP floating-point value from the first vector element of an __m128. It does so in the most efficient manner possible in the context used.
Load Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for load operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_loadh_pi</td>
<td>Load high</td>
<td>MOVHPS reg, mem</td>
</tr>
<tr>
<td>_mm_loadl_pi</td>
<td>Load low</td>
<td>MOVLPS reg, mem</td>
</tr>
<tr>
<td>_mm_load_ss</td>
<td>Load the low value and clear the three high values</td>
<td>MOVSS</td>
</tr>
<tr>
<td>_mm_loadl_ps</td>
<td>Load one value into all four words</td>
<td>MOVSS + Shuffling</td>
</tr>
<tr>
<td>_mm_load_ps</td>
<td>Load four values, address aligned</td>
<td>MOVAPS</td>
</tr>
<tr>
<td>_mm_loadu_ps</td>
<td>Load four values, address unaligned</td>
<td>MOVPFS</td>
</tr>
<tr>
<td>_mm_loadr_ps</td>
<td>Load four values in reverse</td>
<td>MOVAPS + Shuffling</td>
</tr>
</tbody>
</table>

**_mm_loadh_pi**

```c
__m128 _mm_loadh_pi(__m128 a, __m64 const *p);
```

Sets the upper two SP FP values with 64 bits of data loaded from the address `p`; the lower two values are passed through from `a`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
<td>*p0</td>
<td>*p1</td>
</tr>
</tbody>
</table>

**_mm_loadl_pi**

```c
__m128 _mm_loadl_pi(__m128 a, __m64 const *p);
```

Sets the lower two SP FP values with 64 bits of data loaded from the address `p`; the upper two values are passed through from `a`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
<td>*p0</td>
<td>*p1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>*p0</td>
<td>*p1</td>
<td>a2</td>
<td>a3</td>
</tr>
</tbody>
</table>
**_mm_load_ss**

`__m128 _mm_load_ss(float * p);`

Loads a SP FP value into the low word and clears the upper three words.

<table>
<thead>
<tr>
<th></th>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>*p</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td></td>
</tr>
</tbody>
</table>

**_mm_load1_ps**

`__m128 _mm_load1_ps(float * p);`

Loads a SP FP value, copying it into all four words.

<table>
<thead>
<tr>
<th></th>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>*p</td>
<td>*p</td>
<td>*p</td>
<td>*p</td>
<td></td>
</tr>
</tbody>
</table>

**_mm_load_ps**

`__m128 _mm_load_ps(float * p);`

Loads four SP FP values. The address must be 16-byte-aligned.

<table>
<thead>
<tr>
<th></th>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
</table>

**_mm_loadu_ps**

`__m128 _mm_loadu_ps(float * p);`

Loads four SP FP values. The address need not be 16-byte-aligned.

<table>
<thead>
<tr>
<th></th>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
</table>

**_mm_loadr_ps**

`__m128 _mm_loadr_ps(float * p);`

Loads four SP FP values in reverse order. The address must be 16-byte-aligned.

<table>
<thead>
<tr>
<th></th>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
</table>

**Set Intrinsics**

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for set operations are in the `xmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R0, R1, R2, and R3 represent the registers in which results are placed.

### Intrinsic Name | Operation | Corresponding Intel® SSE Instruction
---|---|---
_mm_set_ss | Set the low value and clear the three high values | Composite
_mm_set1_ps | Set all four words with the same value | Composite
_mm_set_ps | Set four values, address aligned | Composite
_mm_setr_ps | Set four values, in reverse order | Composite
_mm_setzero_ps | Clear all four values | Composite

#### _mm_set_ss

```c
__m128 __m128_mm_set_ss(float w);
```

Sets the low word of a SP FP value to `w` and clears the upper three words.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>w</code></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

#### _mm_set1_ps

```c
__m128 __m128_mm_set1_ps(float w);
```

Sets the four SP FP values to `w`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>w</code></td>
<td><code>w</code></td>
<td><code>w</code></td>
<td><code>w</code></td>
</tr>
</tbody>
</table>

#### _mm_set_ps

```c
__m128 __m128_mm_set_ps(float z, float y, float x, float w);
```

Sets the four SP FP values to the inputs `w`, `x`, `y`, and `z`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>w</code></td>
<td><code>x</code></td>
<td><code>y</code></td>
<td><code>z</code></td>
</tr>
</tbody>
</table>

#### _mm_setr_ps

```c
__m128 __m128_mm_setr_ps(float z, float y, float x, float w);
```

Sets the four SP FP values to the inputs `w`, `x`, `y`, and `z` in reverse order.
### _mm_setzero_ps

```c
__m128 _mm_setzero_ps(void);
```

Clears the four SP FP values.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>z</td>
<td>y</td>
<td>x</td>
<td>w</td>
</tr>
</tbody>
</table>

---

### Store Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for store operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The description for each intrinsic contains a table detailing the returns. In these tables, `p[n]` is an access to the `n` element of the result.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_storeh_pi</td>
<td>Store high</td>
<td>MOVHPS mem, reg</td>
</tr>
<tr>
<td>_mm_storel_pi</td>
<td>Store low</td>
<td>MOVLPS mem, reg</td>
</tr>
<tr>
<td>_mm_store_ss</td>
<td>Store the low value</td>
<td>MOVSS</td>
</tr>
<tr>
<td>_mm_storel_ps</td>
<td>Store the low value across all four words, address aligned</td>
<td>Shuffling + MOVSS</td>
</tr>
<tr>
<td>_mm_store_ps</td>
<td>Store four values, address aligned</td>
<td>MOVAPS</td>
</tr>
<tr>
<td>_mm_storeu_ps</td>
<td>Store four values, address unaligned</td>
<td>MOVUPS</td>
</tr>
<tr>
<td>_mm_storer_ps</td>
<td>Store four values, in reverse order</td>
<td>MOVAPS + Shuffling</td>
</tr>
</tbody>
</table>

---

### _mm_storeh_pi

```c
void _mm_storeh_pi(__m64 *p, __m128 a);
```

Stores the upper two SP FP values to the address `p`.

<table>
<thead>
<tr>
<th>*p0</th>
<th>*p1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a2</td>
<td>a3</td>
</tr>
</tbody>
</table>

---

1668
__mm_storel_pi

void __mm_storel_pi(__m64 *p, __m128 a);
Stores the lower two SP FP values of `a` to the address `p`.

<table>
<thead>
<tr>
<th>*p0</th>
<th>*p1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
</tr>
</tbody>
</table>

__mm_store_ss

void __mm_store_ss(float * p, __m128 a);
Stores the lower SP FP value.

<table>
<thead>
<tr>
<th>*p</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
</tr>
</tbody>
</table>

__mm_store1_ps

void __mm_store1_ps(float * p, __m128 a);
Stores the lower SP FP value across four words.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a0</td>
<td>a0</td>
<td>a0</td>
</tr>
</tbody>
</table>

__mm_store_ps

void __mm_store_ps(float *p, __m128 a);
Stores four SP FP values. The address must be 16-byte-aligned.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
<td>a2</td>
<td>a3</td>
</tr>
</tbody>
</table>

__mm_storeu_ps

void __mm_storeu_ps(float *p, __m128 a);
Stores four SP FP values. The address need not be 16-byte-aligned.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
<td>a2</td>
<td>a3</td>
</tr>
</tbody>
</table>

__mm_storer_ps

void __mm_storer_ps(float * p, __m128 a);
Stores four SP FP values in reverse order. The address must be 16-byte-aligned.
Cacheability Support Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for cacheability support are in the xmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding Intel® SSE Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_prefetch</td>
<td>Load</td>
<td>PREFETCH</td>
</tr>
<tr>
<td>_mm_stream_pi</td>
<td>Store</td>
<td>MOVNTQ</td>
</tr>
<tr>
<td>_mm_stream_ps</td>
<td>Store</td>
<td>MOVNTPS</td>
</tr>
<tr>
<td>_mm256_stream_ps</td>
<td>Store</td>
<td>VMOVNTPS</td>
</tr>
<tr>
<td>_mm_sfence</td>
<td>Store fence</td>
<td>SFENCE</td>
</tr>
</tbody>
</table>

_mm_prefetch

void _mm_prefetch(char const*a, int sel);

Loads one cache line of data from address a to a location "closer" to the processor. The value sel specifies the type of prefetch operation: the constants _MM_HINT_T0, _MM_HINT_T1, _MM_HINT_T2, _MM_HINT_NTA, and _MM_HINT_ET0 should be used for systems based on IA-32 architecture, and correspond to the type of prefetch instruction.

**NOTE**
The _MM_HINT_ET0 hint lowers the intrinsic being to the instruction PREFETCHW, which is not included in Intel® SSE instructions. Check if the target CPU supports the PREFETCHW instruction before using _MM_HINT_ET0.

_mm_stream_pi

void _mm_stream_pi(__m64 *p, __m64 a);

Stores the data in a to the address p without polluting the caches. This intrinsic requires you to empty the multimedia state for the MMX™ register. See the topic The EMMS Instruction: Why You Need It.

_mm_stream_ps

void _mm_stream_ps(float *p, __m128 a);

Stores the data in a to the address p without polluting the caches. The address must be 16-byte-aligned.
_mm256_stream_ps
void _mm256_stream_ps(float *p, __m256 a);
Stores the data in a to the address p without polluting the caches. The address must be 32-byte (VEX.256 encoded version) aligned.

_mm_sfence
void _mm_sfence(void);
Guarantees that every preceding store is globally visible before any subsequent store.

The EMMS Instruction: Why You Need It

Integer Intrinsics
The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for integer operations are in the xmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R, R0, R1, ..., R7 represent the registers in which results are placed.

Before using these intrinsics, you must empty the multimedia state for the MMX™ technology register. See The EMMS Instruction: Why You Need It for more details.

</tbody>
</table>

_mm_extract_pi16

```c
int _mm_extract_pi16(__m64 a, int n);
```

Extracts one of the four words of `a`. The selector `n` must be an immediate.

```c
R
(n==0) ? a0 : ( (n==1) ? a1 : ( (n==2) ? a2 : a3 ) )
```

_mm_insert_pi16

```c
__m64 _mm_insert_pi16(__m64 a, int d, int n);
```

Inserts word `d` into one of four words of `a`. The selector `n` must be an immediate.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n==0) ? d : a0;</td>
<td>(n==1) ? d : a1;</td>
<td>(n==2) ? d : a2;</td>
<td>(n==3) ? d : a3;</td>
</tr>
</tbody>
</table>

_mm_max_pi16

```c
__m64 _mm_max_pi16(__m64 a, __m64 b);
```

Computes the element-wise maximum of the words in `a` and `b`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>min(a0, b0)</td>
<td>min(a1, b1)</td>
<td>min(a2, b2)</td>
<td>min(a3, b3)</td>
</tr>
</tbody>
</table>

_mm_max_pu8

```c
__m64 _mm_max_pu8(__m64 a, __m64 b);
```

Computes the element-wise maximum of the unsigned bytes in `a` and `b`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>...</th>
<th>R7</th>
</tr>
</thead>
<tbody>
<tr>
<td>min(a0, b0)</td>
<td>min(a1, b1)</td>

<td>min(a7, b7)</td>
</tr>
</tbody>
</table>

_mm_min_pi16

```c
__m64 _mm_min_pi16(__m64 a, __m64 b);
```

Computes the element-wise minimum of the words in `a` and `b`.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>min(a0, b0)</td>
<td>min(a1, b1)</td>
<td>min(a2, b2)</td>
<td>min(a3, b3)</td>
</tr>
</tbody>
</table>
_mm_min_pu8
__m64 _mm_min_pu8(__m64 a, __m64 b);
Computes the element-wise minimum of the unsigned bytes in a and b.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>

<td>...</td>
<td>min(a7, b7)</td>
</tr>
</tbody>
</table>

_mm_movemask_pi8
__m64 _mm_movemask_pi8(__m64 b);
Creates an 8-bit mask from the most significant bits of the bytes in a.

R
sign(a7)<<7 | sign(a6)<<6 |... | sign(a0)

_mm_mulhi_pu16
__m64 _mm_mulhi_pu16(__m64 a, __m64 b);
Multiplies the unsigned words in a and b, returning the upper 16 bits of the 32-bit intermediate results.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<td>hiword(a3 * b3)</td>
</tr>
</tbody>
</table>

_mm_shuffle_pi16
__m64 _mm_shuffle_pi16(__m64 a, int n);
Returns a combination of the four words of a. The selector n must be an immediate.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>R0</td>
<td>R1</td>
<td>R2</td>

<td>word ((n&gt;&gt;4)&amp;0x3) of a</td>
<td>word ((n&gt;&gt;6)&amp;0x3) of a</td>
</tr>
</tbody>
</table>

_mm_maskmove_si64
void _mm_maskmove_si64(__m64 d, __m64 n, char *p);
Conditionally stores byte elements of d to address p. The high bit of each byte in the selector p determines whether the corresponding byte in d will be stored.

if (sign(n0)) if (sign(n1)) ... if (sign(n7))

_mm_avg_pu8
__m64 _mm_avg_pu8(__m64 a, __m64 b);
Computes the (rounded) averages of the unsigned bytes in a and b.
R0        R1        ...        R7

(t >> 1) | (t & 0x01), where t = 0x01), where t =
(unsigned char)a0 + (unsigned char)a1 +
(unsigned char)b0 (unsigned char)b1

((t >> 1) | (t & 0x01), where t =
(unsigned char)a7 +
(unsigned char)b7

_mm_avg_pu16
__m64 _mm_avg_pu16(__m64 a, __m64 b);

Computes the (rounded) averages of the unsigned short in a and b.

R0        R1        ...        R7

(t >> 1) | (t & 0x01), where t = 0x01), where t =
(unsigned int)a0 + (unsigned int)a1 +
(unsigned int)b0 (unsigned int)b1

(t >> 1) | (t & 0x01), where t =
(unsigned int)a7 +
(unsigned int)b7

_mm_sad_pu8
__m64 _mm_sad_pu8(__m64 a, __m64 b);

Computes the sum of the absolute differences of the unsigned bytes in a and b, returning the value in the lower word. The upper three words are cleared.

R0        R1        R2        R3

abs(a0-b0) +... +
abs(a7-b7)

Intrinsics to Read and Write Registers

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics to read from and write to registers are in the <xmmintrin.h> header file.

To use these intrinsics, include the <immintrin.h> file as follows:

#include <immintrin.h>

Intrinsic Name          Operation                      Corresponding Intel® SSE Instruction
------------------------------------------------------------------------
_mm_getcsr              Return control register          STMXCSR
_mm_setcsr              Set control register            LDMXCSR

_mm_getcsr
unsigned int _mm_getcsr(void);

Returns the contents of the control register.
_mm_setcsr

void _mm_setcsr(unsigned int i);
Sets the control register to the value specified by i.

Miscellaneous Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for miscellaneous operations are in the xmmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R, R0, R1, R2, and R3 represent the registers in which results are placed.

<table>
<thead>

<tr>
<td>_mm_undefined_ps</td>
<td>Return vector of type __m128 with undefined elements.</td>
<td>This is a utility intrinsic that returns some arbitrary value.</td>
</tr>
</tbody>
</table>

_mm_shuffle_ps

__m128 _mm_shuffle_ps(__m128 a, __m128 b, unsigned int imm8);
Selects four specific SP FP values from a and b, based on the mask `imm8`. The mask must be an immediate. See Macro Function for Shuffle Using Intel® Streaming SIMD Extensions for a description of the shuffle semantics.

_mm_unpackhi_ps

__m128 _mm_unpackhi_ps(__m128 a, __m128 b);
Selects and interleaves the upper two SP FP values from a and b.
_mm_unpacklo_ps
__m128 _mm_unpacklo_ps(__m128 a, __m128 b);
Selects and interleaves the lower two SP FP values from a and b.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>b0</td>
<td>a1</td>
<td>b1</td>
</tr>
</tbody>
</table>

_mm_move_ss
__m128 _mm_move_ss(__m128 a, __m128 b);
Sets the low word to the SP FP value of b. The upper three SP FP values are passed through from a.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>

<td>a2</td>
<td>a3</td>
</tr>
</tbody>
</table>

_mm_movelh_ps
__m128 _mm_movelh_ps(__m128 a, __m128 b);
Moves the lower two SP FP values of b to the upper two SP FP values of the result. The lower two SP FP values of a are passed through to the result.

<table>
<thead>
<tr>
<th>R0</th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a0</td>
<td>a1</td>
<td>b0</td>
<td>b1</td>
</tr>
</tbody>
</table>

_mm_movemask_ps
int _mm_movemask_ps(__m128 a);
Creates a 4-bit mask from the most significant bits of the four SP FP values.

<table>
<thead>
<tr>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>sign(a3)&lt;&lt;3</td>
</tr>
</tbody>
</table>

_mm_undefined_ps
extern __m128 _mm_undefined_ps(void);
Returns a vector of four single precision floating point elements. The content of the vector is not specified. The result is usually used as an argument to another intrinsic that requires all operands to be initialized, and when the content of a particular argument does not matter. This intrinsic is declared in the `immintrin.h` header file. It typically maps to a read of some XMM register and gets whatever value happens to live in that register at the time of the read.

For example, you can use such an intrinsic when you need to calculate a sum of packed double-precision floating-point values located in the `xmm` register.

**See Also**
Macro Function for Shuffle Using Intel® Streaming SIMD Extensions

`_mm256_undefined_ps()` Returns a vector of eight single precision floating point elements. No corresponding Intel® AVX instruction.

**Macro Functions**

**Macro Function for Shuffle Operations**

Intel® Streaming SIMD Extensions (Intel® SSE) provide a macro function to help create constants that describe shuffle operations. The macro takes four small integers (in the range of 0 to 3) and combines them into an 8-bit immediate value used by the `SHUFPS` instruction.

**Shuffle Function Macro**

You can view the four integers as selectors for choosing which two words from the first input operand and which two words from the second are to be put into the result word.

**View of Original and Result Words with Shuffle Function Macro**

**Macro Functions to Read and Write Control Registers**

The following macro functions enable you to read and write bits to and from the control register.
### Exception State Macros

<table>
<thead>
<tr>
<th>Macro Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MM_EXCEPT_INVALID</td>
</tr>
<tr>
<td>_MM_EXCEPT_DIV_ZERO</td>
</tr>
<tr>
<td>_MM_EXCEPT_DENORM</td>
</tr>
<tr>
<td>_MM_EXCEPT_OVERFLOW</td>
</tr>
<tr>
<td>_MM_EXCEPT_UNDERFLOW</td>
</tr>
<tr>
<td>_MM_EXCEPT_INEXACT</td>
</tr>
</tbody>
</table>

#### Macro Definitions
Write to and read from the six least significant control register bits, respectively.

The following example tests for a divide-by-zero exception.

#### Exception State Macros with _MM_EXCEPT_DIV_ZERO

```c
if (_MM_GET_EXCEPTION_STATE(x) & _MM_EXCEPT_DIV_ZERO) {
  /* Exception has occurred */
}
```

### Exception Mask Macros

<table>
<thead>
<tr>
<th>Macro Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MM_MASK_INVALID</td>
</tr>
<tr>
<td>_MM_MASK_DIV_ZERO</td>
</tr>
<tr>
<td>_MM_MASK_DENORM</td>
</tr>
<tr>
<td>_MM_MASK_OVERFLOW</td>
</tr>
<tr>
<td>_MM_MASK_UNDERFLOW</td>
</tr>
<tr>
<td>_MM_MASK_INEXACT</td>
</tr>
</tbody>
</table>

#### Macro Definitions
Write to and read from bit 7 – 12 control register bits, respectively.

**NOTE**

All six exception mask bits are always affected. Bits not set explicitly are cleared.

To mask the overflow and underflow exceptions and unmask all other exceptions, use the macros as follows:

```c
_MM_SET_EXCEPTION_MASK(_MM_MASK_OVERFLOW | _MM_MASK_UNDERFLOW)
```

The following table lists the macros to set and get rounding modes, and the macro arguments that can be passed with the macros.
### Rounding Mode

<table>
<thead>
<tr>
<th>Macro Definition</th>
<th>Macro Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MM_SET_ROUNDING_MODE(x)</td>
<td>_MM_ROUND_NEAREST</td>
</tr>
<tr>
<td>_MM_GET_ROUNDING_MODE()</td>
<td>_MM_ROUND_DOWN</td>
</tr>
<tr>
<td>_MM_ROUND_UP</td>
<td></td>
</tr>
<tr>
<td>_MM_ROUND_TOWARD_ZERO</td>
<td></td>
</tr>
</tbody>
</table>

#### To test the rounding mode for round toward zero, use the _MM_ROUND_TOWARD_ZERO macro as follows.

```c
if (_MM_GET_ROUNDING_MODE() == _MM_ROUND_TOWARD_ZERO) {
    /* Rounding mode is round toward zero */
}
```

The following table lists the macros to set and get the flush-to-zero mode and the macro arguments that can be used.

### Flush-to-Zero Mode

<table>
<thead>
<tr>
<th>Macro Definition</th>
<th>Macro Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MM_SET_FLUSH_ZERO_MODE(x)</td>
<td>_MM_FLUSH_ZERO_ON</td>
</tr>
<tr>
<td>_MM_GET_FLUSH_ZERO_MODE()</td>
<td>_MM_FLUSH_ZERO_OFF</td>
</tr>
</tbody>
</table>

#### To disable the flush-to-zero mode, use the _MM_FLUSH_ZERO_OFF macro.

```c
_MM_SET_FLUSH_ZERO_MODE(_MM_FLUSH_ZERO_OFF)
```

### See Also

- Intrinsics to Read and Write Registers
- Intel® Streaming SIMD Extensions (Intel® SSE) provide the following macro function to transpose a 4 by 4 matrix of single precision floating point values.

```c
_MM_TRANSPOSE4_PS(row0, row1, row2, row3)
```

The arguments `row0`, `row1`, `row2`, and `row3` are _m128 values whose elements form the corresponding rows of a 4 by 4 matrix. The matrix transposition is returned in arguments `row0`, `row1`, `row2`, and `row3` where `row0` now holds column 0 of the original matrix, `row1` now holds column 1 of the original matrix, and so on.

The transposition function of this macro is illustrated in the figure below.
Matrix Transposition Using _MM_TRANSPOSE4_PS Macro

![Matrix Transposition Using _MM_TRANSPOSE4_PS Macro](image)

Intrinsics for MMX™ Technology

Overview: Intrinsics for MMX™ Technology

MMX™ technology is an extension to the Intel® architecture instruction set. The MMX™ instruction set adds 57 opcodes and a 64-bit quadword data type, and eight 64-bit registers. Each of the eight registers can be directly addressed using the register names MM0 to MM7.

The prototypes for MMX™ technology intrinsics are in the mmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

Details about MMX™ Technology Intrinsics

The MMX™ technology instructions use the following features:

- **Registers** – Enable packed data of up to 128 bits in length for optimal single-instruction multiple data (SIMD) processing.
- **Data Types** – Enable packing of up to 16 elements of data in one register.

Registers

The MMX™ instructions use eight 64-bit registers (mm0 to mm7) which are aliased on the floating-point stack registers.

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data (SIMD) processing.

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.
**Data Types**

Intrinsic functions use four new C data types as operands, representing the new registers that are used as the operands to these intrinsic functions.

**__m64 Data Type**

The __m64 data type is used to represent the contents of an MMX™ register, which is the register that is used by the MMX™ technology intrinsics. The __m64 data type can hold eight 8-bit values, four 16-bit values, two 32-bit values, or one 64-bit value.

**Data Types Usage Guidelines**

These data types are not basic ANSI C data types. You must observe the following usage restrictions:

- Use data types only on either side of an assignment, as a return value, or as a parameter. You cannot use it with other arithmetic expressions (+, -, etc).
- Use data types as objects in aggregates, such as unions, to access the byte elements and structures.
- Use data types only with the respective intrinsics described in this documentation.

**The EMMS Instruction: Why You Need It**

Using EMMS is like emptying a container to accommodate new content. The EMMS instruction clears the MMX™ registers and sets the value of the floating-point tag word to empty.

You should clear the MMX™ registers before issuing a floating-point instruction because floating-point convention specifies that the floating-point stack be cleared after use. Insert the EMMS instruction at the end of all MMX™ code segments to avoid a floating-point overflow exception.
Why You Need EMMS to Reset After an MMX™ Instruction

Caution
Failure to empty the multimedia state after using an MMX™ technology instruction and before using a floating-point instruction can result in unexpected execution or poor performance.

EMMS Usage Guidelines
Here are guidelines for when to use the EMMS instruction:

- Use `_mm_empty()` after an MMX instruction if the next instruction is a floating-point (FP) instruction. For example, you should use the EMMS instruction before performing calculations on `float`, `double` or `long double`. You must be aware of all situations in which your code generates an MMX™ instruction:
  - when using an MMX™ technology intrinsic
  - when using Intel® Streaming SIMD Extensions (Intel® SSE) integer intrinsics that use the `_m64` data type
  - when referencing an `_m64` data type variable
  - when using an MMX™ instruction through inline assembly
- Use different functions for operations that use floating point instructions and those that use MMX™ instructions. This action eliminates the need to empty the multimedia state within the body of a critical loop.
- Use `_mm_empty()` during runtime initialization of `_m64` and FP data types. This ensures resetting the register between data type transitions.
• Do not use _mm_empty() before an MMX™ instruction, since using _mm_empty() before an MMX™ instruction incurs an operation with no benefit (no-op).
• See the Correct Usage and Incorrect Usage coding examples in the following table.

<table>
<thead>
<tr>
<th>Incorrect Usage</th>
<th>Correct Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>__m64 x = _m_padd(y, z); float f = init();</td>
<td>__m64 x = _m_padd(y, z); float f = ( _mm_empty(), init());</td>
</tr>
</tbody>
</table>

**General Support Intrinsics (MMX™ technology)**

This topic summarizes the MMX™ technology general support intrinsics.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>

</tbody>
</table>

**_mm_empty**

```c
void _mm_empty(void);
```

Empties the multimedia state.

**_mm_cvtsi32_si64**

```c
__m64 _mm_cvtsi32_si64(int i);
```

Converts the integer object \(i\) to a 64-bit __m64 object. The integer value is zero-extended to 64 bits.
\_mm\_cvtsi64\_si32

```cpp
int \_mm\_cvtsi64\_si32(__m64 m);
```
Converts the lower 32 bits of the \_m64 object \textit{m} to an integer.

\_mm\_cvtsi64\_m64

```cpp
__m64 \_mm\_cvtsi64\_m64(__int64 i);
```
Moves the 64-bit integer object \textit{i} to a \_m64 object

\_mm\_cvtm64\_si64

```cpp
__m64 \_mm\_cvtm64\_si64(__m64 m);
```
Moves the \_m64 object \textit{m} to a 64-bit integer

\_mm\_packs\_pi16

```cpp
__m64 \_mm\_packs\_pi16(__m64 m1, __m64 m2);
```
Packs the four 16-bit values from \textit{m1} into the lower four 8-bit values of the result with signed saturation, and pack the four 16-bit values from \textit{m2} into the upper four 8-bit values of the result with signed saturation.

\_mm\_packs\_pi32

```cpp
__m64 \_mm\_packs\_pi32(__m64 m1, __m64 m2);
```
Packs the two 32-bit values from \textit{m1} into the lower two 16-bit values of the result with signed saturation, and pack the two 32-bit values from \textit{m2} into the upper two 16-bit values of the result with signed saturation.

\_mm\_packs\_pu16

```cpp
__m64 \_mm\_packs\_pu16(__m64 m1, __m64 m2);
```
Packs the four 16-bit values from \textit{m1} into the lower four 8-bit values of the result with unsigned saturation, and pack the four 16-bit values from \textit{m2} into the upper four 8-bit values of the result with unsigned saturation.

\_mm\_unpackhi\_pi8

```cpp
__m64 \_mm\_unpackhi\_pi8(__m64 m1, __m64 m2);
```
Interleaves the four 8-bit values from the high half of \textit{m1} with the four values from the high half of \textit{m2}. The interleaving begins with the data from \textit{m1}.

\_mm\_unpackhi\_pi16

```cpp
__m64 \_mm\_unpackhi\_pi16(__m64 m1, __m64 m2);
```
Interleaves the two 16-bit values from the high half of \textit{m1} with the two values from the high half of \textit{m2}. The interleaving begins with the data from \textit{m1}.

\_mm\_unpackhi\_pi32

```cpp
__m64 \_mm\_unpackhi\_pi32(__m64 m1, __m64 m2);
```
Interleaves the 32-bit value from the high half of $m1$ with the 32-bit value from the high half of $m2$. The interleaving begins with the data from $m1$.

⇌\texttt{mm\_unpacklo\_pi8}
\[
\_m64 \ _mm\_unpacklo\_pi8(\_m64 \ m1, \ _m64 \ m2);
\]

Interleaves the four 8-bit values from the low half of $m1$ with the four values from the low half of $m2$. The interleaving begins with the data from $m1$.

⇌\texttt{mm\_unpacklo\_pi16}
\[
\_m64 \ _mm\_unpacklo\_pi16(\_m64 \ m1, \ _m64 \ m2);
\]

Interleaves the two 16-bit values from the low half of $m1$ with the two values from the low half of $m2$. The interleaving begins with the data from $m1$.

⇌\texttt{mm\_unpacklo\_pi32}
\[
\_m64 \ _mm\_unpacklo\_pi32(\_m64 \ m1, \ _m64 \ m2);
\]

Interleaves the 32-bit value from the low half of $m1$ with the 32-bit value from the low half of $m2$. The interleaving begins with the data from $m1$.

**Packed Arithmetic Intrinsics (MMX™ technology)**

This topic summarizes the MMX™ technology packed arithmetic intrinsics.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

\begin{verbatim}
#include <immintrin.h>
\end{verbatim}

<table>

</tbody>
</table>

```c
__m64 _mm_add_pi8(__m64 m1, __m64 m2);
```
Add the eight 8-bit values in \(m1\) to the eight 8-bit values in \(m2\).

```c
__m64 _mm_add_pi16(__m64 m1, __m64 m2);
```
Add the four 16-bit values in \(m1\) to the four 16-bit values in \(m2\).

```c
__m64 _mm_add_pi32(__m64 m1, __m64 m2);
```
Add the two 32-bit values in \(m1\) to the two 32-bit values in \(m2\).

```c
__m64 _mm_adds_pi8(__m64 m1, __m64 m2);
```
Add the eight signed 8-bit values in \(m1\) to the eight signed 8-bit values in \(m2\) using saturating arithmetic.

```c
__m64 _mm_adds_pi16(__m64 m1, __m64 m2);
```
Add the four signed 16-bit values in \(m1\) to the four signed 16-bit values in \(m2\) using saturating arithmetic.

```c
__m64 _mm_adds_pu8(__m64 m1, __m64 m2);
```
Add the eight unsigned 8-bit values in \(m1\) to the eight unsigned 8-bit values in \(m2\) and using saturating arithmetic.

```c
__m64 _mm_adds_pu16(__m64 m1, __m64 m2);
```
Add the four unsigned 16-bit values in \(m1\) to the four unsigned 16-bit values in \(m2\) using saturating arithmetic.
_mm_sub_pi8
__m64 _mm_sub_pi8(__m64 m1, __m64 m2);
Subtract the eight 8-bit values in m2 from the eight 8-bit values in m1.

_mm_sub_pi16
__m64 _mm_sub_pi16(__m64 m1, __m64 m2);
Subtract the four 16-bit values in m2 from the four 16-bit values in m1.

_mm_sub_pi32
__m64 _mm_sub_pi32(__m64 m1, __m64 m2);
Subtract the two 32-bit values in m2 from the two 32-bit values in m1.

_mm_subs_pi8
__m64 _mm_subs_pi8(__m64 m1, __m64 m2);
Subtract the eight signed 8-bit values in m2 from the eight signed 8-bit values in m1 using saturating arithmetic.

_mm_subs_pi16
__m64 _mm_subs_pi16(__m64 m1, __m64 m2);
Subtract the four signed 16-bit values in m2 from the four signed 16-bit values in m1 using saturating arithmetic.

_mm_subs_pu8
__m64 _mm_subs_pu8(__m64 m1, __m64 m2);
Subtract the eight unsigned 8-bit values in m2 from the eight unsigned 8-bit values in m1 using saturating arithmetic.

_mm_subs_pu16
__m64 _mm_subs_pu16(__m64 m1, __m64 m2);
Subtract the four unsigned 16-bit values in m2 from the four unsigned 16-bit values in m1 using saturating arithmetic.

_mm_madd_pi16
__m64 _mm_madd_pi16(__m64 m1, __m64 m2);
Multiply four 16-bit values in m1 by four 16-bit values in m2 producing four 32-bit intermediate results, which are then summed by pairs to produce two 32-bit results.

_mm_mulhi_pi16
__m64 _mm_mulhi_pi16(__m64 m1, __m64 m2);
Multiply four signed 16-bit values in m1 by four signed 16-bit values in m2 and produce the high 16 bits of the four results.
_mm_mullo_pi16
__m64 _mm_mullo_pi16(__m64 m1, __m64 m2);
Multiply four 16-bit values in \textit{m1} by four 16-bit values in \textit{m2} and produce the low 16 bits of the four results.

**Shift Intrinsics (MMX™ technology)**

This topic summarizes the MMX™ technology shift intrinsics.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

```
#include <immintrin.h>
```

_\texttt{mm_sll_pi16}_
__m64 _mm_sll_pi16(__m64 m, __m64 count);
Shifts four 16-bit values in \textit{m} left the amount specified by \textit{count} while shifting in zeros.

_\texttt{mm_slli_pi16}_
__m64 _mm_slli_pi16(__m64 m, int count);
Shifts four 16-bit values in \textit{m} left the amount specified by \textit{count} while shifting in zeros. For the best performance, \textit{count} should be a constant.
**_mm_sll_pi32**

```c
__m64 _mm_sll_pi32(__m64 m, __m64 count);
```

Shifts two 32-bit values in `m` left the amount specified by `count` while shifting in zeros.

**_mm_slli_pi32**

```c
__m64 _mm_slli_pi32(__m64 m, int count);
```

Shifts two 32-bit values in `m` left the amount specified by `count` while shifting in zeros. For the best performance, `count` should be a constant.

**_mm_sll_pi64**

```c
__m64 _mm_sll_pi64(__m64 m, __m64 count);
```

Shifts the 64-bit value in `m` left the amount specified by `count` while shifting in zeros.

**_mm_slli_pi64**

```c
__m64 _mm_slli_pi64(__m64 m, int count);
```

Shifts the 64-bit value in `m` left the amount specified by `count` while shifting in zeros. For the best performance, `count` should be a constant.

**_mm_sra_pi16**

```c
__m64 _mm_sra_pi16(__m64 m, __m64 count);
```

Shifts four 16-bit values in `m` right the amount specified by `count` while shifting in the sign bit.

**_mm_srai_pi16**

```c
__m64 _mm_srai_pi16(__m64 m, int count);
```

Shifts four 16-bit values in `m` right the amount specified by `count` while shifting in the sign bit. For the best performance, `count` should be a constant.

**_mm_sra_pi32**

```c
__m64 _mm_sra_pi32(__m64 m, __m64 count);
```

Shifts two 32-bit values in `m` right the amount specified by `count` while shifting in the sign bit.

**_mm_srai_pi32**

```c
__m64 _mm_srai_pi32(__m64 m, int count);
```

Shifts two 32-bit values in `m` right the amount specified by `count` while shifting in the sign bit. For the best performance, `count` should be a constant.

**_mm_srl_pi16**

```c
__m64 _mm_srl_pi16(__m64 m, __m64 count);
```

Shifts four 16-bit values in `m` right the amount specified by `count` while shifting in zeros.
Logical Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology logical intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```cpp
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Operation</th>
<th>Corresponding MMX™ Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>_mm_and_si64</td>
<td>Bitwise AND</td>
<td>PAND</td>
</tr>
<tr>
<td>_mm_andnot_si64</td>
<td>Bitwise ANDNOT</td>
<td>PANDN</td>
</tr>
<tr>
<td>_mm_or_si64</td>
<td>Bitwise OR</td>
<td>POR</td>
</tr>
<tr>
<td>_mm_xor_si64</td>
<td>Bitwise Exclusive OR</td>
<td>PXOR</td>
</tr>
</tbody>
</table>

Perform a bitwise AND of the 64-bit value in `m1` with the 64-bit value in `m2`. 
Perform a bitwise NOT on the 64-bit value in \texttt{m1} and use the result in a bitwise AND with the 64-bit value in \texttt{m2}.

Perform a bitwise OR of the 64-bit value in \texttt{m1} with the 64-bit value in \texttt{m2}.

Perform a bitwise XOR of the 64-bit value in \texttt{m1} with the 64-bit value in \texttt{m2}.

This topic summarizes the MMX™ technology compare intrinsics.

To use these intrinsics, include the \texttt{immintrin.h} file as follows:

\begin{verbatim}
#include <immintrin.h>
\end{verbatim}

\begin{tabular}{|c|c|c|}
\hline
\textbf{Intrinsic Name} & \textbf{Operation} & \textbf{Corresponding MMX™ Instruction} \\
\hline
\texttt{mm_cmpeq_pi8} & Equal & PCMPEQB \\
\hline
\texttt{mm_cmpeq_pi16} & Equal & PCMPEQW \\
\hline
\texttt{mm_cmpeq_pi32} & Equal & PCMPEQD \\
\hline
\texttt{mm_cmpgt_pi8} & Greater Than & PCMPGTB \\
\hline
\texttt{mm_cmpgt_pi16} & Greater Than & PCMPGTW \\
\hline
\texttt{mm_cmpgt_pi32} & Greater Than & PCMPGTD \\
\hline
\end{tabular}

Sets the corresponding 8-bit resulting values to all ones if the 8-bit values in \texttt{m1} are equal to the corresponding 8-bit values in \texttt{m2}; otherwise sets them to all zeros.

Sets the corresponding 16-bit resulting values to all ones if the 16-bit values in \texttt{m1} are equal to the corresponding 16-bit values in \texttt{m2}; otherwise set them to all zeros.

Sets the corresponding 32-bit resulting values to all ones if the 32-bit values in \texttt{m1} are equal to the corresponding 32-bit values in \texttt{m2}; otherwise set them to all zeros.
Sets the corresponding 32-bit resulting values to all ones if the 32-bit values in \( m1 \) are equal to the corresponding 32-bit values in \( m2 \); otherwise set them to all zeros.

\[ \text{_mm\_cmpgt\_pi8} \]
\[
\text{__m64 \_mm\_cmpgt\_pi8(__m64 m1, \_m64 m2);} \]
Sets the corresponding 8-bit resulting values to all ones if the 8-bit signed values in \( m1 \) are greater than the corresponding 8-bit signed values in \( m2 \); otherwise set them to all zeros.

\[ \text{_mm\_cmpgt\_pi16} \]
\[
\text{__m64 \_mm\_cmpgt\_pi16(__m64 m1, \_m64 m2);} \]
Sets the corresponding 16-bit resulting values to all ones if the 16-bit signed values in \( m1 \) are greater than the corresponding 16-bit signed values in \( m2 \); otherwise set them to all zeros.

\[ \text{_mm\_cmpgt\_pi32} \]
\[
\text{__m64 \_mm\_cmpgt\_pi32(__m64 m1, \_m64 m2);} \]
Sets the corresponding 32-bit resulting values to all ones, if the 32-bit signed values in \( m1 \) are greater than the corresponding 32-bit signed values in \( m2 \); otherwise set them all to zeros.

Set Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology intrinsics.

To use these intrinsics, include the \textit{immintrin.h} file as follows:

\[
\#include <immintrin.h> \]

\[ \text{NOTE} \]
In the descriptions regarding the bits of the MMX™ register, bit 0 is the least significant and bit 63 is the most significant.

Intrinsics for Advanced Encryption Standard Implementation

Overview: Intrinsics for Carry-less Multiplication Instruction and Advanced Encryption Standard Instructions

The Intel® C++ Compiler provides intrinsics to enable carry-less multiplication and encryption based on Advanced Encryption Standard (AES) specifications. The carry-less multiplication intrinsic corresponds to a single new instruction, \texttt{PCLMULQDQ}. The AES extension intrinsics correspond to AES extension instructions.

The AES extension instructions and the \texttt{PCLMULQDQ} instruction follow the same system software requirements for \texttt{XMM} state support and single-instruction multiple data (SIMD) floating-point exception support as Intel® Streaming SIMD Extensions 2 (Intel® SSE2), Intel® Streaming SIMD Extensions 3 (Intel® SSE3), Intel Supplemental Streaming SIMD Extensions 3 (SSSE3), and Intel® Streaming SIMD Extensions 4 (Intel® SSE4) extensions.

Intel®64 processors using 32nm processing technology support the AES extension instructions as well as the \texttt{PCLMULQDQ} instruction.

AES Encryption and Cryptographic Processing

AES encryption involves processing 128-bit input data (plaintext) through a finite number of iterative operation, referred to as "AES round", into a 128-bit encrypted block (ciphertext). Decryption follows the reverse direction of iterative operation using the "equivalent inverse cipher" instead of the "inverse cipher".

The cryptographic processing at each round involves two input data, one is the "state", the other is the "round key". Each round uses a different "round key". The round keys are derived from the cipher key using a "key schedule" algorithm. The "key schedule" algorithm is independent of the data processing of encryption/decryption, and can be carried out independently from the encryption/decryption phase.

The AES standard supports cipher key of sizes 128, 192, and 256 bits. The respective cipher key sizes corresponds to 10, 12, and 14 rounds of iteration.

Carry-less Multiplication Instruction and AES Extension Instructions

A single instruction, \texttt{PCLMULQDQ}, performs carry-less multiplication for two binary numbers that are up to 64-bit wide.

The AES extensions provide:

- two instructions to accelerate AES rounds on encryption (\texttt{AESENC} and \texttt{AESENCLAST})
- two instructions for AES rounds on decryption using the equivalent inverse cipher (\texttt{AESDEC} and \texttt{AESENCLAST})
- instructions for the generation of key schedules (\texttt{AESIMC} and \texttt{AESENCLAST})

Detecting Support for Using Instructions

Before any application attempts to use the \texttt{PCLMULQDQ} or the AES extension instructions, it must first detect if the instructions are supported by the processor.

To detect support for the \texttt{PCLMULQDQ} instruction, your application must check the following:

\texttt{CPUID.01H:ECX.PCLMULQDQ[bit 1]} = 1.

To detect support for the AES extension instructions, your application must check the following:

\texttt{CPUID.01H:ECX.AES[bit 25]} = 1.
Operating systems that support handling of the SSE state also support applications that use AES extension instruction and the PCLMULQDQ instruction.

**Intrinsics for Carry-less Multiplication Instruction and Advanced Encryption Standard Instructions**

The prototypes for the Carry-less multiplication intrinsic and the Advanced Encryption Standard (AES) intrinsics are defined in the `wmmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

**Carry-less Multiplication Intrinsic**

The single general purpose block encryption intrinsic description is provided below.

```
__m128i _mm_clmulepi64_si128(__m128i v1, __m128i v2, const int imm8);
```

Performs a carry-less multiplication of one quadword of `v1` by one quadword of `v2`, and returns the result. The `imm8` value is used to determine which quadwords of `v1` and `v2` should be used.

**Corresponding Instruction:** PCLMULQDQ

**Advanced Encryption Standard Intrinsics**

The AES intrinsics are described below.

```
__m128i _mm_aesdec_si128(__m128i v, __m128i rkey);
```

Performs one round of an AES decryption flow using the Equivalent Inverse Cipher operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

**Corresponding Instruction:** AESDEC

```
__m128i _mm_aesdeclast_si128(__m128i v, __m128i rkey);
```

Performs the last round of an AES decryption flow using the Equivalent Inverse Cipher operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

**Corresponding Instruction:** AESDECLAST

```
__m128i _mm_aesenc_si128(__m128i v, __m128i rkey);
```

Performs one round of an AES encryption flow operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

**Corresponding Instruction:** AESENC

```
__m128i _mm_aesenclast_si128(__m128i v, __m128i rkey);
```

Performs the last round of an AES encryption flow operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

**Corresponding Instruction:** AESENCLAST

```
__m128i _mm_aesimc_si128(__m128i v);
```

Performs the InvMixColumn transformation on a 128-bit round key from `v` and returns the result.

**Corresponding Instruction:** AESIMC
__m128i _mm_aeskeygenassist_si128(__m128i ckey, const int rcon);

Assists in AES round key generation using an 8-bit Round Constant (RCON) specified in `rcon` operating on 128 bits of data specified in `ckey` and returns the result.

Corresponding Instruction: AESKEYGENASSIST

Intrinsics for Converting Half Floats

Overview: Intrinsics to Convert Half Float Types
The half-float or 16-bit float is a popular type in some application domains. The half-float type is regarded as a storage type because although data is often stored as a half-float, computation is never done on values in these type. Usually values are converted to regular 32-bit floats before any computation.

Support for half-float type is restricted to just conversions to/from 32-bit floats. The main benefits of using half float type are:

- reduced storage requirements
- less consumption of memory bandwidth and cache
- accuracy and precision adequate for many applications

Half Float Intrinsics
The half-float intrinsics are provided to convert half-float values to 32-bit floats for computation purposes and conversely, 32-bit float values to half-float values for data storage purposes.

The intrinsics are translated into library calls that do the actual conversions.

The half-float intrinsics are available on IA-32 and Intel® 64 architectures running supported operating systems. The minimum processor requirement is an Intel® Pentium 4 processor and an operating system supporting Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions.

Role of Immediate Byte in Half Float Intrinsic Operations
For all half-float intrinsics an immediate byte controls rounding mode, flush to zero, and other non-volatile set values. The format of the `imm8` byte is as shown in the diagram below.

The `imm8` value is used for special MXCSR overrides.
In the diagram,

- MBZ = Most significant Bit is Zero; used for error checking
- MS1 = 1 : use MXCSR RC, else use imm8.RC
- SAE = 1 : all exceptions are suppressed
- MS2 = 1 : use MXCSR FTZ/DAZ control, else use imm8.FTZ/DAZ.

The compiler passes the bits to the library function, with error checking - the most significant bit must be zero.

**Intrinsics for Converting Half Floats**

There are four intrinsics for converting half-floats to 32-bit floats and 32-bit floats to half-floats. The prototypes for these half-float conversion intrinsics are in the `emmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

- `float _cvtsh_ss(unsigned short x);`
  - This intrinsic takes a half-float value, \( x \), and converts it to a 32-bit float value, which is returned.

- `unsigned short _cvtss_sh(float x, int imm);`
  - This intrinsic takes a 32-bit float value, \( x \), and converts it to a half-float value, which is returned.

- `__m128 _mm_cvtph_ps(__m128i x);`
  - This intrinsic takes four packed half-float values and converts them to four 32-bit float values, which are returned. The upper 64-bits of \( x \) are ignored. The lower 64-bits are taken as four 16-bit float values for conversion.

- `__m128i _mm_cvtps_ph(_m128 x, int imm);`
  - This intrinsic takes four packed 32-bit float values and converts them to four half-float values, which are returned. The upper 64-bits in the returned result are all zeros. The lower 64-bits contain the four packed 16-bit float values.

Includes information on the imm parameter

**Intrinsics for Short Vector Math Library Operations**

**NOTE**

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**Overview: Intrinsics for Short Vector Math Library (SVML) Functions**

The Intel® C++ Compiler provides short vector math library (SVML) intrinsics to compute vector math functions. These intrinsics are available for IA-32 and Intel® 64 architectures running on supported operating systems. The prototypes for the SVML intrinsics are available in the `immintrin.h` file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The SVML intrinsics do not have any corresponding instructions. The SVML intrinsics are vector variants of corresponding scalar math operations using \texttt{__m128}, \texttt{__m128d}, \texttt{__m256}, \texttt{__m256d}, and \texttt{__m256i} data types. They take packed vector arguments, perform the operation on each element of the packed vector argument, and return a packed vector result.

For example, the argument to the \texttt{_mm_sin_ps} intrinsic is a packed 128-bit vector of four 32-bit precision floating point numbers. The intrinsic computes the sine of each of these four numbers and returns the four results in a packed 128-bit vector.

Using SVML intrinsics is faster than repeatedly calling the scalar math functions. However, the intrinsics differ from the scalar functions in accuracy.

\textbf{NOTE}  
Many routines in the \texttt{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

### Intrinsics for Division Operations

\textbf{NOTE}  
Many routines in the \texttt{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

\texttt{\_mm\_div\_epi8/ \_mm256\_div\_epi8}

\textit{Calculates quotient of a division operation. Vector variant of \texttt{div()} function for signed 8-bit integer arguments.}

\textbf{Syntax}

```c
extern __m128i \_mm\_div\_epi8(__m128i v1, __m128i v2);
extern __m256i \_mm256\_div\_epi8(__m256i v1, __m256i v2);
```

\textbf{Parameters}

- \texttt{v1}  
  signed integer source vector containing the dividends
- \texttt{v2}  
  signed integer source vector containing the divisors

\textbf{Description}

Calculates the quotient by dividing value of \texttt{v1} vector elements by corresponding \texttt{v2} vector elements.

\textbf{Returns}

Returns the result of the operation.

\textbf{NOTE}  
Many routines in the \texttt{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.
**_mm_div_epi16/_mm256_div_epi16**
*Calculates quotient of a division operation. Vector variant of div() function for signed 16-bit integer arguments.*

**Syntax**

```c
extern __m128i _mm_div_epi16(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epi16(__m256i v1, __m256i v2);
```

**Parameters**

- **v1**
  - signed integer source vector containing the dividends

- **v2**
  - signed integer source vector containing the divisors

**Description**

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

**Returns**

Returns the result of the operation.

---

**NOTE**

Many routines in the `svm` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**_mm_div_epi32/_mm256_div_epi32**
*Calculates quotient of a division operation. Vector variant of div() function for signed 32-bit integer arguments.*

**Syntax**

```c
extern __m128i _mm_div_epi32(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epi32(__m256i v1, __m256i v2);
```

**Parameters**

- **v1**
  - signed integer source vector containing the dividends

- **v2**
  - signed integer source vector containing the divisors

**Description**

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

**Returns**

Returns the result of the operation.
NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epi64/_mm256_div_epi64
Calculates quotient of a division operation. Vector variant of div() function for signed 64-bit integer arguments.

Syntax
extern _m128i _mm_div_epi64(_m128i v1, _m128i v2);
extern _m256i _mm256_div_epi64(_m256i v1, _m256i v2);

Parameters

v1 signed integer source vector containing the dividends
v2 signed integer source vector containing the divisors

Description
Calculates the quotient by dividing value of v1 vector elements by corresponding v2 vector elements.

Returns
Returns the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu8/_mm256_div_epu8
Calculates quotient of a division operation. Vector variant of div() function for unsigned 8-bit integer arguments.

Syntax
extern _m128i _mm_div_epu8(_m128i v1, _m128i v2);
extern _m256i _mm256_div_epu8(_m256i v1, _m256i v2);

Parameters

v1 unsigned integer source vector containing the dividends
v2 unsigned integer source vector containing the divisors

Description
Calculates the quotient by dividing value of v1 vector elements by corresponding v2 vector elements.
Returns

Returns the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu16/ _mm256_div_epu16

Calculates quotient of a division operation. Vector variant of div() function for unsigned 16-bit integer arguments.

Syntax

extern __m128i _mm_div_epu16(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epu16(__m256i v1, __m256i v2);

Parameters

v1  unsigned integer source vector containing the dividends
v2  unsigned integer source vector containing the divisors

Description

Calculates the quotient by dividing value of v1 vector elements by corresponding v2 vector elements.

Returns

Returns the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu32/ _mm256_div_epu32

Calculates quotient of a division operation. Vector variant of div() function for unsigned 32-bit integer arguments.

Syntax

extern __m128i _mm_div_epu32(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epu32(__m256i v1, __m256i v2);

Parameters

v1  unsigned integer source vector containing the dividends
v2  unsigned integer source vector containing the divisors
Description
Calculates the quotient by dividing value of v1 vector elements by corresponding v2 vector elements.

Returns
Returns the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu64/ _mm256_div_epu64
*Calculates quotient of a division operation. Vector variant of div() function for unsigned 64-bit integer arguments.*

Syntax
extern __m128i _mm_div_epu64(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epu64(__m256i v1, __m256i v2);

Parameters
- **v1**
  unsigned integer source vector containing the dividends
- **v2**
  unsigned integer source vector containing the divisors

Description
Calculates the quotient by dividing value of v1 vector elements by corresponding v2 vector elements.

Returns
Returns the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epi8/ _mm256_rem_epi8
*Calculates remainder of a division operation. Vector variant of rem() function for signed 8-bit integer arguments.*

Syntax
extern __m128i _mm_rem_epi8(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epi8(__m256i v1, __m256i v2);
Parameters

\( v_1 \)  
signed integer source vector containing the dividends

\( v_2 \)  
signed integer source vector containing the divisors

Description

Calculates the remainder from division of \( v_1 \) vector elements by corresponding \( v_2 \) vector elements.

Returns

Returns the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

\_mm\_rem\_epi16/ \_mm256\_rem\_epi16

Calculates remainder of a division operation. Vector variant of \texttt{rem()} function for signed 16-bit integer arguments.

Syntax

\begin{verbatim}
extern __m128i _mm_rem_epi16(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epi16(__m256i v1, __m256i v2);
\end{verbatim}

Parameters

\( v_1 \)  
signed integer source vector containing the dividends

\( v_2 \)  
signed integer source vector containing the divisors

Description

Calculates the remainder from division of \( v_1 \) vector elements by corresponding \( v_2 \) vector elements.

Returns

Returns the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

\_mm\_rem\_epi32/ \_mm256\_rem\_epi32

Calculates remainder of a division operation. Vector variant of \texttt{rem()} function for signed 32-bit integer arguments.

Syntax

\begin{verbatim}
extern __m128i _mm_rem_epi32(__m128i v1, __m128i v2);
\end{verbatim}
extern __m256i _mm256_rem_epi132(__m256i v1, __m256i v2);

**Parameters**

v1  
signed integer source vector containing the dividends

v2  
signed integer source vector containing the divisors

**Description**

Calculates the remainder from division of v1 vector elements by corresponding v2 vector elements.

**Returns**

Returns the result of the operation.

---

**NOTE**

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

_mm_rem_epi64/ _mm256_rem_epi64

*R-calculates remainder of a division operation. Vector variant of rem() function for signed 64-bit integer arguments.*

**Syntax**

extern __m128i _mm_rem_epi64(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epi64(__m256i v1, __m256i v2);

**Parameters**

v1  
signed integer source vector containing the dividends

v2  
signed integer source vector containing the divisors

**Description**

Calculates the remainder from division of v1 vector elements by corresponding v2 vector elements.

**Returns**

Returns the result of the operation.

---

**NOTE**

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

_mm_rem_epu8/ _mm256_rem_epu8

*R-calculates remainder of a division operation. Vector variant of rem() function for unsigned 8-bit integer arguments.*
Syntax

extern __m128i _mm_rem_epu8(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epu8(__m256i v1, __m256i v2);

Parameters

v1                unsigned integer source vector containing the dividends
v2                unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of v1 vector elements by corresponding v2 vector elements.

Returns

Returns the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epu16/_mm256_rem_epu16

Calculates remainder of a division operation. Vector variant of rem() function for unsigned 16-bit integer arguments.

Syntax

extern __m128i _mm_rem_epu16(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epu16(__m256i v1, __m256i v2);

Parameters

v1                unsigned integer source vector containing the dividends
v2                unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of v1 vector elements by corresponding v2 vector elements.

Returns

Returns the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
_mm_rem_epu32/_mm256_rem_epu32
Calculates remainder of a division operation. Vector variant of \texttt{rem()} function for unsigned 32-bit integer arguments.

**Syntax**

\begin{verbatim}
extern __m128i _mm_rem_epu32(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epu32(__m256i v1, __m256i v2);
\end{verbatim}

**Parameters**

\begin{itemize}
  \item \texttt{v1} unsigned integer source vector containing the dividends
  \item \texttt{v2} unsigned integer source vector containing the divisors
\end{itemize}

**Description**

Calculates the remainder from division of \texttt{v1} vector elements by corresponding \texttt{v2} vector elements.

**Returns**

Returns the result of the operation.

---

**NOTE**

Many routines in the \texttt{svm/} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

---

_mm_rem_epu64/_mm256_rem_epu64
Calculates remainder of a division operation. Vector variant of \texttt{rem()} function for unsigned 64-bit integer arguments.

**Syntax**

\begin{verbatim}
extern __m128i _mm_rem_epu64(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epu64(__m256i v1, __m256i v2);
\end{verbatim}

**Parameters**

\begin{itemize}
  \item \texttt{v1} unsigned integer source vector containing the dividends
  \item \texttt{v2} unsigned integer source vector containing the divisors
\end{itemize}

**Description**

Calculates the remainder from division of \texttt{v1} vector elements by corresponding \texttt{v2} vector elements.

**Returns**

Returns the result of the operation.
Intrinsics for Error Function Operations

_mm_cdfnorminv_pd, _mm256_cdfnorminv_pd
Calculates inverse cumulative distribution function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_cdfnorminv_pd(__m128d v1);
extern __m256d _mm256_cdfnorminv_pd(__m256d v1);

Arguments

v1 vector with float64 values

Description
Returns the inverse cumulative distribution function of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

_mm_cdfnorminv_ps, _mm256_cdfnorminv_ps
Calculates inverse cumulative distribution function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_cdfnorminv_ps(__m128 v1);
extern __m256 _mm256_cdfnorminv_ps(__m256 v1);

Arguments

v1 vector with float32 values

Description
Returns the inverse cumulative distribution function of vector v1 elements.
Returns
128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_erf_pd, __mm256_erf_pd__

*Calculates error function. Vector variant of erf(x) function for a 128-bit/256-bit vector argument of float64 values.*

**Syntax**

extern __m128d _mm_erf_pd(__m128d v1);
extern __m256d _mm256_erf_pd(__m256d v1);

**Arguments**

v1 float64 vector used for the operation

**Description**
Calculates error function of v1 elements, which is defined as:

\[
erf(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} \, dt
\]

**Returns**
128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_erf_ps, __mm256_erf_ps__

*Calculates error function. Vector variant of erf(x) function for a 128-bit/256-bit vector argument of float32 values.*

**Syntax**

extern __m128 _mm_erf_ps(__m128 v1);
extern __m256 _mm256_erf_ps(__m256 v1);

**Arguments**

v1 vector with float32 values
Description
Calculates error function of v1 elements, which is defined as:

\[
erf(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt
\]

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfc_pd, _mm256_erfc_pd
Calculates complementary error function. Vector variant of \( \text{erfc}(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_erfc_pd(__m128d v1);
extern __m256d _mm256_erfc_pd(__m256d v1);

Arguments
v1
vector with float64 values

Description
Calculates the complementary error function of vector v1 elements, which is defined as:

\[
1.0 - \text{erf}(x)
\]

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfc_ps, _mm256_erfc_ps
Calculates complementary error function. Vector variant of \( \text{erfc}(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 __mm_erfc_ps(__m128 v1);
extern __m256 __mm256_erfc_ps(__m256 v1);
Arguments

\(v1\)  
vector with float32 values

Description

Calculates the complementary error function of vector \(v1\) elements, which is

\[1.0 - \text{erf}(x)\]

Returns

128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_\texttt{mm\_erfinv\_pd}, \texttt{mm256\_erfinv\_pd}_

*Calculates inverse error function. Vector variant of* \texttt{erfinv(x)} *function for a 128-bit/256-bit vector argument of float64 values.*

Syntax

```c
extern __m128d _mm_erfinv_pd(__m128d v1);
extern __m256d _mm256_erfinv_pd(__m256d v1);
```

Arguments

\(v1\)  
float64 vector used for the operation

Description

Calculates the inverse error function of \(v1\) elements, which is defined as:

\[\frac{1}{\text{erf}(x)}\]

Returns

128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_\texttt{mm\_erfinv\_ps}, \texttt{mm256\_erfinv\_ps}_

*Calculates inverse error function. Vector variant of* \texttt{erfinv(x)} *function for a 128-bit/256-bit vector argument of float32 values.*

Syntax

```c
extern __m128 _mm_erfinv_ps(__m128 v1);
```
extern __m256 _mm256_erfinv_ps(__m256 v1);

**Arguments**

v1 vector with float32 values

**Description**

Calculates the inverse error function of v1 elements, which is defined as:

\[
1 / \text{erf}(x)
\]

**Returns**

128-bit/256-bit vector with the result of the operation.

---

**Intrinsics for Exponential Operations**

---

_Calculation exponential value of 2. Vector variant of \text{exp2}(x) function for a 128-bit/256-bit vector argument of float64 values._

**Syntax**

extern __m128d _mm_exp2_pd(__m128d v1);
extern __m256d _mm256_exp2_pd(__m256d v1);

**Arguments**

v1 vector with float64 values

**Description**

Calculates the exponential value of 2 raised to the power of vector v1 elements.

**Returns**

128-bit/256-bit vector with the result of the operation.
\texttt{\_mm\_exp2\_ps, \_mm256\_exp2\_ps}

Calculates exponential value of 2. Vector variant of \texttt{exp2(x)} function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**

\begin{verbatim}
extern __m128 \_mm\_exp2\_ps(__m128 v1);
extern __m256 \_mm256\_exp2\_ps(__m256 v1);
\end{verbatim}

**Arguments**

\(v1\)  
vector with float32 values

**Description**

Calculates the exponential value of 2 raised to the power of vector \(v1\) elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

\textbf{NOTE}

Many routines in the \texttt{svml} library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

\texttt{\_mm\_exp\_pd, \_mm256\_exp\_pd}

Calculates exponential value of \(e\) (base of natural logarithms). Vector variant of \texttt{exp(x)} function for a 128-bit/256-bit vector argument of float64 values.

**Syntax**

\begin{verbatim}
extern __m128d \_mm\_exp\_pd(__m128d v1);
extern __m256d \_mm256\_exp\_pd(__m256d v1);
\end{verbatim}

**Arguments**

\(v1\)  
vector with float64 values

**Description**

Calculates the exponential value of \(e\) (base of natural logarithms) raised to the power of vector \(v1\) elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

\textbf{NOTE}

Many routines in the \texttt{svml} library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
**_mm_exp_ps, _mm256_exp_ps**  
Calculates exponential value of e (base of natural logarithms). Vector variant of \( \exp(x) \) function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**

```c
extern __m128 _mm_exp_ps(__m128 v1);
extern __m256 _mm256_exp_ps(__m256 v1);
```

**Arguments**

- \( v1 \) vector with float32 values

**Description**

Calculates the exponential value of \( e \) (base of natural logarithms) raised to the power of vector \( v1 \) elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

**NOTE**

Many routines in the svm/ library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**_mm_exp10_pd, _mm256_exp10_pd**

Calculates exponential value of 10. Vector variant of \( \exp(x) \) function for a 128-bit/256-bit vector argument of float64 values.

**Syntax**

```c
extern __m128d _mm_exp10_pd(__m128d v1);
extern __m256d _mm256_exp10_pd(__m256d v1);
```

**Arguments**

- \( v1 \) vector with float64 values

**Description**

Calculates 10 raised to the power of vector \( v1 \) elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

**NOTE**

Many routines in the svm/ library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
_mm_exp10_ps, _mm256_exp10_ps
Calculates exponential value of 10. Vector variant of exp(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_exp10_ps(__m128 v1);
extern __m256 _mm256_exp10_ps(__m256 v1);

Arguments
v1 vector with float32 values

Description
Calculates 10 raised to the power of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_expm1_pd, _mm256_expm1_pd
Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1. Vector variant of expm1(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_expm1_pd(__m128d v1);
extern __m256d _mm256_expm1_pd(__m256d v1);

Arguments
v1 vector with float64 values

Description
Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1.

\[ e^{x} - 1 \]

Returns
128-bit/256-bit vector with the result of the operation.
NOTE
Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**_mm_expm1_ps, _mm256_expm1_ps**
Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1. Vector variant of expm1(x) function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**
```
extern __m128 _mm_expm1_ps(__m128 v1);
extern __m256 _mm256_expm1_ps(__m256 v1);
```

**Arguments**

v1 vector with float32 values

**Description**
Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1.

\[ e^{(x)} - 1 \]

**Returns**
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**_mm_cexp_ps, _mm256_cexp_ps**
Calculates complex exponential value of e (base of natural logarithms). Vector variant of exp(x) function for a 128-bit/256-bit vector argument of _Complex float32 values.

**Syntax**
```
extern __m128 _mm_cexp_ps(__m128 v1);
extern __m256 _mm256_cexp_ps(__m256 v1);
```

**Arguments**

v1 vector with _Complex float32 values

**Description**
Calculates the complex exponential value of e (base of natural logarithms) raised to the power of vector v1 elements.
Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_pow_pd, _mm256_pow_pd
Calculates exponential value of one argument raised to the other argument. Vector variant of pow(x, y) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_pow_pd(__m128d v1, __m128d v2);
extern __m256d _mm256_pow_pd(__m256d v1, __m256d v2);

Arguments
v1 <br> vector with float64 values
v2 <br> vector with float64 values

Description
Calculates the exponential value of each vector v1 element raised to the power of the corresponding vector v2 element.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_pow_ps, _mm256_pow_ps
Calculates exponential value of one argument raised to the other argument. Vector variant of pow(x, y) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_pow_ps(__m128 v1, __m128 v2);
extern __m256 _mm256_pow_ps(__m256 v1, __m256 v2);

Arguments
v1 <br> vector with float32 values
v2 vector with float32 values

Description
Calculates the exponential value of each vector v1 element raised to the power of the corresponding vector v2 element.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_hypot_pd, _mm256_hypot_pd

\textit{Computes the length of the hypotenuse of a right angled triangle. Vector variant of hypot(x) function for a 128-bit/256-bit vector argument of float64 values.}

Syntax
\begin{verbatim}
extern __m128d _mm_hypot_pd(__m128d v1, __m128d v2);
extern __m256d _mm256_hypot_pd(__m256d v1, __m256d v2);
\end{verbatim}

Arguments
\begin{itemize}
  \item \textbf{v1} vector with float64 values
  \item \textbf{v2} vector with float64 values
\end{itemize}

Description
Computes the length of the hypotenuse of a right angled triangle with sides v1 and v2, defined by:
\[
\text{sqrt} (v1^2 + v2^2)
\]

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_hypot_ps, _mm256_hypot_ps

\textit{Computes the length of the hypotenuse of a right angled triangle. Vector variant of hypot(x) function for a 128-bit/256-bit vector argument of float32 values.}

Syntax
\begin{verbatim}
extern __m128 _mm_hypot_ps(__m128 v1, __m128 v2);
extern __m256 _mm256_hypot_ps(__m256 v1, __m256 v2);
\end{verbatim}
Arguments

\( v1 \)  
vector with float32 values

\( v2 \)  
vector with float32 values

Description

Computes the length of the hypotenuse of a right angled triangle with sides \( v1 \) and \( v2 \), defined by:

\[
\sqrt{v1^2 + v2^2}
\]

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

Intrinsics for Logarithmic Operations

NOTE

Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

\_mm\_log2\_pd, \_mm256\_log2\_pd

\textit{Calculates base-2 logarithm. Vector variant of \texttt{log2(x)} function for a 128-bit/256-bit vector argument of float64 values.}

Syntax

\begin{verbatim}
extern __m128d _mm_log2_pd(__m128d v1);
extern __m256d _mm256_log2_pd(__m256d v1);
\end{verbatim}

Arguments

\( v1 \)  
vector with float64 values

Description

Calculates the base-2 logarithm of vector \( v1 \) elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.
_mm_log2_ps, mm256_log2_ps
Calculates base-2 logarithm. Vector variant of log2(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_log2_ps(__m128 v1);
extern __m256 _mm256_log2_ps(__m256 v1);

Arguments
v1 vector with float32 values

Description
Calculates the base-2 logarithm of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log10_pd, mm256_log10_pd
Calculates base-10 logarithm. Vector variant of log10(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_log10_pd(__m128d v1);
extern __m256d _mm256_log10_pd(__m256d v1);

Arguments
v1 vector with float64 values

Description
Calculates the base-10 logarithm of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
**_mm_log10_ps, _mm256_log10_ps**
Calculates base-10 logarithm. Vector variant of \( \log_{10}(x) \) function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**

```
extern __m128 _mm_log10_ps(__m128 v1);
extern __m256 _mm256_log10_ps(__m256 v1);
```

**Arguments**

\( v1 \)  
vector with float32 values

**Description**
Calculates the base-10 logarithm of vector \( v1 \) elements.

**Returns**
128-bit/256-bit vector with the result of the operation.

---

**_mm_log_pd, _mm256_log_pd**
Calculates natural logarithm. Vector variant of \( \log(x) \) function for a 128-bit/256-bit vector argument of float64 values.

**Syntax**

```
extern __m128d _mm_log_pd(__m128d v1);
extern __m256d _mm256_log_pd(__m256d v1);
```

**Arguments**

\( v1 \)  
vector with float64 values

**Description**
Calculates the natural logarithm of vector \( v1 \) elements.

**Returns**
128-bit/256-bit vector with the result of the operation.

---

**NOTE**
Many routines in the *svm* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
**_mm_log_ps, _mm256_log_ps**

Calculates natural logarithm. Vector variant of log(x) function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**

```c
extern __m128 _mm_log_ps(__m128 v1);
extern __m256 _mm256_log_ps(__m256 v1);
```

**Arguments**

- `v1` vector with float32 values

**Description**

Calculates the natural logarithm of vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

**NOTE**

Many routines in the svm/ library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**_mm_logb_pd, _mm256_logb_pd**

Calculates signed exponent. Vector variant of logb(x) function for a 128-bit/256-bit vector argument of float64 values.

**Syntax**

```c
extern __m128d _mm_logb_pd(__m128d v1);
extern __m256d _mm256_logb_pd(__m256d v1);
```

**Arguments**

- `v1` vector with float64 values

**Description**

Returns the signed exponent for vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

**NOTE**

Many routines in the svm/ library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
_mm_logb_ps, _mm256_logb_ps
Calculates signed exponent. Vector variant of \( \log_b(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern __m128 _mm_logb_ps(__m128 v1);
extern __m256 _mm256_logb_ps(__m256 v1);

Arguments

v1 vector with float32 values

Description

Returns the signed exponent for vector \( v1 \) elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the \textit{svml} library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log1p_pd, _mm256_log1p_pd
Calculates natural logarithm. Vector variant of \( \log_1p(x) \) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

extern __m128d _mm_log1p_pd(__m128d v1);
extern __m256d _mm256_log1p_pd(__m256d v1);

Arguments

v1 vector with float64 values

Description

Returns the natural logarithm of vector \( v1 \) elements, defined by:

\[
\ln (v1 + 1)
\]

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the \textit{svml} library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
_calculate natural logarithm. Vector variant of log1p(x) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

```c
extern __m128 _mm_log1p_ps(__m128 v1);
extern __m256 _mm256_log1p_ps(__m256 v1);
```

Arguments

- `v1`: vector with float32 values

Description

Returns the natural logarithm of vector `v1` elements, defined by:

\[ \ln(v_1 + 1) \]

Returns

128-bit/256-bit vector with the result of the operation.

\[\text{NOTE}\]

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_calculate complex natural logarithm. Vector variant of clog(x) function for a 128-bit/256-bit vector argument of _Complex float32 values.

Syntax

```c
extern __m128 _mm_clog_ps(__m128 v1);
extern __m256 _mm256_clog_ps(__m256 v1);
```

Arguments

- `v1`: vector with _Complex float32 values

Description

Calculates the complex natural logarithm of vector `v1` elements.

Returns

128-bit/256-bit vector with the result of the operation.

\[\text{NOTE}\]

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
Intrinsics for Square Root and Cube Root Operations

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sqrt_pd, _mm256_sqrt_pd
**Calculates square root value. Vector variant of sqrt(x) function for a 128-bit/256-bit vector argument of float64 values.**

**Syntax**

```c
extern __m128d _mm_sqrt_pd(__m128d v1);
extern __m256d _mm256_sqrt_pd(__m256d v1);
```

**Arguments**

`v1`  
vector with float64 values

**Description**

Calculates the square root of vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sqrt_ps, _mm256_sqrt_ps
**Calculates square root value. Vector variant of sqrt(x) function for a 128-bit/256-bit vector argument of float32 values.**

**Syntax**

```c
extern __m128 _mm_sqrt_ps(__m128 v1);
extern __m256 _mm256_sqrt_ps(__m256 v1);
```

**Arguments**

`v1`  
vector with float32 values

**Description**

Calculates the square root of vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.
_mm_invsqrt_pd, _mm256_invsqrt_pd
Calculates inverse square root value. Vector variant of invsqrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_invsqrt_pd(__m128d v1);
extern __m256d _mm256_invsqrt_pd(__m256d v1);

Arguments
v1 vector with float64 values

Description
Calculates the inverse square root of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svm/ library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_invsqrt_ps, _mm256_invsqrt_ps
Calculates inverse square root value. Vector variant of invsqrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_invsqrt_ps(__m128 v1);
extern __m256 _mm256_invsqrt_ps(__m256 v1);

Arguments
v1 vector with float32 values

Description
Calculates the inverse square root of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.
NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cbrt_pd, _mm256_cbrt_pd
Calculates cube root value. Vector variant of cbrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_cbrt_pd(__m128d v1);
extern __m256d _mm256_cbrt_pd(__m256d v1);

Arguments
v1 
vector with float64 values

Description
Calculates the cube root of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cbrt_ps, _mm256_cbrt_ps
Calculates cube root value. Vector variant of cbrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_cbrt_ps(__m128 v1);
extern __m256 _mm256_cbrt_ps(__m256 v1);

Arguments
v1 
vector with float32 values

Description
Calculates the cube root of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.
Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**_mm_invcbtrt_pd, _mm256_invcbtrt_pd**

Calculates inverse cube root value. Vector variant of invcbtrt(x) function for a 128-bit/256-bit vector argument of float64 values.

**Syntax**

```c
extern __m128d _mm_invcbtrt_pd(__m128d v1);
extern __m256d _mm256_invcbtrt_pd(__m256d v1);
```

**Arguments**

- `v1` vector with float64 values

**Description**

Calculates the inverse cube root of vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

---

Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**_mm_invcbtrt_ps, _mm256_invcbtrt_ps**

Calculates inverse cube root value. Vector variant of invcbtrt(x) function for a 128-bit/256-bit vector argument of float32 values.

**Syntax**

```c
extern __m128 _mm_invcbtrt_ps(__m128 v1);
extern __m256 _mm256_invcbtrt_ps(__m256 v1);
```

**Arguments**

- `v1` vector with float32 values

**Description**

Calculates the inverse cube root of vector `v1` elements.

**Returns**

128-bit/256-bit vector with the result of the operation.
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

### _mm_csqrt_ps, _mm256_csqrt_ps

Calculates complex square root value. Vector variant of `csqrt(x)` function for a 128-bit/256-bit vector argument of _Complex float32 values.

#### Syntax

```c
extern __m128 _mm_csqrt_ps(__m128 v1);
extern __m256 _mm256_csqrt_ps(__m256 v1);
```

#### Arguments

- `v1` vector with _Complex float32 values

#### Description

Calculates the complex square root of vector `v1` elements.

#### Returns

128-bit/256-bit vector with the result of the operation.

---

NOTE

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

### Intrinsics for Trigonometric Operations

#### _mm_acos_pd, _mm256_acos_pd

Calculates inverse cosine value. Vector variant of `acos(x)` function for a 128-bit/256-bit vector argument of float64 values.

#### Syntax

```c
extern __m128d _mm_acos_pd(__m128d v1);
extern __m256d _mm256_acos_pd(__m256d v1);
```

#### Arguments

- `v1` vector with float64 values

---

NOTE

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
Description
Calculates the arc cosine of vector \( v1 \) elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_acos_ps, __mm256_acos_ps
*Calculates inverse cosine value. Vector variant of \( \text{acos}(x) \) function for a 128-bit/256-bit vector argument of float32 values.*

Syntax
```c
extern __m128 _mm_acos_ps(__m128 v1);
extern __m256 _mm256_acos_ps(__m256 v1);
```

Arguments

\( v1 \)
vector with float32 values

Description
Calculates the arc cosine of vector \( v1 \) elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_acosh_pd, __mm256_acosh_pd
*Calculates the inverse hyperbolic cosine value. Vector variant of \( \text{acosh}(x) \) function for a 128-bit/256-bit vector argument of float64 values.*

Syntax
```c
extern __m128d _mm_acosh_pd(__m128d v1);
extern __m256d _mm256_acosh_pd(__m256d v1);
```

Arguments

\( v1 \)
vector with float64 values
Description
Calculates the inverse hyperbolic cosine of vector \( v1 \) values.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_acosh_ps, _mm256_acosh_ps
Calculates the inverse hyperbolic cosine value. Vector variant of \( \text{acosh}(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_acosh_ps(__m128 v1);
extern __m256 _mm256_acosh_ps(__m256 v1);

Arguments
\( v1 \)
vector with float32 values

Description
Calculates the inverse hyperbolic cosine of vector \( v1 \) values.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asin_pd, _mm256_asin_pd
Calculates inverse sine value. Vector variant of \( \text{asin}(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_asin_pd(__m128d v1);
extern __m256d _mm256_asin_pd(__m256d v1);

Arguments
\( v1 \)
vector with float64 values
Description
Calculates the arc sine of vector v1 values.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asin_ps, _mm256_asin_ps
Calculates inverse sine value. Vector variant of asin(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 _mm_asin_ps(__m128 v1);
extern __m256 _mm256_asin_ps(__m256 v1);

Arguments
v1 vector with float32 values

Description
Calculates the arc sine of vector v1 values.

Returns
128-bit/256-bit vector with result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asinh_pd, _mm256_asinh_pd
Calculates the inverse hyperbolic sine value. Vector variant of asinh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d _mm_asinh_pd(__m128d v1);
extern __m256d _mm256_asinh_pd(__m256d v1);

Arguments
v1 vector with float64 values
Description
Calculates the inverse hyperbolic sine of vector \( v1 \) elements.

Returns
128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the `svm` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

`_mm_asinh_ps, _mm256_asinh_ps`
*Calculates the inverse hyperbolic sine value. Vector variant of asinh(x) function for a 128-bit/256-bit vector argument of float32 values.*

**Syntax**

```c
extern __m128 _mm_asinh_ps(__m128 v1);
extern __m256 _mm256_asinh_ps(__m256 v1);
```

**Arguments**

- \( v1 \) - vector with float32 values

**Description**
Calculates the inverse hyperbolic sine of vector \( v1 \) elements.

**Returns**
128-bit/256-bit vector with the result of the operation.

**NOTE**
Many routines in the `svm` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

`_mm_atan_pd, _mm256_atan_pd`
*Calculates inverse tangent value. Vector variant of atan(x) function for a 128-bit/256-bit vector argument of float64 values.*

**Syntax**

```c
extern __m128d _mm_atan_pd(__m128d v1);
extern __m256d _mm256_atan_pd(__m256d v1);
```

**Arguments**

- \( v1 \) - vector with float64 values
Description
Calculates the arc tangent of vector \( v1 \) elements. In effect, the tangent of each resulting element value is the value of the corresponding \( v1 \) vector element.

Returns
128-bit/256-bit vector with result of the operation.

NOTE
Many routines in the \svml\ library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_atan\_ps, \_mm256\_atan\_ps
Calculates inverse tangent value. Vector variant of \( \text{atan}(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax
extern __m128 \_mm\_atan\_ps(__m128 v1);
extern __m256 \_mm256\_atan\_ps(__m256 v1);

Arguments
\( v1 \)  
vector with float32 values

Description
Calculates the arc tangent of vector \( v1 \) elements. In effect, the tangent of each resulting element value is the value of the corresponding \( v1 \) vector element.

Returns
128-bit/256-bit vector with result of the operation.

NOTE
Many routines in the \svml\ library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_atan2\_pd, \_mm256\_atan2\_pd
Calculates the inverse tangent of float64 variables \( x \) and \( y \). Vector variant of \( \text{atan2}(x, y) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax
extern __m128d \_mm\_atan2\_pd(__m128d v1, __m128 v2);
extern __m256d \_mm256\_atan2\_pd(__m256d v1, __m256 v2);
Arguments

v1 vector with float64 values
v2 vector with float64 values

Description

Calculates the arc tangent of corresponding float64 elements of vectors v1 and v2. The following is an illustration of the atan2 operation:

```
Res[0]  = atan2(v1[0], v2[0])
Res[1]  = atan2(v1[1], v2[1])
Res[2]  = atan2(v1[2], v2[2])
Res[15] = atan2(v1[15], v2[15])
...  
```

**NOTE**

This calculation is similar to calculating the arc tangent of \( y / x \), except that the signs of both arguments are used to determine the quadrant of the result.

Returns

Result of the bitwise operation.

**NOTE**

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_atan2_ps__, __mm256_atan2_ps__

*Calculates the inverse tangent of float32 variables x and y. Vector variant of atan2(x, y) function for a 128-bit/256-bit vector argument of float32 values.*

Syntax

```
extern __m128 _mm_atan2_ps(__m128 v1, __m128 v2);
extern __m256 _mm256_atan2_ps(__m256 v1, __m256 v2);
```

Arguments

v1 vector with float32 values
v2 vector with float32 values

Description

Calculates the arc tangent of corresponding float32 elements of vectors v1 and v2. The following is an illustration of the atan2 operation:

```
Res[0]  = atan2(v1[0], v2[0])
Res[1]  = atan2(v1[1], v2[1])
Res[2]  = atan2(v1[2], v2[2])
Res[15] = atan2(v1[15], v2[15])
...  
```
NOTE
This calculation is similar to calculating the arc tangent of \( \frac{y}{x} \), except that the signs of both arguments are used to determine the quadrant of the result.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_atanh_pd, _mm256_atanh_pd
Calculates inverse hyperbolic tangent value. Vector variant of \( \text{atanh}(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

extern __m128d mm_atanh_pd(__m128d v1);
extern __m256d mm256_atanh_pd(__m256d v1);

Arguments

v1
vector with float64 values

Description
Calculates the inverse hyperbolic tangent of vector \( v1 \) elements. In effect, the hyperbolic tangent of each resulting element value is the value of the corresponding \( v1 \) vector element.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

__mm_atanh_ps, _mm256_atanh_ps
Calculates inverse hyperbolic tangent value. Vector variant of \( \text{atanh}(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern __m128 mm_atanh_ps(__m128 v1, __m128 v2);
extern __m256 mm256_atanh_ps(__m256 v1);
Arguments

\(v1\) vector with float32 values

Description
Calculates the inverse hyperbolic tangent of vector \(v1\) elements. In effect, the hyperbolic tangent of each resulting element value is the value of the corresponding \(v1\) vector element.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the **svml** library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

_mm_cos_pd, _mm256_cos_pd

*Calculates cosine value. Vector variant of \(\cos(x)\) function for a 128-bit/256-bit vector argument of float64 values.*

Syntax

```c
extern __m128d _mm_cos_pd(__m128d v1);
extern __m256d _mm256_cos_pd(__m256d v1);
```

Arguments

\(v1\) vector with float64 values

Description
Calculates the cosine of vector \(v1\) elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the **svml** library are more optimized for Intel\textsuperscript{®} microprocessors than for non-Intel microprocessors.

_mm_cos_ps, _mm256_cos_ps

*Calculates cosine value. Vector variant of \(\cos(x)\) function for a 128-bit/256-bit vector argument of float32 values.*

Syntax

```c
extern __m128 _mm_cos_ps(__m128 v1);
extern __m256 _mm256_cos_ps(__m256 v1);
```
Arguments

v1 vector with float32 values

Description
Calculates the cosine of vector v1 elements.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosd_pd, _mm256_cosd_pd
Calculates cosine value. Vector variant of \( \cos(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

extern __m128d _mm_cosd_pd(__m128d v1);
extern __m256d _mm256_cosd_pd(__m256d v1);

Arguments

v1 vector with float64 values

Description
Calculates the cosine of vector v1 elements, measured in degrees.

Returns
128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosd_ps, _mm256_cosd_ps
Calculates cosine value. Vector variant of \( \cos(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern __m128 _mm_cosd_ps(__m128 v1);
extern __m256 _mm256_cosd_ps(__m256 v1);
Arguments

\( v1 \)  
vector with float32 values

Description

Calculates the cosine of vector \( v1 \) elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\texttt{\_mm\_cosh\_pd, \_mm256\_cosh\_pd}

Calculates the hyperbolic cosine value. Vector variant of \( \cosh(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

\begin{verbatim}
extern __m128d _mm_cosh_pd(__m128d v1, __m128d v2);
extern __m256d _mm256_cosh_pd(__m256d v1);
\end{verbatim}

Arguments

\( v1 \)  
vector with float64 values

Description

Calculates the hyperbolic cosine of vector \( v1 \) elements, which is defined mathematically as:

\[
\frac{\exp(x) + \exp(-x)}{2}
\]

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\texttt{\_mm\_cosh\_ps, \_mm256\_cosh\_ps}

Calculates the hyperbolic cosine value. Vector variant of \( \cosh(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

\begin{verbatim}
extern __m128 _mm_cosh_ps(__m128 v1);
extern __m256 _mm256_cosh_ps(__m256 v1);
\end{verbatim}
Arguments

\( v1 \) vector with float32 values

Description

Calculates the hyperbolic cosine of vector \( v1 \) elements, which is defined mathematically as:

\[
\frac{\exp(x) + \exp(-x)}{2}
\]

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

\_mm\_sin\_pd, \_mm256\_sin\_pd

Calculates sine value. Vector variant of \( \sin(x) \) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

extern \_m128d \_mm\_sin\_pd(__m128d v1);
extern \_m256d \_mm256\_sin\_pd(__m256d v1);

Arguments

\( v1 \) vector with float64 values

Description

Calculates the sine of vector \( v1 \) elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

\_mm\_sin\_ps, \_mm256\_sin\_ps

Calculates sine value. Vector variant of \( \sin(x) \) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern \_m128 \_mm\_sin\_ps(__m128 v1);
extern \_m256 \_mm256\_sin\_ps(__m256 v1);
Arguments

v1 vector with float32 values

Description

Calculates the sine of vector v1 elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sind_pd, _mm256_sind_pd

Calculates sine value. Vector variant of sind(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

extern __m128d _mm_sind_pd(__m128d v1);
extern __m256d _mm256_sind_pd(__m256d v1);

Arguments

v1 vector with float64 values

Description

Calculates the sine of vector v1 elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sind_ps, _mm256_sind_ps

Calculates sine value. Vector variant of sind(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern __m128 __m128_mm_sind_ps(__m128 v1);
extern __m256 __m256_mm_sind_ps(__m256 v1);
Arguments

v1  
vector with float32 values

Description

Calculates the sine of vector v1 elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sinh_pd, _mm256_sinh_pd

Calculates the hyperbolic sine value. Vector variant of sinh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

extern __m128d _mm_sinh_pd(__m128d v1);
extern __m256d _mm256_sinh_pd(__m256d v1);

Arguments

v1  
vector with float64 values

Description

Calculates the hyperbolic sine of vector v1 elements, which is defined mathematically as:

\[
\frac{\exp(x) - \exp(-x)}{2}
\]

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sinh_ps, _mm256_sinh_ps

Calculates the hyperbolic sine value. Vector variant of sinh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

extern __m128 _mm_sinh_ps(__m128 v1);
extern __m256 _mm256_sinh_ps(__m256 v1);

**Arguments**

v1

vector with float32 values

**Description**

Calculates the hyperbolic sine of vector v1 elements, which is defined mathematically as:

\[
\frac{\exp(x) - \exp(-x)}{2}
\]

**Returns**

128-bit/256-bit vector with the result of the operation.

---

**NOTE**

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**_mm_tan_pd, _mm256_tan_pd**

*Calculates tangent value. Vector variant of \( \tan(x) \) function for a 128-bit/256-bit vector arguments with float64 values.*

**Syntax**

extern __m128d _mm_tan_pd(__m128d v1);
extern __m256d _mm256_tan_pd(__m256d v1);

**Arguments**

v1

vector with float64 values

**Description**

Calculates the tangent of vector v1 elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

---

**NOTE**

Many routines in the `svml` library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**_mm_tan_ps, _mm256_tan_ps**

*Calculates tangent value. Vector variant of \( \tan(x) \) function for a 128-bit/256-bit vector arguments with float32 values.*

**Syntax**

extern __m128 _mm_tan_ps(__m128 v1);
extern __m256 _mm256_tan_ps(__m256 v1);

**Arguments**

v1  
vector with float32 values

**Description**

Calculates the tangent of vector v1 elements.

**Returns**

128-bit/256-bit vector with the result of the operation.

---

NOTE

Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

__mm_tan_pd, __mm256_tan_pd__

*Calculates tangent value. Vector variant of tand(x) function for a 128-bit/256-bit vector arguments with float64 values.*

**Syntax**

extern __m128d _mm_tan_pd(__m128d v1);
extern __m256d _mm256_tan_pd(__m256d v1);

**Arguments**

v1  
vector with float64 values

**Description**

Calculates the tangent of vector v1 elements, measured in degrees.

**Returns**

128-bit/256-bit vector with the result of the operation.

---

NOTE

Many routines in the *svml* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

__mm_tand_ps, __mm256_tand_ps__

*Calculates the tangent value. Vector variant of tand(x) function for a 128-bit/256-bit vector arguments with float32 values.*

**Syntax**

extern __m128 _mm_tand_ps(__m128 v1);
extern __m256 _mm256_tand_ps(__m256 v1);
Arguments

\( v1 \)
vector with float32 values

Description
Calculates the tangent of vector \( v1 \) elements, measured in degrees.

Returns
128-bit/256-bit vector with the result of the operation.

\textbf{NOTE}
Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_tanh\_pd, \_mm256\_tanh\_pd
Calculates hyperbolic tangent value. Vector variant of \( \tanh(x) \) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

\begin{verbatim}
extern \_m128d \_mm\_tanh\_pd(__m128d v1);
extern \_m256d \_mm256\_tanh\_pd(__m256d v1);
\end{verbatim}

Arguments

\( v1 \)
vector with float64 values

Description
Calculates the hyperbolic tangent of vector \( v1 \) elements.

Returns
128-bit/256-bit vector with the result of the operation.

\textbf{NOTE}
Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_tanh\_ps, \_mm256\_tanh\_ps
Calculates hyperbolic tangent value. Vector variant of \( \tanh(x) \) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

\begin{verbatim}
extern \_m128 \_mm\_tanh\_ps(__m128 v1);
extern \_m256 \_mm256\_tanh\_ps(__m256 v1);
\end{verbatim}
Arguments

\( v1 \)  
vector with float32 values

Description

Calculates the hyperbolic tangent of vector \( v1 \) elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE

Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_sincos\_pd, \_mm256\_sincos\_pd

\textit{Calculates the sine and cosine values. Vector variant of sincos}(x, \&sin\_x, \&cos\_x) function for a 128-bit/256-bit vector with float64 values.

Syntax

extern \_m128d \_mm\_sincos\_pd(\_m128d *p\_cos, \_m128d v1);
extern \_m256d \_mm256\_sincos\_pd(\_m256d *p\_cos, \_m256d v1);

Arguments

*\( p\_cos \)  
points to vector of cosine results (pointer must be aligned on 16 bytes, or declared as \_m128d* instead)

\( v1 \)  
vector with float64 values

Description

Calculates sine and cosine values of vector \( v1 \) elements.

The cosine and sine values cannot be returned in the result vector. Therefore, the intrinsic stores the cosine values at a location pointed to by \( p\_cos \), and returns only the sine values in the 128-bit result vector.

Returns

128-bit/256-bit vector with the sine results.

NOTE

Many routines in the \textit{svml} library are more optimized for Intel\textsuperscript{\textregistered} microprocessors than for non-Intel microprocessors.

\_mm\_sincos\_ps, \_mm256\_sincos\_ps

\textit{Calculates the sine and cosine values. Vector variant of sincos}(x, \&sin\_x, \&cos\_x) function for a 128-bit/256-bit vector with float32 values.
**Syntax**

```c
extern __m128 _mm_sincos_ps(__m128 *p_cos, __m128 v1);
extern __m256 _mm256_sincos_ps(__m256 *p_cos, __m256 v1);
```

**Arguments**

- *p_cos points to vector of cosine results (pointer must be aligned on 16 bytes, or declared as __m128* instead)
- v2 vector with float32 values

**Description**

Calculates sine and cosine values of vector v1 elements.

The cosine and sine values cannot be returned in the result vector. Therefore, the intrinsic stores the cosine values at a location pointed to by p_cos, and returns only the sine values in the 128-bit result vector.

**Returns**

128-bit/256-bit vector with the sine results.

---

**NOTE**

Many routines in the svml library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**Libraries**

The Intel® C++ Compiler lets you use all the standard run-time libraries that are part of Microsoft® Visual C+++. The options described in this section can help you determine which libraries your application uses.

To create libraries, use the `lib.exe` tool or `xilib.exe` tool.

**Creating Libraries**

Libraries are simply an indexed collection of object files that are included as needed in a linked program. Combining object files into a library makes it easy to distribute your code without disclosing the source. It also reduces the number of command-line entries needed to compile your project.

**Static Libraries**

Executables generated using static libraries are no different than executables generated from individual source or object files. Static libraries are not required at runtime, so you do not need to include them when you distribute your executable. At compile time, linking to a static library is generally faster than linking to individual source files.

To build a static library on Linux*:

1. Use the `-c` option to generate object files from the source files:

   ```bash
   icpc -c my_source1.cpp my_source2.cpp my_source3.cpp
   ```

2. Use the GNU* tool `ar` to create the library file from the object files:

   ```bash
   ar rc my_lib.a my_source1.o my_source2.o my_source3.o
   ```
3. Compile and link your project with your new library:

```shell
icpc main.cpp my_lib.a
```

If your library file and source files are in different directories, use the `L` option to indicate where your library is located:

```shell
icpc -L/cpp/libs main.cpp my_lib.a
```

To build a static library on macOS*:

1. Use the following command to generate object files and create the library file:

```shell
icpc -fpic -o mylib.a -staticlib my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Compile and link your project with your new library:

```shell
icpc main.cpp my_lib.a
```

If your library file and source files are in different directories, use the `L` option to indicate where your library is located:

```shell
icpc -L/cpp/libs main.cpp my_lib.a
```

If you are using Interprocedural Optimization, see the topic on Creating a Library from IPO Objects using `xiar`.

### Shared Libraries

Shared libraries, also referred to as dynamic libraries or Dynamic Shared Objects (DSO), are linked differently than static libraries. At compile time, the linker insures that all the necessary symbols are either linked into the executable, or can be linked at runtime from the shared library. Executables compiled from shared libraries are smaller, but the shared libraries must be included with the executable to function correctly. When multiple programs use the same shared library, only one copy of the library is required in memory.

To build a shared library on Linux*:

1. Use options `fPIC` and `c` to generate object files from the source files:

```shell
icpc -fPIC -c my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Use the `shared` option to create the library file from the object files:

```shell
icpc -shared -o my_lib.so my_source1.o my_source2.o my_source3.o
```

3. Compile and link your project with your new library:

```shell
icpc main.cpp my_lib.so
```

To build a shared library on macOS*:

1. Use the following command to generate object files and create the library file:

```shell
icpc -fPIC -o my_lib.so -dynamiclib my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Compile and link your project with your new library:

```shell
icpc main.cpp my_lib.dylib
```

Use the following options to create libraries on Windows*:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/LD, /LDD</code></td>
<td>Produces a DLL. <code>d</code> indicates debug version.</td>
</tr>
<tr>
<td><code>/MD, /MDd</code></td>
<td>Compiles and links with the dynamic, multi-thread C run time library. <code>d</code> indicates debug version.</td>
</tr>
</tbody>
</table>
**Option** | **Description**
---|---
/MT, /MTd | Compiles and links with the static, multi-thread C run time library. d indicates debug version.
/Zl | Disables embedding default libraries in object files.

**See Also**
Using Intel Shared Libraries

**See Also**
/LD compiler option
/MD compiler option
/MT compiler option

---

**Using Intel Shared Libraries**

This topic applies to Linux* and macOS*.

By default, the Intel® C++ Compiler links Intel® C++ libraries dynamically. The GNU*, Linux*, and macOS* system libraries are also linked dynamically.

**Options for Shared Libraries (Linux*)**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-shared-intel</td>
<td>Use the shared-intel option to link Intel® C++ libraries dynamically (default). This has the advantage of reducing the size of the application binary, but it also requires the libraries to be on the application's target system.</td>
</tr>
<tr>
<td>-shared</td>
<td>The shared option instructs the compiler to build a Dynamic Shared Object (DSO) instead of an executable. For more details, refer to the ld man page documentation.</td>
</tr>
<tr>
<td>-fpic</td>
<td>Use the fpic option when building shared libraries. It is required for the compilation of each object file included in the shared library.</td>
</tr>
</tbody>
</table>

**Options for Shared Libraries (macOS*)**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dynamiclib</td>
<td>Use the dynamiclib option to invoke the libtool command to generate dynamic libraries.</td>
</tr>
<tr>
<td>-fpic</td>
<td>Use the fpic option when building shared libraries. It is required for the compilation of each object file included in the shared library.</td>
</tr>
</tbody>
</table>

**Using Shared Libraries on macOS**

This topic only applies to macOS*.

On macOS*, it is possible to store path information in shared libraries to perform library searches. The compiler installation changes the path to the installation directory, but you will need to modify these paths if you move the libraries elsewhere. For example, you may want to bundle redistributable Intel® libraries with your application. This eliminates the dependency on libraries found on DYLD_LIBRARY_PATH.
If your compilations do not use **DYLD_LIBRARY_PATH** to find libraries, and you distribute executables that depend on shared libraries, then you will need to modify the Intel shared libraries (../*.dylib) using the **install_name_tool** to set the correct path to the shared libraries. This also permits the end-user to launch the application by double-clicking on the executable. The command below will modify each library with the correct absolute path information:

```bash
for i in *.dylib
do
    echo -change $i `pwd`/$i
done > changes
for i in *.dylib
do
    install_name_tool `cat changes` $i
done
```

You can also use the **install_name_tool** to set **@executable_path** to change path information for the libraries bundled in your application by changing the path appropriately.

Be sure to recompile your sources after modifying the libraries.

## Managing Libraries

### Managing Libraries on Linux* and macOS*

During compilation, the compiler reads the **LIBRARY_PATH** environment variable for static libraries it needs to link when building the executable. At runtime, the executable will link against dynamic libraries referenced in the **LD_LIBRARY_PATH** environment variable.

### Modifying **LIBRARY_PATH**

If you want to add a directory, /libs for example, to the **LIBRARY_PATH**, you can do either of the following:

- **command line**: `export LIBRARY_PATH=/libs:$LIBRARY_PATH`
- **startup file**: `export LIBRARY_PATH=/libs:$LIBRARY_PATH`

To compile `file.cpp` and link it with the library `mylib.a`, enter the following command:

```bash
icpc file.cpp mylib.a     //on Linux* and macOS*
```

The compiler passes file names to the linker in the following order:

1. the object file.
2. any objects or libraries specified at the command line, in a response file, or in a configuration file.
3. the Intel® Math Library, `libimf.a`.

By default, the Intel® C++ Compiler uses the GNU* implementation of the C++ Standard Library (libstdc++) on OS* X v10.8, and libc++ implementation on OS* X v10.9. You can change the default using the **-stdlib** option:

```bash
-stdlib=libc++    //to switch to libc++
-stdlib=libstdc++    //to switch to libstdc++
```

### Managing Libraries on Windows*

The **LIB** environment variable contains a semicolon-separated list of directories in which the Microsoft* linker will search for library (.lib) files. The compiler does not specify library names to the linker, but includes directives in the object file to specify the libraries to be linked with each object.

For more information on adding library names to the response file and the configuration file, see Using Response Files and Using Configuration Files.
To specify a library name on the command line, you must first add the library’s path to the `LIB` environment variable. Then, to compile `file.cpp` and link it with the library `mylib.lib`, enter the following command:

```
icl file.cpp mylib.lib
```

### Redistributing Libraries When Deploying Applications

When you deploy your application to systems on which the Intel® C++ Compiler is not installed, you need to redistribute certain Intel® libraries to which your application is linked. You can do so in one of the following ways:

- **Statically link your application.**
  
  An application built with statically-linked libraries eliminates the need to distribute runtime libraries with the application executable. By linking the application to the static libraries, you are not dependent on the Intel® Fortran or Intel® C/C++ dynamic shared libraries.

- **Dynamically link your application.**
  
  If you must build your application with dynamically linked (or shared) compiler libraries, you should address the following concerns:

  - You must build your application with shared or dynamic libraries that are redistributable.
  - Pay careful attention to the directory where the redistributables are installed and how the OS finds them.
  - You should determine which shared or dynamic libraries your application needs.

  See the Intel® Developer Zone articles at http://software.intel.com (search for "redistributable libraries") for:

  - the redistributable library installation package
  - everything you need to know to redistribute these libraries

The redistributable library installation package is available at:

### Intel’s Memory Allocator Library

Intel's `libqkmalloc` library for fast memory allocation provides a C-level interface for memory allocation that is optimized for performance.

You can link the `libqkmalloc` library as a shared library only on Linux® platforms for Intel® 64 architecture. This library provides optimized implementation of standard allocation routines `malloc`, `calloc`, `realloc`, and `free`, and is C99 standard compliant.

**NOTE** This library is limited to work only on Intel® processors and will redirect to standard C routines at runtime if used on non-Intel® processors.

### Using Intel’s Custom Memory Allocator Library

You can use the `libqkmalloc` library by linking directly to it or by using the `LD_PRELOAD` environment variable.

To ensure the application will override the standard library allocation routines with `libqkmalloc`, set the environment variable `LD_PRELOAD` in the command line before the application execution. This environment variable allows you to set the path of the library that will be loaded before any other library (including the C runtime library), and the application will use symbols from this specified library instead of the symbols from the standard library.

### Restrictions

This library does not support threaded code such as OpenMP® and is not thread-safe. It should not be used simultaneously from multiple threads. For the best results this library should be used with large throughput workloads.
Introduction to the SIMD Data Layout Templates

SIMD Data Layout Templates (SDLT) is a C++11 template library providing containers that represent arrays of "Plain Old Data" objects (a struct whose data members do not have any pointers/references and no virtual functions) using layouts that enable generation of efficient SIMD (single instruction multiple data) vector code. SDLT uses standard ISO C++11 code. It does not require a special language or compiler to be functional, but takes advantage of performance features (such as OpenMP* SIMD extensions, Intel® Cilk™ Plus SIMD extensions, and pragma ivdep) that may not be available to all compilers. It is designed to promote scalable SIMD vector programming. To use the library, specify SIMD loops and data layouts using explicit vector programming model and SDLT containers, and let the compiler generate efficient SIMD code in an efficient manner.

Many of the library interfaces employ generic programming, in which interfaces are defined by requirements on types and not specific types. The C++ Standard Template Library (STL) is an example of generic programming.Generic programming enables SDLT to be flexible yet efficient. The generic interfaces enable you to customize components to your specific needs.

The net result is that SDLT enables you to specify a preferred SIMD data layout far more conveniently than re-structuring your code completely with a new data structure for effective vectorization, and at the same time can improve performance.

Motivation

C++ programs often represent an algorithm in terms of high level objects. For many algorithms there is a set of data that the algorithm will need to process. It is common for the data set to be represented as array of "plain old data" objects. It is also common for developers to represent that array with a container from the C++ Standard Template Library, like std::vector. For example:

```cpp
struct Point3s
{
    float x;
    float y;
    float z;
    // helper methods
};

std::vector<Point3s> inputDataSet(count);
std::vector<Point3s> outputDataSet(count);

for(int i=0; i < count; ++i) {
    Point3s inputElement = inputDataSet[i];
    Point3s result = // transformation of inputElement that is independent of other iterations
        // can keep algorithm high level using object helper methods
    outputDataSet[i] = result;
}
```
When possible a compiler may attempt to vectorize the loop above, however the overhead of loading the "Array of Structures" data set into vector registers may overcome any performance gain of vectorizing. Programs exhibiting the scenario above could be good candidates to use a SDLT container with a SIMD-friendly internal memory layout. SDLT containers provide accessor objects to import and export Primitives between the underlying memory layout and the objects original representation. For example:

```cpp
SDLT_PRIMITIVE(Point3s, x, y, z)

dlt::soa1d_container<Point3s> inputDataSet(count);
dlt::soa1d_container<Point3s> outputDataSet(count);

auto inputData = inputDataSet.const_access();
auto outputData = outputDataSet.access();

#pragma forceinline recursive
#pragma omp simd
for(int i=0; i < count; ++i) {
  Point3s inputElement = inputData[i];
  Point3s result = // transformation of inputElement that is independent of other iterations
                   // can keep algorithm high level using object helper methods
  outputData[i] = result;
}
```

When a local variable inside the loop is imported from or exported to using that loop's index, the compiler's vectorizer can now access the underlying SIMD friendly data format and when possible perform unit stride loads. If the compiler can prove nothing outside the loop can access the loop's local object, then it can optimize its private representation of the loop object be "Structure of Arrays" (SOA). In our example, the container's underlying memory layout is also SOA and unit stride loads can be generated. The Container also allocates aligned memory and its accessor objects provide the compiler with the correct alignment information for it to optimize code generation accordingly.

**Version Information**

This documentation is for SDLT version 2, which extends version 1 by introducing support for n-dimensional containers.

**Backwards Compatibility**

Public interfaces of version 2 are fully backward compatible with interfaces of version 1.

The backwards compatibility includes:

- Existing source code compatibility.
  - Any source code using the SDLT v1 public API (non-internal interfaces) can be recompiled against SDLT v2 headers with no changes.
  - Binary compatibility.
    - Because SDLT v2 API's exist in a new name space, sdlt::v2, all ABI linkage should not collide with any existing SDLT v1 ABI's that exist only in sdlt namespace.
    - A binary, dynamically-linked library that uses SDLT v1 internally, can be linked into a program using SDLT v2, and vice versa.
    - Passing SDLT containers or accessors as part of a libraries public API (ABI). When SDLT is used as part of an ABI, that library and the calling code must use the same version of SDLT. They cannot be mixed or matched.

This compatibility doesn't cover internal implementation. Internal implementation for SDLT v1 was updated and unified with parts introduced in v2, so for codes dependent on internal interfaces backwards compatibility is not guaranteed.
Deprecated
The interfaces below are deprecated; use the replacements provided in the table.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

Usage Guidelines: Function Calls and Containers

Function Calls
Function calls are a commonly used programming construct. Follow these simple guidelines when using SDLT containers:

- If an SDLT Primitive is passed to a function by value, by pointer, or by reference, be sure to inline them
- Any Non-inlined functions should be SIMD enabled (for example, marke them with #pragma omp declare simd).

If a loop variable is passed to a non-inlined function, the current C++ Application Binary Interface (ABI) requires the memory layout match object's original which could cause additional data transformations or inhibit vectorization. For that reason, the SDLT approach works best when all the methods or functions called are inlined or use #pragma omp declare simd. Marking a function "inline" explicitly or implicitly is only a hint. Compilers have several limits and heuristics that could cause a function to not be inlined. To avoid this issue, we recommend utilizing the #pragma forceinline recursive which instructs the compiler to ignore its limits and heuristics: causing all functions in the following code block that could be inlined to actually be inlined together with any functions called, and functions they call, and so on. Please also note that this can cause the loop body and/or the function body to become too big to optimize. Under such circumstances, carefully examine and restructure the function call boundaries and consider applying non-inlined, SIMD-enabled function calls.

1-Dimensional Containers Overview
What if that std::vector<typename> could store data SIMD-friendly format internally while exposing an AOS view to the programmer?
The 1-dimensional containers in SDLT aim to achieve that goal. They can abstract the in-memory data layout of an array of objects to:
1. AOS (Array of Structures)
2. SOA (Structure of Arrays) which is SIMD friendly
**Import/Export Only**

As the memory layout is abstracted and may not match the original structure’s layout, containers cannot provide memory references to the underlying data. Only import or export of the object to and from a particular element in the container. In use, an algorithm might require some minor code changes to follow import/export paradigm, however algorithm itself should read/flow the same.

The 1D containers in SDLT are dynamically resizable with an interface similar to `std::vector<T>`. To avoid accidental misuse of copying containers into C++11 lambda functions we chose to delete the container’s copy constructor and instead provide explicit “clone” method instead.

Containers provide SDLT concepts of an accessor and const_accessor for use with SIMD loops, interfaces for `std::vector` compatibility are intended for ease of integration, not high performance.

Just like `std::vector`, the containers own the array data and its scope controls the life of that data.

**n-Dimensional Containers Overview**

Multi-dimensional containers generalize ideas from 1-dimensional containers; they separate multi-dimensional access semantics from storage logic in an abstract way. A multi-dimensional SDLT container is a generic container that handles an arbitrary number of dimensions, and at the same time internally represents data as needed. Unlike 1-dimensional containers, multi-dimensional containers are not resizable and don’t have interfaces like that of `std::vector`. While 1-dimensional containers are like `std::vector` with decoupled storage, multi-dimensional containers are more akin to arrays (statically sized or variable length).

Below is an example of an n-dimensional container parameterized by three concerns: the data item (primitive) type, the storage layout in memory, and the observed shape of the container.

\[ n\text{-}_{\text{container}}\langle \text{PrimitiveT}, \text{LayoutT}, \text{ExtentsT} \rangle \]

**Optimization Notice**

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Constructing an n_container**

**Description**

An N-dimensional (multi-dimensional) container must be constructed before it can be used. The data type to be contained must first be declared as a `SDLT_PRIMITIVE`, then a data layout is chosen, and finally the shape of the container is determined describing the extents of each dimension.

**Specifying Data Layout**
Rather than defining different containers for different data layouts, the data layout to use is specified as a template parameter to the container.

Available layouts are summarized in table below. Full details can found on the table in the topic n_container.

<table>
<thead>
<tr>
<th>Layout</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layout::soa&lt;&gt;</td>
<td>Structure of Arrays (SOA). Each data member of the Primitive will have its own N-dimensional array.</td>
</tr>
<tr>
<td>layout::soa_per_row&lt;&gt;</td>
<td>Structure of Arrays Per Row. Each data member of the Primitive will have its own 1-dimensional array per row. Layout repeats for remaining N-1 dimensions.</td>
</tr>
<tr>
<td>layout::aos_by_struct</td>
<td>Array of Structures (AOS) Accessed by Struct. Native AOS layout and data access.</td>
</tr>
<tr>
<td>layout::aos_by_stride</td>
<td>Array of Structures Accessed by Stride. Native SOA data access through pointers to the built in types of members using a stride to account for the size of the Primitive.</td>
</tr>
</tbody>
</table>

### Numbers and Constants

In order to define shape, integer values can be provided in three different forms, each successively providing less information to compiler. It is advised to use as precise specification as possible. The compiler may optimize better with more information.

<table>
<thead>
<tr>
<th>Integer Value Specification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fixed&lt;int NumberT&gt;</td>
<td>Known at compile time.</td>
</tr>
<tr>
<td>foo(fixed&lt;1080&gt;(), fixed&lt;1920&gt;());</td>
<td>The suffix _fixed will declare an equivalent literal. For example, (1080_fixed is equivalent to fixed&lt;1080&gt;.</td>
</tr>
<tr>
<td>foo(1080_fixed, 1920_fixed);</td>
<td>)</td>
</tr>
<tr>
<td>aligned&lt;int AlignmentT&gt;(number)</td>
<td>Programmer guarantees the number is a multiple of the AlignmentT.</td>
</tr>
<tr>
<td>foo(aligned&lt;8&gt;(height), aligned&lt;128&gt;(width));</td>
<td></td>
</tr>
<tr>
<td>“int”</td>
<td>Arbitrary integer value.</td>
</tr>
<tr>
<td>foo(width, height);</td>
<td></td>
</tr>
</tbody>
</table>

### Specifying Container Shape

`n_extent_t<...>` is a variadic template that accepts any number of arguments defining dimensions. Because construction using this type may look unclear, a generator object, `n_extent`, is provided to construct extents for all dimensions using a familiar array-definition-like syntax. Extent values may be specified using the most precise representation possible, as described above, to allow the compiler to better prove any potential data alignments.

```cpp
n_extent[height][width]; // OK
n_extent[height][aligned<128>(width)]; // Better
n_extent[1080_fixed][1920_fixed]; // Best
```

### Defining an n_container

Using a previously declared primitive (same as SDLT v1),

```cpp
struct RGBAs { float red, green, blue, alpha; }
SDLT_PRIMITIVE(RGBAs, red, green, blue, alpha)
```
A two-dimensional container of RGBAs with HD image size 1920x0180 can be declared and instantiated as in the below example.

```
typedef n_container<RGBAs, layout::soa, n_extent_t<fixed<1080>, fixed<1920>>> HdImage;
HdImage image1;
```

If sizes are not known, a container may be defined with extents unknown to the compiler but known at run-time when an instance of the container is created.

```
typedef n_container<RGBAs, layout::soa, n_extent_t<int, int>> Image;
Image image2(n_extent[height][width]);
```

Additionally, the templated factory function `make_n_container<PrimitiveT, LayoutT>` may be used to create containers.

```
auto image1 = make_n_container<RGBAs, layout::soa>(n_extent[1080_fixed][1920_fixed]);
auto image2 = make_n_container<RGBAs, layout::soa>(n_extent[height][width]);
```

### Accessing Cells

Containers own data. To get to the data inside, use an "accessor."

```
auto ca = image1.const_access();
auto a = image2.access();
```

Specify the index for each dimension with a series of calls to the array subscript operator [], similar to a multi-dimensional array in C.

```
RGBAs pixel = ca[y][x];
float greyscale = (pixel.red + pixel.green + pixel.blue)/3;
a[y][x] = RGBAs(greyscale, greyscale, greyscale);
```

### Discovering Extents

Accessors know their extents.

Use template function `extent_d<int DimensionT>(object)`.

```
for (int y = 0; y < extent_d<0>(ca); ++y)
    for (int x = 0; x < extent_d<1>(ca); ++x) {
        RGBAs pixel = ca[y][x];
        // ...
    }
```

For convenience, non-template methods are also provided.

```
for (int y = 0; y < ca.extent_d0(); ++y)
    for (int x = 0; x < ca.extent_d1(); ++x) {
        RGBAs pixel = ca[y][x];
        // ...
    }
```

### Lowering Dimensions

The result of not specifying all the dimensions required by an accessor is a new accessor with a lower rank that can then be accessed.

```
auto cay = ca[y];
RGBAs pixel = cay[x];
```
Bounds

Description

`bounds_t<LowerT, UpperT>` holds the lower and upper bounds of a half-open interval. It is templated to allow the different integer representations for the lower and upper bounds. The intent is to model a valid iteration space over a single dimension.

Bounds can be used to iterate over an entire extent or to restrict iteration space within an extent.

Creating Bounds

Bounds can be created using full `bounds_t` type, but this may be tedious.

- `bounds_t<int, int>(start, finish)`
- `bounds_t<int, aligned<16>>(start, aligned<16>(finish))`
- `bounds_t<fixed<0>, fixed<1920>>()`

It is simpler and clearer to use factory function `bounds` to build a `bounds_t<>`.

- `bounds(start, finish);`
- `bounds(start, aligned<16>(finish));`
- `bounds(0_fixed, 1920_fixed)`

Discovering Bounds

Accessors know their valid iteration space. Initial bounds for an accessor are set to set the lower bound to be `fixed<0>` and the upper bound set to the value and type of the dimension's extent as specified during construction of the `n_container(fixed<>,aligned<>, or int)`.

To query bounds for given dimension of the accessor use template function `bounds_d<int DimensionT>(object)`.

```cpp
auto b0 = bounds_d<0>(ca);  
auto b1 = bounds_d<1>(ca);  
for (int y = b0.lower(); y < b0.upper(); ++y)  
  for (int x = b1.lower(); x < b1.upper(); ++x)  
    RGBAs pixel = ca[y][x];  
    // ...
```

`bounds_t` can participate in C++11 range-based for loops.

```cpp
for (auto y: bounds_d<0>(ca))  
  for (auto x: bounds_d<1>(ca))  
    RGBAs pixel = ca[y][x];  
    // ...
```

```cpp
for (auto y: ca.bounds_d0())  
  for (auto x: ca.bounds_d1())  
    RGBAs pixel = ca[y][x];  
    // ...
```

N-Dimensional Indexes and Bounds

To model index and bounds values over multiple dimensions, respectively the following template classes are provided: `n_index_t<...>` and `n_bounds_t<...>`. These are both variadic templates, accepting any number of arguments.

`n_index` is a generator to simplify creating instances of `n_index_t`.

```cpp
n_index[540][960]
```
**n_bounds** is a generator to simplify creating instances of **n_bounds_t**.

```cpp
n_bounds[bounds(540,1080)][bounds(960,1920)]
```

Alternatively, **n_bounds_t** can be defined in terms of a **n_index_t** and **n_extent_t**.

```cpp
n_bounds(n_index[540][960], n_extent[540][960]);
```

**Accessing Subsections**

From a container's accessors, a new accessor can be created over a subsection defined by a **n_bounds_t**.

```cpp
auto ca = c.const_access();
auto subsect = ca.section(n_bounds[bounds(540, 1080)][bounds(960,1920)]);
```

The effect is to restrict the results of `bounds_d<int Dimension>` on the subsection accessor.

You can create a new accessor translated to a different index space.

```cpp
auto offsetnewSpace = ca.translated_to(n_index[1000][2000]);
auto zeroSpace = ca.translated_to_zero();
```

Accesses will have a translation applied that maps the **n_index** back to the lower bounds of the accessor that created it. This allows a smaller container to be reused in a larger index space that is being walked over by blocks, or to move a subsection index space back to the origin.

**User-Level Interface**

This section describes the user-level interface for the SIMD Data Layout Templates (SDLT). This API is defined in `sdlt.h` and its associated header files.

**SDLT Primitives (SDLT_PRIMITIVE)**

Primitives represent the data we want to work over in SIMD. They can be more than just data structures. As a C++ object, it can have its own methods that modify its data.

**Rules:**

- Must be Plain Old Data (POD)
  - Has trivial copy constructor
  - Has trivial move constructor
  - Has trivial destructor
  - No virtual functions or virtual bases
- No reference data members
- No unions
- No bit fields
- No bool types
  - Comparison semantics not efficient in SIMD
  - Use 32-bit integer and compare against known values like 0 or 1 explicitly
- Data members need to be public or declare `SDLT_PRIMITIVE_FRIEND` in the object's definition

**Current limitations:**

- No pointer data members
- No C++11 strongly typed enums—use integers instead.
- No array based data members.
- copy constructor and assignment operator (=) defined by individual member assignment—strongly encouraged to facilitate better code generation
They may seem like large restrictions, but often code can easily be re-factored to meet this requirement. For example:

```cpp
class Point3d {
    // methods...
    protected:
        double v[3];
};
```

can be re-factored to have a public data member for each element in the array and update methods to use the $x$, $y$, and $z$ data members rather than the array $v$.

```cpp
class Point3d {
    public:
        // methods...
        double x;
        double y;
        double z;
};
```

For better code generation, explicitly define a copy constructor and assignment operator (=) by individual member assignment.

**SDLT\_PRIMITIVE Macro**

Once an object meets the criteria above, we can consider it a Primitive type in SDLT. In order for Container's to import and export the Primitive, it has to understand its data layout. Unfortunately C++11 lacks compile time reflection, so the user must provide SDLT with a description of your structure's data layout. This is easily done with the SDLT\_PRIMITIVE helper macro that accepts a struct type followed by a comma separated list of its data members.

```cpp
SDLT\_PRIMITIVE(STRUCT_NAME, DATA\_MEMBER\_1, ...)
```

Example Usage:

```cpp
struct UserObject
{
    float x;
    float y;
    double acceleration;
    int behavior;
};
SDLT\_PRIMITIVE(UserObject, x, y, acceleration, behavior)
```

An object must be declared as a Primitive before it can be used in a Container. However, built-in types like float, double, int, etc. do not need to be declared as a Primitive before use with a Container. Built-in's are automatically considered Primitives by SDLT.

Nested Primitives are supported, but the nested Primitive must be declared before the outer Primitive is.

Example: Axis Aligned Bounding Box made up of two 3d points

```cpp
struct Point3s
{
    float x;
    float y;
    float z;
};
struct AABB
{
    Point3s topLeft;
```
Notice the struct definitions themselves do not derive from SDLT or use any of its nomenclature. This independence allows classes to be used in code not using SDLT and only code that does use SDLT Containers needs to see the Primitive declarations.

**soa1d_container**

*Template class for "Structure of Arrays" memory layout of a one-dimensional container of Primitives.*

```cpp
#include <sdlt/soa1d_container.h>
```

**Syntax**

```cpp
template<typename PrimitiveT,
         int AlignD1OnIndexT = 0,
         class AllocatorT = allocator::default_alloc>
class soa1d_container;
```

**Arguments**

- **typename PrimitiveT**
  
  The type that each element in the array will store

- **int AlignD1OnIndexT = 0**
  
  [Optional] The index on which the data access will be aligned (useful for stencils)

- **class AllocatorT = allocator::default_alloc**
  
  [Optional] Specify type of allocator to be used.

  allocator::default Alloc is currently the only allocator supported.

**Description**

Dynamically sized container of Primitive elements with memory layout as a Structure of Arrays internally providing:

- Dynamic resizing with interface similar to std::vector
- Accessor objects suitable for efficient data access inside SIMD loops

**Member**

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typedef size_t size_type;</td>
<td>Type to use when specifying sizes to methods of the container.</td>
</tr>
<tr>
<td>template &lt;typename OffsetT = no_offset&gt; using accessor;</td>
<td>Template alias to an accessor for this container</td>
</tr>
<tr>
<td>template &lt;typename OffsetT = no_offset &gt; using const_accessor;</td>
<td>Template alias to an const_accessor for this container</td>
</tr>
</tbody>
</table>
soa1d_container(
    size_type size_d1 = 0u,
    buffer_offset_in_cachelines buffer_offset
    = buffer_offset_in_cachelines(0),
    const allocator_type & an_allocator = 
    allocator_type());

    Constructs an uninitialized container of size_d1 elements, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

soa1d_container(
    size_type size_d1,
    const PrimitiveT &a_value,
    buffer_offset_in_cachelines buffer_offset
    = buffer_offset_in_cachelines(0),
    const allocator_type & an_allocator = 
    allocator_type());

    Constructs a container of size_d1 elements initializing each with a_value, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

template<typename StlAllocatorT>
soa1d_container(
    const std::vector<PrimitiveT,
    StlAllocatorT> &other,
    buffer_offset_in_cachelines buffer_offset
    = buffer_offset_in_cachelines(0),
    const allocator_type & an_allocator = 
    allocator_type());

    Constructs a container with a copy of each of the elements in other, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

soa1d_container(
    const PrimitiveT *other_array,
    size_type number_of_elements,
    buffer_offset_in_cachelines buffer_offset
    = buffer_offset_in_cachelines(0),
    const allocator_type & an_allocator = 
    allocator_type());

    Constructs a container with a copy of number_of_elements elements from the array other_array, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

template< typename IteratorT >
soa1d_container(
    IteratorT a_begin,
    IteratorT an_end,
    buffer_offset_in_cachelines buffer_offset
    = buffer_offset_in_cachelines(0),
    const allocator_type & an_allocator = 
    allocator_type());

    Constructs a container with as many elements as the range [a_begin - an_end), each with a copy of the value from its corresponding element in that range, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

Returns: a new soa1d_container instance with its own copy of the elements

void resize(size_type new_size_d1);

Resize the container so that it contains new_size_d1 elements. If the new size is greater than the current container size, the new elements are unitialized.

accessor<> access();

Returns: accessor with no embedded index offset.

accessor<int> access(int offset);

Returns: accessor with an integer based embedded index offset.
### Member Type

<table>
<thead>
<tr>
<th>Member Type</th>

</tr>
<tr>
<td>const_accessor&lt;int&gt; const_access(int offset) const;</td>
<td>Returns: const_accessor with an integer based embedded index offset.</td>
</tr>
<tr>
<td>const_accessor&lt;aligned_offset&lt;IndexAlignmentT&gt; &gt; const_access(aligned_offset&lt;IndexAlignmentT&gt; offset) const;</td>
<td>Returns: const_accessor with an aligned_offset&lt;IndexAlignmentT&gt; based embedded index offset.</td>
</tr>
<tr>
<td>template&lt;int OffsetT&gt; const_accessor&lt;fixed_offset&lt;OffsetT&gt; &gt; const_access(fixed_offset&lt;OffsetT&gt;) const;</td>
<td>Returns: const_accessor with a fixed_offset&lt;OffsetT&gt; based embedded index offset.</td>
</tr>
</tbody>
</table>

### STL Compatibility

In addition to the performance oriented interface explained in the table above, soa1d_container implements a subset of the std::vector interface that is intended for ease of integration, not high performance. Due to the import/export only requirement we can't return a reference to the object, instead iterators and operator[] return a Proxy object while other "const' methods return a "value_type const". Furthermore, iterators do not support the -> operator. Despite that limitation the iterators can be passed to any STL algorithm. Also for performance reasons, resize does not initialize new elements. The following std::vector interface methods are implemented:

- size, max_size, capacity, empty, reserve, shrink_to_fit
- assign, push_back, pop_back, clear, insert, emplace, erase
- cbegin, cend, begin, end, begin, end, crbegin, crend, rbegin, rend, rbegin, rend
- operator[], front() const, back() const, at() const
- swap, ==, !=
- swap, soa1d_container(soa1d_container&& donor), soa1d_container & operator=(soa1d_container&& donor)

### aos1d_container

*Template class for "Array of Structures" memory layout of a one-dimensional container of Primitives.*

#include <sdlt/aos1d_container.h>

### Syntax

```cpp
template<
    typename PrimitiveT,
    AccessBy AccessByT,
    class AllocatorT = allocator::default_alloc
>
class aos1d_container;
```
Arguments

typename PrimitiveT

The type that each element in the array will store.

access_by AccessByT

Enum to control how the memory layout will be accessed. Recommend access_by_struct unless you are having issues vectorizing. See the documentation of access_by for more details.

class AllocatorT = allocator::default_alloc

[Optional] Specify the type of allocator to be used. allocator::default_alloc is currently the only allocator supported.

Description

Provide compatible interface with soald_container while keeping the memory layout as an Array of Structures internally. User can easily switch between data layouts by changing the type of container they use. The rest of the code written against accessors and proxy elements and members can stay the same.

- Dynamic resizing with interface similar to std::vector
- Accessor objects suitable for efficient data access inside SIMD loops

<table>

    const allocator_type & an_allocator = allocator_type()); | Constructs a container with a copy of each of the elements in other, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing. |
aos1d_container(const PrimitiveT *other_array, size_type number_of_elements, buffer_offset_in_cachelines buffer_offset = buffer_offset_in_cachelines(0), const allocator_type & an_allocator = allocator_type());

Constructs a container with a copy of number_of_elements elements from the array other_array, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

Constructs a container with as many elements as the range [a_begin-an_end), each with a copy of the value from its corresponding element in that range, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

Returns: a new aos1d_container instance with its own copy of the elements

Resize the container so that it contains new_size_d1 elements. If the new size is greater than the current container size, the new elements are uninitialized

Returns: accessor with no embedded index offset.

Returns: accessor with an integer based embedded index offset.

Returns: accessor with an aligned_offset<IndexAlignmentT> based embedded index offset.

Returns: accessor with a fixed_offset<OffsetT> based embedded index offset.

Returns: const_accessor with no embedded index offset.

Returns: const_accessor with an integer based embedded index offset.

Returns: const_accessor with an aligned_offset<IndexAlignmentT> based embedded index offset.

Returns: const_accessor with a fixed_offset<OffsetT> based embedded index offset.
In addition to the performance oriented interface explained in the table above, `aos1d_container` implements a subset of the `std::vector` interface that is intended for ease of integration, not high performance. Due to the import/export only requirement we can’t return a reference to the object, instead `iterators` and `operator[]` return a `Proxy` object while other "const" methods return a "value_type const". Furthermore, iterators do not support the `->` operator. Despite that limitation the iterators can be passed to any STL algorithm. Also for performance reasons, resize does not initialize new elements. The following `std::vector` interface methods are implemented:

- `size`, `max_size`, `capacity`, `empty`, `reserve`, `shrink_to_fit`  
- `assign`, `push_back`, `pop_back`, `clear`, `insert`, `emplace`, `erase`  
- `operator[]`, `front() const`, `back() const`, `at() const`  
- `swap`, `==`, `!=`  
- `swap`, `aos1d_container(aos1d_container&& donor)`, `aos1d_container & operator=(aos1d_container&& donor)`

**access_by**

*Enum to control how the memory layout will be accessed.*

```cpp
#include <sdlt/access_by.h>
```

**Syntax**

```cpp
enum access_by
{
    access_by_struct,
    access_by_stride
};
```

**Description**

The `access_by_struct` causes data access via structure member access. Nested structures will drill down through the structure members in a nested manner. For example an Axis Aligned Bounding Box (AABB) containing two Point3d objects (with x,y,z data members) will logically expand to something like:

```cpp
AABB local;
local = accessor.mData[i];
```

`access_by_stride` will cause data access through pointers to built in types with a stride to account for the size of the primitive. For an Axis Aligned Bounding Box (AABB) containing two Point3d objects (with x,y,z data members) will logically expand to something like:

```cpp
AABB local;
local.topLeft.x = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,x) + (sizeof(AABB)*i));
local.topLeft.y = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,y) + (sizeof(AABB)*i));
local.topLeft.z = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,z) + (sizeof(AABB)*i));
local.topRight.x = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,x) + (sizeof(AABB)*i));
local.topRight.y = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,y) + (sizeof(AABB)*i));
local.topRight.z = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,z) + (sizeof(AABB)*i));
```

When vectorizing, `access_by_struct` can sometimes generate better code as the compiler could perform wide loads and use shuffle/insert instructions to move data into SIMD registers. However, depending on the complexity of the primitive, it can also fail to vectorize, especially when the primitive contains nested structures.
On the other hand access_by_stride has always vectorized successfully, because the data access is simplified to an array pointer with a stride. The compiler is able to handle any complexity of primitive, because it never sees the complexity and instead just sees the simple array pointer with strided access.

access_by_struct is probably the best choice as it offers a chance of better code generation especially when used outside of a SIMD loop. However if you run into issues when vectorizing, try access_by_stride to see if that alleviates the problem.

We leave this choice up to the developer and require they explicitly make a choice, so this is not hidden behavior.

**n_container**

Template class for N-dimensional container. The contained primitive type, exact memory layout and container shape are defined via template arguments.

**Syntax**

```cpp
template <typename PrimitiveT,
    typename LayoutT,
    typename ExtentsT,
    typename AllocatorT >
class n_container;
```

**Description**

N-dimensional container of PrimitiveT elements with predefined memory layout and shape. Provides accessor interface suitable for flexible and efficient data access inside SIMD loops.

The following table provides information on the template arguments for n_container

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typename PrimitiveT</td>
<td>The type that each cell in the multi-dimensional container will store. Requirements: PrimitiveT must be previously declared with the SDLT_PRIMITIVE macro.</td>
</tr>
<tr>
<td>typename LayoutT</td>
<td>The in-memory data layout of cells in the container. Requirements: LayoutT must be a class from layout namespace.</td>
</tr>
<tr>
<td>typename ExtentsT</td>
<td>The shape of the container. Requirements: ExtentsT must be a concrete type of n_extent_t variadic template.</td>
</tr>
<tr>
<td>class AllocatorT = allocator::default_alloc</td>
<td>[Optional] Specify type of allocator to be used. allocator::default_alloc is currently the only allocator supported.</td>
</tr>
</tbody>
</table>

The following table provides information on the types defined as members of n_container

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typedef PrimitiveT primitive_type;</td>
<td>Type inside each cell of the container.</td>
</tr>
<tr>
<td>typedef PrimitiveT allocator_type;</td>
<td>Type of allocator used by the container.</td>
</tr>
</tbody>
</table>
typedef implementation-defined accessor

Type of an accessor that can write or read cells to and from this container.

typedef implementation-defined const_accessor;

Type of a const_accessor that can read cells from this container.

The following table provides information on the methods of `n_container`

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n_container (const ExtentsT &amp;a_extents, buffer_offset_in_cachelines buffer_offset = buffer_offset_in_cachelines(0), const AllocatorT &amp;an_allocator=AllocatorT())</code></td>
<td>Constructs an uninitialized container of the shape defined as <code>a_extents</code>, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing, using optionally specified allocator instance. ExtentsT must be default constructible. Only true when ExtentsT is made up entirely of fixed&lt;NumberT&gt; types.</td>
</tr>
<tr>
<td><code>n_container (buffer_offset_in_cachelines buffer_offset = buffer_offset_in_cachelines(0), const AllocatorT &amp;an_allocator=AllocatorT())</code></td>

</thead>
<tbody>
<tr>
<td>std::ostream&amp; operator &lt;&lt; (std::ostream&amp; output_stream, const n_container &amp; a_container)</td>
<td>Append string representation of a_container's extents values to a_output_stream. <strong>Returns:</strong> Reference to a_output_stream for chained calls.</td>
</tr>
</tbody>
</table>

### Layouts

**sdlt::layout namespace**

Rather than having different container types for different data layouts, the library uses the types from the layout namespace as a template parameter to the n_container.

Available layouts are defined in the namespace layout and summarized in table below.

<table>
<thead>
<tr>
<th>Layout</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;typename AlignOnColumnIndexT=0&gt; layout::soa</td>
<td>Structure of Arrays: Each data member of the Primitive will have its own N-dimensional array. The arrays are placed back-to-back inside a contiguous buffer. Template parameter AlignOnColumnIndexT identifies which column of the row dimension should be cache line aligned. The AlignOnColumnIndexT of each row is cache line aligned.</td>
</tr>
<tr>
<td>template&lt;typename AlignOnColumnIndexT&gt; layout::soa_per_row</td>
<td>Structure of Arrays Per Row: Each data member of the Primitive will have its own 1-dimensional array for the row dimension (Soa1d) placed back to back. The AlignOnColumnIndexT of each row is cache line aligned. Multiple of these Soa1d’s are laid out sequentially to model the remaining dimensions, effectively becoming an Array of Structures of Arrays where the SOA where the size of the array is the row's extent. This can be particularly efficient when the extent of the row can be fixed&lt;NumberT&gt;. <strong>Note:</strong> If the size of the row isn't known at compile time, consider adding an additional dimension that is fixed&lt;Number&gt; and dividing the row up by that fixed&lt;NumberT&gt;.</td>
</tr>
<tr>
<td>layout::aos_by_struct</td>
<td>Array of Structures Accessed by Struct: Primitives are laid out in native format back to back in memory and access happens via structure or member access. Nested structures will drill down through the structure members in a nested manner.</td>
</tr>
<tr>
<td>layout::aos_by_stride</td>
<td>Array of Structures Accessed by Stride: Primitives are laid out in native format back to back in memory and accessed through pointers to built in types with a stride to account for the size of the Primitive. Can be useful if aos_by_struct doesn't vectorize.</td>
</tr>
</tbody>
</table>
Description

The classes are empty and only for specialization of containers for denoted layouts.

Shape

Variadic template class n_extent_t describes the shape of the n_dimensional container. Specifically, the number of dimensions the size of each.

Syntax

template<typename... TypeListT>
class n_extent_t

Description

n_extent_t represents the shape of a container as a sequence of sizes for each dimension. The size of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare n_extent_t whose dimensions are fully known at compile time with fixed<int NumberT>, or to be only known at runtime with int, or only known at runtime but with a guarantee will be a multiple of an alignment with aligned<int Alignment>. For details, see the Number representation section.

The following table provides information on the template arguments for n_extent_t.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typename... TypeListT</td>
<td>Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array, from leftmost to rightmost. Type must be int, fixed&lt;NumberT&gt;, or aligned&lt;AlignmentT&gt;. for each value describing corresponding dimensions size (extent) in regular order of C++ subscripts - from outer to inner.</td>
</tr>
</tbody>
</table>

Member | Description
--- | ---
explicit n_extent_t(const TypeListT & ... a_values) | **Effects:** Construct n_extent_t, initializing each dimension with the corresponding value from the list of a_values passed as an argument. In use, a_values is a comma separate list of values whose length and types are defined by TypeListT.

**Requirements:** DimensionT >=0 and DimensionT < rank.

**Effects:** Determine the extent of DimensionT.

**Returns:** In the type declared by the DimensionT position of 0-based TypeListT, the extent of the specified DimensionT

**Requirements:** DimensionT >=0 and DimensionT <= rank.

**Effects:** Construct a n_extent_t with a lower rank by copying the rightmost DimensionT values from this instance.

**Returns:** n_extent[get<rank - DimensionT>()]
[get<rank + 1 - DimensionT>()]
[get<...>()]

**Requirements:** rank of a_other is the same as this instance's.

**Effects:** Compare size of each dimension for equality. Only compares numeric values, not the types of each dimension.

**Returns:** true if all dimensions are numerically equal, false otherwise.

**Requirements:** rank of a_other is the same as this instance's.

**Effects:** Compare size of each dimension for inequality. Only compares numeric values, not the types of each dimension.

**Returns:** true if any dimensions are numerically different, false otherwise.

**Returns:** Number of elements specified by extent

**Effects:** Calculates the number of cells represented by the current extent values of each dimension by multiplying them all together.

**Returns:** get<0>() * get<1>() * get<...> () * get<rank-1>()

The following table provides information on the friend functions of n_extent_t.
### Friend function

```cpp
std::ostream& operator << (std::ostream& output_stream, const n_extent_t & a_extents)
```

**Effects:** Append string representation of a_extents' values to a_output_stream

**Returns:** Reference to a_output_stream for chained calls.

### n_extent_generator

To facilitate simpler and clearer creation of n_extent_t objects.

### Syntax

```cpp
template<typename... TypeListT>
class n_extent_generator;
```

```cpp
namespace {
    // Instance of generator object
    n_extent_generator<> n_extent;
}
```

### Description

The generator object provides recursively constructing operators [] for fixed<>, aligned<>, and integer values allowing building of an n_extent_t instance, one dimension at a time. The main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition:

Compare the following examples, instantiating three n_extent_t instances. and using the generator object to instantiate equivalent instances.

```cpp
n_extent_t<int, int> ext1(height, width);
n_extent_t<int, aligned<128>> ext2(height, width);
n_extent_t<fixed<1080>, fixed<1920>> ext3(1080_fixed, 1920_fixed);
```

```cpp
auto ext1 = n_extent[height][width];
auto ext2 = n_extent[height][aligned<128>(width)];
auto ext3 = n_extent[1080_fixed][1920_fixed];
```

### Class Hierarchy

It is expected that n_extent_generator < ... > not be directly used as a data member or parameter, instead only n_extent_t <...> from which it is derived. The generator object n_extent can be automatically downcast any place expecting an n_extent_t<...>.

The following table provides the template arguments for n_extent_generator

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typename... TypeListT</td>
<td>Comma separated list of types, where the number of types provided controls how many dimensions the generator currently represent. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. <strong>Requirements:</strong> Type is int, fixed&lt;NumberT&gt;, or aligned&lt;AlignmentT&gt;.</td>
</tr>
</tbody>
</table>

The following table provides information on the types defined as members of n_extent_generator in addition to those inherited from n_extent_t.
typedef n_extent_t<TypeListT...> value_type

Type value that the any chained [] operator calls have produced.

The following table provides information on the members of n_extent_generator in addition to those inherited from n_extent_t

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
</table>
| n_extent_generator () | Requirements: TypeListT is empty  
Effects: Construct generator with no extents specified |
| n_extent_generator (const n_extent_generator &a_other) | Effects: Construct generator copying any extent values from a_other |
| n_extent_generator<TypeListT..., int> operator [] (int a_size) const | Requirements: a_size >= 0  
Returns: n_extent_generator<...> with additional rightmost integer based extent. |
| n_extent_generator<TypeListT..., fixed<NumberT>> operator [] (fixed<NumberT> a_size) const | Requirements: a_size >= 0  
Returns: n_extent_generator<...> with additional rightmost fixed<NumberT> extent. |
| n_extent_generator<TypeListT..., aligned<AlignmentT>> operator [] (aligned<AlignmentT> a_size) | Requirements: a_size >= 0  
Returns: n_extent_generator<...> with additional rightmost aligned<AlignmentT> based extent. |
| value_type value() const | Returns: n_extent_t<...> with the correct types and values of the multi-dimensional extents aggregated by the generator. |

**make_n_container template function**

Factory function to construct an instance of a properly-typed n_container<...> based on n_extent_t passed to it.

**Syntax**

```cpp
template<
    typename PrimitiveT,
    typename LayoutT,
    typename AllocatorT = allocator::default_alloc,
    typename ExtentsT
>
auto make_n_container(const ExtentsT &_extents) -> n_container<PrimitiveT, LayoutT, ExtentsT, AllocatorT>
```

**Description**

Use make_n_container to more easily create an n-dimensional container using template argument deduction, and avoid specifying the type of extents.

An example of the instantiation of a High Definition image object is below.

```cpp
typedef n_container<RGBAs, layout::soa,  
n_extent_t<int, int>> HdImage;
HdImage image1(n_extent[1080][1920]);
```
Alternatively, it is possible to use factory function with the C++11 keyword `auto`, as shown below.

```cpp
auto image1 = make_n_container<RGBAs,
    layout::soa>(n_extent[1080][1920]);
```

### extent_d template function

**Syntax**

```cpp
template<int DimensionT, typename ObjT>
auto extent_d(const ObjT &a_obj)
```

**Description**

The template function offers a consistent way to determine the extent of a dimension for a multi-dimensional object. It can avoid extracting an entire `n_extent_t<...>` when only the extent of a single dimension is needed.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int DimensionT</td>
<td>0 based index starting at the leftmost dimension indicating which n-dimensions to query the extent of.</td>
</tr>
<tr>
<td></td>
<td><strong>Requirements</strong>: <code>DimensionT &gt;=0</code> and <code>DimensionT &lt; ObjT::rank</code></td>
</tr>
<tr>
<td>typename ObjT</td>
<td>The type of n-dimensional object from which to retrieve the extent.</td>
</tr>
<tr>
<td></td>
<td><strong>Requirements</strong>: <code>ObjT</code> is one of:</td>
</tr>
<tr>
<td></td>
<td><code>n_container&lt;...&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>n_extent_t&lt;...&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>n_extent_generator&lt;...&gt;</code></td>
</tr>
</tbody>
</table>

**Returns**

The correctly typed extent corresponding to the requested `DimensionT` of `a_obj`.

**Example**

```cpp
template <typename VolumeT>
void foo(const VolumeT & a_volume)
{
    int extent_z = extent_d<0>(volume);
    int extent_y = extent_d<1>(volume);
    int extent_x = extent_d<2>(volume);
    /...
}
```

### Bounds

**bounds_t**

Class represents a half-open interval with lower and upper bounds. `#include <sdlt/bounds.h>`

**Syntax**

```cpp
template<typename LowerT = int, typename UpperT = int>
struct bounds_t
```
**Description**

`bounds_t` holds the lower and upper bounds of a half open interval. It is templated to allow the different representations for the lower and upper bounds. Supported types include `fixed<NumberT>`, `aligned<AlignmentT>` and integer values. `bounds_t` models a valid iteration space over a single dimension.

`bounds_t` can be used to represent an iteration space over the entire extent of a dimension or to restrict iteration space within the extent. `n_bounds_t` aggregates a number of `bounds_t` objects to allow construction of multi-dimensional subsections restricting multiple extents.

The class interface is compatible with C++ range-based loops to simplify iteration.

**Template Argument**

<table>

</tr>
</tbody>
</table>
### Member

```cpp
bool operator != (const bounds_t &a) const
```

**Description**

Effects: Inequality comparison with same-typed bounds_t object

Returns: `(lower() != a.lower() || upper() != a.upper())`

### Friend Function

```cpp
std::ostream& operator << (std::ostream& a_output_stream, const bounds_t &a_bounds)
```

**Description**

Effects: append string representation of bounds_t lower and upper values to a_output_stream

Returns: reference to a_output_stream for chained calls

### Range-based loops support

The bounds_t provides `begin()` and `end()` methods returning iterators to enable C++11 range-based loops. The may save quite some typing and improve code clarity when iterating over bounds of a multidimensional container.

Compare:

```cpp
auto ca = image_container.const_access();
auto b0 = bounds_d<0>(ca);
auto b1 = bounds_d<1>(ca);
for (auto y = b0.lower(); y < b0.upper(); ++y)
    for (auto x = b1.lower(); x < b1.upper(); ++x) {
        RGBAs pixel = ca[y][x];
        // …
    }
```

and

```cpp
auto ca = image_container.const_access();
for (auto y: bounds_d<0>(ca))
    for (auto x: bounds_d<1>(ca)) {
        RGBAs pixel = ca[y][x];
        // …
    }
```

Note that iterator only gives an index value within the bounds, not an object value. It is expected to be used to index into accessors like in example above.

#### sdl::bounds Template Function

Factory function provided for creation of bounds_t objects. `#include <sdl/ bounds.h>`

**Syntax**

```cpp
template<typename LowerT, typename UpperT>
auto bounds(LowerT a_lower, UpperT a_upper)
```
Description

In order to make creation of objects of `bounds_t` cleaner the factory function `bounds` is provided. It basically enables `LowerT` and `UpperT` to be deduced from the arguments passed into it.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>typename LowerT = int</code></td>
<td>Type of lower bound. Requirements: type is int, or <code>fixed&lt;NumberT&gt;</code>, or <code>aligned&lt;AlignmentT&gt;</code></td>
</tr>
<tr>
<td><code>typename UpperT = int</code></td>
<td>Type of upper bound. Requirements: type is int, or <code>fixed&lt;NumberT&gt;</code>, or <code>aligned&lt;AlignmentT&gt;</code></td>
</tr>
</tbody>
</table>

Returns:

The correctly typed `bounds_t<LowerT, UpperT>` corresponding to types of `a_lower` and `a_upper` passed to the factory function.

Example:

Compare two ways of instantiating a bounds:

```cpp
bounds_t<fixed<0>, aligned<16>> my_bounds1(0_fixed, aligned<16>(upper))
auto my_bounds2 = bounds_t<fixed<0>, aligned<16>>(0_fixed, aligned<16>(upper))
```

With the factory function:

```cpp
auto my_bounds = bounds(0_fixed, aligned<16>(upper))
```

n_bounds_t

Variadic template class to describe the valid iteration space over an N-dimensional container. 

#include 

<sdlt/n_bounds.h>

Syntax

```cpp
template<typename... TypeListT>
class n_bounds_t
```

Description

`n_bound_t` represents the valid iteration space over a `n_container` or its accessor as as a sequence of `bounds_t` for each dimension. The `bounds_t` of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare `n_bounds_t` whose dimensions are fully known at compile time with `fixed<int NumberT>`, or to be only known at runtime with `int`, or only known at runtime but with a guarantee will be a multiple of an alignment with `aligned<int Alignment>`. For details see the Number Representation section).

When an `n_container` is created, its `n_bounds_t` always start at `fixed<0>` for the inclusive lower bounds of each dimension, and exclusive upper bounds match the extent of the dimension. Accessors can be translated to different index spaces as well as restrict their iteration space to subsections, which will change the `n_bounds_t` those accessors provide.

The following table provides information on the template arguments for `n_bounds_t`. 

Intel® C++ Compiler 19.0 Developer Guide and Reference
Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the bounds of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost.

Requirements: types in the list be bounds_t<LowerT, UpperT>

The following table provides information on the member types of n_bounds_t

<table>
<thead>

| upper_type upper() | Effects: build n_index<...> representing the exclusive upper bounds for all dimensions  
Returns: n_index[get<0>().upper()]  
[get<1>(). upper ()]  
[get<...>(). upper ()]  
[get<row_dimension>().upper()] |
| template<typename... OtherTypeListT> bool contains(n_bounds_t<OtherTypeListT...> &a_other) const | Requirements: rank of a_other is the same as this instance’s.  
Effects: Determine whether each dimension of the passed n_bounds_t is fully contained within bounds of each dimension of this object.  
Returns: get<0>().contains(a_other.get<0>() ) && get<1>().contains(a_other.get<1>() ) && get<...>().contains(a_other.get<...>() ) && get<row_dimension>().contains(a_other.get<row_dimension>() ) |
| template<class... OtherTypeListT> bool operator == (const n_bounds_t<OtherTypeListT...> a_other) const | Requirements: rank of a_other is the same as this instance’s.  
Effects: Compare bounds each of dimension for equality. Only compares numeric values, not the types of each dimension.  
Returns: true if all dimensions are numerically equal, false otherwise. |
| template<class... OtherTypeListT> bool operator != (const n_bounds_t<OtherTypeListT...> a_other) const | Requirements: rank of a_other is the same as this instance’s.  
Effects: Compare bounds of each dimension for inequality. Only compares numeric values, not the types of each dimension.  
Returns: true if any dimensions are numerically different, false otherwise. |
| template<class ...OtherTypeListT> auto operator+ (const n_index_t<OtherTypeListT...> a_offset) const | Requirements: rank of a_other is the same as this instance’s.  
Effects: construct a n_bound_t whose types and bounds value for each dimension are determined by taking the bounds for each dimension and adding the an offset for that dimension from a_offset.  
Returns: n_bounds[get<0>() + a_offset.get<0>()]  
[get<1>() + a_offset.get<1>()]  
[get<...>() + a_offset.get<...>()]  
[get<row_dimension>() + a_offset.get<row_dimension>()] |
**Member**

```cpp
template<int DimensionT>
auto rightmost_dimensions() const
```

Requirements: DimensionT >= 0 and DimensionT <= rank.

Effects: Construct a n_bounds_t with a lower rank by copying the rightmost DimensionT values from this instance.

Returns: n_bounds[get<rank - DimensionT>()]
[get<rank + 1 - DimensionT>()]
[get<...>()]
[get<row_dimension>()]

```cpp
template<class... OtherTypeListT>
auto overlay_rightmost(const n_bounds_t<OtherTypeListT...> & a_other) const
```

Requirements: rank of a_other is <= rank

Effects: Construct copy of n_bounds_t where the rightmost dimensions' values are copied from a_other, effectively overlaying a_other on top of rightmost dimensions of this instance.

Returns:

n_bounds[get<0>()]
[get<1>()]
[get<...>()]
[get<rank-a_other::rank>()]
[a_other.get<0>()]
[a_other.get<...>()]
[a_other.get<a_other::row_dimension>()]

| `std::ostream& operator << (std::ostream& output_stream, const n_bounds_t & a_bounds_list)` | Effects: append string representation of a_bounds_list values to a_output_stream
|                                                      | Returns: reference to a_output_stream for chained calls.                   |

**n_bounds_generator**

*Facilitates simple creation of n_bounds_t objects.*

`#include <sdlt/n_bounds.h>`

**Syntax**

```cpp
template<typename... TypeListT>
class n_bounds_generator;
```

```cpp
namespace {
    // Instance of generator object
    n_bounds_generator<> n_bounds;
}
```
Description

The generator object provides recursively constructing operators \([\]\) for \(\text{bounds}_t<\text{LowerT}, \text{UpperT}>\) values allowing building of a \(\text{n_bounds}_t<<...>>\) instance one dimension at a time. Its main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition:

Compare creating two \(\text{n_bounds}_t\) instances:

\[
\text{n_bounds}_t<\text{bounds}_t<\text{fixed}<540>, \text{fixed}<1080>>, \text{bounds}_t<\text{fixed}<960>, \text{fixed}<1920>> \text{bounds}_1(\text{bounds}_t<\text{fixed}<540, \text{fixed}<1080>>(), \text{bounds}_t<\text{fixed}<960, \text{fixed}<1920>>());
\]

\[
\text{n_bounds}_t<\text{bounds}_t<\text{int}, \text{int}>>, \text{bounds}_t<\text{int}, \text{int}>> \text{bounds}_2(\text{bounds}_t<\text{int}, \text{int}>(540,960), \text{bounds}_t<\text{int}, \text{int}>(960, 1920));
\]

and the equivalent instances using the generator objects and factory functions

\[
\text{auto bounds}_1 = \text{n_bounds}[\text{bounds}(540, 1080)]
\]

\[
[\text{bounds}(960, 1920)];
\]

\[
\text{auto bounds}_2 = \text{n_bounds}[\text{bounds}(540, 1080)]
\]

\[
[\text{bounds}(960, 1920)];
\]

or alternatively using the operator() with \(\text{n_index}_t\) and \(\text{n_extent}_t\) generator objects

\[
\text{auto bounds}_1 = \text{n_bounds}(\text{n_index}[540][960], \text{n_extent}[540][960]);
\]

\[
\text{auto bounds}_2 = \text{n_bounds}(\text{n_index}[540][960], \text{n_extent}[540][960]);
\]

Class Hierarchy

It is expected that \(\text{n_bounds}_\text{generator}<...>\) not be directly used as a data member or parameter, instead only \(\text{n_bounds}_t<...>\) from which it is derived. The generator object \(\text{n_bounds}\) can be automatically downcast any place expecting a \(\text{n_bounds}_t<...>\).

The following table provides information on the template arguments for \(\text{n_bounds}_\text{generator}\)

The following table provides information on the members of \(\text{n_bounds}_\text{generator}\) in addition to those inherited from \(\text{n_bounds}_t\)
Member | Description
---|---
n_bounds_generator() | Requirements: TypeListT is empty
| Effects: Construct generator with no bounds specified
n_bounds_generator(const n_bounds_generator &a_other) | Effects: Construct generator copying any bounds values from a_other
template<typename LowerT, typename UpperT>
auto operator [] (const bounds_t<LowerT, UpperT> & a_bounds) const | Effects: build a n_bounds_generator<...> with additional rightmost bounds_t<LowerT, UpperT> based dimension.
| Returns: n_bounds_generator<TypeListT..., bounds_t< LowerT, UpperT >>
template<class... IndexTypeListT, class... ExtentTypeListT>
auto operator () (const n_index_t<IndexTypeListT...> & a_indices, const n_extent_t<ExtentTypeListT...> & a_extents) const | Requirements: rank of a_indices is same as rank of a_extents and TypeListT be empty
| Effects: build a n_bounds_generator<...> where n-lower bounds are specified by a_indices, and n-upper bounds are calculated by adding a_extents to a_indices
| Returns: n_bounds[bounds(a_indices.get<0>(), a_indices.get<0>() + a_extents.get<0>())]
| [bounds(a_indices.get<1>(), a_indices.get<1>() + a_extents.get<1>())]
| [bounds(a_indices.get<...>(), a_indices.get<...>() + a_extents.get<...>())]
| [bounds( a_indices.get<row_dimension>(), a_indices.get< row_dimension >() + a_extents.get< row_dimension >())]
value_type value() const | Returns: n_bounds_t<...> with the correct types and values of the multi-dimensional bounds aggregated by the generator.

**bounds_d Template Function**

*Provides a consistent way to determine the bounds of a dimension for a multi-dimensional object.*

```cpp
#include <sdlt/n_extent.h>

template<int DimensionT, typename ObjT>
auto bounds_d(const ObjT &a_obj)
```

**Description**

Consistent way to determine the bounds of a dimension for a multi-dimensional object. Can avoid extracting an entire n_bounds_t<...> when only the extent of a single dimension is needed.
<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int DimensionT</td>
<td>0 based index starting at the leftmost dimension indicating which n-dimensions to query the bounds of. Requirements: DimensionT &gt;=0 and DimensionT &lt; ObjT::rank</td>
</tr>
<tr>
<td>typename ObjT</td>
<td>The type of n-dimensional object from which to retrieve the extent. Requirements: ObtT is one of: n_container&lt;...&gt; n_bounds_t&lt;...&gt; n_bounds_generator&lt;...&gt; n_container&lt;...&gt;::accessor n_container&lt;...&gt;::const_accessor or any sectioned or translated accessor.</td>
</tr>
</tbody>
</table>

**Returns:**
The correctly typed bounds_t<LowerT, UpperT> corresponding to the requested DimensionT of a_obj.

**Example:**

```cpp
template <typename VolumeT>
void foo(const VolumeT & a_volume)
{
    auto bounds_z = bounds_d<0>(volume);
    auto bounds_y = bounds_d<1>(volume);
    auto bounds_x = bounds_d<2>(volume);
    for(auto z : bounds_z)
        for(auto y : bounds_y)
            for(auto x : bounds_x) {
                // ...
            }
}
```

**Accessors**

**soa1d_container::accessor and aos1d_container::accessor**

Lightweight object provides efficient array subscript [] access to the read or write elements from inside a soa1d_container or aos1d_container. #include <sdlt/soa1d_container.h> and #include <sdlt/aos1d_container.h>

**Syntax**

```cpp```
template <typename OffsetT> soa1d_container::accessor;
template <typename OffsetT> aos1d_container::accessor;
```
Arguments

typename OffsetT

The type offset that will be applied to each operator[] call determined by
the type of offset passed into soa1d_container::access(offset)/
aos1d_container::access(offset) which constructs an accessor.

Description

accessor provides [] operator that returns a proxy object representing an Element inside the Container that
can export or import the Primitive's data. Can re-access with an offset to create a new accessor that when
accessed at [0] will really be accessing at index corresponding to the embedded offset. Lightweight and
meant to be passed by value into functions or lambda closures. Use accessors in place of pointers to access
the logical array data.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessor();</td>

</tr>
</tbody>
</table>
| auto operator [] (const IndexT_D1 index_d1); | When: IndexT_D1 is one of the SDLT defined or generated Index types,
| | Returns: proxy Element representing element at index_d1 in the container. |
| auto reaccess(const int offset) const; | Returns: accessor with an integer-based embedded index offset. |
| auto reaccess(aligned_offset<IndexAlignmentT> offset) const; | Returns: accessor with an aligned_offset<IndexAlignmentT> based embedded index offset. |
| auto reaccess(fixed_offset<fixed_offsetT>) const; | Returns: accessor with a fixed_offset<OffsetT> based embedded index offset. |

soa1d_container::const_accessor and aos1d_container::const_accessor

Lightweight object provides efficient array subscript []
access to the read elements from inside a
soa1d_container or aos1d_container. #include
<sdlt/soa1d_container.h> and #include <sdlt/
aos1d_container.h>

Syntax

template <typename OffsetT> soa1d_container::const_accessor;
template <typename OffsetT> aos1d_container::const_accessor;
Arguments

typename OffsetT

The type offset that embedded offset that will be applied to each operator[]
call

Description

const_accessor provides [] operator that returns a proxy object representing a const Element inside the
Container that can export the Primitive's data. Can re-access with an offset to create a new const_accessor
that when accessed at [0] will really be accessing at index corresponding to the embedded offset.
Lightweight and meant to be passed by value into functions or lambda closures. Use const_accessors in place
of const pointers to access the logical array data.

reaccess(fixed_offset<fixed_offsetT>) const;                           | Returns: const_accessor with an

aligned_offset<IndexAlignmentT> based
embedded index offset. |

Accessor Concept

Accessor and const_accessor objects obtained via
n_container::access() and
n_container::const_access() provide access to
read from or write to cells inside an n_container.
Syntax

The following methods return objects meeting the requirements of the accessor concept.

```cpp
auto n_container::access();
auto n_container::const_access();
auto accessor_concept::section(n_bounds_t<…>);
auto accessor_concept::translated_to(n_index_t<…>);
auto accessor_concept::translated_to_zero();
```

Description

Accessor objects provide read/write access to individual cells of an n-dimensional container. Index values passed to a sequence of array subscript operator calls will produce a proxy concept that can import to or export the primitive data the corresponding cell inside the container.

```cpp
auto image = make_n_container<MyStruct, layout::soa>({n_extent[128][256]});
auto acc = image.access();
MyStruct in_value(100.0f, 200.0f, 300.0f);
acc[64][128] = in_value;
MyStruct out_value = acc[64][128];
assert(out_value == in_value);
```

Accessors also know their valid iteration space, which can queried using the template function bound_d<int DimensionT>(accessor).

```cpp
assert(bounds_d<0>(acc) == bounds(0_fixed,128));
assert(bounds_d<1>(acc) == bounds(0_fixed,256));
```

An accessor may have a non-zero index space if it has a translation embedded into it, `bounds_d` will reflect any such translation.

```cpp
auto shifted_acc = acc.translated_to(n_index[1000][2000]);
assert(bounds_d<0>(shifted_acc) == bounds(1000,1128));
assert(bounds_d<1>(shifted_acc) == bounds(2000,2256));
```

This is useful to have a smaller sized container participate in a calculation over a portion of a larger index space, simplifying programming as the same index variable can be used, and the accessor takes care of applying the necessary translation. An accessor may represent a subsection over the original extents, `bounds_d` will identify the valid iteration space for that accessor.

```cpp
auto subsection_acc = a.section(n_bounds[bounds(64,96)][bounds(128,160)]);
assert(bounds_d<0>(subsection_acc) == bounds(64, 96));
assert(bounds_d<1>(subsection_acc) == bounds(128, 160));
```

It can also be useful to have subsections be translated back to start their iteration space at 0. For efficiency, the `translated_to_zero()` method is provided to create an accessor shifted back to zero.

```cpp
auto zb_sub_acc = a.section( n_bounds[bounds(64, 96)][bounds(128, 160)] ).translated_to_zero();
assert(bounds_d<0>(zb_sub_acc) == bounds(0, 32));
assert(bounds_d<1>(zb_sub_acc) == bounds(0, 32));
```

If fewer array subscript calls applied to an accessor than its rank, the result is another accessor of a lower rank. This can be useful to obtain accessors suitable to pass to code expecting lower rank accessors. Such as a obtaining a 3d accessor from a 4d container by specifying only a single index via array subscript. This has
the effect of embedding the index value of the dimension inside accessor. When the final dimension is sliced, the result is a proxy object to the cell inside the container corresponding to the embedded index values inside the sliced accessors.

```cpp
auto image4d = make_n_container<MyStruct, layout::soa>(n_extent[10][20][128][256]);
MyStruct in_value(100.0f, 200.0f, 300.0f);
auto acc4d = image4d.access();
auto acc3d = acc4d[5];
auto acc2d = acc3d[10];
auto acc1d = acc2d[64];
acc1d[128] = in_value;
MyStruct out_value = acc4d[5][10][64][128];
assert(out_value == in_value);
```

The following table provides information on the requirements of the accessor concept.

Easy way to think of it is that current iteration space is translated to [0] for all free dimensions. <br>**Returns:** accessor_concept whose bounds have the same extents, but whose lower bounds start at [0]...[0]
| template<typename ...IndexListT> accessor_concept translated_to(            |                                                                                                                                                                                                          |
|     n_index_t<IndexListT...> a_n_index) const                                |                                                                                                                                                                                                          |
| template<typename ...IndexListT> accessor_concept translated_to_zero()    |                                                                                                                                                                                                          |
template<typename ...BoundsTypeListT>
auto
section(const
n_bounds_t<BoundsTypeListT...> &a_n_bounds) const

**Requirements:** a_n_bounds has same rank as the accessor and a_n_bounds is contained by the accessors current bounds.

**Effects:** construct an accessor_concept with using the supplied a_n_bounds to represent its valid iteration space. Because a_n_bounds must be contained within the existing bounds, we are effectively creating an accessor over a section of the container. Easy way to think of it is that current bounds are being restricted to a_n_bounds. Note: can be useful to chain a call translated_to_zero() on to the return value.

**Returns:** accessor_concept whose bounds are set to the supplied a_n_bounds

---

**Proxy Objects**

Accessors can’t return a reference to the Primitive because its memory layout is abstracted. Instead a Proxy object is returned. That Proxy supports importing or exporting data to and from the Container. The actual type of Proxy objects is an implementation detail, but they all support the same public interface which we will document.

Each accessor [index] operator returns a Proxy object.

Each const_accessor [index] operator returns a ConstProxy object.

The Proxy objects provide a Data Member Interface where for each data member of value_type they are representing, a member access method is defined which returns a new Proxy or ConstProxy representing just that data member. Users can drill down through a complex data structure to get a Proxy representing the exact data member they need versus importing and exporting the entire Primitive value.

Proxy objects also overload the following operators if the underlying value_type supports the operator:

==, !=, <, >, <=, >=, +, -, *, /, %, &&, ||, |, ^, ~, *, +, -, !, +=, -=, *=, /=, %=, >>=, <<=, &=, |=, ^=, ++, --

**Proxy**

Proxy object provides access to a specific Primitive, Primitive data member, or nested data member within a Primitive for an element in a container.

**Description**

Accessor [index] or a Proxy object’s Data Member Interfaces return Proxy objects. That Proxy object represents the Primitive, Primitive data member, or nested data member within a Primitive for an element in a container. The Proxy object has the following features:

- A value_type can be exported or imported from the Proxy.
  - Conversion operator is used to export the value_type
  - Alternatively the Proxy can be passed to the function unproxy to export a value_type
  - Assignment operator = is used to import value_type into the Proxy
  - Overloads the following operators if the underlying value_type supports the operator
    - ==, !=, <, >, <=, >=, +, -, *, /, %, &&, ||, |, ^, ~, *, +, -, !, +=, -=, *=, /=, %=, >>=, <<=, &=, |=, ^=, ++, --
  - When an operator is called the following occurs:
- value_type is exported
- The operator applied to the exported value
- If the operator was an assignment, the result is imported back into the Member and returns the proxy
- Otherwise a result is returned.

**Data Member Interface.**
- For each data member of value_type
  - A member access method is defined which returns a Member proxy representing just that member.

</tbody>
</table>
**ConstProxy**

*ConstProxy* object provides access to a specific constant primitive, primitive data member, or nested data member within a primitive for an element in a container.

**Description**

`const_accessor [index]` or a `ConstProxy` object’s Data Member Interfaces return `ConstProxy` objects. That `ConstProxy` object represents the constant primitive, primitive data member, or nested data member within a primitive for an element in a container. The `ConstProxy` object has the following features:

- A `value_type` can be exported or imported from the `ConstProxy`.
  - Conversion operator is used to export the `value_type`
  - Alternatively the `ConstProxy` can be passed to the function `unproxy` to export a `value_type`
- Overloads the following operators if the underlying `value_type` supports the operator
  - `==, !=, <, <=, >, >=, +, -, *, /, %, &&, ||, &, |, ^, ~, *, +, -, !`
- When an operator is called the following occurs:
  - `value_type` is exported
  - The operator applied to the exported value
  - returns the result.

- Data Member Interface.
  - For each data member of `value_type`
    - A member access method is defined which returns a Member `ConstProxy` representing just that member.

Member Description

auto name_of_values_data_member_N()const; Returns: ConstProxy instance representing the Nth data member of the value_type.

NOTE: actual method name is the name of the value_type’s Nth data member

Number Representation

When specifying extents, positions inside of, or bounds of a container, numeric values can be represented three different ways: fixed, aligned, and int. Fixed is most precise and int is least precise. It is advised to use as precise specification as possible. The compiler may optimize better with more information.

Fixed

Represent a numerical constant whose value specified at compile time.

template <int NumberT> class fixed;

If offsets applied to index values inside a SIMD loop are known at compile time, then the compiler can use that information. For example, to maintain aligned access, if boundary is fixed and known to be aligned when accessing underlying data layout. When multiple accesses are happening near each other, the compiler will have the opportunity to detect which accesses occur in the same cache lines and potentially avoid prefetching the same cache line repeatedly. Additionally, if the start of an iteration space is known at compile time, if it’s a multiple of the SIMD lane count, the compiler could skip generating a peel loop. Whenever possible, fixed values should be used over aligned or arbitrary integer values.

Although std::integral_constant<int> provides the same functionality, the library defines own type to provide overloaded operators and avoid collisions with any other code's interactions with std::integral_constant<int>.

The following table provides information about the template arguments for fixed.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int Number T</td>
<td>The numerical value the fixed will represent.</td>
</tr>
</tbody>
</table>

The following table provides information about the members of fixed.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static constexpr int value = NumberT</td>
<td>The numerical value known at compile-time.</td>
</tr>
<tr>
<td>constexpr operator value_type() const</td>
<td>Returns: The numerical value</td>
</tr>
<tr>
<td>constexpr value_type operator()() const;</td>
<td>Returns: The numerical value</td>
</tr>
</tbody>
</table>

Constant expression arithmetic operators +,- (both unary and binary), * and / are defined for type std::fixed<> and will be evaluated at compile-time.

The suffix _fixed is a C++11 user-defined equivalent literal. For example, 1080_fixed is equivalent to fixed<1080>. Consider the readability of the two samples below.

foo3d(fixed<1080>(), fixed<1920>());

versus

foo3d(1080_fixed, 1920_fixed);
NOTE The sdl::fixed<NumberT> type supersedes the deprecated sdl::fixed_offset<OffsetT> type found in SDLT v1. It is strongly advised to use sdl::fixed<NumberT>. However, in this release, a template alias is provided mapping sdl::fixed_offset<OffsetT> onto sdl::fixed<NumberT>.

**Aligned**

Represent integer value known at compile time to be a multiple of an IndexAlignment.

```cpp
template <int IndexAlignmentT> class aligned;
```

If you can tell the compiler that you know that an integer will be a multiple of known value, then, when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access when accessing underlying data layout.

Internally, the integer value is converted to a block count, where:

```cpp
block_count = value/IndexAlignmentT;
```

Overloaded math operations can then use that aligned block count as needed. The value() is represented by `AlignmentT*block_count` allowing the compiler to easily prove that the value() is a multiple of `AlignmentT`, which can utilize alignment optimizations.

The following table provides information about the template arguments for `aligned`.

<table>
<thead>
<tr>

</tr>
<tr>
<td><code>aligned operator -(const aligned &amp;)</code></td>
<td>Returns: Same type <code>aligned</code> for value of difference.</td>
</tr>
</tbody>
</table>
### Operation Description

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
</table>
| template<int OtherAl>
aligned<?> operator -(const aligned<OtherAl>&) const | Difference with other alignment. Behavior and returned alignment type depend on relation between alignments of operands.                      |
| **Returns**: Value for difference as lower of incoming alignments |
| template<int V>
aligned<?> operator -(const fixed<V>&) const | Difference with fixed value. Behavior and returned alignment type depend on relation between alignments of aligned<>() operand and the value of V. |
| **Returns**: Adjusted aligned value of a difference |
| aligned operator +(const aligned &) const | Sum with other alignment. Behavior and returned alignment type depend on relation between alignments of operands.                           |
| **Returns**: Value for sum as lower of incoming alignments |
| template<int V>
aligned<?> operator +(const fixed<V>&) const | Sum with fixed value. Behavior and returned alignment type depend on relation between alignments of aligned<>() operand and the value of V. |
| **Returns**: Adjusted aligned value of a sum. |
| template<int OtherAl>
aligned operator +=(const aligned<OtherAl> &) const | Increments value for the aligned object if IndexAlignmentT is compatible with OtherAl.                                               |
| **Returns**: Aligned with incremented value. |
| template<int OtherAl>
aligned operator -= (const aligned<OtherAl> &) const | Decrements value for the aligned object if IndexAlignmentT is compatible with OtherAl.                                               |
| **Returns**: Same type aligned with decremented value. |
| template<int OtherAl>
aligned operator *= (const aligned<OtherAl> &) const | Multiplies value for the aligned object if IndexAlignmentT is compatible with OtherAl.                                              |
| **Returns**: Same type aligned with multiplied value. |
| template<int OtherAl>
aligned operator /= (const aligned<OtherAl> &) const | Divides value for the aligned object if IndexAlignmentT is compatible with OtherAl.                                                  |
| **Returns**: Same type aligned with divided value. |

**NOTE** The `sdlt::aligned<>` type supersedes the deprecated `sdlt::aligned_offset<>` type found in SDLT v1. It is strongly advised to use `sdlt::aligned<>`, however in this release a template alias is provided mapping `sdlt::aligned_offset<>` onto `sdlt::aligned<>`.
int
Represents an arbitrary integer value. In interfaces where fixed<> and aligned<> values supported you may also use plain old integer value. It provides least information among these 3 and so least facilitates compiler optimizations.

aligned_offset
Represents an integer based offset whose value is a multiple of an IndexAlignment specified at compile time. #include <sdlt/aligned_offset.h>

Syntax
```cpp
template<int IndexAlignmentT>
class aligned_offset;
```

Arguments
```
int IndexAlignmentT
```
The index alignment the user is stating that the offset have.

Description
aligned_offset is a deprecated feature.

If we can tell the compiler that we know an offset will be a multiple of known value, then when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access when accessing underlying data layout.

Internally, the offset value is converted to a block count.

```
Block Count = offsetValue/IndexAlignmentT;
```

Indices can then use that aligned block count as needed.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>

</tr>
<tr>
<td>static aligned_offset from_block_count(int aligned_block_count);</td>
<td>Returns: Instance based on aligned_block_count, where the offset value = IndexAlignment*aligned_block_count</td>
</tr>
<tr>
<td>int aligned_block_count() const;</td>
<td>Returns: number of blocks of IndexAlignment it takes to represent the offset value.</td>
</tr>
<tr>
<td>int value() const;</td>
<td>Returns: offset value</td>
</tr>
</tbody>
</table>

fixed_offset
Represents an integer based offset whose value specified at compile time. #include <sdlt/fixed_offset.h>

Syntax
```cpp
template <int OffsetT> fixed_offset;
```
Arguments

int OffsetT

The value the fixed_offset will represent

Description

fixed_offset is a deprecated feature.

If we can tell the compiler that we know an offset at compile time, then when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access (should the offset be aligned) when accessing underlying data layout. When multiple accesses are happening near each other, the compiler will have the opportunity to detect which accesses occur in the same cache lines and potentially avoid prefetching the same cache line repeatedly. Whenever possible, a fixed_offset should be used over an aligned_offset or integer based offset.

<table>

<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static constexpr int value = OffsetT</td>
<td>The offset value known at compile</td>
</tr>
</tbody>
</table>

Indexes

soa1d_container’s and aos1d_container’s accessors [] operator can accept an integer based loop index. However if any modifications were applied to that loop index, the fact that it’s a loop index may be lost by the compiler as it is handled before being passed to the [] operator.

To avoid this situation, SDLT provides classes to wrap loop indexes that capture multiple additions or subtractions of offsets (see the Offsets section). The resulting index can be passed to [] and preserve the original loop index and track any arithmetic with Offsets to be applied to underlying data layout.

It is common for stencil based algorithms to need to apply offsets during data access.

For a regular linear loop, use linear_index to wrap your loop index.

linear_index

Wraps an integer-based loop index that is iterating linearly through an iteration space. #include <sdlt/linear_index.h>

Syntax

class linear_index;

Description

Inside of a linear loop, wrap the loop index with a linear_index to allow addition or subtraction of offsets.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>explicit linear_index(int an_index);</td>

n_index_t (needs new content)

Variadic template class n_index_t describes a position inside of the N-dimensional container. Specifically, the number of dimensions and the of index value of each.

Syntax

template<typename... TypeListT>
class n_index_t
n_index_t represents a position inside an n-dimensional space as a sequence of index value for each dimension. The index of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare n_index_t with indices that are fully known at compile time with fixed<int NumberT>, or to be only known at runtime with int, or only known at runtime but with a guarantee will be a multiple of an alignment with aligned<int Alignment>. For more details, see the Number representation section.

Objects of this class may be used to identify a cell in a container, describe the inclusive lower bounds for n_bounds(), n-dimensional position for accessor's translated_to().

The following table provides information about the template arguments for n_index_t.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typename... TypeListT</td>
<td>Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the index of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array, from leftmost to rightmost. Requirements: Type must be int, or fixed&lt;NumberT&gt;, or aligned&lt;AlignmentT&gt;.</td>
</tr>

**n_index_generator**

To facilitate simpler creation of `n_index_t` objects, the generator object `n_index` is provided.

### Syntax

```cpp
template<typename... TypeListT>
class n_index_generator;
```

```cpp
namespace {
    // Instance of generator object
    n_index_generator<> n_index;
}
```

### Description

The generator object provides recursively constructing operators `[]` for `fixed<>`, `aligned<>`, and integer values allowing building of a `n_index_t<...>` instance one dimension at a time. Its main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition.

Compare the following examples, instantiating three `n_index_t` instances, and using the generator object to instantiate equivalent instances.

```cpp
n_index_t<int, int> idx1(row, col);
n_index_t<int, aligned<16>> idx2(row, aligned<16>(col));
n_index_t<fixed<540>, fixed<960>> idx3(540_fixed, 960_fixed);
```

```cpp
auto idx1 = n_index[row][col];
auto idx2 = n_index[row][aligned<16>(col)];
auto idx3 = n_index[540_fixed][960_fixed];
```

### Class Hierarchy

It is expected that `n_index_generator<...>` not be directly used as a data member or parameter, instead only `n_index_t<...>` from which it is derived. The generator object `n_index` can be automatically downcast any place expecting an `n_index_t<...>`.

The following table provides the template arguments for `n_index_generator`.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>typename... TypeListT</code></td>
<td>Comma separated list of types, where the number of types provided controls how many dimensions the generator currently represents. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. <strong>Requirements:</strong> Type is <code>int</code>, <code>fixed&lt;NumberT&gt;</code>, or <code>aligned&lt;AlignmentT&gt;</code>.</td>
</tr>
</tbody>
</table>

The following table provides information on the types defined as members of `n_index_generator` in addition to those inherited from `n_index_t`.

The following table provides information on the members of `n_index_generator` in addition to those inherited from `n_index_t`:

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
</table>
| `n_index_generator()` | **Requirements:** TypeListT is empty.  
 **Effects:** Construct generator with no indices specified. |
| `n_index_generator(const n_index_generator &a_other)` | **Effects:** Construct generator copying any index values from `a_other` |
| `n_index_generator<TypeListT..., int> operator[](int a_index) const` | **Requirements:** `a_size` >= 0.  
 **Returns:** `n_index_generator<...>` with additional rightmost integer based index. |
| `n_index_generator<TypeListT..., fixed<NumberT>> operator[](fixed<NumberT> a_index) const` | **Requirements:** `a_size` >= 0.  
 **Returns:** `n_index_generator<...>` with additional rightmost fixed<NumberT> index. |
| `n_index_generator<TypeListT..., aligned<AlignmentT>> operator[](aligned<AlignmentT> a_index)` | **Requirements:** `a_size` >= 0.  
 **Returns:** `n_index_generator<...>` with additional rightmost aligned<AlignmentT> based index. |
| `value_type value() const` | **Returns:** `n_extent_t<...>` with the correct types and values of the multi-dimensional extents aggregated by the generator. |

**index_d template function**

**Syntax**

```cpp
template<int DimensionT, typename ObjT>
auto index_d(const ObjT &a_obj)
```

**Description**
The template function offers a consistent way to determine the index of a dimension for a multi-dimensional object. It can avoid extracting an entire `n_index_t<...>` when only the extent of a single dimension is needed.

<table>
<thead>
<tr>
<th>Template Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| `int DimensionT`  | 0 based index starting at the leftmost dimension indicating which n-dimensions to query the index of.  
 **Requirements:** `DimensionT` >=0 and `DimensionT` < `ObjT::rank` |
| `typename ObjT`   | The type of n-dimensional object from which to retrieve the extent.  
 **Requirements:** `ObjT` is one of:  
 `n_index_t<...>`  
 `n_index_generator<...>` |

**Returns**
The correctly typed index corresponding to the requested DimensionT of a_obj.

Example

template<typename IndicesT>
void foo(const IndicesT & a_pos)
{
    int z = index_d<0>(a_pos);
    int y = index_d<1>(a_pos);
    int x = index_d<2>(a_pos);
    /…
}

Convenience and Correctness

Users can include a single header file sdlt.h that includes all the supported public features, or users can include the individual headers of features they will be using (which might build faster). In other words,

```
#include <sdlt/sdlt.h>
```

instead of

```
#include <sdlt/primitive.h>
#include <sdlt/soa1d_container.h>
```

For convenience, SDLT provides a macro to encapsulate `#pragma forceinline recursive`.

```
SDLT_INLINE_BLOCK
```

SDLT reduces overhead by trusting the programmer to pass it valid values for template and function parameters. Adding conditional checks inside of a SIMD loop can cause unnecessary code generation and inhibit vectorization by creating multiple exit points in a loop. To assist in verifying that a program is indeed passing valid values to SDLT, the programmer can add a compilation flag to their build to define `SDLT_DEBUG=1`.

```
-DSDLT_DEBUG=1
```

If `_DEBUG` is defined and `SDLT_DEBUG` has not been defined to 0 or 1, then `SDLT_DEBUG` is automatically set to 1. When set to 1, every operator[] is bounds checked and all addresses are validated for correct alignment. It is very useful for tracking down any usage bugs.

The macro `_SDLT_VERSION` is predefined to be 2001. Programs could use it for conditional compilation if incompatibilities arise in future updates.

C++ implementations of `std::min` and `std::max` sometimes have a negative impact on performance. SDLT defines `min_val` and `max_val` that help avoid such performance penalties.

`max_val`

Return the right value if the right value is greater than left, otherwise returns the left value. `#include <sdlt/min_max_val.h>`

Syntax

template<typename T>
T max_val(const T left, const T right);

Arguments

typename T The type of the left and right values
Description

C++ implementations of std::min and std::max create a conditional control flow that returns references to its parameters, which may cause inefficient vector code generation. max_val is a really simple template that returns by value instead of reference, allowing more efficient vector code to be generated. For most cases the algorithm didn’t need a reference to the inputs and a copy by value should suffice. It should inline, adding no overhead. Inside of SIMD loops, we suggest using sdlt::max_val in place of std::max.

Requires < operator be defined for the type T.

min_val

Return the left value if the right value is greater than left, otherwise returns the right value. #include <sdlt/min_max_val.h>

Syntax

```
template<typename T>
T min_val(const T left, const T right);
```

Arguments

- typename T: The type of the left and right values

Description

C++ implementations of std::min and std::max create a conditional control flow that returns references to its parameters, which may cause inefficient vector code generation. min_val is a really simple template that returns by value instead of reference, allowing more efficient vector code to be generated. For most cases the algorithm didn’t need a reference to the inputs and a copy by value should suffice. It should inline, adding no overhead. Inside of SIMD loops, we suggest using sdlt::min_val in place of std::min.

Requires < operator be defined for the type T.

Examples

The example programs in this section demonstrate
- the efficiency of using SDLT and its Structure of Arrays approach rather than a typical Array of Structures
- construction of more complex SDLT primitives,
- performance improvement in case of a forward-dependency
- use of offsets and calling methods on the SDLT primitive, and
- RGB to YUV conversion.

Example 1

Example 1 demonstrates the efficiency of using a Structure of Arrays (SoA) approach by comparing the assembly generated from a simple SIMD loop using an Array of Structures (AoS) approach with the assembly generated using the SoA approach of SDLT.

Array of Structures: Non-unit stride access version

Source:

```
#include <stdio.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
```
float b;
} RGBTy;

void main()
{
    RGBTy a[N];
    #pragma omp simd
    for (int k = 0; k<N; ++k) {
        a[k].r = k*1.5;  // non-unit stride access
        a[k].g = k*2.5;  // non-unit stride access
        a[k].b = k*3.5;  // non-unit stride access
    }
    std::cout << "k =" << 10 <<
    " , a[k].r =" << a[10].r <<
    " , a[k].g =" << a[10].g <<
    " , a[k].b =" << a[10].b << std::endl;
}

Structure of Arrays: Using SDLT for unit stride access

To introduce the use of SDLT, the code below will:

- declares a primitive,
- use an `soa1d_container` instead of an array,
- use an accessor inside a SIMD loop to generate efficient code,
- and use a proxy object’s data member interface to access individual data members of an element inside the container.

Source:

```c
#include <stdio.h>
#include <sdlt/sdlt.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
    float b;
} RGBTy;

SDLT_PRIMITIVE(RGBTy, r, g, b)

void main()
```

```c
vmovss %xmm15, 148(%rsp,%rax)

  vmovups %ymm3, 32(%r13,%rax,4)
  vmovups %ymm9, 32(%r15,%rax,4)
  vmovups %ymm11, 32(%rbx,%rax,4)
  vpadd   %ymm4, %ymm12, %ymm3
  addq    $16, %rax
  cmpq    $1024, %rax
  jb      ..TOP_OF_LOOP

Both versions appear to have unrolled the loop twice. When examining the assembly generated for AVX2
instruction set, we can see a measurable reduction in the number of instructions (19 vs. 69) when we are
able to perform unit stride access using SDLT. Also, at runtime, the soa1d_container aligned its data
allocation and will gain any of the architectural advantages that come with using aligned instead of unaligned
SIMD stores.

**Example 2**

Example 2 demonstrates use of nested primitives and the use of an accessor inside a SIMD loop to generate
efficient code.

```cpp
#include <stdio.h>
#include <sdlt/sdlt.h>
#define N 1024

typedef struct XYZs {
    float x;
```
float y;
float z;
) XYZTy;
SDLT_PRIMITIVE(XYZTy, x, y, z)

typedef struct RGBs {
    float r;
    float g;
    float b;
    XYZTy w;
} RGBTy;
SDLT_PRIMITIVE(RGBs, r, g, b, w)

void main()
{
    sdlt::soa1d_container<RGBTy> aContainer(N);
    auto a = aContainer.access();

    #pragma omp simd
    for (int k = 0; k<N; k++) {
        RGBTy c;
        c.r = k*1.5f;
        c.g = k*2.5f;
        c.b = k*3.5f;
        c.w.x = k*4.5f;
        c.w.y = k*5.5f;
        c.w.z = k*6.5f;
        a[k] = c;
    }
    const RGBTy c = a[10];
    printf("k = %d, a[k].r = %f, a[k].g = %f, a[k].b = %f \n",
           10, c.r, c.g, c.b);
    printf("k = %d, a[k].w.x = %f, a[k].w.y = %f, a[k].w.z = %f \n",
           10, c.w.x, c.w.y, c.w.z);

Example 3
Example 3 demonstrates the declaration of a Structure of Arrays (SoA) interacting with a forward dependency.

#include <stdio.h>
#include <sdlt/primitive.h>
#include <sdlt/soa1d_container.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
    float b;
} RGBTy;
SDLT_PRIMITIVE(RGBTy, r, g, b)

void main()
{
// RGBTy a[N]; // AOS data layout

sdl::soa1d_container<RGBTy> aContainer(N);
auto a = aContainer.access(); // SOA data layout

// use SDLT access method to access struct members r, g, and b.
// with unit-stride access after vectorization
#pragma omp simd
for (int k = 0; k<N; k++) {
    a[k].r() = k*1.5;
    a[k].g() = k*2.5;
    a[k].b() = k*3.5;
}

// Test forward-dependency on SOA memory access
#pragma omp simd
for (int i = 0; i<N - 1; i++) {
    sdl::linear_index k(i);
    a[k].r() = a[k + 1].r() + k*1.5;
    a[k].g() = a[k + 1].g() + k*2.5;
    a[k].b() = a[k + 1].b() + k*3.5;
}
std::cout << "k =" << 10 << ", a[k].r =" << a[10].r() << ", a[k].g =" << a[10].g() << ", a[k].b =" << a[10].b() << std::endl;

Example 4

Example 4 demonstrates a linearized 2d stencil using embedded offsets and calling methods on the primitive.

#include <sdlt/sdlt.h>

// Typical C++ object to represent a pixel in an image
struct RGBs {
    float red;
    float green;
    float blue;

    RGBs() {} // Constructor
    RGBs(const RGBs &iOther) :
        red(iOther.red),
        green(iOther.green),
        blue(iOther.blue)
    {} // Copy constructor

    RGBs & operator =(const RGBs &iOther) {
        red = iOther.red;
        green = iOther.green;
        blue = iOther.blue;
        return *this;
    }

    RGBs operator + (const RGBs &iOther) const {
        // Implementation
    }

    RGBs operator - (const RGBs &iOther) const {
        // Implementation
    }

    RGBs operator * (const RGBs &iOther) const {
        // Implementation
    }

    RGBs operator / (const RGBs &iOther) const {
        // Implementation
    }
};
RGBs sum;
sum.red = red + iOther.red;
sum.green = green + iOther.green;
sum.blue = blue + iOther.blue;
return sum;
}

RGBs operator * (float iScalar) const
{
    RGBs scaledColor;
scaledColor.red = red * iScalar;
scaledColor.green = green * iScalar;
scaledColor.blue = blue * iScalar;
return scaledColor;
};

SDLT_PRIMITIVE(RGBs, red, green, blue)

const int StencilHaloSize = 1;
const int width = 1920;
const int height = 1080;
template<typename AccessorT> void loadImageStub(AccessorT) {}
template<typename AccessorT> void saveImageStub(AccessorT) {}

// performs average color filtering with neighbors left, right, above, below
void main(void)
{
    // We are padding +-1 so we can avoid boundary conditions
    const int paddedWidth = width + 2 * StencilHaloSize;
    const int paddedHeight = height + 2 * StencilHaloSize;
    int elementCount = paddedWidth*paddedHeight;
    sdlt::soa1d_container<RGBs> inputImage(elementCount);
    sdlt::soa1d_container<RGBs> outputImage(elementCount);

    loadImageStub(inputImage.access());

    SDLT_INLINE_BLOCK
    {
        const int endOfY = StencilHaloSize + height;
        const int endOfX = StencilHaloSize + width;
        for (int y = StencilHaloSize; y < endOfY; ++y)
        {
            // Embed offsets into Accessors to get the to correct row
            auto prevRow = inputImage.const_access((y - 1)*paddedWidth);
            auto curRow = inputImage.const_access(y*paddedWidth);
            auto nextRow = inputImage.const_access((y + 1)*paddedWidth);

            auto outputRow = outputImage.access(y*paddedWidth);

            #pragma omp simd
            for (int ix = StencilHaloSize; ix < endOfX; ++ix)
            {
                sdl::linear_index x(ix);

                const RGBs color1 = curRow[x - 1];
Example 5

Example 5 converts a 2D image from the RGB format to the YUV format. It demonstrates how storing both images in 2D SoA n_containers can improve performance.
/* Creating a typedef for SoA N-dimensional container.
   RGBTy and YUVTy are user defined structures whose collection needs to be stored in SoA
   format in memory.
   Layout in memory specified as layout::soa.
   In the below case N-dimensional SoA container is used in 2-D context
 */
typedef sdlt::n_container< RGBs, LayoutT, decltype(extents) > ContainerRGB;
typedef sdlt::n_container< YUVs, LayoutT, decltype(extents) > ContainerYUV;

// Instantiate Input and Output Containers
ContainerRGB inputRGB(extents);
ContainerYUV outputYUV(extents);

auto input = inputRGB.const_access(); // Get Constant Accessor object for inputRGB
auto output = outputYUV.access();       // Get Accessor object for outputYUV

// Select the iteration range in each dimension
const auto iRGB1 = bounds_d<1>(input); // bound_d<1>(input);
const auto iRGB0 = bounds_d<0>(input); // bound_d<0>(input);

for(int y = iRGB0.lower(); y < iRGB0.upper(); y++)
{
    #pragma simd
    for(int x = iRGB1.lower(); x < iRGB1.upper(); x++)
    {
        const RGBs temp1 = input[y][x];
        YUVs temp2 = temp1;
        output[y][x] = temp2;
    }

    return 0;
}

**Intel® C++ Class Libraries**

The Intel® C++ Class Libraries enable Single-Instruction, Multiple-Data (SIMD) operations. The principle of SIMD operations is to exploit microprocessor architecture through parallel processing. The effect of parallel processing is increased data throughput using fewer clock cycles. The objective is to improve application performance of complex and computation-intensive audio, video, and graphical data bit streams.

**Hardware and Software Requirements**

The Intel® C++ Class Libraries are functions abstracted from the instruction extensions available on Intel® processors.

**Details About the Libraries**

The Intel® C++ Class Libraries for SIMD Operations provide a convenient interface to access the underlying instructions for processors as specified above. These processor-instruction extensions enable parallel processing using the single instruction-multiple data (SIMD) technique as illustrated in the following figure.
SIMD Data Flow

Performing four operations with a single instruction improves efficiency by a factor of four for that particular instruction.

These new processor instructions can be implemented using assembly inlining, intrinsics, or the C++ SIMD classes. Compare the coding required to add four 32-bit floating-point values, using each of the available interfaces:

Comparison Between Inlining, Intrinsics and Class Libraries

<table>
<thead>
<tr>
<th>Assembly Inlining</th>
<th>Intrinsics</th>
<th>SIMD Class Libraries</th>
</tr>
</thead>
<tbody>
<tr>
<td>... __m128 a,b,c;</td>
<td>#include &lt;xmmintrin.h&gt; ...</td>
<td>#include &lt;fvec.h&gt; ...</td>
</tr>
<tr>
<td>__asm{ movaps xmm0,b</td>
<td>_m128 a,b,c; a =</td>
<td>F32vec4 a,b,c; a = b</td>
</tr>
<tr>
<td>movaps xmm1,c addps</td>
<td>_mm_add_ps(b,c); ...</td>
<td>+c; ...</td>
</tr>
<tr>
<td>xmm0,xmm1 movaps a,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>xmm0 } ...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This table shows an addition of four single-precision floating-point values using assembly inlining, intrinsics, and the libraries. You can see how much easier it is to code with the Intel C++ SIMD Class Libraries. Besides using fewer keystrokes and fewer lines of code, the notation is like the standard notation in C++, making it much easier to implement over other methods.

C++ Classes and SIMD Operations

Use of C++ classes for SIMD operations allows for operating on arrays or vectors of data in a single operation. Consider the addition of two vectors, \( A \) and \( B \), where each vector contains four elements. Using an integer vector class, the elements \( A[i] \) and \( B[i] \) from each array are summed as shown in the following example.

Typical Method of Adding Elements Using a Loop

```c
int a[4], b[4], c[4];
for (i=0; i<4; i++) /* needs four iterations */
c[i] = a[i] + b[i]; /* computes c[0], c[1], c[2], c[3] */
```

The following example shows the same results using one operation with an integer class.

SIMD Method of Adding Elements Using Ivec Classes

```c
Is16vec4 ivecA, ivecB, ivec C; /*needs one iteration*/
ivecC = ivecA + ivecB; /*computes ivecC0, ivecC1, ivecC2, ivecC3 */
```

Available Classes

The Intel® C++ SIMD classes provide parallelism, which is not easily implemented using typical mechanisms of C++. The following table shows how the Intel® C++ classes use the SIMD classes and libraries.

<tr>
<td>Intel® SSE</td>
<td><code>#include &lt;fvec.h&gt;</code></td>
</tr>
</tbody>
</table>

Most classes contain similar functionality for all data types and are represented by all available intrinsics. However, some capabilities do not translate from one data type to another without suffering from poor performance, and are therefore excluded from individual classes.

**NOTE**
Intrinsics that take immediate values and cannot be expressed easily in classes are not implemented. For example:
- `_mm_shuffle_ps`
- `_mm_shuffle_pi16`
- `_mm_shuffle_ps`
- `_mm_shuffle_pi16`
- `_mm_extract_pi16`
- `_mm_insert_pi16`

Access to Classes Using Header Files
The required class header files are installed in the include directory with the Intel® C++ Compiler. To enable the classes, use the `#include` directive in your program file as shown in the table that follows.
### Instruction Set Extension and Include Directive

<table>
<thead>
<tr>
<th>Instruction Set Extension</th>
<th>Include Directive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® SSE 2</td>
<td>#include &lt;dvec.h&gt;</td>
</tr>
<tr>
<td>Intel® SSE 3</td>
<td>#include &lt;dvec.h&gt;</td>
</tr>
<tr>
<td>Intel® SSE 4</td>
<td>#include &lt;dvec.h&gt;</td>
</tr>
<tr>
<td>Intel® AVX</td>
<td>#include &lt;dvec.h&gt;</td>
</tr>
</tbody>
</table>

Each succeeding file from the top down includes the preceding class. You only need to include `fvec.h` if you want to use both the `Ivec` and `Fvec` classes. Similarly, to use all the classes including those for Intel® Streaming SIMD Extensions 2, you only need to include the `dvec.h` file.

### Usage Precautions

When using the C++ classes, you should follow some general guidelines. More detailed usage rules for each class are listed in Integer Vector Classes, and Floating-point Vector Classes.

#### Clear MMX Registers

If you use both the `Ivec` and `Fvec` classes at the same time, your program could mix Intel® MMX™ instructions, called by `Ivec` classes, with Intel® architecture floating-point instructions, called by `Fvec` classes. x87 floating-point instructions exist in the following `Fvec` functions:

- `fvec` constructors
- debug functions (`cout` and element access)
- `rsqrt_nr`

**NOTE**

Intel® MMX™ technology registers are aliased on the floating-point registers, so you should clear the MMX state with the EMMS instruction intrinsic before issuing an x87 floating-point instruction, as in the following example.

```cpp
ivecA = ivecA & ivecB;  // Ivec logical operation that uses MMX instructions
empty ();                // clear state
cout << f32vec4a;       // F32vec4 operation that uses x87 floating-point instructions
```

**Caution**

Failure to clear the Intel® MMX™ technology registers can result in incorrect execution or poor performance due to an incorrect register state.

### Capabilities of C++ SIMD Classes

The fundamental capabilities of each C++ SIMD class include:

- computation
- horizontal data support
- branch compression/elimination
- caching hints
Understanding each of these capabilities and how they interact is crucial to achieving desired results.

**Computation**

The SIMD C++ classes contain vertical operator support for most arithmetic operations, including shifting and saturation.

Computation operations include: 
- Addition (+)
- Subtraction (−)
- Multiplication (×)
- Division (/)
- Reciprocal (rcp and rcp_nr)
- Square root (sqrt)
- Reciprocal square root (rsqrt and rsqrt_nr)

Operations rcp and rsqrt are approximating instructions with very short latencies that produce results with at least 12 bits of accuracy. You may get a different answer if used on non-Intel processors. Operations rcp_nr and rsqrt_nr use software refining techniques to enhance the accuracy of the approximations, with a minimal impact on performance. (The "nr" stands for Newton-Raphson, a mathematical technique for improving performance using an approximate result.)

**Horizontal Data Support**

The C++ SIMD classes provide horizontal support for some arithmetic operations. The term "horizontal" indicates computation across the elements of one vector, as opposed to the vertical, element-by-element operations on two different vectors.

The add_horizontal, unpack_low and pack_sat functions are examples of horizontal data support. This support enables certain algorithms that cannot exploit the full potential of SIMD instructions.

Shuffle intrinsics are another example of horizontal data flow. Shuffle intrinsics are not expressed in the C++ classes due to their immediate arguments. However, the C++ class implementation enables you to mix shuffle intrinsics with the other C++ functions. For example:

```c++
F32vec4 fveca, fvecb, fvecd;
fveca += fvecb;
fvecd = _mm_shuffle_ps(fveca,fvecb,0);
```

**Branch Compression/Elimination**

Branching in SIMD architectures can be complicated and expensive. The SIMD C++ classes provide functions to eliminate branches, using logical operations, max and min functions, conditional selects, and compares.

Consider the following example:

```c++
short a[4], b[4], c[4];
for (i=0; i<4; i++)
c[i] = a[i] > b[i] ? a[i] : b[i];
```

This operation is independent of the value of i. For each i, the result could be either a or b depending on the actual values. A simple way of removing the branch altogether is to use the select_gt function, as follows:

```c++
Is16vec4 a, b, c
  c = select_gt(a, b, a, b)
```

**Caching Hints**

Intel® Streaming SIMD Extensions provide prefetching and streaming hints. Prefetching data can minimize the effects of memory latency. Streaming hints allow you to indicate that certain data should not be cached.

**Integer Vector Classes**

The Ivec classes provide an interface to single instruction, multiple data (SIMD) processing using integer vectors of various sizes. The class hierarchy is represented in the following figure.
The M64 and M128 classes define the __m64 and __m128i data types from which the rest of the Ivec classes are derived. The first generation of child classes (the intermediate classes) are derived on element sizes of 128, 64, 32, 16, and 8 bits:

I128vec1, I64vec1, I64vec2, I32vec2, I32vec4, I16vec4, I16vec8, I8vec8, I8vec16

The second generation specify the signedness:

Is64vec2, Iu64vec2, Is32vec2, Iu32vec2, Is32vec4, Iu32vec4, Is16vec4, Iu16vec4, Is16vec8, Iu16vec8, Is8vec8, Iu8vec8, Is8vec16, Iu8vec16

**Caution**
Intermixing the M64 and M128 data types will result in unexpected behavior.

---

**Terms, Conventions, and Syntax Defined**

The following are special terms and syntax used in this chapter to describe functionality of the classes with respect to their associated operations.

**Ivec Class Syntax Conventions**

The name of each class denotes the data type, signedness, bit size, and number of elements using the following generic format:

```
<type><signedness><bits>vec<elements>
```

where:

- **type** Indicates floating point (F) or integer (I).
- **signedness** Indicates signed (s) or unsigned (u). For the Ivec class, leaving this field blank indicates an intermediate class. For the Fvec classes, this field is blank because there are no unsigned Fvec classes.
- **bits** Specifies the number of bits per element.
- **elements** Specifies the number of elements.

**Special Terms and Conventions**

The following terms are used to define the functionality and characteristics of the classes and operations defined in this manual.
• **Nearest Common Ancestor:** This is the intermediate or parent class of two classes of the same size. For example, the nearest common ancestor of \texttt{Iu8vec8} and \texttt{Is8vec8} is \texttt{I8vec8}, and the nearest common ancestor between \texttt{Iu8vec8} and \texttt{I16vec4} is \texttt{M64}.

• **Casting:** Changes the data type from one class to another. When an operation uses different data types as operands, the return value of the operation must be assigned to a single data type, and one or more of the data types must be converted to a required data type. This conversion is known as a typecast. While typescasting is occasionally automatic, in cases where it is not automatic you must use special syntax to explicitly typecast it yourself.

• **Operator Overloading:** This is the ability to use various operators on the user-defined data type of a given class. In the case of the Ivec and Fvec classes, once you declare a variable, you can add, subtract, multiply, and perform a range of operations. Each family of classes accepts a specified range of operators, and must comply by rules and restrictions regarding typescasting and operator overloading as defined in the header files.

---

**Rules for Operators**

To use operators with the \texttt{Ivec} classes you must use one of the following three syntax conventions:

\[
\texttt{[ Ivec\_Class ] R = [ Ivec\_Class ] A [ operator ] [ Ivec\_Class ] B}
\]

**Example 1:** \texttt{I64vec1 R = I64vec1 A \& I64vec1 B;}

\[
\texttt{[ Ivec\_Class ] R = [ operator ] ([ Ivec\_Class ] A, [ Ivec\_Class ] B)}
\]

**Example 2:** \texttt{I64vec1 R = andnot(I64vec1 A, I64vec1 B);}

\[
\texttt{[ Ivec\_Class ] R [ operator ] = [ Ivec\_Class ] A}
\]

**Example 3:** \texttt{I64vec1 R \&= I64vec1 A;}

\[
\texttt{[ operator ] represents an operator (for example, \&, |, or ^)}
\]

\[
\texttt{[ Ivec\_Class ] represents an Ivec class}
\]

\[
\texttt{R, A, B variables are declared using the pertinent Ivec classes}
\]

The table that follows shows automatic and explicit sign and size typescasting. "Explicit" means that it is illegal to mix different types without an explicit typescasting. "Automatic" means that you can mix types freely and the compiler will do the typescasting for you.

<td>Iu8vec16 A(unsigned char A15, ..., unsigned char A0);</td>
</tr>
</tbody>
</table>

### Assignment Operator

Any Ivec object can be assigned to any other Ivec object; conversion on assignment from one Ivec object to another is automatic.

### Assignment Operator Examples

```cpp
Is16vec4 A;
Is8vec8 B;
I64vec1 C;
A = B; /* assign Is8vec8 to Is16vec4 */
B = C; /* assign I64vec1 to Is8vec8 */
B = A & C; /* assign M64 result of '&' to Is8vec8 */
```

### Logical Operators

The logical operators use the symbols and intrinsics listed in the following table.
Bitwise Operation | Operator Symbols | Syntax Usage | Corresponding Intrinsic
---|---|---|---
AND | & | & R = A & B | \_\_mm\_and\_si64
OR | | | \_\_mm\_and\_si64
XOR | ^ | ^= R = A ^ B | \_\_mm\_and\_si64
ANDNOT | andnot | N/A | N/A

Logical Operators and Miscellaneous Exceptions
A and B converted to M64. Result assigned to Iu8vec8.

I64vec1 A;
I64vec8 B;
Iu8vec8 C;
C = A & B;

Same size and signedness operators return the nearest common ancestor.
I32vec2 R = Is32vec2 A ^ Iu32vec2 B;
A&B returns M64, which is cast to Iu8vec8.
C = Iu8vec8(A&B)+ C;

When A and B are of the same class, they return the same type. When A and B are of different classes, the return value is the return type of the nearest common ancestor.
The logical operator returns values for combinations of classes, listed in the following tables, apply when A and B are of different classes.

Ivec Logical Operator Overloading

<table>
<thead>
<tr>
<th>Return (R)</th>
<th>AND</th>
<th>OR</th>
<th>XOR</th>
<th>NAND</th>
<th>A Operand</th>
<th>B Operand</th>
</tr>
</thead>
<tbody>
<tr>
<td>I64vec1 R</td>
<td>&amp;</td>
<td></td>
<td></td>
<td>andnot</td>
<td>I[s]</td>
<td>u)64vec2 A u)64vec2 B</td>
</tr>
<tr>
<td>I64vec2 R</td>
<td>&amp;</td>
<td></td>
<td></td>
<td>andnot</td>
<td>I[s]</td>
<td>u)64vec2 A u)64vec2 B</td>
</tr>
<tr>

<td>I[x]8vec8 R</td>
<td>&amp;</td>
<td></td>
<td>^</td>
<td>I[s</td>
</tr>
</tbody>
</table>

**Addition and Subtraction Operators**

The addition and subtraction operators return the class of the nearest common ancestor when the right-side operands are of different signs. The following code provides examples of usage and miscellaneous exceptions.

**Syntax Usage for Addition and Subtraction Operators**

Return nearest common ancestor type, I16vec4.

```c++
Is16vec4 A;
Iu16vec4 B;
I16vec4 C;
C = A + B;
```

Returns type left-hand operand type.

```c++
Is16vec4 A;
Iu16vec4 B;
A += B;
B -= A;
```

Explicitly convert B to Is16vec4.

```c++
Is16vec4 A,C;
```
$$\text{Iu32vec24 B;}
\text{C = A + C;}
\text{C = A + (Is16vec4)B;}
$$

### Addition and Subtraction Operators with Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbols</th>
<th>Syntax</th>
<th>Corresponding Intrinsics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Addition</td>
<td>+</td>
<td>R = A + B</td>
<td>_mm_add_epi64</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_add_epi1</td>
</tr>
<tr>
<td>Subtraction</td>
<td>-</td>
<td>R = A - B</td>
<td>_mm_sub_epi64</td>
</tr>
<tr>
<td></td>
<td>-=</td>
<td>R -= A</td>
<td>_mm_sub_epi32</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_sub_epi16</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_sub_epi8</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_sub_epi4</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_sub_epi1</td>
</tr>
</tbody>
</table>

The following table lists addition and subtraction return values for combinations of classes when the right side operands are of different signedness. The two operands must be the same size, otherwise you must explicitly indicate the typecasting.

### Addition and Subtraction Operator Overloading

<table>
<thead>
<tr>
<th>Return Value (R)</th>
<th>Available Operators</th>
<th>Right Side Operands</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Add</td>
<td>Sub</td>
</tr>
<tr>
<td>I64vec2 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I32vec4 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I32vec2 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I16vec8 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I16vec4 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I8vec8 R</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>I8vec16 R</td>
<td>+</td>
<td></td>
</tr>
</tbody>
</table>

The following table shows the return data type values for operands of the addition and subtraction operators with assignment. The left side operand determines the size and signedness of the return value. The right side operand must be the same size as the left operand; otherwise, you must use an explicit typecast.

### Addition and Subtraction with Assignment

<table>
<thead>
<tr>
<th>Return Value (R)</th>
<th>Left Side (R)</th>
<th>Add</th>
<th>Sub</th>
<th>Right Side (A)</th>
</tr>
</thead>
<tbody>
<tr>
<td>I[x]32vec4</td>
<td>I[x]32vec2 R</td>
<td>+=</td>
<td></td>
<td>I[s</td>
</tr>
<tr>
<td>I[x]32vec2 R</td>
<td>I[x]32vec2 R</td>
<td>+=</td>
<td></td>
<td>I[s</td>
</tr>
</tbody>
</table>
## Multiplication Operators

The multiplication operators can only accept and return data types from the I[s|u]16vec4 or I[s|u]16vec8 classes, as shown in the following example.

### Syntax Usage for Multiplication Operators

Explicitly convert B to Is16vec4.

```cpp
Is16vec4 A, C;
Iu32vec2 B;
C = A * C;
C = A * (Is16vec4)B;
```

Return nearest common ancestor type, I16vec4

```cpp
Is16vec4 A;
Iu16vec4 B;
I16vec4 C;
C = A + B;
```

The `mul_high` and `mul_add` functions take Is16vec4 data only.

```cpp
Is16vec4 A, B, C, D;
C = mul_high(A, B);
D = mul_add(A, B);
```

### Multiplication Operators with Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Symbols</th>
<th>Syntax Usage</th>
<th>Intrinsic</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>*=</td>
<td>R = A * B</td>
</tr>
<tr>
<td></td>
<td></td>
<td>R *= A</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_mullo_pi16</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_mullo_epi16</td>
</tr>
<tr>
<td>mul_high</td>
<td>N/A</td>
<td>R = mul_high(A, B)</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_mulhi_pi16</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_mulhi_epi16</td>
</tr>
<tr>
<td>mul_add</td>
<td>N/A</td>
<td>R = mul_high(A, B)</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_madd_pi16</td>
</tr>
<tr>
<td></td>
<td>**</td>
<td>_mm_madd_epi16</td>
</tr>
</tbody>
</table>

The multiplication return operators always return the nearest common ancestor as listed in the table that follows. The two operands must be 16 bits in size, otherwise you must explicitly indicate typecasting.

### Multiplication Operator Overloading

<table>
<thead>
<tr>
<th>R</th>
<th>Mul</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>I16vec4</td>
<td>*</td>
<td>I[s</td>
<td>u]16vec4</td>
</tr>
<tr>
<td>I16vec4</td>
<td>*</td>
<td>I[s</td>
<td>u]16vec4</td>
</tr>
</tbody>
</table>
### Multiplication with Assignment

<table>
<thead>
<tr>
<th>Return Value (R)</th>
<th>Left Side (R)</th>
<th>Mul</th>
<th>Right Side (A)</th>
</tr>
</thead>
<tbody>
<tr>
<td>I[x]16vec8</td>
<td>I[x]16vec8</td>
<td>*</td>
<td>I[s</td>
</tr>
</tbody>
</table>
| I[x]16vec4       | I[x]16vec4    | *       | I[s|u]16vec4 A;

### Shift Operators

The right shift argument can be any integer or Ivec value, and is implicitly converted to a M64 data type. The first or left operand of a `<<` can be of any type except `I[s|u]8vec[8|16]`.

**Example Syntax Usage for Shift Operators**

Automatic size and sign conversion.

```
Is16vec4 A,C;
Iu32vec2 B;
C = A;
A&B returns **I16vec4**, which must be cast to **Iu16vec4** to ensure logical shift, not arithmetic shift.
```

```
Is16vec4 A, C;
Iu16vec4 B, R;
R = (Iu16vec4)(A & B) C;
A&B returns **I16vec4**, which must be cast to **Is16vec4** to ensure arithmetic shift, not logical shift.
```

### Shift Operators with Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbols</th>
<th>Syntax Usage</th>
<th>Intrinsic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shift Left</td>
<td><code>&lt;&lt;</code></td>
<td><code>R = A &lt;&lt; B</code></td>
<td>_mm_sll_si64</td>
</tr>
<tr>
<td></td>
<td><code>&amp;=</code></td>
<td><code>R &amp;= A</code></td>
<td>_mm_slli_si64</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_sll_pi32</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>_mm_slli_pi32</td>

</tbody>
</table>

**Comparison Operators**

The equality and inequality comparison operands can have mixed signedness, but they must be of the same size. The comparison operators for less-than and greater-than must be of the same sign and size.

**Example of Syntax Usage for Comparison Operator**

The nearest common ancestor is returned for compare for equal/not-equal operations.

`Iu8vec8 A;`
`Is8vec8 B;`
`I8vec8 C;`
`C = cmpneq(A,B);`

Type cast needed for different-sized elements for equal/not-equal comparisons.

`Iu8vec8 A, C;`
`Is16vec4 B;`
C = cmpeq(A, (Iu8vec8)B);

Type cast needed for sign or size differences for less-than and greater-than comparisons.

Iu16vec4 A;
Is16vec4 B, C;
C = cmpge((Is16vec4)A, B);
C = cmpgt(B, C);

### Inequality Comparison Symbols and Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Compare For:</th>
<th>Operators</th>
<th>Syntax</th>

<td>Is16vec4 B</td>
</tr>
</tbody>
</table>
**Conditional Select Operators**

For conditional select operands, the third and fourth operands determine the type returned. Third and fourth operands with same size, but different signedness, return the nearest common ancestor data type.

**Conditional Select Syntax Usage**

Return the nearest common ancestor data type if third and fourth operands are of the same size, but different signs.

\[
\text{I}16\text{vec}4 \ R = \text{select}_\text{neq}(\text{Is}16\text{vec}4, \text{Is}16\text{vec}4, \text{Is}16\text{vec}4, \text{Iu}16\text{vec}4);
\]

**Conditional Select for Equality**

\[
\begin{align*}
R_0 & := (A_0 == B_0) \ ? \ C_0 : D_0; \\
R_1 & := (A_1 == B_1) \ ? \ C_1 : D_1; \\
R_2 & := (A_2 == B_2) \ ? \ C_2 : D_2; \\
R_3 & := (A_3 == B_3) \ ? \ C_3 : D_3;
\end{align*}
\]

**Conditional Select for Inequality**

\[
\begin{align*}
R_0 & := (A_0 != B_0) \ ? \ C_0 : D_0; \\
R_1 & := (A_1 != B_1) \ ? \ C_1 : D_1; \\
R_2 & := (A_2 != B_2) \ ? \ C_2 : D_2; \\
R_3 & := (A_3 != B_3) \ ? \ C_3 : D_3;
\end{align*}
\]

### Conditional Select Symbols and Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Conditional Select For:</th>
<th>Operators</th>
<th>Syntax</th>
<th>Corresponding Intrinsic</th>
<th>Additional Intrinsic (Applies to All)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td>select_eq</td>
<td>R = \text{select}_\text{eq}(A, B, C, D)</td>
<td>_mm_cmpeq_pi32</td>
<td>_mm_cmpeq_pi16</td>
</tr>
<tr>
<td>Inequality</td>
<td>select_neq</td>
<td>R = \text{select}_\text{neq}(A, B, C, D)</td>
<td>_mm_cmpeq_pi32</td>
<td>_mm_cmpeq_pi16</td>
</tr>
<tr>
<td>Greater Than</td>
<td>select_gt</td>
<td>R = \text{select}_\text{gt}(A, B, C, D)</td>
<td>_mm_cmpgt_pi32</td>
<td>_mm_cmpgt_pi16</td>
</tr>
<tr>
<td>Greater Than or Equal To</td>
<td>select_ge</td>
<td>R = \text{select}_\text{ge}(A, B, C, D)</td>
<td>_mm_cmpge_pi32</td>
<td>_mm_cmpge_pi16</td>
</tr>
<tr>
<td>Less Than</td>
<td>select_lt</td>
<td>R = \text{select}_\text{lt}(A, B, C, D)</td>
<td>_mm_cmplt_pi32</td>
<td>_mm_cmplt_pi16</td>
</tr>
<tr>
<td>Less Than or Equal To</td>
<td>select_le</td>
<td>R = \text{select}_\text{le}(A, B, C, D)</td>
<td>_mm_cmple_pi32</td>
<td>_mm_cmple_pi16</td>
</tr>
</tbody>
</table>
All conditional select operands must be of the same size. The return data type is the nearest common ancestor of operands \( C \) and \( D \). For conditional select operations using greater-than or less-than operations, the first and second operands must be signed as listed in the table that follows.

### Conditional Select Operator Overloading

</table>

The following table shows the mapping of return values from \( R_0 \) to \( R_7 \) for any number of elements. The same return value mappings also apply when there are fewer than four return values.

### Conditional Select Operator Return Value Mapping

</table>

### Debug Operations

The debug operations do not map to any compiler intrinsics for MMX™ instructions. They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

### Output

The four 32-bit values of \( A \) are placed in the output buffer and printed in the following format (default in decimal):
cout << Is32vec4 A;
cout << Iu32vec4 A;
cout << hex << Iu32vec4 A; /* print in hex format */
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"

Corresponding Intrinsics: none

The two 32-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):
cout << Is32vec2 A;
cout << Iu32vec2 A;
cout << hex << Iu32vec2 A; /* print in hex format */
"[1]:A1 [0]:A0"

Corresponding Intrinsics: none

The eight 16-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):
cout << Is16vec8 A;
cout << Iu16vec8 A;
cout << hex << Iu16vec8 A; /* print in hex format */
"[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"

Corresponding Intrinsics: none

The four 16-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):
cout << Is16vec4 A;
cout << Iu16vec4 A;
cout << hex << Iu16vec4 A; /* print in hex format */
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"

Corresponding Intrinsics: none

The sixteen 8-bit values of $A$ are placed in the output buffer and printed in the following format (default is decimal):
cout << Is8vec16 A; cout << Iu8vec16 A; cout << hex << Iu8vec8 A;
/* print in hex format instead of decimal*/

Corresponding Intrinsics: none

The eight 8-bit values of $A$ are placed in the output buffer and printed in the following format (default is decimal):
cout << Is8vec8 A; cout << Iu8vec8 A; cout << hex << Iu8vec8 A;
/* print in hex format instead of decimal*/
"[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
Element Access Operators

```
int R = Is64vec2 A[i];
unsigned int R = Iu64vec2 A[i];
int R = Is32vec4 A[i];
unsigned int R = Iu32vec4 A[i];
int R = Is32vec2 A[i];
unsigned int R = Iu32vec2 A[i];
short R = Is16vec8 A[i];
unsigned short R = Iu16vec8 A[i];
short R = Is16vec4 A[i];
unsigned short R = Iu16vec4 A[i];
signed char R = Is8vec16 A[i];
unsigned char R = Iu8vec16 A[i];
signed char R = Is8vec8 A[i];
unsigned char R = Iu8vec8 A[i];
```

Access and read element i of A. If DEBUG is enabled and the user tries to access an element outside of A, a diagnostic message is printed and the program aborts.

Element Assignment Operators

```
Is64vec2 A[i] = int R;
Is32vec4 A[i] = int R;
Iu32vec4 A[i] = unsigned int R;
Is32vec2 A[i] = int R;
Iu32vec2 A[i] = unsigned int R;
Is16vec8 A[i] = short R;
Iu16vec8 A[i] = unsigned short R;
Is16vec4 A[i] = short R;
Iu16vec4 A[i] = unsigned short R;
Is8vec16 A[i] = signed char R;
Iu8vec16 A[i] = unsigned char R;
Is8vec8 A[i] = signed char R;
Iu8vec8 A[i] = unsigned char R;
```

Assign R to element i of A. If DEBUG is enabled and the user tries to assign a value to an element outside of A, a diagnostic message is printed and the program aborts.
Unpack Operators

Interleave the 64-bit value from the high half of A with the 64-bit value from the high half of B.

I64vec2 unpack_high(I64vec2 A, I64vec2 B);
I64vec2 unpack_high(Is64vec2 A, Is64vec2 B);
I64vec2 unpack_high(Iu64vec2 A, Iu64vec2 B);
R0 = A1;
R1 = B1;

**Corresponding intrinsic:** _mm_unpackhi_epi64

Interleave the two 32-bit values from the high half of A with the two 32-bit values from the high half of B.

I32vec4 unpack_high(I32vec4 A, I32vec4 B);
I32vec4 unpack_high(Is32vec4 A, Is32vec4 B);
I32vec4 unpack_high(Iu32vec4 A, Iu32vec4 B);
R0 = A1;
R1 = B1;
R2 = A2;
R3 = B2;

**Corresponding intrinsic:** _mm_unpackhi_epi32

Interleave the 32-bit value from the high half of A with the 32-bit value from the high half of B.

I32vec2 unpack_high(I32vec2 A, I32vec2 B);
I32vec2 unpack_high(Is32vec2 A, Is32vec2 B);
I32vec2 unpack_high(Iu32vec2 A, Iu32vec2 B);
R0 = A1;
R1 = B1;

**Corresponding intrinsic:** _mm_unpackhi_pi32

Interleave the four 16-bit values from the high half of A with the two 16-bit values from the high half of B.

I16vec8 unpack_high(I16vec8 A, I16vec8 B);
I16vec8 unpack_high(Is16vec8 A, Is16vec8 B);
I16vec8 unpack_high(Iu16vec8 A, Iu16vec8 B);
R0 = A2;
R1 = B2;
R2 = A3;
R3 = B3;

**Corresponding intrinsic:** _mm_unpackhi_epi16

Interleave the two 16-bit values from the high half of A with the two 16-bit values from the high half of B.

I16vec4 unpack_high(I16vec4 A, I16vec4 B);
I16vec4 unpack_high(Is16vec4 A, Is16vec4 B);
I16vec4 unpack_high(Iu16vec4 A, Iu16vec4 B);
R0 = A2; R1 = B2;
R2 = A3; R3 = B3;

**Corresponding intrinsic:** _mm_unpackhi_pi16

Interleave the four 8-bit values from the high half of A with the four 8-bit values from the high half of B.
I8vec8 unpack_high(I8vec8 A, I8vec8 B);
Is8vec8 unpack_high(Is8vec8 A, I8vec8 B);
Iu8vec8 unpack_high(Iu8vec8 A, I8vec8 B);
R0 = A4;
R1 = B4;
R2 = A5;
R3 = B5;
R4 = A6;
R5 = B6;
R6 = A7;
R7 = B7;

Corresponding intrinsic: _mm_unpackhi_pi8
Interleave the sixteen 8-bit values from the high half of A with the four 8-bit values from the high half of B.

I8vec16 unpack_high(I8vec16 A, I8vec16 B);
Is8vec16 unpack_high(Is8vec16 A, I8vec16 B);
Iu8vec16 unpack_high(Iu8vec16 A, I8vec16 B);
R0 = A8;
R1 = B8;
R2 = A9;
R3 = B9;
R4 = A10;
R5 = B10;
R6 = A11;
R7 = B11;
R8 = A12;
R9 = B12;
R2 = A13;
R3 = B13;
R4 = A14;
R5 = B14;
R6 = A15;
R7 = B15;

Corresponding intrinsic: _mm_unpackhi_epi16
Interleave the 32-bit value from the low half of A with the 32-bit value from the low half of B.

R0 = A0;
R1 = B0;

Corresponding intrinsic: _mm_unpacklo_epi32
Interleave the 64-bit value from the low half of A with the 64-bit values from the low half of B.

R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;

Corresponding intrinsic: _mm_unpacklo_epi32
Interleave the two 32-bit values from the low half of A with the two 32-bit values from the low half of B.
I32vec4 unpack_low(I32vec4 A, I32vec4 B);
Is32vec4 unpack_low(Is32vec4 A, Is32vec4 B);
Iu32vec4 unpack_low(Iu32vec4 A, Iu32vec4 B);
R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;

Corresponding intrinsic: _mm_unpacklo_epi32
Interleave the 32-bit value from the low half of A with the 32-bit value from the low half of B.

I32vec2 unpack_low(I32vec2 A, I32vec2 B);
Is32vec2 unpack_low(Is32vec2 A, Is32vec2 B);
Iu32vec2 unpack_low(Iu32vec2 A, Iu32vec2 B);
R0 = A0;
R1 = B0;

Corresponding intrinsic: _mm_unpacklo_pi32
Interleave the two 16-bit values from the low half of A with the two 16-bit values from the low half of B.

I16vec8 unpack_low(I16vec8 A, I16vec8 B);
Is16vec8 unpack_low(Is16vec8 A, Is16vec8 B);
Iu16vec8 unpack_low(Iu16vec8 A, Iu16vec8 B);
R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;
R4 = A2;
R5 = B2;
R6 = A3;
R7 = B3;

Corresponding intrinsic: _mm_unpacklo_epi16
Interleave the two 16-bit values from the low half of A with the two 16-bit values from the low half of B.

I16vec4 unpack_low(I16vec4 A, I16vec4 B);
Is16vec4 unpack_low(Is16vec4 A, Is16vec4 B);
Iu16vec4 unpack_low(Iu16vec4 A, Iu16vec4 B);
R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;

Corresponding intrinsic: _mm_unpacklo_pi16
Interleave the four 8-bit values from the high low of A with the four 8-bit values from the low half of B.

I8vec16 unpack_low(I8vec16 A, I8vec16 B);
Is8vec16 unpack_low(Is8vec16 A, Is8vec16 B);
Iu8vec16 unpack_low(Iu8vec16 A, Iu8vec16 B);
R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;
R4 = A2;
R5 = B2;

R8 = A4;
R9 = B4;
R10 = A5;
R11 = B5;
R12 = A6;
R13 = B6;
R14 = A7;
R15 = B7;

Corresponding intrinsic: _mm_unpacklo_epi8

Interleave the four 8-bit values from the high low of A with the four 8-bit values from the low half of B.

I8vec8 unpack_low(I8vec8 A, I8vec8 B);
Is8vec8 unpack_low(Is8vec8 A, Is8vec8 B);
Iu8vec8 unpack_low(Iu8vec8 A, Iu8vec8 B);

R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;
R4 = A2;
R5 = B2;
R6 = A3;
R7 = B3;

Corresponding intrinsic: _mm_unpacklo_pi8

Pack Operators

Pack the eight 32-bit values found in A and B into eight 16-bit values with signed saturation.

Is16vec8 pack_sat(Is32vec2 A, Is32vec2 B);
Corresponding intrinsic: _mm Packs_epi32

Pack the four 32-bit values found in A and B into eight 16-bit values with signed saturation.

Is16vec4 pack_sat(Is32vec2 A, Is32vec2 B);
Corresponding intrinsic: _mm Packs_pi32

Pack the sixteen 16-bit values found in A and B into sixteen 8-bit values with signed saturation.

Is8vec16 pack_sat(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm Packs_epi16

Pack the eight 16-bit values found in A and B into eight 16-bit values with signed saturation.

Is8vec8 pack_sat(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm packs_pi16

Pack the sixteen 16-bit values found in A and B into sixteen 8-bit values with unsigned saturation.

Iu8vec16 packu_sat(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm packs_pu16

Pack the eight 16-bit values found in A and B into eight 8-bit values with unsigned saturation.

Iu8vec8 packu_sat(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm packs_pu16
**Clear MMX™ State Operator**

Empty the MMX™ registers and clear the MMX state. Read the guidelines for using the EMMS instruction intrinsic.

```c
void empty(void);
Corresponding intrinsic: _mm_empty
```

**Integer Functions for Streaming SIMD Extensions**

NOTE
You must include fvec.h header file for the following functionality.

Compute the element-wise maximum of the respective signed integer words in A and B.
```
Is16vec4 simd_max(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm_max_pi16
```

Compute the element-wise minimum of the respective signed integer words in A and B.
```
Is16vec4 simd_min(Is16vec4 A, Is16vec4 B);
Corresponding intrinsic: _mm_min_pi16
```

Compute the element-wise maximum of the respective unsigned bytes in A and B.
```
Iu8vec8 simd_max(Iu8vec8 A, Iu8vec8 B);
Corresponding intrinsic: _mm_max_pu8
```

Compute the element-wise minimum of the respective unsigned bytes in A and B.
```
Iu8vec8 simd_min(Iu8vec8 A, Iu8vec8 B);
Corresponding intrinsic: _mm_min_pu8
```

Create an 8-bit mask from the most significant bits of the bytes in A.
```
int move_mask(I8vec8 A);
Corresponding intrinsic: _mm_movemask_pi8
```

Conditionally store byte elements of A to address p. The high bit of each byte in the selector B determines whether the corresponding byte in A will be stored.
```
void mask_move(I8vec8 A, I8vec8 B, signed char *p);
Corresponding intrinsic: _mm_maskmove_si64
```

Store the data in A to the address p without polluting the caches. A can be any Ivec type.
```
void store_nta(__m64 *p, M64 A);
Corresponding intrinsic: _mm_stream_pi
```

Compute the element-wise average of the respective unsigned 8-bit integers in A and B.
```
Iu8vec8 simd_avg(Iu8vec8 A, Iu8vec8 B);
Corresponding intrinsic: _mm_avg_pu8
```

Compute the element-wise average of the respective unsigned 16-bit integers in A and B.
```
Iu16vec4 simd_avg(Iu16vec4 A, Iu16vec4 B);
Corresponding intrinsic: _mm_avg_pu16
```

**Conversions between Fvec and Ivec**

Convert the lower double-precision floating-point value of A to a 32-bit integer with truncation.
```
int F64vec2ToInt(F64vec42 A);
r := (int)A0;
```
Convert the four floating-point values of \( A \) to two the two least significant double-precision floating-point values.

```cpp
F64vec2 F32vec4ToF64vec2(F32vec4 A);
```

\[
\begin{align*}
\text{r0} & := \text{(double)}A0; \\
\text{r1} & := \text{(double)}A1;
\end{align*}
\]

Convert the two double-precision floating-point values of \( A \) to two single-precision floating-point values.

```cpp
F32vec4 F64vec2ToF32vec4(F64vec2 A);
```

\[
\begin{align*}
\text{r0} & := \text{(float)}A0; \\
\text{r1} & := \text{(float)}A1;
\end{align*}
\]

Convert the signed int in \( B \) to a double-precision floating-point value and pass the upper double-precision value from \( A \) through to the result.

```cpp
F64vec2 IntToF64vec2(F64vec2 A, int B);
```

\[
\begin{align*}
\text{r0} & := \text{(double)}B; \\
\text{r1} & := A1;
\end{align*}
\]

Convert the lower floating-point value of \( A \) to a 32-bit integer with truncation.

```cpp
int F32vec4ToInt(F32vec4 A);
```

\[
\begin{align*}
\text{r} & := \text{(int)}A0;
\end{align*}
\]

Convert the two lower floating-point values of \( A \) to two 32-bit integer with truncation, returning the integers in packed form.

```cpp
Is32vec2 F32vec4ToIs32vec2 (F32vec4 A);
```

\[
\begin{align*}
\text{r0} & := \text{(int)}A0; \\
\text{r1} & := \text{(int)}A1;
\end{align*}
\]

Convert the 32-bit integer value \( B \) to a floating-point value; the upper three floating-point values are passed through from \( A \).

```cpp
F32vec4 IntToF32vec4(F32vec4 A, int B);
```

\[
\begin{align*}
\text{r0} & := \text{(float)}B; \\
\text{r1} & := A1; \\
\text{r2} & := A2; \\
\text{r3} & := A3;
\end{align*}
\]

Convert the two 32-bit integer values in packed form in \( B \) to two floating-point values; the upper two floating-point values are passed through from \( A \).

```cpp
F32vec4 Is32vec2ToF32vec4(F32vec4 A, Is32vec2 B);
```

\[
\begin{align*}
\text{r0} & := \text{(float)}B0; \\
\text{r1} & := \text{(float)}B1; \\
\text{r2} & := A2; \\
\text{r3} & := A3;
\end{align*}
\]

**Floating-point Vector Classes**

The floating-point vector classes, \( F64vec2 \), \( F32vec4 \), and \( F32vec1 \), provide an interface to SIMD operations. The class specifications are as follows:

- \( F64vec2 \) \( \text{A(double x, double y)}; \)
- \( F32vec4 \) \( \text{A(float z, float y, float x, float w)}; \)
- \( F32vec1 \) \( \text{B(float w)}; \)

The packed floating-point input values are represented with the right-most value lowest as shown in the following table.

**Single-Precision Floating-point Elements**
Fvec Notation Conventions

This reference uses the following conventions for syntax and return values.

Fvec Classes Syntax Notation

Fvec classes use the syntax conventions shown the following examples:

Example 1:F64vec2 R = F64vec2 A & F64vec2 B;

[Fvec_Class] R = [operator]( [Fvec_Class] A, [Fvec_Class] B);

Example 2:F64vec2 R = andnot(F64vec2 A, F64vec2 B);

[Fvec_Class] R [operator]= [Fvec_Class] A;

Example 3:F64vec2 R &= F64vec2 A;

where

[operator] is an operator (for example, &, |, or ^)

[Fvec_Class] is any Fvec class (F64vec2, F32vec4, or F32vec1)

R, A, B are declared Fvec variables of the type indicated.

Return Value Notation

Because the Fvec classes have packed elements, the return values typically follow the conventions presented in the Return Value Convention Notation Mappings table. F32vec4 returns four single-precision floating-point values (R0, R1, R2, and R3); F64vec2 returns two double-precision, floating-point values, and F32vec1 returns the lowest single-precision floating-point value (R0).

Return Value Convention Notation Mappings

<td>R0 := A0 andnot B0;</td>
<td>R0 &amp;= A0;</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>
**Data Alignment**

Memory operations using the Intel® Streaming SIMD Extensions should be performed on 16-byte-aligned data whenever possible. Memory operations using the Intel® Advanced Vector Extensions should be performed on 32-byte-aligned data whenever possible.

F32vec4 and F64vec2 object variables are properly aligned by default. Note that floating point arrays are not automatically aligned. To get 16-byte alignment, you can use the alignment __declspec:

```
__declspec( align(16) ) float A[4];
```

**Conversions**

All Fvec object variables can be implicitly converted to __m128 data types. For example, the results of computations performed on F32vec4 or F32vec1 object variables can be assigned to __m128 data types.

```
__m128d mm = A & B; /* where A,B are F64vec2 object variables */
__m128 mm = A & B; /* where A,B are F32vec4 object variables */
__m128 mm = A & B; /* where A,B are F32vec1 object variables */
```

**Constructors and Initialization**

The following table shows how to create and initialize F32vec objects with the Fvec classes.

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>F64vec2 A(double d0, double d1);</td>
<td>A0 := d0;</td>
<td>A1 := d1;</td>
</tr>
</tbody>
</table>
Double Initialization

F64vec2 A = F64vec2(double d0, double d1);
F64vec2 A(double d0);  // mm_set1_pd
/* Initializes both return 
values 
with the same double 
precision value */.

Float Initialization

F32vec4 A(float f3, float f2, float f1, float f0);
F32vec4 A = F32vec4(float f3, float f2, float f1, float f0);
F32vec4 A(float f0);  // mm_set1_ps
/* Initializes all return 
values 
with the same floating 
point value. */
F32vec4 A(double d0);  // mm_set1_ps(d)
/* Initialize all return 
values with 
the same double-precision 
value. */
F32vec1 A(double d0);  // mm_set_ss(d)
/* Initializes the lowest 
value of A 
with d0 and the other 
values with 0.*/
F32vec1 B(float f0);  // mm_set_ss
/* Initializes the lowest 
value of B 
with f0 and the other 
values with 0.*/
F32vec1 B(int I);  // mm_cvtsi32_ss
/* Initializes the lowest 
value of B 
with f0, other values are undefined.*/

Arithmetic Operators

The following table lists the arithmetic operators of the Fvec classes and generic syntax. The operators have been divided into standard and advanced operations, which are described in more detail later in this section.
Fvec Arithmetic Operators

<table>
<thead>

</table>
### Reciprocal Square Root Newton Raphson

| 1 float | \( \text{F32vec1 } R = \) \_mm\_sub\_ss \( \text{rsqrt\_nr}(\text{F32vec1 } A); \) \_mm\_mul\_ss \_mm\_rsqrt\_ss |

### Horizontal Add

| 1 float | float \( f = \) \_mm\_add\_ss \add\_horizontal(\text{F32vec4 } A); | 1 double | double \( d = \) \_mm\_add\_sd \add\_horizontal(\text{F64vec2 } A); |

### Minimum and Maximum Operators

**Compute the minimums of the two double precision floating-point values of \( A \) and \( B \).**

\[
\text{F64vec2 } R = \text{simd\_min}(\text{F64vec2 } A, \text{F64vec2 } B)
\]
\[
R0 := \text{min}(A0, B0);
R1 := \text{min}(A1, B1);
\]
**Corresponding intrinsic:** \_mm\_min\_pd

**Compute the minimums of the four single precision floating-point values of \( A \) and \( B \).**

\[
\text{F32vec4 } R = \text{simd\_min}(\text{F32vec4 } A, \text{F32vec4 } B)
\]
\[
R0 := \text{min}(A0, B0);
R1 := \text{min}(A1, B1);
R2 := \text{min}(A2, B2);
R3 := \text{min}(A3, B3);
\]
**Corresponding intrinsic:** \_mm\_min\_ps

**Compute the minimum of the lowest single precision floating-point values of \( A \) and \( B \).**

\[
\text{F32vec1 } R = \text{simd\_min}(\text{F32vec1 } A, \text{F32vec1 } B)
\]
\[
R0 := \text{min}(A0, B0);
\]
**Corresponding intrinsic:** \_mm\_min\_ss

**Compute the maximums of the two double precision floating-point values of \( A \) and \( B \).**

\[
\text{F64vec2 } \text{simd\_max}(\text{F64vec2 } A, \text{F64vec2 } B)
\]
\[
R0 := \text{max}(A0, B0);
R1 := \text{max}(A1, B1);
\]
**Corresponding intrinsic:** \_mm\_max\_pd

**Compute the maximums of the four single precision floating-point values of \( A \) and \( B \).**

\[
\text{F32vec4 } R = \text{simd\_max}(\text{F32vec4 } A, \text{F32vec4 } B)
\]
\[
R0 := \text{max}(A0, B0);
R1 := \text{max}(A1, B1);
R2 := \text{max}(A2, B2);
R3 := \text{max}(A3, B3);
\]
**Corresponding intrinsic:** \_mm\_max\_ps

**Compute the maximum of the lowest single precision floating-point values of \( A \) and \( B \).**

\[
\text{F32vec1 } \text{simd\_max}(\text{F32vec1 } A, \text{F32vec1 } B)
\]
\[
R0 := \text{max}(A0, B0);
\]
**Corresponding intrinsic:** \_mm\_max\_ss
**Logical Operators**

The following table lists the logical operators of the Fvec classes and generic syntax. The logical operators for F32vec1 classes use only the lower 32 bits.

**Fvec Logical Operators Return Value Mapping**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### Compare Operators

The operators described in this section compare the single precision floating-point values of A and B. Comparison between objects of any Fvec class return the same class being compared.

The following table lists the compare operators for the Fvec classes.

<table>
<thead>
<tr>
<th>Compare For:</th>
<th>Operators</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td>cmpeq</td>
<td>R = cmpeq(A, B)</td>
</tr>
<tr>
<td>Inequality</td>
<td>cmpneq</td>
<td>R = cmpneq(A, B)</td>
</tr>
<tr>
<td>Greater Than</td>
<td>cmpgt</td>
<td>R = cmpgt(A, B)</td>
</tr>
<tr>

<td>cmpge</td>
<td>R = cmpge(A, B)</td>
</tr>
<tr>
<td>Not Greater Than</td>
<td>cmpngt</td>
<td>R = cmpngt(A, B)</td>
</tr>
<tr>
<td>Not Greater Than or Equal To</td>
<td>cmpnge</td>
<td>R = cmpnge(A, B)</td>
</tr>
<tr>
<td>Less Than</td>
<td>cmplt</td>
<td>R = cmplt(A, B)</td>
</tr>
<tr>
<td>Less Than or Equal To</td>
<td>cmple</td>
<td>R = cmple(A, B)</td>
</tr>
<tr>
<td>Not Less Than</td>
<td>cmpnlt</td>
<td>R = cmpnlt(A, B)</td>
</tr>
<tr>
<td>Not Less Than or Equal To</td>
<td>cmpnle</td>
<td>R = cmpnle(A, B)</td>
</tr>
</tbody>
</table>

### Compare Operators

The mask is set to 0xffffffff for each floating-point value where the comparison is true and 0x00000000 where the comparison is false. The following table shows the return values for each class of the compare operators, which use the syntax described earlier in the Return Value Notation section.
The following table shows examples for arithmetic operators and intrinsics.

### Compare Operations for Fvec Classes

<table>
<thead>

<td>F32vec4 R = cmpnlt(F32vec4 A); _mm_cmpnlt_ps</td>
</tr>
<tr>
<td>2 doubles</td>
<td>F64vec2 R = cmpnlt(F64vec2 A); _mm_cmpnlt_pd</td>
</tr>
<tr>
<td>1 float</td>
<td>F32vec1 R = cmpnlt(F32vec1 A); _mm_cmpnlt_ss</td>
</tr>
</tbody>
</table>
Conditional Select Operators for Fvec Classes

Each conditional function compares single-precision floating-point values of A and B. The C and D parameters are used for return value. Comparison between objects of any Fvec class returns the same class.

## Conditional Select Operators for Fvec Classes

<table>
<thead>
<tr>
<th>Conditional Select for:</th>
<th>Operators</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td>select_eq</td>
<td>R = select_eq(A, B)</td>
</tr>
<tr>
<td>Inequality</td>
<td>select_neq</td>
<td>R = select_neq(A, B)</td>
</tr>
<tr>
<td>Greater Than</td>
<td>select_gt</td>
<td>R = select_gt(A, B)</td>
</tr>
<tr>
<td>Greater Than or Equal To</td>
<td>select_ge</td>
<td>R = select_ge(A, B)</td>
</tr>
<tr>
<td>Not Greater Than</td>
<td>select_gt</td>
<td>R = select_gt(A, B)</td>
</tr>
<tr>
<td>Not Greater Than or Equal To</td>
<td>select_ge</td>
<td>R = select_ge(A, B)</td>
</tr>
<tr>
<td>Less Than</td>
<td>select_lt</td>
<td>R = select_lt(A, B)</td>
</tr>
<tr>
<td>Less Than or Equal To</td>
<td>select_le</td>
<td>R = select_le(A, B)</td>
</tr>
</tbody>
</table>
### Conditional Select for:

<table>
<thead>
<tr>
<th>Operators</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Less Than</td>
<td>select_nlt ( A, B )</td>
</tr>
<tr>
<td>Not Less Than or Equal To</td>
<td>select_nle ( A, B )</td>
</tr>
</tbody>
</table>

### Conditional Select Operator Usage

For conditional select operators, the return value is stored in C if the comparison is true or in D if false. The following table shows the return values for each class of the conditional select operators, using the **Return Value Notation** described earlier.

#### Compare Operator Return Value Mapping

<table>
<thead>
<tr>
<th>( R )</th>
<th>( A_0 )</th>
<th>Operators</th>
<th>( B )</th>
<th>( C )</th>
<th>( D )</th>
<th>( F32v_{ec4} )</th>
<th>( F64v_{ec2} )</th>
<th>( F32v_{ec1} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_0 := )</td>
<td>((A_1 ! (A_1 \text{select}_[\text{eq}</td>

## Cacheability Support Operators

Stores (non-temporal) the two double-precision, floating-point values of \( A \). Requires a 16-byte aligned address.

```c
void store_nta(double *p, F64vec2 A);
```

**Corresponding intrinsic:** `_mm_stream_pd`

Stores (non-temporal) the four single-precision, floating-point values of \( A \). Requires a 16-byte aligned address.

```c
void store_nta(float *p, F32vec4 A);
```

**Corresponding intrinsic:** `_mm_stream_ps`
**Debug Operations**

The debug operations do not map to any compiler intrinsics for MMX™ technology or Intel® Streaming SIMD Extensions. They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

**Output Operations**

The two single, double-precision floating-point values of A are placed in the output buffer and printed in decimal format as follows:

```cpp
cout << F64vec2 A;
"[1]:A1 [0]:A0"
```

Corresponding intrinsics: none

The four, single-precision floating-point values of A are placed in the output buffer and printed in decimal format as follows:

```cpp
cout << F32vec4 A;
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding intrinsics: none

The lowest, single-precision floating-point value of A is placed in the output buffer and printed.

```cpp
cout << F32vec1 A;
```

Corresponding intrinsics: none

**Element Access Operations**

```cpp
double d = F64vec2 A[int i]
```

Read one of the two, double-precision floating-point values of A without modifying the corresponding floating-point value. Permitted values of i are 0 and 1. For example:

If DEBUG is enabled and i is not one of the permitted values (0 or 1), a diagnostic message is printed and the program aborts.

```cpp
double d = F64vec2 A[1];
```

Corresponding intrinsics: none

Read one of the four, single-precision floating-point values of A without modifying the corresponding floating point value. Permitted values of i are 0, 1, 2, and 3. For example:

```cpp
float f = F32vec4 A[int i]
```

If DEBUG is enabled and i is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

```cpp
float f = F32vec4 A[2];
```

Corresponding intrinsics: none

**Element Assignment Operations**

```cpp
F64vec4 A[int i] = double d;
```

Modify one of the two, double-precision floating-point values of A. Permitted values of int i are 0 and 1. For example:

```cpp
F32vec4 A[int i] = float f;
```
Modify one of the four, single-precision floating-point values of A. Permitted values of \texttt{int} \texttt{i} are 0, 1, 2, and 3. For example:

If \texttt{DEBUG} is enabled and \texttt{int} \texttt{i} is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

\begin{verbatim}
Corresponding intrinsics: none.
\end{verbatim}

**Load and Store Operators**

Loads two, double-precision floating-point values, copying them into the two, floating-point values of A. No assumption is made for alignment.

\begin{verbatim}
void loadu(F64vec2 A, double *p)
Corresponding intrinsic: \_mm_loadu\_pd
\end{verbatim}

Stores the two, double-precision floating-point values of A. No assumption is made for alignment.

\begin{verbatim}
void storeu(float *p, F64vec2 A);
Corresponding intrinsic: \_mm_storeu\_pd
\end{verbatim}

Loads four, single-precision floating-point values, copying them into the four floating-point values of A. No assumption is made for alignment.

\begin{verbatim}
void loadu(F32vec4 A, double *p)
Corresponding intrinsic: \_mm_loadu\_ps
\end{verbatim}

Stores the four, single-precision floating-point values of A. No assumption is made for alignment.

\begin{verbatim}
void storeu(float *p, F32vec4 A);
Corresponding intrinsic: \_mm_storeu\_ps
\end{verbatim}

**Unpack Operators**

Selects and interleaves the lower, double-precision floating-point values from A and B.

\begin{verbatim}
F64vec2 R = unpack\_low(F64vec2 A, F64vec2 B);
Corresponding intrinsic: \_mm\_unpacklo\_pd(a, b)
\end{verbatim}

Selects and interleaves the higher, double-precision floating-point values from A and B.

\begin{verbatim}
F64vec2 R = unpack\_high(F64vec2 A, F64vec2 B);
Corresponding intrinsic: \_mm\_unpackhi\_pd(a, b)
\end{verbatim}

Selects and interleaves the lower two, single-precision floating-point values from A and B.

\begin{verbatim}
F32vec4 R = unpack\_low(F32vec4 A, F32vec4 B);
Corresponding intrinsic: \_mm\_unpacklo\_ps(a, b)
\end{verbatim}

Selects and interleaves the higher two, single-precision floating-point values from A and B.

\begin{verbatim}
F32vec4 R = unpack\_high(F32vec4 A F32vec4 B);
Corresponding intrinsic: \_mm\_unpackhi\_ps(a, b)
\end{verbatim}

**Move Mask Operators**

Creates a 2-bit mask from the most significant bits of the two, double-precision floating-point values of A, as follows:

\begin{verbatim}
int i = move\_mask(F64vec2 A)
i := sign(a1)<<1 | sign(a0)<<0
Corresponding intrinsic: \_mm\_movemask\_pd
\end{verbatim}

Creates a 4-bit mask from the most significant bits of the four, single-precision floating-point values of A, as follows:
int i = move_mask(F32vec4 A)
i := sign(a3)<<3 | sign(a2)<<2 | sign(a1)<<1 | sign(a0)<<0
Corresponding intrinsic: _mm_movemask_ps

Classes Quick Reference

This appendix contains tables listing operators to perform various SIMD operations, corresponding intrinsics to perform those operations, and the classes that implement those operations. The classes listed here belong to the Intel® C++ Class Libraries for SIMD Operations.

In the following tables,

- N/A indicates that the operator is not implemented in that particular class. For example, in the Logical Operations table, the Andnot operator is not implemented in the F32vec4 and F32vec1 classes.
- All other entries under Classes indicate that those operators are implemented in those particular classes, and the entries under the Classes columns provide the suffix for the corresponding intrinsic. For example, consider the Arithmetic Operations: Part1 table, where the corresponding intrinsic is _mm_add_[x] and the entry epi16 is under the I16vec8 column. It means that the I16vec8 class implements the addition operators and the corresponding intrinsic is _mm_add_epi16.

Programming Example

This sample program uses the F32vec4 class to average the elements of a twenty element floating point array.

```cpp
#include <fvec.h>

#define SHUFFLE(a,b,i) (F32vec4)_mm_shuffle_ps(a,b,i)
#define SIZE 20

float result;
_MM_ALIGN16 float array[SIZE];

void Add20ArrayElements (F32vec4 *array, float *result) {
    F32vec4 vec0, vec1;
    vec0 = _mm_load_ps ((float *) array); // Load array's first four floats

    vec0 += array[1]; // Add elements 5-8
    vec0 += array[2]; // Add elements 9-12
    vec0 += array[3]; // Add elements 13-16
    vec0 += array[4]; // Add elements 17-20

    vec1 = SHUFFLE(vec1, vec0, 0x40);
    vec0 += vec1;
    vec1 = SHUFFLE(vec1, vec0, 0x30);
    vec0 += vec1;
    vec0 = SHUFFLE(vec0, vec0, 2);
    _mm_store_ss (result, vec0); // Store the final sum
}

void main(int argc, char *argv[]) {
    int i;

    for (i=0; i < SIZE; i++) { array[i] = (float) i; }

    Add20ArrayElements (array, &result);
}
```
C++ Library Extensions

This section contains descriptions of Intel's C++ library extensions that assist users in parallel programming. The following C++ library specialization is included:

- **Introduction to Intels valarray Implementation:** Enables users to leverage a custom valarray header file that uses the Intel® Integrated Performance Primitives (Intel® IPP) for performance benefit.

**Intel's valarray Implementation**

The Intel® Compiler provides a high performance implementation of specialized one-dimensional valarray operations for the C++ standard STL valarray container.

The standard C++ valarray template consists of array/vector operations for high performance computing. These operations are designed to exploit high performance hardware features such as parallelism and achieve performance benefits.

Intel's valarray implementation uses the Intel® Integrated Performance Primitives (Intel® IPP), which is part of the product. Select IPP when you install the product.

The valarray implementation consists of a replacement header, `<valarray>`, that provides a specialized, high-performance implementation for the following operators and types:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Valarrays of Type</th>
<th>Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs, acos, acosh, asin, asinh, atan, atan2, atanh, cbrt, cdfnorm, ceil, cos, cosh, erf, erfc, erfinv, exp, expm1, floor, hypot, inv, invcbrt, invsqr, ln, log, log10, log1p, nearbyint, pow, pow2o3, pow3o2, powx, rint, round, sin, sinh, sqrt, tan, tanh, trunk</td>
<td>float, double</td>
<td></td>
</tr>
<tr>
<td>add, conj, div, mul, mulbyconj, mul, sub</td>

<td>(all unsigned) char, short, int</td>
<td></td>
</tr>
<tr>
<td>min, max, sum</td>
<td>signed or short/signed int, float, double</td>
<td></td>
</tr>
</tbody>
</table>

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Using Intel's valarray Implementation

Intel's valarray implementation allows you to declare huge arrays for parallel processing. Improved implementation of valarray is tied up with calling the IPP libraries that are part of Intel® Integrated Performance Primitives (Intel® IPP).

Using valarray in Source Code

To use valarrays in your source code, include the valarray header file, `<valarray>`. The `<valarray>` header file is located in the path `<installdir>/perf_header`.

The example code below shows a valarray addition operation (+) specialized through use of Intel's implementation of valarray:

```cpp
#include <valarray>

void test() {
  std::valarray<float> vi(N), va(N);
  ...
  vi = vi + va; // array addition
  ...
}
```

**NOTE**

To use the static merged library containing all CPU-specific optimized versions of the library code, you need to call the `ippStaticInit` function first, before any IPP calls. This ensures automatic dispatch to the appropriate version of the library code for Intel® processor and the generic version of the library code for non-Intel processors at runtime. If you do not call `ippStaticInit` first, the merged library will use the generic instance of the code. If you are using the dynamic version of the libraries, you do not need to call `ippStaticInit`.

Compiling valarray Source Code

To compile your valarray source code, the compiler option, `/Quse-intel-optimized-headers` (for Windows*) or `-use-intel-optimized-headers` (for Linux* and macOS*), is used to include the required valarray header file and all the necessary IPP library files.

The following examples illustrate how to compile and link a program to include the Intel valarray replacement header file and link with the Intel® IPP libraries. Refer to the Intel® IPP documentation for details.

In the following examples, "merged" libraries refers to using a static library that contains all the CPU-specific variants of the library code.

**Windows* OS examples:**

The following command line performs a one-step compilation for a system based on IA-32 architecture, running Windows OS:

```
icl /Quse-intel-optimized-headers source.cpp
```

The following command lines perform separate compile and link steps for a system based on IA-32 architecture, running Windows OS:

**DLL (dynamic):**

```
icl /Quse-intel-optimized-headers /c source.cpp
icl source.obj /Quse-intel-optimized-headers
```
Merged (static):

icl /Quse-intel-optimized-headers /Qipp-link:static /c source.cpp
icl source.obj /Quse-intel-optimized-headers /Qipp-link:static

Linux* OS examples:
The following command line performs a one-step compilation for a system based on Intel® 64 architecture, running Linux OS:

iclpc -use-intel-optimized-headers source.cpp

The following command lines perform separate compile and link steps for a system based on Intel® 64 architecture, running Linux OS:

so (dynamic):

iclpc -use-intel-optimized-headers -c source.cpp
iclpc source.o -use-intel-optimized-headers -shared-intel

Merged (static):

iclpc -use-intel-optimized-headers -c source.cpp
iclpc source.o -use-intel-optimized-headers

Intel's C++ Asynchronous I/O Extensions for Windows* Operating Systems

This topic only applies to Windows* OS.

Intel's C/C++ asynchronous input/output (Intel's C/C++ AIO) extensions, like library functions or classes, can be used to improve the performance of C/C++ applications by executing I/O operations in asynchronous mode. The extensions initiate I/O operation and immediately resume normal tasks while the I/O operations are executed in parallel.

Intel's C/C++ asynchronous I/O extensions are supported on IA-32 architecture- and Intel® 64 architecture-based Windows* platforms.

Intel's C/C++ AIO library functions and template class are implemented in the libicaio.lib library. This library is supplied as part of the Intel® C/C++ Compiler package and is installed into the common directory: <install-dir>/lib.

Types of Intel's C/C++ Asynchronous I/O Extensions

Intel's C/C++ asynchronous I/O extensions comprise the following:

- **Asynchronous I/O Library:** A set of POSIX*-based asynchronous I/O library functions, supported on Windows* operating systems, for applications written in C/C++ language. The interface file is aio.h.
• **Asynchronous I/O Template Class:** An `asych_class` template class, supported on Windows* operating systems, for applications written in C++ language. This template class can be used to introduce asynchronous execution of I/O operations with the Standard Template Library's (STL's) streams classes. The interface file is `aiostream.h`.

**See Also**
Intel's C++ Asynchronous I/O Library for Windows* OS
Intel's C++ Asynchronous I/O Class for Windows* OS

**Intel's C++ Asynchronous I/O Library for Windows* Operating Systems**

This topic only applies to Windows* OS.

Intel's C/C++ asynchronous I/O (AIO) library implementation for the Windows* operating system (on IA-32 and Intel® 64 platforms) is similar to the POSIX* AIO library implementation for the Linux* operating system. The differences between Intel's C/C++ AIO Windows* OS implementation and the standard POSIX* AIO implementation are listed below:

- **In `struct aiocb`,**
  - The Windows* OS compatible type `HANDLE` replaces the POSIX* AIO type `unsigned int` for the file descriptor `aio_fildes`.
  - The type `intptr_t` replaces the POSIX* AIO types `ssize_t` and `__off_t`.
  - The structure specifying the signal event descriptor, `struct sigevent` is similar to the Linux* operating system implementation of the POSIX* AIO library. It differs from the Linux* implementation in the following ways:
    - Signal notification and non-notification for thread call-back is supported
    - Signal notification on completion of the AIO operation is **not** supported

This is true for programs that were already written for Linux/Unix and ported to Windows* OS that wish to setup an AIO completion handler without the name of the handler set in the `aiocb struct`. Because of the way that signals are supported in Windows, this is impossible to implement. For new applications, or to port existing applications, the programmer should set the name of the handler before calling the `aio_read` or `aio_write` routines. For example:

```cpp
static void aio_CompletionRoutine(sigval_t sigval)
{
    // ... code ...
}

... code ...

my_aio.aio_sigevent.sigev_notify = SIGEV_THREAD;
my_aio.aio_sigevent.sigev_notify_function = aio_CompletionRoutine;
```

**NOTE**
The POSIX* AIO library and the Microsoft* SDK provide similar AIO functions. The main difference between the POSIX* AIO functions and the Windows* operating system-based AIO functions is that while POSIX* allows you to execute AIO operations with any file, the Windows* operating system executes AIO operations only with files flagged with `FILE_FLAG_OVERLAPPED`.

Intel's asynchronous I/O library functions listed below are all based on POSIX* AIO functions. They are defined in the `aio.h` file.

- `aio_read()`
- `aio_write()`
- `aio_suspend()`
- `aio_error()`
The aio_read() function requests an asynchronous read operation, calling the function,
"ReadFile(hFile, lpBuffer, nNumberOfBytesToRead, lpNumberOfBytesRead, NULL);"
where,
- hFile is given by aiocbp->aio_fildes
- lpBuffer is given by aiocbp->aio_buf
- nNumberOfBytesToRead is given by aiocbp->aio_nbytes

Use the function aio_return() to retrieve the actual bytes read in lpNumberOfBytesRead.

Use the extension aiocb->aio_offset == (intptr_t)-1 to start the read operation after the last read record. This extension avoids extra file positioning and enhances performance.

Returns
-0: On success
-1: On error
To get the correct error code, use errno. To get the error that occurred during asynchronous read operation, use aio_error() function.

See Also
Example Code for aio_read()

The aio_write() function requests an asynchronous write operation, calling the function,
"WriteFile(hFile, lpBuffer, nNumberOfBytesToWrite, lpNumberOfBytesWritten, NULL);"
where,
- hFile is given by aiocbp->aio_fildes
- lpBuffer is given by aiocbp->aio_buf
- nNumberOfBytesToWrite is given by aiocbp->aio_nbytes

Use the function aio_return() to retrieve the actual bytes written in lpNumberOfBytesWritten.

Use the extension aiocb->aio_offset == (intptr_t)-1 to start the write operation after the last written record. This extension avoids extra file positioning and enhances performance.
Returns

0: On success
-1: On error

To get the correct error code, use errno. To get the error that occurred during asynchronous write operation, use aio_error() function.

See Also
Example Code for aio_write()

Example for aio_read and aio_write Functions

The example illustrates the performance gain of the asynchronous I/O usage in comparison with synchronous I/O usage. In the example, 5.6 MB of data is asynchronously written with the main program computation, which is the scalar multiplication of two vectors with some normalization.

C-source file executing a scalar multiplication:

```c
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

double do_compute(double A, double B, int arr_len)
{
  int i;
  double res = 0;
  double *xA = malloc(arr_len * sizeof(double));
  double *xB = malloc(arr_len * sizeof(double));
  if (!xA || !xB)
    abort();
  for (i = 0; i < arr_len; i++) {
    xA[i] = sin(A);
    xB[i] = cos(B);
    res = res + xA[i]*xA[i];
  }
  free(xA);
  free(xB);
  return res;
}
```

C-main-source file using asynchronous I/O implementation:

```c
#define DIM_X 123/*123*/
#define DIM_Y 70000
double aio_dat[DIM_Y /*12MB*/] = {0};
double aio_dat_tmp[DIM_Y /*12MB*/];

#include <stdio.h>
#include <aio.h>
typedef struct aiocb aiocb_t;
    aiocb_t my_aio;
    aiocb_t *my_aio_list[1] = &my_aio;

int main()
{
  double do_compute(double A, double B, int arr_len);
  int i, j;
  HANDLE fd = CreateFile("aio.dat",
  GENERIC_READ | GENERIC_WRITE,
  ...
FILE_SHARE_READ,
NULL,
OPEN_ALWAYS,
FILE_ATTRIBUTE_NORMAL,
NULL);
/* Do some complex computation */
for (i = 0; i < DIM_X; i++) {
for (j = 0; j < DIM_Y; j++)
aio_dat[j] = do_compute(i, j, DIM_X);

if (i) aio_suspend(my_aio_list, 1, 0);
my_aio.aio_fildes = fd;
my_aio.aio_buf = memcpyp(aio_dat_tmp, aio_dat, sizeof(aio_dat_tmp));
my_aio.aio_nbytes = sizeof(aio_dat_tmp);
my_aio.aio_offset = (intptr_t) -1;
my_aio.aio_sigevent.sigeve_notify = SIGEV_NONE;

if (aio_write((void *)&my_aio) == -1) {
printf("ERROR!! %s\n", "aio_write()==-1");
abort();
}
aio_suspend(my_aio_list, 1, 0);
return 0;
}

C-main-source file example 2 using asynchronous I/O implementation:

// icl -c do_compute.c
// icl aio_sample2.c do_compute.obj
// aio_sample2.exe

#define DIM_X 123
#define DIM_Y 70
double aio_dat[DIM_Y] = {0};
double aio_dat_tmp[DIM_Y];
static volatile int aio_flg = 1;

#include <aio.h>
typedef struct aiocb aiocb_t;
aiocb_t my_aio;
#define WAIT { while (!aio_flg); aio_flg = 0; }
#define aio_OPEN(_fname) \
CreateFile(_fname, \
    GENERIC_READ | GENERIC_WRITE, \
    FILE_SHARE_READ, \
    NULL, \
    OPEN_ALWAYS, \
    FILE_ATTRIBUTE_NORMAL, \
    NULL)

static void aio_CompletionRoutine(sigval_t sigval)
{
    aio_flg = 1;
}

int main()
{
    double do_compute(double A, double B, int arr_len);
    int i, j, res;
char *fname = "aio_sample2.dat";
HANDLE aio_fildes = aio_OPEN(fname);

my_aio.aio_fildes = aio_fildes;
my_aio.aio_nbytes = sizeof(aio_dat_tmp);
my_aio.aio_sigevent.sigev_notify = SIGEV_THREAD;
my_aio.aio_sigevent.sigev_notify_function = aio_CompletionRoutine;

/*
** writing
*/
my_aio.aio_offset = -1;
printf("Writing\n");
for (i = 0; i < DIM_X; i++) {
    for (j = 0; j < DIM_Y; j++)
        aio_dat[j] = do_compute(i, j, DIM_X);
    WAIT;
    my_aio.aio_buf = memcpy(aio_dat_tmp, aio_dat, sizeof(aio_dat_tmp));
    res = aio_write(&my_aio);
    if (res) {printf("res!=0\n"); abort();}
}

// flushing
//
printf("Flushing\n");
WAIT;
res = aio_fsync(O_SYNC, &my_aio);
if (res) {printf("res!=0\n"); abort();}
WAIT;

// reading
//
printf("Reading\n");
my_aio.aio_offset = 0;
my_aio.aio_buf = (volatile char*)aio_dat_tmp;
for (i = 0; i < DIM_X; i++) {
    aio_read(&my_aio);
    for (j = 0; j < DIM_Y; j++)
        aio_dat[j] = do_compute(i, j, DIM_X);
    WAIT;
    res = aio_return(&my_aio);
    if (res != sizeof(aio_dat)) {
        printf("aio_read() did read %d bytes, expecting %d bytes\n", res, sizeof(aio_dat));
    }
    for (j = 0; j < DIM_Y; j++)
        if (aio_dat[j] != aio_dat_tmp[j])
            {printf("ERROR: aio_dat[j] != aio_dat_tmp[j]\n I=%d J=%d\n", i, j); abort();}
    my_aio.aio_offset += my_aio.aio_nbytes;
}
CloseHandle(aio_fildes);
printf("\nDone\n");

aio_write()
aio_suspend
Suspends the calling process until one of the asynchronous I/O operations completes.

Syntax
int aio_suspend(const struct aiocb * const cblist[], int n, const struct timespec *timeout);

Arguments
cblist[]  Pointer to a control block on which I/O is initiated
n        Length of cblist list
*timeout Time interval to suspend the calling process

Description
The aio_suspend() function is like a wait operation. It suspends the calling process until,

• At least one of the asynchronous I/O requests in the list cblist of length n has completed
• A signal is delivered
• The time interval indicated in timeout is not NULL and has passed.

Each item in the cblist list must either be NULL (when it is ignored), or a pointer to a control block on which I/O was initiated using aio_read(), aio_write(), or lio_listio() functions.

Returns
0: On success
-1: On error

To get the correct error code, use errno.

See Also
Example Code for aio_suspend()

Example for aio_suspend Function
The following example illustrates a wait operation execution using the aio_suspend() function.

```c
int aio_ex_2(HANDLE fd)
{
    static struct aiocb   aio[2];
    static struct aiocb  *aio_list[2] = {&aio[0], &aio[1]};
    int i, ret;

    /* Data initialization */
    IC_AIO_DATA_INIT(aio[0], fd, "rec#1\n", strlen("rec#1\n"), 0)
```
IC_AIO_DATA_INIT(aio[1], fd, "rec#2\n", strlen("rec#2\n"), aio[0].aio_nbytes)

/* Asynch-write */
if (aio_write(&aio[0]) == -1) return errno;
if (aio_write(&aio[1]) == -1) return errno;

/* Do some complex computation */
printf("do_compute(1000, 1.123)=%f", do_compute(1000, 1.123));

/* do the wait operation using sleep() */
ret = aio_suspend(aio_list, 2, 0);
if (ret == -1) return errno;

return 0;
}/* aio_ex_2 */

Result upon execution:

-bash-3.00$ ./a.out
-bash-3.00$ cat dat
rec#1
t
rec#2

Remarks:

1. In the example, the IC_AIO_DATA_INIT is defined as follows:

```c
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)
    {memset(&_aio, 0, sizeof(_aio));
     _aio.aio_fildes = _fd;
     _aio.aio_buf    = _dat;
     _aio.aio_nbytes = _len;
     _aio.aio_offset = _off;}
```

2. The file descriptor fd is obtained as:

```c
HANDLE fd = CreateFile("dat",
    GENERIC_READ | GENERIC_WRITE,
    FILE_SHARE_READ,
    NULL,
    OPEN_ALWAYS,
    FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
    NULL);
```

See Also

aio_suspend()

aio_error

Returns error status for asynchronous I/O requests.

Syntax

```c
int aio_error(const struct aiocb *aiocbp);
```

Arguments

*aiocbp

Pointer to control block from where asynchronous I/O request is generated
Description
The `aio_error()` function returns the error status for the asynchronous I/O request in the control block, which is pointed to by `aiocbp`.

Returns
**EINPROGRESS**: When asynchronous I/O request is not completed

**ECANCELED**: When asynchronous I/O request is cancelled

**0**: On success

**Error value**: On error

To get the correct error value/code, use `errno`. This is the same error value returned when an error occurs during a `ReadFile()`, `WriteFile()`, or a `FlushFileBuffers()` operation.

See Also
Example Code for `aio_error()`

**aio_return**
Returns the final return status for the asynchronous I/O request.

Syntax
```c
ssize_t aio_return(struct aiocb *aiocbp);
```

Arguments
`*aiocbp`  
Pointer to control block from where asynchronous I/O request is generated

Description
The `aio_return` function returns the final return status for the asynchronous I/O request with control block pointed to by `aiocbp`.

Call this function only once for any given request, after `aio_error()` returns a value other than `EINPROGRESS`.

Returns
**Return value for synchronous ReadFile() / WriteFile() / FlushFileBuffers() requests**: When asynchronous I/O operation is completed

**Undefined return value**: When asynchronous I/O operation is not completed

**Error value**: When an error occurs

To get the correct error code/value, use `errno`.

See Also
Example Code for `aio_return()`

Example for `aio_error()` and `aio_return()` Functions
The following example illustrates how the `aio_error()` and `aio_return()` functions can be used.

```c
int aio_ex_3(HANDLE fd)
{
    static struct aiocb aio;
    static struct aiocb *aio_list[] = {&aio};
```
int ret;
char *dat = "Hello from Ex-3\n";

/* Data initialization and asynchronously writing */
IC_AIO_DATA_INIT(aio, fd, dat, strlen(dat), 0);
if (aio_write(& aio) == -1) return errno;

ret = aio_error(& aio);
if ( ret == EINPROGRESS ) {fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));

ret = aio_suspend(aio_list, 1, NULL);
if (ret == -1) return errno;
else if (ret)
  return ret;

ret = aio_error(& aio);
if (ret) return ret;

ret = aio_return(& aio);
printf("ret=%d\n", ret);
return 0;
} /* aio_ex_3 */

Result upon execution:
-bash-3.00$ ./a.out
ERRNO=115 STR=Operation now in progress
ret=16
-bash-3.00$ cat dat
Hello from Ex-3

Remarks:
1. In the example, the IC_AIO_DATA_INIT is defined as follows:

#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\{
  memset(&_aio, 0, sizeof(_aio)); \/_
  _aio.aio_fildes = _fd; \/_
  _aio.aio_buf = _dat; \/_
  _aio.aio_nbytes = _len; \/_
  _aio.aio_offset = _off;\}

2. The file descriptor fd is obtained as:

HANDLE fd = CreateFile("dat",
  GENERIC_READ | GENERIC_WRITE,
  FILE_SHARE_READ,
  NULL,
  OPEN_ALWAYS,
  FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
  NULL);

See Also
  aio_error()
  aio_return()
**aio_fsync**

*Syncrhonizes all outstanding asynchronous I/O operations.*

**Syntax**

```c
int aio_fsync(int op, struct aiocb *aiocbp);
```

**Arguments**

- `op`: Type of synchronization request operation
- `*aiocbp`: Pointer to control block from where asynchronous I/O request is generated

**Description**

The `aio_fsync()` function performs a synchronization request operation on all outstanding asynchronous I/O operations associated with `aiocbp->aio_fildes`.

**Returns**

- **0**: On successfully performing a synchronization request.
- **-1**: On error; to get the correct error code, use `errno`.

**aio_cancel**

*Cancels outstanding asynchronous I/O requests for the file descriptor fd.*

**Syntax**

```c
int aio_cancel(HANDLE fd, struct aiocb *aiocbp);
```

**Arguments**

- `fd`: File descriptor
- `*aiocbp`: Pointer to control block from where asynchronous I/O request is generated

**Description**

The `aio_cancel()` function cancels outstanding asynchronous I/O requests for the file descriptor `fd`. If `aiocbp` is NULL, all outstanding asynchronous I/O requests are cancelled. If `aiocbp` is not NULL, only the requests described by the control block pointed to by `aiocbp` are cancelled.

Normal asynchronous notification occurs for cancelled requests. The request return status is set to -1, and the request error status is set to ECANCELED. The control block of requests that cannot be cancelled is not changed.

Unspecified results occur if `aiocbp` is not NULL and the `fd` differs from the file descriptor with which the asynchronous operation was initiated.

**Returns**

- **AIO_CANCELLED**: When all specified requests are cancelled successfully.
- **AIO_NOTCANCELLED**: When at least one of the specified requests is still in process of being cancelled; check the status of request using `aio_error`.
- **AIO_ALLDONE**: When all specified requests were completed before cancel call was placed.
- **-1**: When some error occurs. To get the correct error code, use `errno`.

Example Code for aio_cancel()

Example for aio_cancel Function

The following example illustrates how \texttt{aio\_cancel()} function can be used.

```c
int aio_ex_4(HANDLE fd)
{
    static struct aiocb aio;
    static struct aiocb *aio_list[] = {&aio};
    int ret;
    char *dat = "Hello from Ex-4\n";

    printf("AIO_CANCELED=%d AIO_NOTCANCELED=%d
", AIO_CANCELED, AIO_NOTCANCELED);

    /* Data initialization and asynchronously writing */
    IC_AIO_DATA_INIT(aio, fd, dat, strlen(dat), 0);
    if (aio_write(&aio) == -1) return errno;

    ret = aio_cancel(fd, &aio);
    if ( ret == AIO_NOTCANCELED ) {
        fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));
        ret = aio_suspend(aio_list, 1, NULL);
        if (ret == -1) return errno;
    }

    ret = aio_cancel(fd, &aio);
    if ( ret == AIO_CANCELED )
        fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));
    else if (ret) return ret;

    return 0;
} /* aio_ex_4 */
```

Result upon execution:

```bash
-bash-3.00$ ./a.out
AIO_CANCELED=0 AIO_NOTCANCELED=1
ERRNO=1 STR=Operation not permitted
-bash-3.00$ cat dat
Hello from Ex-4
-bash-3.00$
```

Remarks:

1. In the example, the \texttt{IC\_AIO\_DATA\_INIT} is defined as follows:

   ```c
   #define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\n   {memset(&_aio, 0, sizeof(_aio)); \n    _aio.aio_fildes = _fd; \n    _aio.aio_buf = _dat; \n    _aio.aio_nbytes = _len; \n    _aio.aio_offset = _off;}
   ```

2. The file descriptor \texttt{fd} is obtained as:

   ```c
   HANDLE fd = CreateFile("dat", GENERIC_READ | GENERIC_WRITE, FILE_SHARE_READ, NULL,
   ```

aio_cancel()

lio_listio
Performs an asynchronous read operation.

Syntax
int lio_listio(int mode, struct aiocb *list[], int nent, struct sigevent *sig);

Arguments

mode
Takes following values declared in <aio.h> file:

- LIO_WAIT: Use when you want the function to return only after completing I/O operations (synchronous I/O operations)
- LIO_NOWAIT: Use when you want the function to return as soon as I/O operations are queued (asynchronous I/O requests)

*list[]
Array of the aiocb pointers specifying the submitted I/O requests; NULL elements in the array are ignored

nent
Number of elements in the array

*sig
Determines if asynchronous notification is sent after all I/O operations completes; takes following values:

- 0: Asynchronous notification occurs; a queued signal, with an application-defined value, is generated when an asynchronous I/O request occurs
- 1: Asynchronous notification does not occur even when asynchronous I/O requests are processed
- 2: Asynchronous notification occurs; a notification function is called to perform notification

Description

The lio_listio() function initiates a list of I/O requests with a single function call.

The mode argument determines whether the function returns when all the I/O operations are completed, or as soon as the operations are queued.

If the mode argument is LIO_WAIT, the function waits until all I/O operations are complete. The sig argument is ignored in this case.

If the mode argument is LIO_NOWAIT, the function returns immediately. Asynchronous notification occurs according to the sig argument after all the I/O operations complete.

Returns

When mode=LIO_NOWAIT the lio_listio() function returns:

- 0: I/O operations are successfully queued
- -1: Error; I/O operations not queued; to get the proper error code, use errno.

When mode=LIO_WAIT the lio_listio() function returns:
• 0: I/O operations specified completed successfully
• -1: Error; I/O operations not completed; to get the proper error code, use errno.

See Also
Example Code for lio_listio()

Example for lio_listio Function
The following example illustrates how the lio_listio() function can be used.

```c
int aio_ex_5(HANDLE fd)
{
    static struct aiocb   aio[2];
    static struct aiocb  *aio_list[2] = {&aio[0], &aio[1]};
    int               i, ret;

    /*
    ** Data initialization and Synchronously writing
    */
    IC_AIO_DATA_INIT(aio[0], fd, "rec#1\n", strlen("rec#1\n"), 0)
    IC_AIO_DATA_INIT(aio[1], fd, "rec#2\n", strlen("rec#2\n"),
        aio[0].aio_nbytes)
    aio[0].aio_lio_opcode = aio[1].aio_lio_opcode = LIO_WRITE;
    ret = lio_listio(LIO_WAIT, aio_list, 2, 0);
    if (ret) return ret;

    return 0;
}/* aio_ex_5 */
```

Result upon execution:

```
$ ./a.out
$ cat dat
rec#1
rec#2
```

Remarks:

1. In the example, the IC_AIO_DATA_INIT is defined as follows:

```c
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\n{memset(&_aio, 0, sizeof(_aio)); \n    _aio.aio_fildes = _fd; \n    _aio.aio_buf = _dat; \n    _aio.aio_nbytes = _len; \n    _aio.aio_offset = _off;}
```

2. The file descriptor fd is obtained as:

```c
HANDLE fd = CreateFile("dat",
    GENERIC_READ | GENERIC_WRITE,
    FILE_SHARE_READ,
    NULL,
    OPEN_ALWAYS,
    FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
    NULL);
```

3. The aio_lio_opcode refers to the field of each aiocb structure that specifies the operation to be performed. The supported operations are LIO_READ (do a 'read' operation), LIO_WRITE (do a 'write' operation), and LIO_NOP (do no operation); these symbols are defined in <aio.h>.

Results upon execution:
Handling Errors Caused by Asynchronous I/O Functions

This topic only applies to Windows* OS.

The `errno` macro is used to obtain the errors that occur during asynchronous request functions such as `aio_read()`, `aio_write()`, `aio_fsync()`, and `lio_listio()` or asynchronous control functions, such as `aio_cancel()`, `aio_error()`, `aio_return()`, and `aio_suspend()`.

The following example illustrates how `errno` can be used.

```c
#include <stdio.h>
#include <stdlib.h>
#include <aio.h>

struct aiocb    my_aio;
struct aiocb   *my_aio_list[1] = {&my_aio};

int main()
{
    int   res;
    double  arr[123456];
timespec_t   my_t = {1, 0};

    /* Data initialization */
    my_aio.aio_fildes = CreateFile("dat",
        GENERIC_READ | GENERIC_WRITE,
        FILE_SHARE_READ,
        NULL,
        OPEN_ALWAYS,
        FILE_ATTRIBUTE_NORMAL,
        NULL);
    my_aio.aio_buf    = (volatile char *)arr;
    my_aio.aio_nbytes = sizeof(arr);

    /* Do asynchronous writing with computation overlapping */
    aio_write(&my_aio);
    do_compute(arr, 123456);

    /* Suspend the asynchronous writing for 1 sec */
    res = aio_suspend(my_aio_list, 1, &my_t);
    if ( res ) {

        /* The call was ended by timeout, before the indicated operations had completed. */
        if ( errno == EAGAIN ) {
            res = aio_suspend(my_aio_list, 1, 0);
            if ( res ) {
                printf("aio_suspend returned non-0\n"); return errno;
            }
        } else
            if ( res ) { printf("aio_suspend returned neither 0 nor EAGAIN\n"); return errno; }
    }

    CloseHandle(my_aio.aio_fildes);
}
```
In the example, the program executes an asynchronous write operation, using `aio_write()`, overlapping with some computation, the `do_compute()` function execution. The pending write operation is suspended for one second using `aio_suspend()`.

On successful execution of the asynchronous write operation, zero is returned. `EAGAIN` or any other error value is returned when the call is ended by timeout before the indicated operation has completed.

You can check `EAGAIN` using the `errno` macro.

**Intel's C++ Asynchronous I/O Class for Windows* Operating Systems**

This topic only applies to Windows* OS.

Intel's C++ asynchronous I/O template class, `async_class`, is an implementation for the Windows* operating system on IA-32 and Intel® 64 architectures.

The `async_class` template class allows users to perform I/O operations asynchronously to the main program thread. In particular, the `async_class` template class can be used to introduce asynchronous execution of I/O operations with the STL streams classes. Users can quickly switch any of the I/O operations of the STL streams to asynchronous mode with minimal changes to the application code.

The template class `async_class` is defined in the `aiostream.h` file.

**See Also**

Details of template class `async_class`

**Template Class async_class**

This topic only applies to Windows* OS.

Intel's C++ asynchronous I/O class implementation contains two main classes within the `async` namespace: the `async_class` template class and the `thread_control` base class.

The header/typedef definitions are as follows:

```cpp
namespace async {

    template<class A>
    class async_class:
    public thread_control, public A

}
```

The template class `async_class` inherits support for asynchronous execution of I/O operations that are integrated within the base `thread_control` class.

All functionality to control asynchronous execution of a queue of STL stream operations is encapsulated in the base class `thread_control` and is inherited by template class `async_class`.

In most cases it is enough to add the header file `aiostream.h` to the source file and declare the file object as an instance of the new template class `async:async_class`. The initial stream class must be the parameter for the template class. Consequently, the defined output operator `<<` and input operator `>>` are executed asynchronously.
NOTE
The header file aiostream.h includes all necessary declarations for the STL stream I/O operations to add asynchronous functionality of the thread_control class. It also contains the necessary declarations of extensions for the standard C++ STL streams I/O operations: output operator >> and input operator <<.

You can call synchronization method wait() to wait for completion of any I/O operations with the file object. If the wait() method is not called explicitly, it is called implicitly in the object destructor.

Public Interface of Template Class async_class
The following methods define the public interface of the template class async_class:

- get_last_operation_id()
- wait()
- get_status()
- get_last_error()
- get_error_operation_id()
- stop_queue()
- resume_queue()
- clear_queue()

Library Restrictions
Intel's C++ asynchronous I/O template class does not control the integrity or validity of the objects during asynchronous operation. Such control should be done by the user.

For application stability in the Visual Studio 2003 environment, link the C++ part of libacaio.lib library with multi-threaded msvcr71 run-time library. Use /MT or /MTd compiler option.

See Also
Example of Using async_class Template Class

get_last_operation_id
Returns ID of the last added operation.

Syntax
void get_last_operation_id(void)

Description
This method returns the ID of the last added operation. Use this ID to get the status of operation or to wait for the operation to complete.

Return Values
Nothing

wait
Stops execution of current thread.

Syntax
int wait(void)
int wait(unsigned int operation_id)
**Description**
Method `wait(void)` stops execution of the current thread until all the asynchronous operations are completed.
Method `wait(operation_id)` stops execution of the current thread until the operation identified by `operation_id` is completed.

**Return Values**
- `-1`: On error during queue execution

Call the `get_last_error()` method to check the error code.

**get_status**
*Returns status of specified operation.*

**Syntax**
```c
void get_status(unsigned int operation_id)
```

**Description**
This method returns the status of an operation, specified by `operation_id`, without stopping current thread execution.

**Return Values**
- `STATUS_WAIT`: Operation is waiting for execution.
- `STATUS_COMPLETED`: Operation finished execution.
- `STATUS_ERROR`: An error occurred during operation execution.
- `STATUS_EXECUTE`: Operation is executing.
- `STATUS_BLOCKED`: Execution of the queue was blocked after some earlier errors.

**get_last_error**
*Returns the error code of the last failed operation.*

**Syntax**
```c
unsigned int get_last_error()
```

**Description**
This method returns the error code of the last failed operation. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of asynchronous operations and waits for new user requests.

To obtain the error status, use the `wait()` and `get_status()` methods.

**Return Values**
Error code of last failed operation.

This error code is equal to the value returned by `GetLastError()` function on the Windows* platform. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of asynchronous operations and waits for new user requests.
**get_error_operation_id**

*Returns the ID of the last failed operation.*

**Syntax**

```c
unsigned int get_error_operation_id()
```

**Description**

This method returns the ID of the last failed operation. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of the asynchronous operations and waits for new user requests.

To obtain the error status of the failed operation, use the `wait()` and `get_status()` methods.

**Return Values**

ID of last failed operation.

**stop_queue**

*Stops queue execution.*

**Syntax**

```c
int stop_queue()
```

**Description**

This method allows you to control the asynchronous operations queue by stopping queue execution.

**Return Values**

- **0**: On success
- **-1**: On error

**resume_queue**

*Resumes queue execution.*

**Syntax**

```c
int resume_queue()
```

**Description**

This method allows you to control the asynchronous operations queue by resuming queue execution.

**Return Values**

- **0**: On success
- **-1**: On error

**clear_queue**

*Clears stopped or error-interrupted queues.*

**Syntax**

```c
void push_back_operation(class base_operation*)
```
Description
This method clears the content of stopped queues or queues interrupted by errors.

Return Values
0: On success
-1: On error

Example for Using async_class Template Class
The following example illustrates how Intel's C++ asynchronous I/O template class can be used. Consider the following code that writes arrays of floats to an external file.

```cpp
// Data is array of floats
std::vector<float> v(10000);

// User defines new operator << for std::vector<float> type
std::ofstream& operator<<(std::ofstream & str, std::vector<float> & vec)
{
    // User’s output actions
    ...
}

// Output file declaration – object of standard ofstream STL class
std::ofstream external_file("output.txt");
...

// Output operations
external_file << v;
```

The following code illustrates the changes to be made to the above code to execute the output operation asynchronously.

```cpp
// Add new header to support STL asynchronous IO operations
#include <aiostream.h>
...

std::vector<float> v(10000);
std::ofstream& operator<<(std::ofstream & str, std::vector<float> & vec)
{
    // Declare output file as the instance of new async::async_class template class.
    // New inherited from STL ofstream type is declared
    async::async_class<std::ofstream> external_file("output.txt");
    ...
    external_file << v;
    ...
    // Add stop operation, to wait the completion of all asynchronous IO operations
    external_file.wait();
    ...
```

Performance Recommendations
It is recommended not to use asynchronous mode for small objects. For example, do not use asynchronous mode when the output standard type value in a loop where execution of other loop operations takes less time than output of the same value to the STL stream.

However, if you can find the balance between output of small data and its previous calculation inside the loop, you still have some stable performance improvement.
For example, in the following code, the program reads two matrices from external files, calculates the elements of a third matrix, and prints out the elements inside the loop.

```c++
#define ARR_LEN 900
{
    std::ifstream fA("A.txt");
    fA >> A;
    std::ifstream fB("B.txt");
    fB >> B;
    std::ofstream fC(f);

    for(int i=0; i< ARR_LEN; i++)
    {
        for(int j=0; j< ARR_LEN; j++)
        {
            C[i][j] = 0;
            for(int k=0; k < ARR_LEN; k++)
                C[i][j] += A[i][k]*B[k][j]*sin((float)(k))*cos((float)(-k))*sin((float)(k+1))*cos((float)(-k-1));
            fC << C[i][j] << std::endl;
        }
    }
}
```

By increasing matrix size, you can also achieve performance improvement during parallel data reading from two files.

**IEEE 754-2008 Binary Floating-Point Conformance Library**

The Intel® IEEE 754-2008 Binary Floating-Point Conformance Library provides all operations mandated by the IEEE 754-2008 standard for binary32 and binary64 binary floating-point interchange formats.

Many routines in the `libbfp754` Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Overview: Intel® IEEE 754-2008 Binary Floating-Point Conformance Library**

The Intel® IEEE 754-2008 Binary Floating-Point Conformance Library provides all operations mandated by the IEEE 754-2008 standard for binary32 and binary64 binary floating-point interchange formats. The minimum requirements for correct operation of the library are an Intel® Pentium® 4 processor and an operating system supporting Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions.
The library supports all four rounding-direction attributes mandated by the IEEE 754-2008 standard for binary floating-point arithmetic: roundTiesToEven, roundTowardPositive, roundTowardNegative, roundTowardZero. The additional rounding-direction attribute, roundTiesToAway, is not required by the standard, hence, not fully supported in this library. The default rounding-direction attribute is set as roundTiesToEven.

The library also supports all mandated exceptions (invalid operation, division by zero, overflow, underflow, and inexact) and sets flags accordingly under default exception handling. Alternate exception handling, which is optional in the standard, is not supported.

The bfp754.h header file includes prototypes for the library functions. For a complete list of the functions available, refer to the Function List. The user also needs to specify linker option -lbfp754 and floating-point semantics control option -fp-model source -fp-model except in order to use the library.

Many routines in the libbfp754 Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**Operations**

The IEEE standard 754-2008 defines four types of operations.

1. General-computational operations that produce correctly rounded floating-point or integer results. These operations might signal the floating-point exceptions.
2. Quiet-computational operations that produce floating-point results. These operations do not signal any floating-point exceptions.
3. Signaling-computational operations that produce no floating-point results. These operations might signal floating-point exceptions.
4. Non-computational operations that produce no floating-point results. These operations do not signal floating-point exceptions.

<table>
<thead>
<tr>
<th>Produce result</th>
<th>Produce no result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Might signal FP exception</strong></td>
<td>General-computational</td>
</tr>
<tr>
<td><strong>Do not signal FP exception</strong></td>
<td>Quiet-computational</td>
</tr>
</tbody>
</table>

The standard also distinguishes among operations by their floating-point operand formats and result format for general-computational operations:

1. Homogenous general-computational operations whose floating-point operands and floating-point result are in the same format.
2. formatOf general-computational operations whose floating-point operands and floating-point result have different formats.
NOTE
The IEEE 754-2008 standard requires that all formatOf general-computational operations be computed without any lost of precision before converting to the destination format. This may differ from how these operations are implemented on most hardware and software.

For example, when all operands are in binary64 format and the destination format is binary32, most hardware and software implementations would first compute an intermediate result rounded in binary64 and then convert the intermediate result to binary32. This double rounding procedure may produce a result different from what is defined in the standard under certain rounding mode. For example: \( x = 0x3ff0000010000000 = 1.00000000000000000000000_2 \), \( y = 0x3ca0000000000000 = 1.0_2*2^{-53} \) \( x+y = 1.000000000000000000000001_2 \)

When the rounding-direction attribute is set to `roundTiesToEven`, using double rounding procedure, the addition result rounds to \( 1.00000000000000000000001_2 \) \( 0x3ff0000010000000 \) in binary64, which would then round to \( 1 \) \( 0x3f800000 \) in binary32. On the other hand, according to the standard, the addition result should round to \( 1.00000000000000000000001_2 \) \( 0x3f8000001 \) in binary32.

Data Types
The following table correlates the names of the formats used in defining operations in the standard with their C99 types used in this library.

<table>
<thead>
<tr>
<th>Format Name</th>
<th>Definition</th>
<th>C99 Type</th>

Using the Intel® IEEE 754-2008 Binary Floating-Point Conformance Library

Many routines in the libbfp754 Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

To use the library, include the header file, bfp754.h, in your program.

Here is an example program illustrating the use of the library on Linux* OS.

```c
//binary.c
#include <stdio.h>
#include <bfp754.h>
int main(){
    double a64, b64;
    float c32;
    a64 = 1.000000059604644775390625;
    b64 = 1.110223024625156404236316680908203125e-16;
    c32 = __binary32_add_binary64_binary64(a64, b64);
    printf("The addition result using the library: %8.8f\n", c32);
    c32 = a64 + b64;
    printf("The addition result without the library: %8.8f\n", c32);
    return 0;
}
```

The command for compiling binary.c is:

```
icc -fp-model source -fp-model except binary.c -lbfp754
```

The output of a.out will look similar to the following:

```
The addition result using the library: 1.00000012
The addition result without the library: 1.00000000
```

**Homogeneous General-Computational Operations Functions**

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for homogeneous general-computational operations:
**round_integral_nearest_even**

**Description:** The function rounds floating-point number $x$ to its nearest integral value, with the halfway (tied) case rounding to even.

**Calling interface:**

```c
float __binary32_round_integral_nearest_even(float x);
double __binary64_round_integral_nearest_even(double x);
```

**round_integral_nearest_away**

**Description:** The function rounds floating-point number $x$ to its nearest integral value, with the halfway (tied) case rounding away from zero.

**Calling interface:**

```c
float __binary32_round_integral_nearest_away(float x);
double __binary64_round_integral_nearest_away(double x);
```

**round_integral_zero**

**Description:** The function rounds floating-point number $x$ to the closest integral value toward zero.

**Calling interface:**

```c
float __binary32_round_integral_zero(float x);
double __binary64_round_integral_zero(double x);
```

**round_integral_positive**

**Description:** The function rounds floating-point number $x$ to the closest integral value toward positive infinity.

**Calling interface:**

```c
float __binary32_round_integral_positive(float x);
double __binary64_round_integral_positive(double x);
```

**round_integral_negative**

**Description:** The function rounds floating-point number $x$ to the closest integral value toward negative infinity.

**Calling interface:**

```c
float __binary32_round_integral_negative(float x);
double __binary64_round_integral_negative(double x);
```

**round_integral_exact**

**Description:** The function rounds floating-point number $x$ to the closest integral value according to the rounding-direction applicable.

**Calling interface:**

```c
float __binary32_round_integral_exact(float x);
double __binary64_round_integral_exact(double x);
```

**next_up**

**Description:** The function returns the least floating-point number in the same format as $x$ that is greater than $x$.

**Calling interface:**

```c
float __binary32_next_up(float x);
```
double __binary64_next_up(double x);

next_down
Description: The function returns the largest floating-point number in the same format as \( x \) that is less than \( x \).
Calling interface:
float __binary32_next_down(float x);
double __binary64_next_down(double x);

rem
Description: The function returns the remainder of \( x \) and \( y \).
Calling interface:
float __binary32_rem(float x, float y);
double __binary64_rem(double x, double y);

minnum
Description: The function returns the minimal value of \( x \) and \( y \).
Calling interface:
float __binary32_minnum(float x, float y);
double __binary64_minnum(double x, double y);

maxnum
Description: The function returns the maximal value of \( x \) and \( y \).
Calling interface:
float __binary32_maxnum(float x, float y);
double __binary64_maxnum(double x, double y);

minnum_mag
Description: The function returns the minimal absolute value of \( x \) and \( y \).
Calling interface:
float __binary32_minnum_mag(float x, float y);
double __binary64_minnum_mag(double x, double y);

maxnum_mag
Description: The function returns the maximal absolute value of \( x \) and \( y \).
Calling interface:
float __binary32_maxnum_mag(float x, float y);
double __binary64_maxnum_mag(double x, double y);

scalbn
Description: The function computes \( x \times 2^n \) for integer value \( n \).
Calling interface:
float __binary32_scalbn(float x, int n);
double __binary64_scalbn(double x, int n);
**ilogb**

**Description:** The function returns the exponent part of \( x \) as integer.

**Calling interface:**

```c
int __binary32_ilogb(float x);
int __binary64_ilogb(double x);
```

---

**formatOf General-Computational Operations Functions**

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for *formatOf* general-computational operations:

**add**

**Description:** The function computes the addition of two floating-point numbers; the result is then converted to the destination format.

**Calling interface:**

```c
float __binary32_add_binary32_binary32(float x, float y);
float __binary32_add_binary32_binary64(float x, double y);
float __binary32_add_binary64_binary32(double x, float y);
float __binary32_add_binary64_binary64(double x, double y);
float __binary64_add_binary32_binary32(float x, float y);
float __binary64_add_binary32_binary64(float x, double y);
float __binary64_add_binary64_binary32(double x, float y);
float __binary64_add_binary64_binary64(double x, double y);
```

**sub**

**Description:** The function computes the subtraction of two floating-point numbers; the result is then converted to the destination format.

**Calling interface:**

```c
float __binary32_sub_binary32_binary32(float x, float y);
float __binary32_sub_binary32_binary64(float x, double y);
float __binary32_sub_binary64_binary32(double x, float y);
float __binary32_sub_binary64_binary64(double x, double y);
float __binary64_sub_binary32_binary32(float x, float y);
float __binary64_sub_binary32_binary64(float x, double y);
float __binary64_sub_binary64_binary32(double x, float y);
float __binary64_sub_binary64_binary64(double x, double y);
```

**mul**

**Description:** The function computes the multiplication of two floating-point numbers; the result is then converted to the destination format.

**Calling interface:**

```c
float __binary32_mul_binary32_binary32(float x, float y);
float __binary32_mul_binary32_binary64(float x, double y);
float __binary32_mul_binary64_binary32(double x, float y);
float __binary32_mul_binary64_binary64(double x, double y);
float __binary64_mul_binary32_binary32(float x, float y);
float __binary64_mul_binary32_binary64(float x, double y);
float __binary64_mul_binary64_binary32(double x, float y);
float __binary64_mul_binary64_binary64(double x, double y);
```
double __binary64_mul_binary64_binary32(double x, float y);
double __binary64_mul_binary64_binary64(double x, double y);

div
Description: The function computes the division of two floating-point numbers; the result is then converted to the destination format.

Calling interface:
float __binary32_div_binary32_binary32(float x, float y);
float __binary32_div_binary32_binary64(float x, double y);
float __binary32_div_binary64_binary32(double x, float y);
float __binary32_div_binary64_binary64(double x, double y);
double __binary64_div_binary32_binary32(float x, float y);
double __binary64_div_binary32_binary64(float x, double y);
double __binary64_div_binary64_binary32(double x, float y);
double __binary64_div_binary64_binary64(double x, double y);

sqrt
Description: The function computes the square root of a floating-point number; the result is then converted to the destination format.

Calling interface:
float __binary32_sqrt_binary32(float x);
float __binary32_sqrt_binary64(double x);
double __binary32_sqrt_binary32(float x);
double __binary32_sqrt_binary64(double x);

fma
Description: The function computes the fused multiply and add of three floating-point numbers x, y, and z as (x×y) + z; the result is then converted to the destination format.

Calling interface:
float __binary32_fma_binary32_binary32_binary32(float x, float y, float z);
float __binary32_fma_binary32_binary32_binary64(float x, float y, double z);
float __binary32_fma_binary32_binary64_binary32(float x, double y, float z);
float __binary32_fma_binary32_binary64_binary64(float x, double y, double z);
float __binary32_fma_binary64_binary32_binary32(double x, float y, float z);
float __binary32_fma_binary64_binary32_binary64(double x, float y, double z);
float __binary32_fma_binary64_binary64_binary32(double x, double y, float z);
float __binary32_fma_binary64_binary64_binary64(double x, double y, double z);
double __binary64_fma_binary32_binary32_binary32(float x, float y, float z);
double __binary64_fma_binary32_binary32_binary64(float x, float y, double z);
double __binary64_fma_binary32_binary64_binary32(float x, double y, float z);
double __binary64_fma_binary32_binary64_binary64(float x, double y, double z);
double __binary64_fma_binary64_binary32_binary32(double x, float y, float z);
double __binary64_fma_binary64_binary32_binary64(double x, float y, double z);
double __binary64_fma_binary64_binary64_binary32(double x, double y, float z);
double __binary64_fma_binary64_binary64_binary64(double x, double y, double z);

from_int32 / from_uint32 / from_int64 / from_uint64
Description: This function converts integral values in the specified integer format to floating-point number.
Calling interface:
float __binary32_from_int32(int n);
double __binary64_from_int32(int n);
float __binary32_from_uint32(unsigned int n);
double __binary64_from_uint32(unsigned int n);
float __binary32_from_int64(long long int n);
double __binary64_from_int64(long long int n);
float __binary32_from_uint64(unsigned long long int n);
double __binary64_from_uint64(unsigned long long int n);

to_int32_rnint / to_uint32_rnint / to_int64_rnint / to_uint64_rnint

Description: This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded to even, without signaling the inexact exception.

Calling interface:
int __binary32_to_int32_rnint(float x);
int __binary64_to_int32_rnint(double x);
unsigned int __binary32_to_uint32_rnint(float x);
unsigned int __binary64_to_uint32_rnint(double x);
long long int __binary32_to_int64_rnint(float x);
long long int __binary64_to_int64_rnint(double x);
unsigned long long int __binary32_to_uint64_rnint(float x);
unsigned long long int __binary64_to_uint64_rnint(double x);

to_int32_int / to_uint32_int / to_int64_int / to_uint64_int

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward zero, without signaling the inexact exception.

Calling interface:
int __binary32_to_int32_int(float x);
int __binary64_to_int32_int(double x);
unsigned int __binary32_to_uint32_int(float x);
unsigned int __binary64_to_uint32_int(double x);
long long int __binary32_to_int64_int(float x);
long long int __binary64_to_int64_int(double x);
unsigned long long int __binary32_to_uint64_int(float x);
unsigned long long int __binary64_to_uint64_int(double x);

to_int32.ceil / to_uint32.ceil / to_int64.ceil / to_uint64.ceil

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward positive infinity, without signaling the inexact exception.

Calling interface:
int __binary32_to_int32.ceil(float x);
int __binary64_to_int32.ceil(double x);
unsigned int __binary32_to_uint32.ceil(float x);
unsigned int __binary64_to_uint32.ceil(double x);
long long int __binary32_to_int64.ceil(float x);
long long int __binary64_to_int64.ceil(double x);
unsigned long long int __binary32_to_uint64.ceil(float x);
unsigned long long int __binary64_to_uint64.ceil(double x);
**to_int32_floor / to_uint32_floor / to_int64_floor / to_uint64_floor**

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format toward negative infinity, without signaling the inexact exception.

**Calling interface:**

```c
int __binary32_to_int32_floor(float x);
int __binary64_to_int32_floor(double x);
unsigned int __binary32_to_uint32_floor(float x);
unsigned int __binary64_to_uint32_floor(double x);
long long int __binary32_to_int64_floor(float x);
long long int __binary64_to_int64_floor(double x);
unsigned long long int __binary32_to_uint64_floor(float x);
unsigned long long int __binary64_to_uint64_floor(double x);
```

**to_int32_rninta / to_uint32_rninta / to_int64_rninta / to_uint64_rninta**

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded away from zero, without signaling the inexact exception.

**Calling interface:**

```c
int __binary32_to_int32_rninta(float x);
int __binary64_to_int32_rninta(double x);
unsigned int __binary32_to_uint32_rninta(float x);
unsigned int __binary64_to_uint32_rninta(double x);
long long int __binary32_to_int64_rninta(float x);
long long int __binary64_to_int64_rninta(double x);
unsigned long long int __binary32_to_uint64_rninta(float x);
unsigned long long int __binary64_to_uint64_rninta(double x);
```

**to_int32_xrnint / to_uint32_xrnint / to_int64_xrnint / to_uint64_xrnint**

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded to even, signaling if inexact.

**Calling interface:**

```c
int __binary32_to_int32_xrnint(float x);
int __binary64_to_int32_xrnint(double x);
unsigned int __binary32_to_uint32_xrnint(float x);
unsigned int __binary64_to_uint32_xrnint(double x);
long long int __binary32_to_int64_xrnint(float x);
long long int __binary64_to_int64_xrnint(double x);
unsigned long long int __binary32_to_uint64_xrnint(float x);
unsigned long long int __binary64_to_uint64_xrnint(double x);
```

**to_int32_xint / to_uint32_xint / to_int64_xint / to_uint64_xint**

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format toward zero, signaling if inexact.

**Calling interface:**

```c
int __binary32_to_int32_xint(float x);
int __binary64_to_int32_xint(double x);
unsigned int __binary32_to_uint32_xint(float x);
unsigned int __binary64_to_uint32_xint(double x);
long long int __binary32_to_int64_xint(float x);
```
long long int __binary64_to_int64_xint(double x);
unsigned long long int __binary32_to_uint64_xint(float x);
unsigned long long int __binary64_to_uint64_xint(double x);

to_int32_xceil / to_uint32_xceil / to_int64_xceil / to_uint64_xceil

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format toward positive infinity, signaling if inexact.

**Calling interface:**
int __binary32_to_int32_xceil(float x);
int __binary64_to_int32_xceil(double x);
unsigned int __binary32_to_uint32_xceil(float x);
unsigned int __binary64_to_uint32_xceil(double x);
long long int __binary32_to_int64_xceil(float x);
long long int __binary64_to_int64_xceil(double x);
unsigned long long int __binary32_to_uint64_xceil(float x);
unsigned long long int __binary64_to_uint64_xceil(double x);

to_int32_xfloor / to_uint32_xfloor / to_int64_xfloor / to_uint64_xfloor

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format toward negative infinity, signaling if inexact.

**Calling interface:**
int __binary32_to_int32_xfloor(float x);
int __binary64_to_int32_xfloor(double x);
unsigned int __binary32_to_uint32_xfloor(float x);
unsigned int __binary64_to_uint32_xfloor(double x);
long long int __binary32_to_int64_xfloor(float x);
long long int __binary64_to_int64_xfloor(double x);
unsigned long long int __binary32_to_uint64_xfloor(float x);
unsigned long long int __binary64_to_uint64_xfloor(double x);

to_int32_xrninta / to_uint32_xrninta / to_int64_xrninta / to_uint64_xrninta

**Description:** This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded away from zero, signaling if inexact.

**Calling interface:**
int __binary32_to_int32_xrninta(float x);
int __binary64_to_int32_xrninta(double x);
unsigned int __binary32_to_uint32_xrninta(float x);
unsigned int __binary64_to_uint32_xrninta(double x);
long long int __binary32_to_int64_xrninta(float x);
long long int __binary64_to_int64_xrninta(double x);
unsigned long long int __binary32_to_uint64_xrninta(float x);
unsigned long long int __binary64_to_uint64_xrninta(double x);

binary32_to_binary64

**Description:** This function converts floating-point number in binary32 format to binary64 format.

**Calling interface:**
double __binary32_to_binary64(float x);
**binary64_to_binary32**

**Description:** This function rounds floating-point number in binary64 format to binary32 format.

**Calling interface:**

```c
float __binary64_to_binary32(double x);
```

**from_string**

**Description:** This function converts decimal character sequence to floating-point number.

**Calling interface:**

```c
float __binary32_from_string(char * s);
double __binary64_from_string(char * s);
```

**to_string**

**Description:** This function converts floating-point number to decimal character sequence.

**Calling interface:**

```c
char *__binary32_to_string(float x);
char *__binary64_to_string(double x);
```

**from_hexstring**

**Description:** This function converts hexadecimal character sequence to floating-point number.

**Calling interface:**

```c
float __binary32_from_hexstring(char * s);
double __binary64_from_hexstring(char * s);
```

**to_hexstring**

**Description:** This function converts floating-point number to hexadecimal character sequence.

**Calling interface:**

```c
char *__binary32_to_hexstring(float x);
char *__binary64_to_hexstring(double x);
```

**Quiet-Computational Operations Functions**

Many routines in the libbfp754 Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for quiet-computational operations:

**copy**

**Description:** The function copies input floating-point number x to output in the same floating-point format, without any change to the sign.

**Calling interface:**

```c
float __binary32_copy(float x);
double __binary64_copy(double x);
```
NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

negate
Description: The function copies input floating-point number \( x \) to output in the same floating-point format, reversing the sign.

Calling interface:
```c
float __binary32_negate(float x);
double __binary64_negate(double x);
```

NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

abs
Description: The function copies input floating-point number \( x \) to output in the same floating-point format, setting the sign to positive.

Calling interface:
```c
float __binary32_abs(float x);
double __binary64_abs(double x);
```

NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

copysign
Description: The function copies input floating-point number \( x \) to output in the same floating-point format, with the same sign as \( y \).

Calling interface:
```c
float __binary32_copysign(float x, float y);
double __binary64_copysign(double x, double y);
```

NOTE
When the first input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.
Signaling-Computational Operations Functions

Many routines in the libbfp754 Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for signaling-computational operations:

quiet_equal

Description: The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is in the inputs.

Calling interface:

```c
int __binary32_quiet_equal_binary32 (float x, float y);
int __binary32_quiet_equal_binary64(float x, double y);
int __binary64_quiet_equal_binary32(double x, float y);
int __binary64_quiet_equal_binary64(double x, double y);
```

quiet_not_equal

Description: The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is not equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

Calling interface:

```c
int __binary32_quiet_not_equal_binary32 (float x, float y);
int __binary32_quiet_not_equal_binary64(float x, double y);
int __binary64_quiet_not_equal_binary32(double x, float y);
int __binary64_quiet_not_equal_binary64(double x, double y);
```

signaling_equal

Description: The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is equal, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:

```c
int __binary32_signaling_equal_binary32 (float x, float y);
int __binary32_signaling_equal_binary64(float x, double y);
int __binary64_signaling_equal_binary32(double x, float y);
int __binary64_signaling_equal_binary64(double x, double y);
```

signaling_greater

Description: The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is greater, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:

```c
int __binary32_signaling_greater_binary32 (float x, float y);
int __binary32_signaling_greater_binary64(float x, double y);
int __binary64_signaling_greater_binary32(double x, float y);
int __binary64_signaling_greater_binary64(double x, double y);
```

signaling_greater_equal

Description: The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is greater or equal, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.
Calling interface:
int __binary32_signaling_greater_equal_binary32(float x, float y);
int __binary32_signaling_greater_equal_binary64(float x, double y);
int __binary64_signaling_greater_equal_binary32(double x, float y);
int __binary64_signaling_greater_equal_binary64(double x, double y);

signaling_less

**Description:** The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is less, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:
int __binary32_signaling_less_binary32(float x, float y);
int __binary32_signaling_less_binary64(float x, double y);
int __binary64_signaling_less_binary32(double x, float y);
int __binary64_signaling_less_binary64(double x, double y);

signaling_less_equal

**Description:** The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is less or equal, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:
int __binary32_signaling_less_equal_binary32(float x, float y);
int __binary32_signaling_less_equal_binary64(float x, double y);
int __binary64_signaling_less_equal_binary32(double x, float y);
int __binary64_signaling_less_equal_binary64(double x, double y);

signaling_not_equal

**Description:** The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is not equal, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:
int __binary32_signaling_not_equal_binary32(float x, float y);
int __binary32_signaling_not_equal_binary64(float x, double y);
int __binary64_signaling_not_equal_binary32(double x, float y);
int __binary64_signaling_not_equal_binary64(double x, double y);

signaling_not_greater

**Description:** The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is not greater, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:
int __binary32_signaling_not_greater_binary32(float x, float y);
int __binary32_signaling_not_greater_binary64(float x, double y);
int __binary64_signaling_not_greater_binary32(double x, float y);
int __binary64_signaling_not_greater_binary64(double x, double y);

signaling_less_unordered

**Description:** The function returns 1 (true) if the relation between the two inputs \(x\) and \(y\) is less or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when NaN is in the inputs.

Calling interface:
int __binary32_signaling_less_unordered_binary32(float x, float y);
int __binary32_signaling_less_unordered_binary64(float x, double y);
int __binary64_signaling_less_unordered_binary32(double x, float y);
int __binary64_signaling_less_unordered_binary64(double x, double y);

signaling_not_less

**Description:** The function returns 1 (true) if the relation between the two inputs \( x \) and \( y \) is not less, returns 0 (false) otherwise. The function signals invalid operation exception when \( \text{NaN} \) is in the inputs.

**Calling interface:**
int __binary32_signaling_not_less_binary32(float x, float y);
int __binary32_signaling_not_less_binary64(float x, double y);
int __binary64_signaling_not_less_binary32(double x, float y);
int __binary64_signaling_not_less_binary64(double x, double y);

signaling_greater_unordered

**Description:** The function returns 1 (true) if the relation between the two inputs \( x \) and \( y \) is greater or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when \( \text{NaN} \) is in the inputs.

**Calling interface:**
int __binary32_signaling_greater_unordered_binary32(float x, float y);
int __binary32_signaling_greater_unordered_binary64(float x, double y);
int __binary64_signaling_greater_unordered_binary32(double x, float y);
int __binary64_signaling_greater_unordered_binary64(double x, double y);

quiet_greater

**Description:** The function returns 1 (true) if the relation between the two inputs \( x \) and \( y \) is greater, returns 0 (false) otherwise. The function signals invalid operation exception when signaling \( \text{NaN} \) is one of the inputs.

**Calling interface:**
int __binary32_quiet_greater_binary32(float x, float y);
int __binary32_quiet_greater_binary64(float x, double y);
int __binary64_quiet_greater_binary32(double x, float y);
int __binary64_quiet_greater_binary64(double x, double y);

quiet_greater_equal

**Description:** The function returns 1 (true) if the relation between the two inputs \( x \) and \( y \) is greater or equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling \( \text{NaN} \) is one of the inputs.

**Calling interface:**
int __binary32_quiet_greater_equal_binary32(float x, float y);
int __binary32_quiet_greater_equal_binary64(float x, double y);
int __binary64_quiet_greater_equal_binary32(double x, float y);
int __binary64_quiet_greater_equal_binary64(double x, double y);

quiet_less

**Description:** The function returns 1 (true) if the relation between the two inputs \( x \) and \( y \) is less, returns 0 (false) otherwise. The function signals invalid operation exception when signaling \( \text{NaN} \) is one of the inputs.

**Calling interface:**
quiet_less_equal

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is less or equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**

```c
int __binary32_quiet_less_equal_binary32(float x, float y);
int __binary32_quiet_less_equal_binary64(float x, double y);
int __binary64_quiet_less_equal_binary32(double x, float y);
int __binary64_quiet_less_equal_binary64(double x, double y);
```

quiet_unordered

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is unordered, returns zero (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**

```c
int __binary32_quiet_unordered_binary32(float x, float y);
int __binary32_quiet_unordered_binary64(float x, double y);
int __binary64_quiet_unordered_binary32(double x, float y);
int __binary64_quiet_unordered_binary64(double x, double y);
```

quiet_not_greater

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is not greater, returns zero (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**

```c
int __binary32_quiet_not_greater_binary32(float x, float y);
int __binary32_quiet_not_greater_binary64(float x, double y);
int __binary64_quiet_not_greater_binary32(double x, float y);
int __binary64_quiet_not_greater_binary64(double x, double y);
```

quiet_less_unordered

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is less or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**

```c
int __binary32_quiet_less_unordered_binary32(float x, float y);
int __binary32_quiet_less_unordered_binary64(float x, double y);
int __binary64_quiet_less_unordered_binary32(double x, float y);
int __binary64_quiet_less_unordered_binary64(double x, double y);
```
quiet_not_less

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is not less, returns zero (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**
- `int __binary32_quiet_not_less_binary32(float x, float y);`
- `int __binary32_quiet_not_less_binary64(float x, double y);`
- `int __binary64_quiet_not_less_binary32(double x, float y);`
- `int __binary64_quiet_not_less_binary64(double x, double y);`

quiet_greater_unordered

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is greater or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**
- `int __binary32_quiet_greater_unordered_binary32(float x, float y);`
- `int __binary32_quiet_greater_unordered_binary64(float x, double y);`
- `int __binary64_quiet_greater_unordered_binary32(double x, float y);`
- `int __binary64_quiet_greater_unordered_binary64(double x, double y);`

quiet_ordered

**Description:** The function returns 1 (true) if the relation between the two inputs $x$ and $y$ is ordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling NaN is one of the inputs.

**Calling interface:**
- `int __binary32_quiet_ordered_binary32(float x, float y);`
- `int __binary32_quiet_ordered_binary64(float x, double y);`
- `int __binary64_quiet_ordered_binary32(double x, float y);`
- `int __binary64_quiet_ordered_binary64(double x, double y);`

Non-Computational Operations Functions

Many routines in the `libbfp754` Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for non-computational operations:

is754version1985

**Description:** The function returns 1, if and only if this programming environment conforms to IEEE Std. 754-1985, otherwise returns 0.

**Calling interface:**
- `int __binary_is754version1985(void);`

**NOTE**
This function in this library always returns 0.
**is754version2008**

**Description:** The function returns 1, if and only if this programming environment conforms to IEEE Std. 754-2008, otherwise returns 0.

**Calling interface:**
```c
int __binary_is754version2008(void);
```

**NOTE**
This function in this library always returns 1.

---

**class**

**Description:** The function returns which class of the ten classes (signalingNaN, quietNaN, negativeInfinity, negativeNormal, negativeSubnormal, negativeZero, positiveZero, positiveSubnormal, positiveNormal, positiveInfinity) the input floating-point number x belongs.

<table>
<thead>
<tr>
<th>Return value</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>signalingNaN</td>
</tr>
<tr>
<td>1</td>
<td>quietNaN</td>
</tr>
<tr>
<td>2</td>
<td>negativeInfinity</td>
</tr>
<tr>
<td>3</td>
<td>negativeNormal</td>
</tr>
<tr>
<td>4</td>
<td>negativeSubnormal</td>
</tr>
<tr>
<td>5</td>
<td>negativeZero</td>
</tr>
<tr>
<td>6</td>
<td>positiveZero</td>
</tr>
<tr>
<td>7</td>
<td>positiveSubnormal</td>
</tr>
<tr>
<td>8</td>
<td>positiveNormal</td>
</tr>
<tr>
<td>9</td>
<td>positiveInfinity</td>
</tr>
</tbody>
</table>

**Calling interface:**
```c
int __binary32_class(float x);
int __binary64_class(double x);
```

---

**isSignMinus**

**Description:** The function returns 1, if and only if its argument has negative sign.

**Calling interface:**
```c
int __binary32_isSignMinus(float x);
int __binary64_isSignMinus(double x);
```

---

**isNormal**

**Description:** The function returns 1, if and only if its argument is normal (not zero, subnormal, infinite, or NaN).

**Calling interface:**
```c
int __binary32_isNormal(float x);
```
int __binary64_isNormal(double x);

**isFinite**

**Description:** The function returns 1, if and only if its argument is finite (not infinite or NaN).

**Calling interface:**

**isZero**

**Description:** The function returns 1, if and only if its argument is ±0.

**Calling interface:**

```c
int __binary32_isZero(float x);
int __binary64_isZero(double x);
```

**isSubnormal**

**Description:** The function returns 1, if and only if its argument is subnormal.

**Calling interface:**

```c
int __binary32_isSubnormal(float x);
int __binary64_isSubnormal(double x);
```

**isInfinite**

**Description:** The function returns 1, if and only if its argument is infinite

**Calling interface:**

```c
int __binary32_isInfinite(float x);
int __binary64_isInfinite(double x);
```

**isNaN**

**Description:** The function returns 1, if and only if its argument is a NaN.

**Calling interface:**

```c
int __binary32_isNaN(float x);
int __binary64_isNaN(double x);
```

**isSignaling**

**Description:** The function returns 1, if and only if its argument is a signaling NaN.

**Calling interface:**

```c
int __binary32_isSignaling(float x);
int __binary64_isSignaling(double x);
```

**isCanonical**

**Description:** The function returns 1, if and only if its argument is a finite number, infinity, or NaN that is canonical.

**Calling interface:**

```c
int __binary32_isCanonical(float x);
int __binary64_isCanonical(double x);
```
NOTE
This function in this library always returns 1, as only canonical floating-point numbers are expected.

radix

Description: The function returns the radix of the format of the input floating-point number.

Calling interface:
```c
int __binary32_radix(float x);
int __binary64_radix(double x);
```

NOTE
This function in this library always returns 2, as the library is intended for binary floating-point numbers.

totalOrder

Description: The function returns 1 if and only if two floating-point inputs x and y is total ordered and 0 otherwise.

Calling interface:
```c
int _binary32_totalOrder(float x, float y);
int _binary64_totalOrder(double x, double y);
```

totalOrderMag

Description: totalOrderMag(x, y) is the same as totalOrder(abs(x), abs(y)).

Calling interface:
```c
int _binary32_totalOrderMag(float x, float y);
int _binary64_totalOrderMag(double x, double y);
```

lowerFlags

Description: The function lowers the flags of the exception group specified by the input.

<table>
<thead>
<tr>
<th>Value</th>
<th>Exception name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>__BFP754_INVALID</td>
</tr>
<tr>
<td>2</td>
<td>__BFP754_DIVBYZERO</td>
</tr>
<tr>
<td>4</td>
<td>__BFP754_OVERFLOW</td>
</tr>
<tr>
<td>8</td>
<td>__BFP754_UNDERFLOW</td>
</tr>
<tr>
<td>16</td>
<td>__BFP754_INEXACT</td>
</tr>
</tbody>
</table>

Calling interface:
```c
void __binary_lowerFlags(int x);
```

raiseFlags

Description: The function raises the flags of the exception group specified by the input.

Calling interface:
```c
void __binary_raiseFlags(int x);
```
**testFlags**
*Description:* The function returns 1, if and only if any flag of the exception group specified by the input is raised, and 0 otherwise.

*Calling interface:*
```c
int __binary_testFlags(int x);
```

**testSavedFlags**
*Description:* The function returns 1, if and only if any flag of the exception group specified by the input `y` is raised in `x`, and 0 otherwise.

*Calling interface:*
```c
int __binary_testSavedFlags(int x, int y);
```

**restoreFlags**
*Description:* The function restores the flags to their states represented in `x`.

*Calling interface:*
```c
void __binary_restoreFlags(int x);
```

**saveFlags**
*Description:* The function returns a representation of the state of all status flags.

*Calling interface:*
```c
int __binary_saveFlags(void);
```

**getBinaryRoundingDirection**
*Description:* The function returns an integer representing the rounding direction in use.

<table>
<thead>
<tr>
<th>Value</th>
<th>Exception name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>__BFP754_ROUND_TO_NEAREST_EVEN</td>
</tr>
<tr>
<td>1</td>
<td>__BFP754_ROUND_TOWARD_POSITIVE</td>
</tr>
<tr>
<td>2</td>
<td>__BFP754_ROUND_TOWARD_NEGATIVE</td>
</tr>
<tr>
<td>3</td>
<td>__BFP754_ROUND_TOWARD_ZERO</td>
</tr>
</tbody>
</table>

*Calling interface:*
```c
int __binary_getBinaryRoundingDirection(void);
```

**setBinaryRoundingDirection**
*Description:* The function sets the rounding direction based on input integer.

*Calling interface:*
```c
void __binary_setBinaryRoundingDirection(int x);
```

**saveModes**
*Description:* The function saves the values of all dynamic-specifiable modes.

*Calling interface:*
```c
int __binary_saveModes(void);
```
NOTE
saveModes behaves in the same way as getBinaryRoundingDirection does, as the rounding mode is the only dynamic-specifiable mode supported.

**restoreModes**
Description: The function restores the values of all dynamic-specifiable modes to the input.
Calling interface:
int __binary_restoreModes(void);

NOTE
restoreModes behaves in the same way as setBinaryRoundingDirection does, as the rounding mode is the only dynamic-specifiable mode supported.

**defaultMode**
Description: The function sets the values of all dynamic-specifiable modes to default.
Calling interface:
void __binary_defaultMode(void);

NOTE
defaultMode sets the rounding-direction attribute to roundTiesToEven, as the rounding mode is the only dynamic-specifiable mode supported.

**Intel's Numeric String Conversion Library**
Intel's Numeric String Conversion Library, libistrconv, provides a collection of routines for converting between ASCII strings and C data types, which are optimized for performance.

**Overview: Intel's Numeric String Conversion Library**
Intel's Numeric String Conversion Library, libistrconv, provides a collection of routines for converting between ASCII strings and C data types, which are optimized for performance. The istrconv.h header file declares prototypes for the library functions.

You can link the libistrconv library as a static or shared library on Linux* and macOS* platforms. On Windows* platforms, you must link libistrconv as a static library only.
Using Intel's Numeric String Conversion Library

To use the `libistrconv` library, include the header file, `istrconv.h`, in your program.

Consider the following example `conv.c` file that illustrates how to use the library to convert between string and floating-point data type.

```c
// conv.c
#include <stdio.h>
#include <istrconv.h>
#define LENGTH 20

int main() {
    const char pi[] = "3.14159265358979323";
    char s[LENGTH];
    int prec;
    float fx;
    double dx;
    printf("PI: %s\n", pi);
    printf("single-precision\n");
    fx = __IML_string_to_float(pi, NULL);
    prec = 6;
    __IML_float_to_string(s, LENGTH, prec, fx);
    printf("prec: %2d, val: %s\n", prec, s);
    printf("double-precision\n");
    dx = __IML_string_to_double(pi, NULL);
    prec = 15;
    __IML_double_to_string(s, LENGTH, prec, dx);
    printf("prec: %2d, val: %s\n", prec, s);
    return 0;
}
```

To compile the `conv.c` file on Linux* platforms, use the following command:

`icc conv.c -libistrconv`

To compile the `conv.c` file on macOS* platforms, use the following command:

`icc conv.c -libistrconv`

To compile the `conv.c` file on Windows* platforms, use the following command:

`icl conv.c libistrconv.lib`

After you compile this example and run the program, you should get the following results:

```
PI: 3.14159265358979323
single-precision
prec: 6, val: 3.14159
double-precision
prec: 15, val: 3.14159265358979
```

**Integer Conversion Functions Optimized with SSE4.2 Instructions**

The following integer conversion functions are optimized for better performance with SSE4.2 string processing instructions:

- `__IML_int_to_string`
- `__IML_uint_to_string`
- `__IML_int64_to_string`
The SSE4.2 optimized versions of these functions can be deployed in the following situations:

• Used automatically on post-SSE4.2 processors through Intel run-time processor dispatching
• Called directly by defining the "__SSE4_2__" macro to the C preprocessor where <istrconv.h> is included.

The generic versions of these functions can be deployed in the following situations:

• Used automatically on pre-SSE4.2 processors through Intel run-time processor dispatching
• Called directly by adding _generic suffix to the function names

The SSE4.2 optimized versions of these functions moves strings from memory to XMM registers and vice versa directly to maximize performance. The functions would not overwrite the memory beyond the boundary; however, this may introduce memory access violation when the memory location immediately trailing the strings is not allocated or accessible. Users with concerns about potential memory access violation should use the generic versions instead.

Function List

Intel's Numeric String Conversion library (libistrconv) functions are listed in this topic.

Routines to convert floating-point numbers to ASCII strings

Intel's Numeric String Conversion Library supports the following functions to convert floating-point number \( x \) to string \( s \) in various formats, where \( l \) represents the length of the formatted string allowing for full conversion (not including the null terminator).

\[ \_IML\_float\_to\_string, \_IML\_double\_to\_string \]

**Description:** These functions are similar to `snprintf(s, n, "%.g", p, x)` in stdio.h, where \( p \) specifies the maximum number of significant digits in either fixed-point or exponential notation format. If \( n \) is zero, nothing is written and \( s \) may be a null pointer. Output characters beyond the \((n-1)\)th character are discarded and a null character is appended at the end. \( l \) is returned on success; otherwise the result is undefined.

**Calling interface:**

```c
int \_IML\_float\_to\_string(char * s, size_t n, int p, float x);
int \_IML\_double\_to\_string(char * s, size_t n, int p, double x);
\_IML\_float\_to\_string\_f, \_IML\_double\_to\_string\_f
```
Description: These functions are similar to `snprintf(s, n, "%.*f", p, x)` in `stdio.h`, where `p` specifies the number of digits after the decimal point in the fixed-point notation format. If `n` is zero, nothing is written and `s` may be a null pointer. Output characters beyond the `(n-1)th` character are discarded and a null character is appended at the end. `l` is returned on success; otherwise the result is undefined.

Calling interface:

```c
int _IML_float_to_string_f(char * s, size_t n, int p, float x);
int _IML_double_to_string_f(char * s, size_t n, int p, double x);
```

Description: These functions are similar to `snprintf(s, n, "%.*e", p, x)` in `stdio.h`, where `p` specifies the number of digits after the decimal point in the exponential notation format. If `n` is zero, nothing is written and `s` may be a null pointer. Output characters beyond the `(n-1)th` character are discarded and a null character is appended at the end. `l` is returned on success; otherwise, the result is undefined.

Calling interface:

```c
int _IML_float_to_string_e(char * s, size_t n, int p, float x);
int _IML_double_to_string_e(char * s, size_t n, int p, double x);
```

Description: These functions are similar to `snprintf(s, n, "%.*g", p, x)` in `stdio.h`, where `p` specifies the maximum number of significant digits in either fixed-point or exponential notation format. If `l < n`, all output characters are stored in `s` with a null terminator at the end. Otherwise, output characters beyond the `nth` character are discarded and no null character is appended at the end. If `n` is zero, nothing is written and `s` may be a null pointer. `l` is returned on success; otherwise the result is undefined.

Calling interface:

```c
int _IML_f_to_str(char * s, size_t n, int p, float x);
int _IML_d_to_str(char * s, size_t n, int p, double x);
```

Description: These functions are similar to `snprintf(s, n, "%.*f", p, x)` in `stdio.h`, where `p` specifies the number of digits after the decimal point in the fixed-point notation format. If `l < n`, all output characters are stored in `s` with a null terminator at the end. Otherwise, output characters beyond the `nth` character are discarded and no null character is appended at the end. If `n` is zero, nothing is written and `s` may be a null pointer. `l` is returned on success; otherwise the result is undefined.

Calling interface:

```c
int _IML_f_to_str_f(char * s, size_t n, int p, float x);
int _IML_d_to_str_f(char * s, size_t n, int p, double x);
```

Description: These functions are similar to `snprintf(s, n, "%.*e", p, x)` in `stdio.h`, where `p` specifies the number of digits after the decimal point in the exponential notation format. If `l < n`, all output characters are stored in `s` with a null terminator at the end. Otherwise, output characters beyond the `nth` character are discarded and no null character is appended at the end. If `n` is zero, nothing is written and `s` may be a null pointer. `l` is returned on success; otherwise the result is undefined.

Calling interface:

```c
int _IML_f_to_str_e(char * s, size_t n, int p, float x);
int _IML_d_to_str_e(char * s, size_t n, int p, double x);
```
int __IML_d_to_str_e(char * s, size_t n, int p, double x);

**Routines to convert integers to ASCII strings**

Intel's Numeric String Conversion Library supports the following functions to convert integer x to string s, where l represents the length of the formatted string allowing for full conversion (not including the null terminator).

__IML_int_to_string, __IML_uint_to_string, __IML_int64_to_string, __IML_uint64_to_string  

**Description:** These functions are similar to `snprintf(s, n, "%[d|u|lld|llu]", x)` in stdio.h. If n is zero, nothing is written and s may be a null pointer. Output characters beyond the (n-1)th character are discarded and a null character is appended at the end. l is returned on success; otherwise the result is undefined.

**Calling interface:**

int __IML_int_to_string(char * s, size_t n, int x);
int __IML_uint_to_string(char * s, size_t n, unsigned int x);
int __IML_int64_to_string(char * s, size_t n, long long x);
int __IML_uint64_to_string(char * s, size_t n, unsigned long long x);

__IML_int_to_oct_string, __IML_uint_to_oct_string, __IML_int64_to_oct_string, __IML_uint64_to_oct_string  

**Description:** These functions are similar to `snprintf(s, n, "%[o|llo]", x)` in stdio.h. If n is zero, nothing is written and s may be a null pointer. Output characters beyond the (n-1)th character are discarded and a null character is appended at the end. l is returned on success; otherwise the result is undefined.

**Calling interface:**

int __IML_int_to_oct_string(char * s, size_t n, int x);
int __IML_uint_to_oct_string(char * s, size_t n, unsigned int x);
int __IML_int64_to_oct_string(char * s, size_t n, long long x);
int __IML_uint64_to_oct_string(char * s, size_t n, unsigned long long x);

__IML_int_to_hex_string, __IML_uint_to_hex_string, __IML_int64_to_hex_string, __IML_uint64_to_hex_string  

**Description:** These functions are similar to `snprintf(s, n, "%[x|llx]", x)` in stdio.h. If n is zero, nothing is written and s may be a null pointer. Output characters beyond the (n-1)th character are discarded and a null character is appended at the end. l is returned on success; otherwise the result is undefined.

**Calling interface:**

int __IML_int_to_hex_string(char * s, size_t n, int x);
int __IML_uint_to_hex_string(char * s, size_t n, unsigned int x);
int __IML_int64_to_hex_string(char * s, size_t n, long long x);
int __IML_uint64_to_hex_string(char * s, size_t n, unsigned long long x);

__IML_i_to_str, __IML_u_to_str, __IML_ll_to_str, __IML_ull_to_str  

**Description:** These functions are similar to `snprintf(s, n, "%[d|u|lld|llu]", x)` in stdio.h. If l < n, all output characters are stored in s with a null terminator at the end. Otherwise, output characters beyond the nth character are discarded and no null character is appended at the end. If n is zero, nothing is written, and s may be a null pointer. l is returned on success, otherwise the result is undefined.
Calling interface:

```c
int __IML_i_to_str(char * s, size_t n, int x);
int __IML_u_to_str(char * s, size_t n, unsigned int x);
int __IML_ll_to_str(char * s, size_t n, long long x);
int __IML_ull_to_str(char * s, size_t n, unsigned long long x);
```

--\_IML_i_to_oct_str, __IML_u_to_oct_str, __IML_ll_to_oct_str, __IML_ull_to_oct_str

**Description:** These functions are similar to `snprintf(s, n, "%[o|llo]", x)` in `stdio.h`. If \( l < n \), all output characters are stored in \( s \) with a null terminator at the end. Otherwise, output characters beyond the \( n \)th character are discarded and no null character is appended at the end. If \( n \) is zero, nothing is written, and \( s \) may be a null pointer. \( l \) is returned on success, otherwise the result is undefined.

Calling interface:

```c
int __IML_i_to_oct_str(char * s, size_t n, int x);
int __IML_u_to_oct_str(char * s, size_t n, unsigned int x);
int __IML_ll_to_oct_str(char * s, size_t n, long long x);
int __IML_ull_to_oct_str(char * s, size_t n, unsigned long long x);
```

--\_IML_i_to_hex_str, __IML_u_to_hex_str, __IML_ll_to_hex_str, __IML_ull_to_hex_str

**Description:** These functions are similar to `snprintf(s, n, "%[x|llx]", x)` in `stdio.h`. If \( l < n \), all output characters are stored in \( s \) with a null terminator at the end. Otherwise, output characters beyond the \( n \)th character are discarded and no null character is appended at the end. If \( n \) is zero, nothing is written, and \( s \) may be a null pointer. \( l \) is returned on success, otherwise the result is undefined.

Calling interface:

```c
int __IML_i_to_hex_str(char * s, size_t n, int x);
int __IML_u_to_hex_str(char * s, size_t n, unsigned int x);
int __IML_ll_to_hex_str(char * s, size_t n, long long x);
int __IML_ull_to_hex_str(char * s, size_t n, unsigned long long x);
```

**Routines to convert ASCII strings to floating-point numbers**

Intel's Numeric String Conversion Library supports the following functions to convert the initial portion of decimal string \( s \) to floating-point number \( x \). If no conversion could be performed, zero is returned. If the correct value is outside the range of the return type, plus (+) or minus (-) `HUGE_VALF`, `HUGE_VAL`, or `HUGE_VALL` is returned, and the value of macro `ERANGE` is stored in `errno`.

\( __IML_string_to_float, __IML_string_to_double, __IML_string_to_long_double \)

**Description:** These functions are similar to `strtof(nptr, endptr)`, `strtod(nptr, endptr)`, and `strtol(nptr, endptr)` in `stdlib.h`, where `endptr` points to the object that stores the final part of `nptr` when `endptr` is not a null pointer.

Calling interface:

```c
float __IML_string_to_float(const char * nptr, char ** endptr);
double __IML_string_to_double(const char * nptr, char ** endptr);
long double __IML_string_to_long_double(const char * nptr, char ** endptr);
```

\( __IML_str_to_f, __IML_str_to_d, __IML_str_to_ld \)
**Description:** These functions convert the initial $n$ decimal digits of the significand string multiplied by 10 raised to power of exponent to floating-point number as return. endptr points to the object that stores the final part of significand, provided that endptr is not a null pointer.

**Calling interface:**

```c
float __IML_str_to_f(const char * significand, size_t n, int exponent, char ** endptr);
double __IML_str_to_d(const char * significand, size_t n, int exponent, char ** endptr);
long double __IML_str_to_ld(const char * significand, size_t n, int exponent, char ** endptr);
```

**Routines to convert ASCII strings to integers**

Intel's Numeric String Conversion Library supports the following functions to convert the initial portion of string s to integer x. If no conversion could be performed, zero is returned. If the correct value is outside the range of the return type, INT_MIN, INT_MAX, UINT_MAX, LLONG_MIN, LLONG_MAX, ULLONG_MAX is returned, and the value of macro ERANGE is stored in errno.

```c
__IML_string_to_int, __IML_string_to_uint, __IML_string_to_int64, __IML_string_to_uint64
```

**Description:** These functions are similar to ([unsigned] int)strtol(nptr, endptr, 10) and strtoll(nptr, endptr, 10) functions in stdlib.h, where endptr points to the object that stores the final part of nptr when endptr is not a null pointer.

**Calling interface:**

```c
int __IML_string_to_int(const char * nptr, char ** endptr);
unsigned int __IML_string_to_uint(const char * nptr, char ** endptr);
long long __IML_string_to_int64(const char * nptr, char ** endptr);
unsigned long long __IML_string_to_uint64(const char * nptr, char ** endptr);
```

**Description:** These functions are similar to ([unsigned] int)strtol(nptr, endptr, 8) and strtoll(nptr, endptr, 8) functions in stdlib.h, where endptr points to the object that stores the final part of nptr when endptr is not a null pointer.

**Calling interface:**

```c
int __IML_oct_string_to_int(const char * nptr, char ** endptr);
unsigned int __IML_oct_string_to_uint(const char * nptr, char ** endptr);
long long __IML_oct_string_to_int64(const char * nptr, char ** endptr);
unsigned long long __IML_oct_string_to_uint64(const char * nptr, char ** endptr);
```

**Description:** These functions are similar to ([unsigned] int)strtol(nptr, endptr, 16) and strtoll(nptr, endptr, 16) functions in stdlib.h, where endptr points to the object that stores the final part of nptr when endptr is not a null pointer.

**Calling interface:**

```c
int __IML_hex_string_to_int(const char * nptr, char ** endptr);
```
unsigned int __IML_hex_string_to_uint(const char * nptr, char ** endptr);
long long __IML_hex_string_to_int64(const char * nptr, char ** endptr);
unsigned long long __IML_hex_string_to_uint64(const char * nptr, char ** endptr);

__IML_str_to_i, __IML_str_to_u, __IML_str_to_ll, __IML_str_to_ull

**Description:** These functions convert the initial \( n \) decimal digits pointed by \( nptr \) to integral values. When \( endptr \) is not a null pointer it points to the object that stores the final part of \( nptr \).

**Calling interface:**

int __IML_str_to_i(const char * nptr, size_t n, char ** endptr);
unsigned int __IML_str_to_u(const char * nptr, size_t n, char ** endptr);
long long __IML_str_to_ll(const char * nptr, size_t n, char ** endptr);
unsigned long long __IML_str_to_ull(const char * nptr, size_t n, char ** endptr);

__IML_oct_str_to_i, __IML_oct_str_to_u, __IML_oct_str_to_ll, __IML_oct_str_to_ull

**Description:** These functions convert the initial \( n \) octal digits pointed by \( nptr \) to integral values. When \( endptr \) is not a null pointer it points to the object that stores the final part of \( nptr \).

**Calling interface:**

int __IML_oct_str_to_i(const char * nptr, size_t n, char ** endptr);
unsigned int __IML_oct_str_to_u(const char * nptr, size_t n, char ** endptr);
long long __IML_oct_str_to_ll(const char * nptr, size_t n, char ** endptr);
unsigned long long __IML_oct_str_to_ull(const char * nptr, size_t n, char ** endptr);

__IML_hex_str_to_i, __IML_hex_str_to_u, __IML_hex_str_to_ll, __IML_hex_str_to_ull

**Description:** These functions convert the initial \( n \) hexadecimal digits pointed by \( nptr \) to integral values. When \( endptr \) is not a null pointer it points to the object that stores the final part of \( nptr \).

**Calling interface:**

int __IML_hex_str_to_i(const char * nptr, size_t n, char ** endptr);
unsigned int __IML_hex_str_to_u(const char * nptr, size_t n, char ** endptr);
long long __IML_hex_str_to_ll(const char * nptr, size_t n, char ** endptr);
unsigned long long __IML_hex_str_to_ull(const char * nptr, size_t n, char ** endptr);

---

**Macros**

**ISO Standard Predefined Macros**

The ISO/ANSI standard for the C language requires that certain predefined macros be supplied with conforming compilers.

The compiler includes predefined macros in addition to those required by the standard. The default predefined macros differ among Windows®, Linux®, and macOS® operating systems due to the default /Za compiler option on Windows®. Differences also exist on Linux® and macOS® as a result of the -std compiler option. The following table lists the macros that the Intel® C++ Compiler supplies in accordance with this standard:
The Intel® C++ Compiler supports the predefined macros listed in the table below. The compiler also includes predefined macros specified by the ISO/ANSI standard. Unless otherwise stated, the macros are supported on systems based on IA-32 and Intel® 64 architectures.

### Additional Predefined Macros

You can specify this symbol to protect code that should only be compiled for and executed on the processor, such as intrinsic functions that only run on Intel® Xeon Phi™ processors, or the corresponding header files, such as zmmintrin.h.
Pragmas

Pragmas are directives that provide instructions to the compiler for use in specific cases. For example, you can use the `#pragma novector` pragma to specify that a loop should never be vectorized. The keyword `#pragma` is standard in the C++ language, but individual pragmas are machine-specific or operating system-specific, and vary by compiler.

Some pragmas provide the same functionality as compiler options. Pragmas override behavior specified by compiler options.

Some pragmas are available for both Intel® and non-Intel microprocessors but they may perform additional optimizations for Intel® microprocessors than they perform for non-Intel microprocessors. Refer to the individual pragma name for detailed description.

The Intel® C++ Compiler pragmas are categorized as follows:

- **Intel-specific Pragmas** - pragmas developed or modified by Intel to work specifically with the Intel® C++ Compiler
- **Intel Supported Pragmas** - pragmas developed by external sources that are supported by the Intel® C++ Compiler for compatibility reasons

### Using Pragmas

You enter pragmas into your C++ source code using the following syntax:

```
#pragma <pragma name>
```

### Individual Pragma Descriptions

Each pragma description has the following details:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short Description</td>
<td>Contains a brief description of what the pragma does.</td>
</tr>
<tr>
<td>Syntax</td>
<td>Contains the pragma syntax.</td>
</tr>
<tr>
<td>Arguments</td>
<td>Contains a list of the arguments (parameters).</td>
</tr>
<tr>
<td>Description</td>
<td>Contains a detailed description of what the pragma does.</td>
</tr>
<tr>
<td>Example</td>
<td>Contains typical usage example/s.</td>
</tr>
</tbody>
</table>
### Intel-specificPragma Reference

The pragmas that are specific to the Intel® C++ Compiler are described below. Click on each pragma name for a more detailed description.

Some pragmas are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alloc_section</td>
<td>Allocates one or more variables in the specified section. Controls section attribute specification for variables.</td>
</tr>
<tr>
<td>cilk grainsize</td>
<td>Specifies the grain size for one cilk_for loop. Intel® Cilk™ Plus is a deprecated feature.</td>
</tr>
<tr>
<td>distribute_point</td>
<td>Instructs the compiler to prefer loop distribution at the location indicated.</td>
</tr>
<tr>
<td>inline</td>
<td>Specifies inlining of all calls in a statement. This also describes pragmas forceinline and noinline.</td>
</tr>
<tr>
<td>intel_omp_task</td>
<td>For Intel legacy tasking, specifies a unit of work, potentially executed by a different thread.</td>
</tr>
<tr>
<td>intel_omp_taskq</td>
<td>For Intel legacy tasking, specifies an environment for the while loop in which to queue the units of work specified by the enclosed task pragma.</td>
</tr>
<tr>
<td>ivdep</td>
<td>Instructs the compiler to ignore assumed vector dependencies.</td>
</tr>
<tr>
<td>loop_count</td>
<td>Specifies the iterations for a for loop.</td>
</tr>
<tr>
<td>nofusion</td>
<td>Prevents a loop from fusing with adjacent loops.</td>
</tr>
<tr>
<td>novector</td>
<td>Specifies that a particular loop should never be vectorized.</td>
</tr>
<tr>
<td>offload</td>
<td>Executes the statements on the target. This pragma applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>offload_attribute</td>
<td>Specifies that all functions and variables declared subsequent to the pragma are available on the target. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>offload_transfer</td>
<td>Initiates and completes a synchronous data transfer. If used with the signal clause, initiates an asynchronous data transfer. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>offload_wait</td>
<td>Specifies a wait for a previously initiated asynchronous data transfer. This pragma only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>optimization_level</td>
<td>Controls optimization for one function or all functions after its first occurrence.</td>
</tr>
<tr>
<td>optimization_parameter</td>
<td>Passes certain information about a function to the optimizer.</td>
</tr>
<tr>
<td>optimize</td>
<td>Enables or disables optimizations for code after this pragma until another optimize pragma or end of the translation unit.</td>
</tr>
<tr>
<td>Pragma</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>parallel/noparallel</td>
<td>Resolves dependencies to facilitate auto-parallelization of the immediately following loop (parallel) or prevents auto-parallelization of the immediately following loop (noparallel).</td>
</tr>
<tr>
<td>prefetch/noprefetch</td>
<td>Invites the compiler to issue or disable requests to prefetch data from memory. This pragma applies only to Intel MIC Architecture and Intel Advanced Vector Extensions 512 (Intel AVX-512).</td>
</tr>
<tr>
<td>simd</td>
<td>Enforces vectorization of loops.</td>
</tr>
<tr>
<td>simdoff</td>
<td>Specifies a block of code in the SIMD loop or SIMD-enabled function that should be executed serially, in a logical order of SIMD lanes.</td>
</tr>
<tr>
<td>unroll/nounroll</td>
<td>Indicates to the compiler to unroll or not to unroll a counted loop.</td>
</tr>
<tr>
<td>unroll_and_jam/</td>
<td>Enables or disables loop unrolling and jamming. These pragmas can only be applied to iterative for loops.</td>
</tr>
<tr>
<td>nounroll_and_jam</td>
<td></td>
</tr>
<tr>
<td>unused</td>
<td>Describes variables that are unused (warnings not generated).</td>
</tr>
<tr>
<td>vector</td>
<td>Indicates to the compiler that the loop should be vectorized according to the argument keywords.</td>
</tr>
</tbody>
</table>

**alloc_section**

Allocates one or more variables in the specified section. Controls section attribute specification for variables.

**Syntax**

```c
#pragma alloc_section(var1, var2, ..., "r;attribute-list")
```

**Arguments**

- **var**
  - A variable that can be used to define a symbol in the section.

- **"r;attribute-list"**
  - A comma-separated list of attributes; defined values are: 'short' and 'long'.

**Description**

The `alloc_section` pragma places the listed variables, `var1`, `var2`, etc., in the specified section. This pragma controls section attribute specification for variables. The compiler decides whether the variable, as defined by `var1`, `var2`, etc., should go to a "data", "bss", or "rdata" section.

The section name must be enclosed in double quotation marks. It should be previously introduced into the program using `#pragma section`. The list of comma-separated variable names follows the section name after a separating comma.

All listed variables must be defined before this pragma, in the same translation unit and in the same scope. The variables have static storage; their linkage does not matter in C modules, but in C++ modules they are defined with the extern "C" linkage specification.
Example: Using #pragma alloc_section

```c
#pragma alloc_section(var1, "r;short")
int var1 = 20;
#pragma alloc_section(var2, "r;short")
extern int var2;
```

**block_loop/noblock_loop**

Enables or disables loop blocking for the immediately following nested loops. BLOCK_LOOP enables loop blocking for the nested loops. NOBLOCK_LOOP disables loop blocking for the nested loops.

**Syntax**

```c
#pragma block_loop [clause[,clause]...]
#pragma noblock_loop
```

**Arguments**

can be any of the following:

- **factor(expr)**  
  expr is a positive scalar constant integer expression representing the blocking factor for the specified loops. This clause is optional. If the factor clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the pragma. At most only one factor clause can appear in a block_loop pragma.

- **level(level_expr[, level_expr]...)**  
  level_expr is specified in the form const1 or const1:const2 where const1 is a positive integer constant m<= 8 representing the loop at level m, where the immediate following loop is level 1. The const2 is a positive integer constant n<= 8 representing the loop at level n, where n > m. const1:const2 represents the nested loops from level const1 through const2.

The clauses can be specified in any order. If you do not specify any clause, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.

**Description**

The block_loop pragma lets you exert greater control over optimizations on a specific loop inside a nested loop.

Using a technique called loop blocking, the block_loop pragma separates large iteration counted loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no level and factor clause, the blocking factor will be determined based on the processor's type and memory access patterns and it will apply to all the levels in the nested loops following this pragma.
You can use the `noblock_loop` pragma to tune the performance by disabling loop blocking for nested loops. The loop-carried dependence is ignored during the processing of `BLOCK_LOOP` pragmas.

```c
#pragma block_loop factor(256) level(1)    /* applies blocking factor 256 to */
#pragma block_loop factor(512) level(2)    /* the top level loop in the following
nested loop and blocking factor 512 to */
#pragma block_loop factor(256) level(2)    /* the 2nd level (1st nested) loop */
#pragma block_loop factor(512) level(1)    /* levels can be specified in any order */
#pragma block_loop factor(256) level(1:2)   /* adjacent loops can be specified as a range */
#pragma block_loop factor(256)              /* the blocking factor applies to all levels */
#pragma noblock_loop                        /* the blocking factor will be determined based on */
#pragma noblock_loop                        /* processor type and memory access patterns and will */
#pragma noblock_loop                        /* be applied to all the levels in the nested loop */
#pragma noblock_loop                        /* following the directive */
```

Consider the following:

```c
#pragma block_loop factor(256) level(1:2)
for (j = 1 ; j<n ; j++){
    f = 0 ;
    for (i =1 ;i<n i++){
        f = f + a[i] * b [i] ;
    }
    c [j]  = c[j]  + f ;
}
```

The above code produces the following result after loop blocking:

```c
for ( jj=1 ; jj<n/256+1 ; jj+){
    for ( ii = 1 ; ii<n/256+1 ;ii++){
        for ( j = (jj-1)*256+1 ;  min(jj*256, n) ;j++){
            f = 0 ;
            for ( i = (ii-1)*256+1 ;i<min(ii*256,n) ;i++){
                f = f + a[i] * b [i];
            }
            c[j]  = c[j]  + f ;
        }
    }
}
```

cilk grainsize

Specifies the grain size for one cilk_for loop.

**Syntax**

```c
#pragma cilk grainsize = expression
```
Arguments

expression

Specifies the grain size of a loop. The expression is evaluated at run time. The result of a grain size less than zero is undefined. If the grainsize pragma is omitted or a grainsize of zero is specified, the system calculates a default value that works well for most loops.

Description

This pragma allows you to specify the grain size for a single instance of a cilk_for loop.

The grain size is the maximum number of iterations that the cilk_for loop will spawn as a single chunk. The cilk_for statement divides the loop into chunks (grains) containing one or more loop iterations. Each grain is executed serially and is spawned as a chunk during the execution of the loop.

For loops where individual iterations are particularly large or where the amount of work varies widely between iterations, use this pragma to reduce the grain size, probably down to 1. A small grain size increases parallelism and improves load balancing at the cost of increased scheduling and function call overhead. In general, the larger and more unbalanced the loop iterations, the smaller the grain size should be.

For loops whose body is short, use a larger grain size to reduce the scheduling overhead. For grain sizes larger than 1000 to 2000 iterations, the overhead of the cilk_for statement becomes inconsequential, even when the amount of work per iteration is very small. Thus, the benefit of increasing the grain size beyond these numbers is negligible. Using a grain size that is too large will reduce parallelism and impede load balancing. Specifically, you should not try to divide the loop, so that there is one grain per worker (CPU), as that will completely defeat the scheduler's attempts at load balancing and will almost certainly result in lost performance.

The default grainsize, when this pragma is not used, works well for most loops. If you do choose to change the grain size, be sure to carry out performance testing to ensure that you have made the loop faster, not slower.

If you do not specify a grain size or if you specify a grain size of zero, the system calculates the default value as if the following pragma were used:

```
#pragma cilk grainsize = min(2048, ceil(N / (8 * p)))
```

where:

- \( N \) is the number of loop iterations.
- \( p \) is the number of workers created during the current run of the program.

This formula provides good results for most loops. For loops with less than eight times the number of workers, the grain size is set to 1 and each loop iteration may be run in parallel. For loops with more than 16,484 times the number of workers iterations, the grain size will be set to 2048.

**NOTE**

The formula for calculating the default value is not part of the Intel® Cilk™ Plus specification.

---

**Example: Setting grain size according to the number of workers**

```c
#pragma cilk grainsize = n/(410*_cilkrts_get_nworkers())
```

This example sets the grain size according to the number of workers, so the grain size will be smaller on systems with more cores (and hence more workers):
**code_align**
Specifies the byte alignment for a loop

**Syntax**
#pragma code_align(n)

**Arguments**
- `n`
  Optional. A positive integer initialization expression indicating the number of bytes for the minimum alignment boundary. Its value must be a power of 2, between 1 and 4096, such as 1, 2, 4, 8, and so on.

  If you specify 1 for `n`, no alignment is performed. If you do not specify `n`, the default alignment is 16 bytes.

**Description**
This pragma must precede the loop to be aligned. If the code is compiled with the Qalign-loops:m option, and a `code_align(n)` pragma precedes a loop, the loop is aligned on a max `(m, n)` byte boundary. If a procedure has the `code_align(k)` attribute and a `code_align(n)` pragma precedes a loop, then both the procedure and the loop are aligned on a max `(k, n)` byte boundary.

**distribute_point**
Instructs the compiler to prefer loop distribution at the location indicated.

**Syntax**
#pragma distribute_point

**Arguments**
- None

**Description**
The `distribute_point` pragma is used to suggest to the compiler to split large loops into smaller ones; this is particularly useful in cases where optimizations like vectorization cannot take place due to excessive register usage.

The following rules apply to this pragma:
- When the pragma is placed inside a loop, the compiler distributes the loop at that point. All loop-carried dependencies are ignored.
- When inside the loop, pragmas cannot be placed within an `if` statement.
- When the pragma is placed outside the loop, the compiler distributes the loop based on an internal heuristic. The compiler determines where to distribute the loops and observes data dependency. If the pragmas are placed inside the loop, the compiler supports multiple instances of the pragma.

**Example: Using the distribute_point pragma outside the loop**

```c
#define NUM 1024
void loop_distribution_pragma1(
    double a[NUM], double b[NUM], double c[NUM],
    double x[NUM], double y[NUM], double z[NUM] ) {
```
Example: Using the `distribute_point` pragma outside the loop

```c
int i;

// Before distribution or splitting the loop
#pragma distribute_point
for (i=0; i< NUM; i++) {
    a[i] = a[i] + i;
    b[i] = b[i] + i;
    c[i] = c[i] + i;
    x[i] = x[i] + i;
    y[i] = y[i] + i;
    z[i] = z[i] + i;
}
```

Example: Using the `distribute_point` pragma inside the loop

```c
#define NUM 1024
void loop_distribution_pragma2(
    double a[NUM], double b[NUM], double c[NUM],
    double x[NUM], double y[NUM], double z[NUM] ) {
    int i;

    // After distribution or splitting the loop.
    for (i=0; i< NUM; i++) {
        a[i] = a[i] +i;
        b[i] = b[i] +i;
        c[i] = c[i] +i;
        //pragma distribute_point
        x[i] = x[i] +i;
        y[i] = y[i] +i;
        z[i] = z[i] +i;
    }
}
```

Example: Using the `distribute_point` pragma inside and outside the loop

```c
void dist1(int a[], int b[], int c[], int d[]) {
    #pragma distribute_point
    // Compiler will automatically decide where to
    // distribute. Data dependency is observed.
    for (int i=1; i<1000; i++) {
        b[i] = a[i] + 1;
        c[i] = a[i] + b[i];
        d[i] = c[i] + 1;
    }
}

void dist2(int a[], int b[], int c[], int d[]) {
    for (int i=1; i<1000; i++) {
        b[i] = a[i] + 1;
        #pragma distribute_point
    }
}
Example: Using the distribute_point pragma inside and outside the loop

```c
// Distribution will start here,
// ignoring all loop-carried dependency.
c[i] = a[i] + b[i];
d[i] = c[i] + 1;
}
```

**inline, noinline, forceinline**

*Specifies inlining of all calls in a statement. This also describes pragmas forceinline and noinline.*

**Syntax**

```c
#pragma inline [recursive]
#pragma forceinline [recursive]
#pragma noinline
```

**Arguments**

- `recursive` indicates that the pragma applies to all of the calls that are called by these calls, recursively, down the call chain.

**Description**

These are statement-specific inlining pragmas. Each can be placed before a C/C++ statement, and will then apply to all of the calls within a statement and all calls within statements nested within that statement.

The `forceinline` pragma indicates that the calls in question should be inlined whenever the compiler is capable of doing so.

The `inline` pragma is a hint to the compiler that the user prefers that the calls in question be inlined, but expects the compiler not to inline them if its heuristics determine that the inlining would be overly aggressive and might slow down the compilation of the source code excessively, create too large of an executable, or degrade performance.

The `noinline` pragma indicates that the calls in question should not be inlined.

These statement-specific pragmas take precedence over the corresponding function-specific pragmas.

Example: Using the `forceinline` recursive pragma

```c
#include <stdio.h>

static void fun(float a[100][100], float b[100][100]) {
    int i, j;
    for (i = 0; i < 100; i++) {
        for (j = 0; j < 100; j++) {
            a[i][j] = 2 * i;
            b[i][j] = 4 * j;
        }
    }
}
```
The `forceinline recursive` pragma applies to the call 'sun(a,b)' as well as the call 'fun(a,b)' called inside 'sun(a,b)'.

**intel_omp_task**

*For Intel legacy tasking, specifies a unit of work, potentially executed by a different thread.*

**Syntax**

```
#pragma intel_omp_task [clause[,clause]...]  
structured-block
```

**Arguments**

*clause*

Can be any of the following:

- **private**(variable-list)

  Creates a private, default-constructed version for each object in `variable-list` for the task. The original object referenced by the variable has an indeterminate value upon entry to the construct,
must not be modified within the dynamic extent of the construct, and has an indeterminate value upon exit from the construct.

**captureprivate**(variable-list) Creates a private, copy-constructed version for each object in variable-list for the task at the time the task is queued. The original object referenced by each variable retains its value but must not be modified within the dynamic extent of the task construct.

**Description**

The **intel_omp_task** pragma specifies a unit of work, potentially executed by a different thread.

**NOTE** This pragma affects parallelization done using the -qopenmp option. Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

**intel_omp_taskq**

*For Intel legacy tasking, specifies an environment for the while loop in which to queue the units of work specified by the enclosed task pragma.*

**Syntax**

```
#pragma intel_omp_taskq[[,]clause]... structured-block
```

**Arguments**

<table>
<thead>
<tr>
<th>clause</th>
<th>Can be any of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>private</strong>(variable-list)</td>
<td>Creates a private, default-constructed version for each object in variable-list for the taskq. It also implies captureprivate on each enclosed task. The original object referenced by each variable has an indeterminate value upon entry to the construct, must not be modified within the dynamic extent of the construct, and has an indeterminate value upon exit from the construct.</td>
</tr>
<tr>
<td><strong>firstprivate</strong>(variable-list)</td>
<td>Creates a private, copy-constructed version for each object in variable-list for the taskq. It also implies captureprivate on each enclosed task. The original object referenced by each variable must not be modified within the dynamic extent of the task construct.</td>
</tr>
</tbody>
</table>
be modified within the dynamic extent of the construct and has an indeterminate value upon exit from the construct.

**lastprivate**(variable-list) Creates a private, default-constructed version for each object in variable-list for the taskq. It also implies captureprivate on each enclosed task. The original object referenced by each variable has an indeterminate value upon entry to the construct, must not be modified within the dynamic extent of the construct, and is copy-assigned the value of the object from the last enclosed task after that task completes execution.

**reduction**(operator : variable-list) Performs a reduction operation with the given operator in enclosed task constructs for each object in variable-list. operator and variable-list are defined the same as in the OpenMP* Specifications.

**ordered** Organizes ordered constructs in enclosed task constructs in original sequential execution order. The taskq pragma, to which the ordered is bound, must have an ordered clause present.

**nowait** Removes the implied barrier at the end of the taskq. Threads may exit the taskq construct before completing all the task constructs queued within it.

**Description**

The `intel_omp_taskq` pragma specifies the environment within which the enclosed units of work (tasks) are to be executed. From among all the threads that encounter a `taskq` pragma, one is chosen to execute it initially.

Conceptually, the `taskq` pragma causes an empty queue to be created by the chosen thread, and then the code inside the `taskq` block is executed as single-threaded. All the other threads wait for work to be queued on the conceptual queue.

The `task` pragma specifies a unit of work, potentially executed by a different thread. When a `task` pragma is encountered lexically within a `taskq` block, the code inside the `task` block is conceptually queued on the queue associated with the `taskq`. The conceptual queue is disbanded when all work queued on it finishes, and when the end of the `taskq` block is reached.

**NOTE** This pragma affects parallelization done using the Qopenmp (Windows*) or qopenmp (Linux* or macOS*) option. Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.
ivdep
Instructs the compiler to ignore assumed vector dependencies.

Syntax
#pragma ivdep

Arguments
None

Description
The ivdep pragma instructs the compiler to ignore assumed vector dependencies. To ensure correct code, the compiler treats an assumed dependence as a proven dependence, which prevents vectorization. This pragma overrides that decision. Use this pragma only when you know that the assumed loop dependencies are safe to ignore.

In addition to the ivdep pragma, the vector pragma can be used to override the efficiency heuristics of the vectorizer.

NOTE
The proven dependencies that prevent vectorization are not ignored, only assumed dependencies are ignored.

Examples

Example

```c
void ignore_vec_dep(int *a, int k, int c, int m) {
    #pragma ivdep
    for (int i = 0; i < m; i++)
        a[i] = a[i + k] * c;
}
```

The loop in this example will not vectorize without the ivdep pragma, since the value of k is not known; vectorization would be illegal if k<0.

The pragma binds only the for loop contained in current function. This includes a for loop contained in a sub-function called by the current function.

Example

```c
#pragma ivdep
for (i=1; i<n; i++) {
    e[ix[2][i]] = e[ix[2][i]]+1.0;
    e[ix[3][i]] = e[ix[3][i]]+2.0;
}
```

This loop requires the parallel option in addition to the ivdep pragma to indicate there is no loop-carried dependencies:
Example

```c
#pragma ivdep
    for (j=0; j<n; j++) { a[b[j]] = a[b[j]] + 1; }
```

This loop requires the parallel option in addition to the `ivdep` pragma to ensure there is no loop-carried dependency for the store into `a()`.

novector  
vector  

`loop_count`

*Specifies the iterations for a for loop.*

**Syntax**

```
#pragma loop_count(n)
#pragma loop_count=n
```

or

```
#pragma loop_count(n1[, n2]...)
#pragma loop_count=n1[, n2]...
```

or

```
#pragma loop_count min(n), max(n), avg(n)
#pragma loop_count min=n, max=n, avg=n
```

**Arguments**

- `(n) or =n`
  
  A non-negative integer value. The compiler will attempt to iterate the next loop the number of times specified in `n`; however, the number of iterations is not guaranteed.

- `(n1[,n2]...) or = n1[,n2]...`
  
  Non-negative integer values. The compiler will attempt to iterate the next loop the number of time specified by `n1` or `n2`, or some other unspecified number of times. This behavior allows the compiler some flexibility in attempting to unroll the loop. The number of iterations is not guaranteed.

- `min(n), max(n), avg(n) or min=n, max=n, avg=n`
  
  Non-negative integer values. Specify one or more in any order without duplication. The compiler insures the next loop iterates for the specified maximum, minimum, or average number (`n1`) of times. The specified number of iterations is guaranteed for min and max.

**Description**

The `loop_count` pragma specifies the minimum, maximum, or average number of iterations for a `for` loop. In addition, a list of commonly occurring values can be specified to help the compiler generate multiple versions and perform complete unrolling.

You can specify more than one pragma for a single loop; however, do not duplicate the pragma.

**Example**

The following example illustrates how to use the pragma to iterate through the loop a minimum of three, a maximum of ten, and average of five times.

<table>
<thead>
<tr>
<th>Example: Using the loop_count pragma min(n), max(n), avg(n)</th>
</tr>
</thead>
<tbody>
<tr>
<td>#include &lt;stdio.h&gt;</td>
</tr>
<tr>
<td>int i;</td>
</tr>
<tr>
<td>int mysum(int start, int end, int a) {</td>
</tr>
<tr>
<td>int iret=0;</td>
</tr>
<tr>
<td>#pragma loop_count min(3), max(10), avg(5)</td>
</tr>
<tr>
<td>for (i=start;i&lt;=end;i++)</td>
</tr>
<tr>
<td>iret += a;</td>
</tr>
<tr>
<td>return iret;</td>
</tr>
<tr>
<td>}</td>
</tr>
<tr>
<td>int main() {</td>
</tr>
<tr>
<td>int t;</td>
</tr>
<tr>
<td>t = mysum(1, 10, 3);</td>
</tr>
<tr>
<td>printf(&quot;t1=%d\n&quot;,t);</td>
</tr>
<tr>
<td>t = mysum(2, 6, 2);</td>
</tr>
<tr>
<td>printf(&quot;t2=%d\n&quot;,t);</td>
</tr>
<tr>
<td>t = mysum(5, 12, 1);</td>
</tr>
<tr>
<td>printf(&quot;t3=%d\n&quot;,t);</td>
</tr>
<tr>
<td>}</td>
</tr>
</tbody>
</table>

**nofusion**

Prevents a loop from fusing with adjacent loops.

**Syntax**

#pragma nofusion

**Arguments**

None

**Description**

The nofusion pragma lets you fine tune your program on a loop-by-loop basis. This pragma should be placed immediately before the loop that should not be fused.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>#define SIZE 1024</td>
</tr>
<tr>
<td>int sub () {</td>
</tr>
<tr>
<td>int B[SIZE], A[SIZE];</td>
</tr>
<tr>
<td>int i, j, k=0;</td>
</tr>
<tr>
<td>for(j=0; j&lt;SIZE; j++)</td>
</tr>
<tr>
<td>#pragma nofusion</td>
</tr>
<tr>
<td>for (i=0; i&lt;SIZE; i++)</td>
</tr>
</tbody>
</table>
novector
Specifies that a particular loop should never be vectorized.

Syntax
#pragma novector

Arguments
None

Description
The novector pragma specifies that a particular loop should never be vectorized, even if it is legal to do so. When avoiding vectorization of a loop is desirable (when vectorization results in a performance regression rather than improvement), the novector pragma can be used in the source text to disable vectorization of a loop. This behavior is in contrast to the vector always pragma.

Example: Using the novector pragma

```c
void foo(int lb, int ub) {
    #pragma novector
    for(j=lb; j<ub; j++) { a[j]=a[j]+b[j]; }
}
```

When the trip count \( (ub - lb) \) is too low to make vectorization worthwhile, you can use the novector pragma to tell the compiler not to vectorize, even if the loop is considered vectorizable.

Function Annotations and the SIMD Directive for Vectorization

vector pragma

offload
Executes the statements on the target. This pragma applies to Intel® MIC Architecture.

Syntax
#pragma offload clause[, clause...] <expression-stmt>

Where clause can be the following required and optional clauses:

Required Clauses
- offload-parameter
- target ( target-name [:target-number ] )

Optional Clauses

Example

```c
k += A[i] + 1;
return k;
}
• if (if-clause)
• mandatory
• optional
• signal (tag)
• status (statusvarname)

This clause is only available on Intel® MIC Architecture.

• stream (handle)

This clause is only available on Intel® MIC Architecture.

• wait (tag [, tag, ...])

**Arguments**

**Required Clauses**

*offload-parameter*

Controls how the program variables and the amount of data are copied between the host and the target. This clause can be one of the following:

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>The variable is strictly an input to the target region. The value is not copied back after the region completes. Syntax: <code>in (variable-ref [, variable-ref ...] [modifier [modifier ...]])</code></td>
</tr>
<tr>
<td>out</td>
<td>The variable is strictly an output of the target region. The host does not copy the variable to the target. Syntax: <code>out (variable-ref [, variable-ref ...] [modifier [modifier ...]])</code></td>
</tr>
<tr>
<td>inout</td>
<td>The variable is both copied from the host to the target and back from the target to the host. Syntax: <code>inout (variable-ref [, variable-ref ...] [modifier [modifier ...]])</code></td>
</tr>
<tr>
<td>nocopy</td>
<td>A variable whose value is reused from a previous target execution or one that is used entirely within the offloaded code section may be named in a nocopy clause to avoid any copying. Syntax: <code>nocopy (variable-ref [, variable-ref ...] [modifier [modifier ...]])</code></td>
</tr>
<tr>
<td>pin</td>
<td>A variable whose value is shared between the host and the target. Syntax: <code>pin (variable-ref [, variable-ref ...] [modifier [modifier ...]])</code></td>
</tr>
</tbody>
</table>

The data selected for transfer is a combination of variables implicitly transferred because the variables are lexically referenced within offload constructs, and variables explicitly listed in offload-parameter.

An in or out `element-count-expr` expression (see description below within modifier) is evaluated at a point in the program before the statement or clause in which it is used.
An array variable whose size is known from the declaration is copied in its entirety. If a subset of an array is to be processed, use a pointer to the starting element of the subset and the `element-count-expr` to transfer the array subset.

Because a data pointer variable not listed in an `in` clause is uninitialized within the construct, it must be assigned a value before it can be dereferenced.

The following are the variables to use with this argument:

<table>
<thead>
<tr>
<th>variable-ref</th>
<th>Is one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• A C/C++ identifier.</td>
</tr>
<tr>
<td></td>
<td>• <code>variable-ref.identifier</code></td>
</tr>
<tr>
<td></td>
<td>Use the following syntax for the variables in this arguments:</td>
</tr>
<tr>
<td></td>
<td>• <code>var: length(j)</code></td>
</tr>
<tr>
<td></td>
<td>• <code>var[0:length]</code></td>
</tr>
<tr>
<td></td>
<td>• <code>array-slice</code></td>
</tr>
<tr>
<td></td>
<td>An expression that denotes one contiguous set of array elements.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>modifier</th>
<th>Is one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <code>align (align-expression)</code></td>
</tr>
<tr>
<td></td>
<td>where value of <code>expression</code> is a scalar integral expression or an array slice expression. This modifier is only available on Intel® MIC Architecture. Use it with:</td>
</tr>
<tr>
<td></td>
<td>• Pointer variables.</td>
</tr>
<tr>
<td></td>
<td><code>align-expression</code> must be a scalar integral expression. It specifies the minimum alignment for pointer data allocated on the target. The value must be a power of two.</td>
</tr>
<tr>
<td></td>
<td>• Pointer arrays.</td>
</tr>
<tr>
<td></td>
<td><code>align-expression</code> may be either a scalar integral expression or an array slice expression. The specified value(s) requests the minimum alignment for pointer data allocated on the target. The value(s) must be a power of two.</td>
</tr>
<tr>
<td></td>
<td>• <code>alloc (array-slice)</code></td>
</tr>
<tr>
<td></td>
<td>where <code>array-slice</code> specifies a set of elements of the array that need allocation. Data specified by the <code>in/out</code> expression is transferred into the corresponding section of the array allocated on the target. This modifier is only available on Intel® MIC Architecture.</td>
</tr>
</tbody>
</table>
Use the following syntax for the argument in this modifier:

- `var[start : length]`

For more information, see Allocating Memory for Parts of Arrays.

- `alloc_if (condition)`

where `condition` is a scalar Boolean expression or a Boolean array slice expression. Use it with:

- Pointer variables.
  
  `condition` must be a scalar Boolean expression. It controls whether to allocate the memory allocated for the variables in the `in/out/inout/nocopy` clause. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused (data persistence). You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a `free_if (0)` clause on an earlier offload.

- Pointer arrays.
  
  `condition` may be either a Boolean expression or a Boolean array slice expression. The specified value(s) control whether to allocate the memory for the variables in the `in/out/inout/nocopy` clause on the target.

  `condition` that is an array slice expression specifies a set of Boolean values that apply one-to-one with the pointers in the pointer array. The first Boolean value applies to the first pointer, the second Boolean value to the second pointer, and so on.

The following are the default settings for this modifier:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>true</td>
</tr>
<tr>
<td>inout</td>
<td>true</td>
</tr>
<tr>

- `alloc_extent (start : length)`

where `start` and `length` are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. This modifier is only available on Intel® MIC Architecture. Use this modifier with:
• Pointer arrays.

\textit{start} and \textit{length} may be integral expressions or array slice expressions. If an integral expression is specified then it is assumed to apply to each of the pointers. If an array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.

\textit{start} specifies the first element to be allocated on the target. \textit{length} specifies the number of elements to allocate. If \textit{start} is negative a runtime error occurs.

• \texttt{extent ( start : length )}

where \texttt{start} and \texttt{length} are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. Use this modifier with:

• Pointer arrays.

The values of the pointers in the array are never copied across the host/target interface because there is no correspondence between the memory addresses of the host and the target. Instead, objects that the pointers point to are copied to or from the target, and the pointer array is recreated.

\textit{start} and \textit{length} may be integral expressions or array slice expressions. If an integral expression is specified, it is assumed to apply to each of the pointers. If an array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.

\textit{start} specifies the first element to be transferred. \textit{length} specifies the number of elements to transfer. If \textit{start} is negative a runtime error occurs.

• \texttt{free_if (condition)}

where \texttt{condition} is a scalar Boolean expression or a Boolean array slice expression. Use it with:

• Pointer variables.

\texttt{condition} must be a scalar Boolean expression. It controls whether to deallocate the memory allocated for the variables in the \texttt{in/out/inout/nocopy} clause. If the expression evaluates to \texttt{false}, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

• Pointer arrays.
**condition** may be either a Boolean expression or a Boolean array slice expression. The specified value(s) control whether to deallocate the memory for the variables in the **in/out/inout/nocopy** clause on the target.

**condition** that is an array slice expression specifies a set of Boolean values that apply one-to-one with the pointers in the pointer array. The first Boolean value applies to the first pointer, the second Boolean value to the second pointer, and so on.

The following are the default settings for this modifier:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>true</td>
</tr>
<tr>
<td>inout</td>
<td>true</td>
</tr>
<tr>
<td>out</td>
<td>true</td>
</tr>
<tr>
<td>nocopy</td>
<td>false</td>
</tr>
</tbody>
</table>

For more information, see Managing Memory Allocation for Pointer Variables.

- **into** (`var-exp`)

  where `var-exp` is a variable expression. This modifier allows data to be transferred from one variable on the host to another variable on the target, and vice versa. Only one item is allowed in **variable-ref** when using this modifier. This modifier is only available on Intel® MIC Architecture.

  Use the following syntax for the argument in this clause:
  
  - `var` (when a **length** modifier is also used).
  - `var[start:length]` (when a separate **length**
    modifier is not used).

  For more information, see Moving Data from One Variable to Another.

- **into_extent** (`start:length`)

  where `start` and `length` are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. This modifier is only available on Intel® MIC Architecture. Use this modifier with:

  - Pointer arrays used with the **into** modifier.

  `start` and `length` may be integral expressions or array slice expressions. If an integral expression is specified, it is assumed to apply to each of the pointers. If an
array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.

`start` specifies the first element to allocated on the target. `length` specifies the number of elements to allocate. If `start` is negative a runtime error occurs.

- `length (element-count-expr)`

where `element-count-expr` is a scalar integral expression or an array slice expression, computed at runtime. Use it with:

- Pointer variables.
  
  Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host and the target. Instead, objects that a pointer points to are copied to or from the target, and the value of the pointer variable is recreated.

  You can use a scalar integral expression `element-count-expr` to specify how many elements of the pointer type should be considered as the data the pointer points to. If the expression value is zero or negative, a runtime error occurs. For scalar pointer variables, an array slice expression may not be specified.

- Variable-length arrays.

  `element-count-expr` specifies a number of elements copied between the host and target.

- Pointer arrays.

  You can specify a scalar integral expression as `element-count-expr` to specify how many elements of each of the pointers in the array should be transferred, beginning with the 0th element. If the expression value is zero or negative, a runtime error occurs.

  `element-count-expr` that is an array slice expression specifies a set of length values that apply one-to-one with the pointers in the pointer array. The first length value applies to the first pointer, the second length to the second pointer and so on. The starting element to transfer is 0 in each case.

- `[preallocated] targetptr`

  Permits allocating memory for Intel® MIC Architecture only. No CPU memory is allocated. If you want to do memory allocation on Intel® MIC Architecture yourself, specify `preallocated`. It specifies that the memory on Intel® MIC Architecture is already allocated by the user and has to be made available for data transfer. For more information, see Device-Only Memory Allocation.
target ( target-name [ :target-number ] )

*target-name* represents the target and can be the following value:

- **mic** Intel® Xeon Phi™ products

*target-number* is an integer expression whose value is interpreted as follows:

- **>=0** Executes the statement on a specified target according to the following formula:
  
  \[
  target = target-number \% number_of_targets
  \]

  For example, in a system with four targets:

  1. Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 \% 4 and 6 \% 4 is 2.
  2. Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 \% 4 is 0.

- **-1 or no value** Executes the statements on a target selected by the runtime system.

- **<-1** Reserved.

*target-number* is required for the *signal* and *wait* clauses.

**Optional Clauses**

*if-clause*

A Boolean expression.

<table>
<thead>
<tr>
<th>If the expression evaluates to ...</th>
<th>... then the following occurs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The statements are executed on the target.</td>
</tr>
<tr>
<td>false</td>
<td>The statements are executed on the host. The behavior is undefined if the <em>if-clause</em> is used with either the <em>signal</em> or <em>wait</em> clauses.</td>
</tr>
</tbody>
</table>

**NOTE**

Use this clause to control whether offload is enabled. A set of related pragmas should use this clause in a coordinated fashion, so that either all or none of the related offload statements are enabled.

*mandatory*

Specifies execution on the target is required. Execution on the host is not allowed.

To continue the program if the correct target hardware is not available, initialize a variable *statusvarname* and use the *status ( statusvarname )* clause in this pragma. The Description section below explains how to initialize a status variable and the possible values for the status variable.

This clause is implied if the *optional* clause is not specified. You can explicitly specify this clause to reinforce the implied default.

*optional*

Specifies execution on the target is requested but not required. Execution on the host is allowed if the target is not available.
To determine why the statements were executed on the host instead of the target, initialize a variable `statusvarname` and use the `status (statusvarname)` clause in this pragma. The Description section below explains how to initialize a status variable and the possible values for the status variable.

**NOTE**
Do not use this clause and the mandatory clause in the same pragma as these clauses are opposites of each other.

`signal (tag)`

A handle on an asynchronous data transfer or computational activity. The computation performed by the `offload` clause and any results returned from the offload using `out` clauses, occurs concurrently with host execution of the code after the pragma. If this clause is not used, then the entire offload and associated data transfer are executed synchronously. The host will not continue past the pragma until it has completed.

`tag` is an expression that is a pointer-size value in the baseline language which serves as a handle on an asynchronous activity, either data transfer or computation.

**NOTE**
You must specify a `target` clause with a `target-number` that is greater than or equal to zero with this clause.

`status (statusvarname)`

Determine the status of the execution of an offloading construct. The `statusvarname` variable contains the value that explains the status of the execution. The Description section below explains how to initialize a status variable and the possible values for this variable.

When used with the `optional` clause and the target is unavailable, the statements to be executed on the target are instead executed on the host.

When used with the `mandatory` clause and the target is unavailable, the statements are ignored and the program continues. To determine why the statements were ignored or executed on the host, examine the value of this variable.

`stream (handle)`

Offloads to the stream specified by `handle`. The `handle` is obtained from the function `_Offload_create_stream`, which specifies on which Intel® MIC Architecture device to create the stream. The offload is to the device on which the stream had been created. For more information, see Offload Using Streams.

`wait (tag [, tag, ...])`

Specifies a wait until a previously initiated asynchronous data transfer or asynchronous computation is completed.

`tag` is an expression that is a pointer-size value in the baseline language. This expression serves as a handle on a previously initiated asynchronous activity which used the same expression value in a `signal` clause. The activity could be an asynchronous computation or asynchronous data transfer.
**NOTE**
You must specify a target clause with a target-number that is greater than or equal to zero with this clause.

Querying a signal before the signal has been initiated results in undefined behavior and a runtime abort of the application. For example, querying a signal on target:0 that was initiated for target:1 results in a runtime abort of the application because the signal was initiated for target:1, so there is no signal associated with target:0.

**Description**
This pragma both transfers data and offloads computation to the target.

You can use this pragma before any statement, including a compound statement, or an OpenMP* parallel pragma, to specify remote execution of that compound statement or top-level OpenMP* construct, or a single call statement.

**NOTE**
Do not use the __MIC__ macro inside this pragma. You can, however, use the __MIC__ macro in a subprogram called from the pragma.

Conceptually, this is the sequence of events when this pragma is encountered:

1. If there is no if clause, go to step 3.
2. On the host, evaluate the if-clause clause. If the clause evaluates to true, go to step 3. Otherwise, execute the statements on the host and be done.
3. Attempt to acquire the target. If successful, go to step 4. Otherwise, execute the statements on the host and be done.
4. On the host, compute all alloc_if, free_if, and element-count-expr expressions used in the in and out clauses, and element-count-expr expressions used in out clause.
5. On the host, gather all variable values that are inputs to the offload.
6. Send the input values from the host to the target.
7. On the target, allocate memory for variable-length out variables.
8. On the target, copy input values into corresponding target variables.
9. On the target, execute the statements.
10. On the target, compute all element-count-expr expressions used in out clauses.
11. On the target, gather all variable values that are outputs of the offload.
12. Send output values back from the target to the host.
13. On the host, copy values received into corresponding host variables.

The statements following this pragma are executed on the target if the target is available. If the target is not available, the optional, mandatory, and status (statusvarname) clauses determine how the statements are executed.

<table>
<thead>
<tr>
<th>If you specify these clauses and the target is unavailable ...</th>
<th>... then the following occurs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>optional</td>
<td>The statements are executed on the host.</td>
</tr>
<tr>
<td>optional and status (statusvarname)</td>
<td>The statements are executed on the host and the statusvarname contains the reason why the target was unavailable.</td>
</tr>
</tbody>
</table>
If you specify these clauses and the target is unavailable ...

| mandatory | The statements are ignored and the program ends. |
| mandatory and status (statusvarname) | The statements are ignored and the program continues. The statusvarname contains the reason why the target was unavailable. |

To initialize a status variable statusvarname, use the OFFLOAD_STATUS_INIT(statusvarname) macro. The values of the status variables are defined in offload.h and can be the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD_SUCCESS = 0</td>
<td>The statements were successfully executed on the target.</td>
</tr>
<tr>
<td>OFFLOAD_DISABLED</td>
<td>The statements were not executed on the target. If you specified if-clause and the value of this clause is false, the statements were successfully executed on the host.</td>
</tr>
<tr>
<td>OFFLOAD_UNAVAILABLE</td>
<td>The statements were not executed on the target because the target was unavailable.</td>
</tr>
<tr>
<td>OFFLOAD_OUT_OF_MEMORY</td>
<td>The statements were not executed on the target because there was not enough memory available for offload-parameter.</td>
</tr>
<tr>
<td>OFFLOAD_PROCESS_DIED</td>
<td>The statements were not executed on the target because a runtime error occurred on the target that caused in the target process to terminate.</td>
</tr>
<tr>
<td>OFFLOAD_ERROR</td>
<td>The statements were not executed on the target because of an error.</td>
</tr>
</tbody>
</table>

Examples

Using a variable-length array to specify a number of elements copied between the host and target

```c
void sample(const int nx) {
    float temp[nx];
    #pragma offload target(mic) in(temp : length(nx))
    { ... }
}
```

Using variable-ref in the in/out clauses

```c
typedef int ARRAY[10][10];
int a[1000][500];
int *p;
ARRAY *q;
int *r[10][10];
int i, j;
struct { int y; } x;
#pragma offload ... in(a)
#pragma offload ... out(a[i:j][:])
#pragma offload ... in(p[0:100])
```
Using variable-ref in the in/out clauses

```c
#pragma offload ... in ( (*q)[5][:] )
#pragma offload ... in ( r[5][5][0:2] )
#pragma offload ... out ( x.y )
```

Example of pointer array with special alignment on target

```c
#define ARRAY_SIZE 4
#define DATA_ELEMS 100

__declspec(target(mic)) int start[ARRAY_SIZE];
__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) int align[ARRAY_SIZE];
__declspec(target(mic)) float *p[ARRAY_SIZE];
float *q[ARRAY_SIZE];

int main() {
    int i, j;
    bool failed = false;
    bool align_failed = false;

    for (i=0; i<ARRAY_SIZE; i++) {
        // Alloc ptr array elements; assume memory is available
        p[i] = (float *)malloc(sizeof(float)*DATA_ELEMS);
        q[i] = (float *)malloc(sizeof(float)*DATA_ELEMS);
        p[i][0:DATA_ELEMS] = i;
        q[i][0:DATA_ELEMS] = p[i][0:DATA_ELEMS];
    }

    start[0] = 0;
    start[1] = 1;
    start[2] = 1;
    start[3] = 0;
    len[0] = DATA_ELEMS;
    len[1] = DATA_ELEMS - 2;
    len[2] = DATA_ELEMS - 2;
    len[3] = DATA_ELEMS;
    align[0] = 2048;
    align[1] = 4096;
    align[2] = 8192;
    align[3] = 8;

    // Start is a section and length is also a section
    // Default values of alloc_if, free_if
    // Special alignment
    // Array allocations will start at element 0, but transfers will not
    // Update some elements and get them from MIC
    // UUUUUUUUUUUUUU
    // .UUUUUUUUUUUU.
    // .UUUUUUUUUUUU.
    // UUUUUUUUUUUUU

    #pragma offload target(mic) \ 
    inout ( p[0:ARRAY_SIZE] : \ 
    extent (start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \ 
```
Example of pointer array with special alignment on target

```c
align(align[0:ARRAY_SIZE])
for (i=0; i<ARRAY_SIZE; i++) {
    if (((long long)&p[i][0] & (align[i]-1)) != 0) {
        align_failed = true;
        printf("p[%d] failed alignment\n", i);
        fflush(0);
    }
    p[i][start[i]:len[i]] += 1.0;
}
...
return 0;
```

Example of pointer array and alloc_if and free_if using array sections

```c
#define ARRAY_SIZE 4
#define DATA_ELEMS 100
__declspec(target(mic)) int start[ARRAY_SIZE];
__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) int allocif[ARRAY_SIZE];
__declspec(target(mic)) int freeif[ARRAY_SIZE];
__declspec(target(mic)) int *p[ARRAY_SIZE];

int main() {
    int i, j;
    bool failed = false;

    for (i=0; i<ARRAY_SIZE; i++) {
        // Alloc ptr array elements; assume memory is available
        p[i] = (int *)malloc(sizeof(int)*DATA_ELEMS);
        p[i][0:DATA_ELEMS] = i;
    }

    start[:] = 1;
    len[:] = 98;

    // Start is a section and length is also a section
    // Default values of free_if and align
    // alloc_if uses a vector and free_if a scalar that is expanded
    // Allocate only
    allocif[:] = 1;
    #pragma offload_transfer target(mic) \
    nocopy( p[0:ARRAY_SIZE] : \
        extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \
        alloc_if(allocif[0:ARRAY_SIZE]) \
        free_if(0) )

    // Do the offload reusing memory
    #pragma offload target(mic) \
    inout( p[0:ARRAY_SIZE] : \
        extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \
        alloc_if(0) \
    
```
Example of pointer array and `alloc_if` and `free_if` using array sections

```
free_if(0) {  
    for (i=0; i<ARRAY_SIZE; i++) { p[i][start[i]:len[i]] += 1; }  
}
// Free the memory  
// alloc_if uses a scalar, free_if a vector  
freeif[:] = 1;  
#pragma offload_transfer target(mic)  
nocopy( p[0:ARRAY_SIZE] :  
        extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE])  
        alloc_if(0)  
        free_if(freeif[0:ARRAY_SIZE]) )
...
return 0;
}
```

---

Example of pointer array with `into`, `into_extent` and `alloc_extent`

```
#define ARRAY_SIZE 4
#define DATA_ELEMS 100  
#define SEND_ROWS 2
#define SEND_COLS 50  
#define P_OFFSET_IN 2  
#define P_OFFSET_OUT 0  
#define Q_OFFSET 0  
#define COL_OFFSET 50
__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) short int *p[ARRAY_SIZE];
__declspec(target(mic)) short int *q[ARRAY_SIZE*2];

#ifdef RUN_ON_CPU
bool run_on_cpu = true;
#else
__declspec(target(mic)) bool run_on_cpu = false;
#endif

int main() {
    int i, j;
    bool failed = false;

    for (i=0; i<ARRAY_SIZE; i++) {
        // Alloc ptr array elements; assume memory is available
        p[i] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        q[i] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        q[i+ARRAY_SIZE] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        p[i][0:DATA_ELEMS] = i;
    }

    len[:] = SEND_COLS;
// Scalars used for extent start and extent length
// Default values of alloc_if, free_if and align
```
Example of pointer array with \texttt{into}, \texttt{into\_extent} and \texttt{alloc\_extent}

\begin{verbatim}
// Data sent to MIC and fetched from MIC
// p[2][50:50] -> q[0][50:50] allocate only those 50 elements
// p[3][50:50] -> q[1][50:50] allocate only those 50 elements
// compute
// p[0][50:50] <- q[0][50:50]
// p[1][50:50] <- q[1][50:50]

#pragma offload target(mic) \n in (p[P\_OFFSET\_IN:SEND\_ROWS] : extent(COL\_OFFSET:SEND\_COLS) \n into(q[Q\_OFFSET\_SEND\_ROWS]) into_extent(COL\_OFFSET:SEND\_COLS) \n alloc\_extent(COL\_OFFSET:len[0:SEND\_ROWS])) } \n out(q[Q\_OFFSET\_SEND\_ROWS] : extent(COL\_OFFSET:SEND\_COLS) \n into(p[P\_OFFSET\_OUT:SEND\_ROWS]) into_extent(COL\_OFFSET:SEND\_COLS) ) { 
 for (i=0; i<SEND\_ROWS; i++) { 
   // If running on CPU, mimic the "in into"
   if (run_on_cpu) {
     q[Q\_OFFSET+i][COL\_OFFSET:SEND\_COLS] = p[P\_OFFSET\_IN+i][COL\_OFFSET:SEND\_COLS];
   } 

   q[Q\_OFFSET+i][COL\_OFFSET:SEND\_COLS] += i*2;

   // If running on CPU, mimic the "out into"
   if (run_on_cpu) {
     p[P\_OFFSET\_OUT+i][COL\_OFFSET:SEND\_COLS] = q[Q\_OFFSET+i][COL\_OFFSET:SEND\_COLS];
   } 
} 
...
return 0;

\end{verbatim}

Writing Target-Specific Code

\texttt{offload\_attribute}

\textit{Specifies that all functions and variables declared subsequent to the pragma are available on the target. This pragma only applies to Intel\textsuperscript{\textregistered} MIC Architecture.}

\textbf{Syntax}

\begin{verbatim}
#pragma offload_attribute([push, ] target(target-name)
#pragma offload\_attribute(pop)
\end{verbatim}
Arguments

push

Pushes functions and variables on the internal compiler stack to be offloaded to the target until the statement \texttt{#pragma offload_attribute (pop)} or until the end of the compilation unit.

This is the default.

target(\texttt{target-name})

Represents the target. Can be the following value:

\begin{itemize}
  \item \texttt{mic} \quad Intel\textsuperscript{	extregistered} Xeon Phi\textsuperscript{™} products
\end{itemize}

pop

Removes the functions and variables from the top of the internal compiler stack.

none

Turns off the pragma.

Description

This pragma specifies that all functions and variables declared subsequent to the pragma are available on the target.

This pragma enables you to avoid the need to put target attributes or target declspec on individual declarations.

To turn on the pragma, specify \texttt{push} and \texttt{target(\texttt{target-name})}, or specify only a \texttt{target(\texttt{target-name})}. \texttt{push} pushes \texttt{target-name} onto a stack. If you specify \texttt{target(\texttt{target-name})} only, the compiler does not remember the state before the pragma.

Examples

The following examples demonstrates how to use this pragma.

In the following example, the pragma specifies that all functions and variables between the \texttt{push} and \texttt{pop} statements are sent to the target. Both class A and class B get the \texttt{target(mic)} attribute.

\begin{itemize}
  \item \texttt{Example}
    \begin{verbatim}
    // Push mic target onto the stack.
    #pragma offload_attribute (push, target (mic))

    // Functions and variables.
    ...

    // Remove mic target from the stack, return to previous state.
    #pragma offload_attribute (pop)
    \end{verbatim}
  \item \texttt{Example}
    \begin{verbatim}
    fileA.h
    #include <vector>

    class A {
      ...
      private:
        std::vector<int> av;
    };

    fileB.cpp
    \end{verbatim}
\end{itemize}
All data members of the classes, both those added by the user such as the data member \texttt{av}, as well as the internal data members created by the compiler, such as their virtual function tables, get the \texttt{target(mic)} attribute, because they are enclosed within the \texttt{offload_attribute} pragma region.

Notice that the \texttt{target(mic)} or \texttt{_Cilk_shared} attribute on a class is not inherited, therefore the classes need to be individually marked either explicitly in their definition or through the push/pop mechanism. Also notice that for the correct offloading of member functions via virtual dispatch, all classes in the hierarchy must be marked with the \texttt{target(mic)} or \texttt{_Cilk_shared} attribute.

In the previous example, class \texttt{C} and the contents of namespace \texttt{U} in the original definition get the \texttt{target(mic)} attribute because they are enclosed with the \texttt{offload_attribute} pragma. However, the namespace \texttt{U} itself does not get marked with the attribute.

Consequently, class \texttt{D} and the contents of the extended namespace \texttt{U} do not get the \texttt{target(mic)} attribute because they are not enclosed with the \texttt{offload_attribute} pragma.

**offload_transfer**

*Initiates and completes a synchronous data transfer.*

*If used with the \texttt{signal} clause, initiates an asynchronous data transfer. This pragma only applies to Intel® MIC Architecture.*

**Syntax**

\texttt{#pragma offload_transfer [clause[clause...]]}

**Required Clauses**

- \texttt{offload-parameter}
- \texttt{target (target-name [ :target-number ])}

**Optional Clauses**

- \texttt{if-clause}
- \texttt{mandatory}
- \texttt{optional}
- \texttt{signal (tag )}
Arguments

Required Clauses

offload-parameter

Controls how the program variables and the amount of data are copied between the host and the target. This clause can be one of the following:

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description</th>
</tr>
</thead>
</table>
| **in** | The variable is strictly an input to the target region. The value is not copied back after the region completes.  
**Syntax:** `in ( variable-ref [, variable-ref ...] [ modifier[ , modifier... ] ] )` |
| **out** | The variable is strictly an output of the target region. The host does not copy the variable to the target.  
**Syntax:** `out ( variable-ref [, variable-ref ...] [ modifier[ , modifier... ] ] )` |
| **nocopy** | A variable whose value is reused from a previous target execution or one that is used entirely within the offloaded code section may be named in a nocopy clause to avoid any copying.  
**Syntax:** `nocopy ( variable-ref [, variable-ref ...] [ modifier[ , modifier... ] ] )` |

An in or out expression (see description below within modifier) is evaluated at a point in the program before the statement or clause in which it is used.

An array variable whose size is known from the declaration is copied in its entirety. If a subset of an array is to be processed, use a pointer to the starting element of the subset and the `element-count-expr` to transfer the array subset.

The following are the variables to use with this argument:

| variable-ref | Is one of the following:  
• A C/C++ identifier.  
• `variable-ref . identifier`  
Use the following syntax for the variables in this argument:  
• `var : length ( l )`  
• `var [ 0 : length ]`  
• `array-slice`  
An array expression that denotes one contiguous set of array elements. |
|---|---|
| modifier | Is one of the following:  
• `align ( expression)` |
where *align-expression* is a scalar integral expression or an array slice expression. Use it with:

- Pointer variables.
  
  *align-expression* must be a scalar integral expression. It specifies the minimum alignment for pointer data allocated on the target. The value must be a power of two.

- Pointer arrays.
  
  *align-expression* may be either a scalar integral expression or an array slice expression. The specified value(s) requests the minimum alignment for pointer data allocated on the target. The value(s) must be a power of two.

  *align-expression* that is an array slice expression specifies a set of alignment values that apply one-to-one with the pointers in the pointer array. The first alignment value applies to the first pointer, the second alignment to the second pointer, and so on.

- alloc (array-slice)

  where *array-slice* specifies a set of elements of the array that need allocation. Data specified by the *in(out)* expression is transferred into the corresponding section of the array allocated on the target.

  Use the following syntax for the argument in this modifier:

  - var[start : length]

  For more information, see Allocating Memory for Parts of Arrays.

- alloc_if (condition)

  where *condition* is a scalar Boolean expression or a Boolean array slice expression. Use it with:

  - Pointer variables.

    *condition* must be a scalar Boolean expression. It controls whether to allocate the memory allocated for the variables in the *in(out/inout/nocopy)* clause. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused (data persistence). You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a free_if (0) clause on an earlier offload.

  - Pointer arrays.
condition may be either a Boolean expression or a Boolean array slice expression. The specified value(s) control whether to allocate the memory for the variables in the in/out/inout/nocopy clause on the target.

condition that is an array slice expression specifies a set of Boolean values that apply one-to-one with the pointers in the pointer array. The first Boolean value applies to the first pointer, the second Boolean value to the second pointer, and so on.

The following are the default settings for this modifier:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>true</td>
</tr>
<tr>
<td>inout</td>
<td>true</td>
</tr>
<tr>
<td>out</td>
<td>true</td>
</tr>
<tr>
<td>nocopy</td>
<td>false</td>
</tr>
</tbody>
</table>

• alloc_extent (start : length)

where start and length are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. Use this modifier with:

• Pointer arrays.

start and length may be integral expressions or array slice expressions. If an integral expression is specified then it is assumed to apply to each of the pointers. If an array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.

start specifies the first element to be allocated on the target. length specifies the number of elements to allocate. If start is negative a runtime error occurs.

• extent (start : length)

where start and length are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. Use this modifier with:

• Pointer arrays.

The values of the pointers in the array are never copied across the host/target interface because there is no correspondence between the memory addresses of the host and the target. Instead, objects that the pointers point to are copied to or from the target, and the pointer array is recreated.
**start** and **length** may be integral expressions or array slice expressions. If an integral expression is specified, it is assumed to apply to each of the pointers. If an array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.

**start** specifies the first element to be transferred. **length** specifies the number of elements to transfer. If **start** is negative a runtime error occurs.

- **free_if**(**condition**)  
  where **condition** is a scalar Boolean expression or a Boolean array slice expression. Use it with:

  - Pointer variables.  
    **condition** must be a scalar Boolean expression. It controls whether to deallocate the memory allocated for the variables in the in/out/inout/nocopy clause. If the expression evaluates to false, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

  - Pointer arrays.  
    **condition** may be either a Boolean expression or a Boolean array slice expression. The specified value(s) control whether to deallocate the memory for the variables in the in/out/inout/nocopy clause on the target.

    **condition** that is an array slice expression specifies a set of Boolean values that apply one-to-one with the pointers in the pointer array. The first Boolean value applies to the first pointer, the second Boolean value to the second pointer, and so on.

The following are the default settings for this modifier:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>true</td>
</tr>
<tr>
<td>inout</td>
<td>true</td>
</tr>
<tr>
<td>out</td>
<td>true</td>
</tr>
<tr>
<td>nocopy</td>
<td>false</td>
</tr>
</tbody>
</table>

For more information, see Managing Memory Allocation for Pointer Variables.

- **into**(**var-exp**)  
  where **var-exp** is a variable expression.
This modifier allows data to be transferred from one variable on the host to another variable on the target, and vice versa. Only one item is allowed in variable-ref when using this modifier.

Use the following syntax for the argument in this clause:

- **var** (when a length modifier is also used).
- **var[start:length]** (when a separate length modifier is not used).

For more information, see Moving Data from One Variable to Another.

- **into_extent (start : length)**

  where start and length are either integral expressions or array slice expressions that yield sets of integral values. Both forms of expressions are computed at runtime. Use this modifier with:

  - Pointer arrays used with the into modifier.
    
    start and length may be integral expressions or array slice expressions. If an integral expression is specified, it is assumed to apply to each of the pointers. If an array slice, then there is a one-to-one correspondence between elements of the pointer array and elements of the array slice.
    
    start specifies the first element to allocated on the target. length specifies the number of elements to allocate. If start is negative a runtime error occurs.
  
  - **length (element-count-expr)**

    where element-count-expr is a scalar integral expression or an array slice expression, computed at runtime. Use it with:

    - Pointer variables.
      
      Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host and the target. Instead, objects that a pointer points to are copied to or from the target, and the value of the pointer variable is recreated.
      
      You can use a scalar integral expression element-count-expr to specify how many elements of the pointer type should be considered as the data the pointer points to. If the expression value is zero or negative, a runtime error occurs. For scalar pointer variables, an array slice expression may not be specified.
      
    - Variable-length arrays.
      
      element-count-expr specifies a number of elements copied between the host and target.
    
    - Pointer arrays.
You can specify a scalar integral expression as `element-count-expr` to specify how many elements of each of the pointers in the array should be transferred, beginning with the 0th element. If the expression value is zero or negative, a runtime error occurs.

`element-count-expr` that is an array slice expression specifies a set of length values that apply one-to-one with the pointers in the pointer array. The first length value applies to the first pointer, the second length to the second pointer and so on. The starting element to transfer is 0 in each case.

- `[preallocated] targetptr`

Permits allocating memory for Intel® MIC Architecture only. No CPU memory is allocated. If you want to do memory allocation on Intel® MIC Architecture yourself, specify `preallocated`. It specifies that the memory on Intel® MIC Architecture is already allocated by the user and has to be made available for data transfer. For more information, see Device-Only Memory Allocation.

target (target-name [ : target-number])

`target-name` represents the target. Use `mic` for Intel® Xeon Phi™ products. `target-number` is required for the `signal` and `wait` clauses. `target-number` is an integer expression whose value is interpreted as follows:

- `>=0` Executes the statements on a specified target according to the following formula:
  
  \[
  target = target-number \mod number_of_targets
  \]

  For example, in a system with four targets:
  
  - Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 \% 4 and 6 \% 4 is 2.
  - Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 \% 4 is 0.

- `-1` or no value Executes the statements on a target selected by the runtime system.

- `<= -1` Reserved.

`target-number` is required for the `signal` and `wait` clauses.

If the target is not available, the program fails with an error message unless you also specify the `optional` clause. The `optional` clause allows the statements to execute on the host if the target is not available.

**Optional Clauses**

- `if-clause` A Boolean expression.
If the expression evaluates to ...

<table>
<thead>
<tr>
<th>true</th>
<th>The statements are executed on the target.</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>The statements are executed on the host. The behavior is undefined if the if-clause is used with either the signal or wait clauses.</td>
</tr>
</tbody>
</table>

**NOTE**
Use this clause to control whether offload is enabled. A set of related pragmas should use this clause in a coordinated fashion, so that either all or none of the related offload statements are enabled.

**mandatory**

Specifies execution on the target is required. Execution on the host is not allowed.

To continue the program if the correct target hardware is not available, initialize a variable statusvarname and use the status (statusvarname) clause in this pragma. The Description section below explains how to initialize a status variable and the possible values for the status variable.

This clause is implied if the optional clause is not specified. You can explicitly specify this clause to reinforce the implied default.

**optional**

Specifies execution on the target is requested but not required. Execution on the host is allowed if the target is not available.

To determine why the statements were executed on the host instead of the target, initialize a variable statusvarname and use the status (statusvarname) clause in this pragma. The Description section below explains how to initialize a status variable and the possible values for the status variable.

**NOTE**
Do not use this clause and the mandatory clause in the same pragma as these clauses are opposites of each other.

**signal (tag)**

A handle on an asynchronous data transfer or computational activity. The computation performed by the offload clause and any results returned from the offload using out clauses occurs concurrently with host execution of the code after the pragma. If this clause is not used, then the entire offload and associated data transfer are executed synchronously. The host will not continue past the pragma until it has completed.

tag is an expression that is a pointer-size value in the baseline language which serves as a handle on an asynchronous activity, either data transfer or computation.
status ( statusvarname )

Determine the status of the execution of an offloading construct. The statusvarname variable contains the value that explains the status of the execution. The Description section below explains how to initialize a status variable and the possible values for this variable.

When used with the optional clause and the target is unavailable, the statements to be executed on the target are instead executed on the host.

When used with the mandatory clause and the target is unavailable, the statements are ignored and the program continues. To determine why the statements were ignored or executed on the host, examine the value of this variable.

stream ( handle )

Offloads to the stream specified by handle. The handle is obtained from the function _Offload_create_stream, which specifies on which Intel® MIC Architecture device to create the stream. The offload is to the device on which the stream had been created. For more information, see Offload Using Streams.

wait ( tag [, tag, ...] )

Specifies a wait until a previously initiated asynchronous data transfer or asynchronous computation is completed.

tag is an expression that is a pointer-size value in the baseline language. This expression serves as a handle on a previously initiated asynchronous activity which used the same expression value in a signal clause. The activity could be an asynchronous computation or asynchronous data transfer.

NOTE
You must specify a target clause with a target-number that is greater than or equal to zero with this clause.

Querying a signal before the signal has been initiated results in undefined behavior and a runtime abort of the application. For example, querying a signal on target:0 that was initiated for target:1 results in a runtime abort of the application because the signal was initiated for target:1, so there is no signal associated with target:0.

Description
This pragma initiates asynchronous data transfer and also initiates and completes synchronous data transfer.

The statements following this pragma are executed on the target if the target is available. If the target is not available, the optional, mandatory, and status ( statusvarname ) clauses determine how the statements are executed.
If you specify these clauses and the target is unavailable ...

<table>
<thead>
<tr>
<th>Clause Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>optional and status (statusvarname )</td>
<td>The statements are executed on the host and the statusvarname contains the reason why the target was unavailable.</td>
</tr>
<tr>
<td>mandatory</td>
<td>The statements are ignored and the program ends.</td>
</tr>
<tr>
<td>mandatory and status (statusvarname )</td>
<td>The statements are ignored and the program continues. The statusvarname contains the reason why the target was unavailable.</td>
</tr>
</tbody>
</table>

To initialize a status variable statusvarname, use the OFFLOAD_STATUS_INIT(statusvarname) macro. The values of the status variables are defined in offload.h and can be the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD_SUCCESS = 0</td>
<td>The statements were successfully executed on the target.</td>
</tr>
<tr>
<td>OFFLOAD_DISABLED</td>
<td>The statements were not executed on the target. If you specified if-clause and the value of this clause is false, the statements were successfully executed on the host.</td>
</tr>
<tr>
<td>OFFLOAD_UNAVAILABLE</td>
<td>The statements were not executed on the target because the target was unavailable.</td>
</tr>
<tr>
<td>OFFLOAD_OUT_OF_MEMORY</td>
<td>The statements were not executed on the target because there was not enough memory available for offload-parameter.</td>
</tr>
<tr>
<td>OFFLOAD_PROCESS_DIED</td>
<td>The statements were not executed on the target because a runtime error occurred on the target that caused in the target process to terminate.</td>
</tr>
<tr>
<td>OFFLOAD_ERROR</td>
<td>The statements were not executed on the target because of an error.</td>
</tr>
</tbody>
</table>

Examples

Using two different pragmas to receive data asynchronously from the target and the host

```
01   const int N = 4086;
02   float *f1, *f2;
03   f1 = (float *)memalign(64, N*sizeof(float));
04   f2 = (float *)memalign(64, N*sizeof(float));
...  
10   // Host sends f1 as input synchronously
11   // The output is in f2, but is not needed immediately
12   #pragma offload target (mic:0) signal(f2) \
13      in( f1 : length(N) ) \
14      nocopy( f2 : length(N) ) signal(f2)
15   {
16       foo(N, f1, f2);
```
Using two different pragmas to receive data asynchronously from the target and the host

```
17   }
18   
20   #pragma offload_transfer (mic:0) wait(f2) \  
21   out( f2 : length(N) alloc_if(0) free_if(1))
22   // Host can now use the result in f2
```

The `offload_target` performs the computation but only initiates data transfer. The `offload_transfer` pragma causes a wait for the data transfer to complete.

Using double buffers for inputs to an offload

```
#pragma offload_attribute(push, target(mic))
int count = 25000000;
int iter = 10;
float *in1, *out1;
float *in2, *out2;
#pragma offload_attribute(pop)

void do_async_in() {
  int i;
  #pragma offload_transfer target(mic:0) in(in1 : length(count) alloc_if(0) free_if(0) )
  signal(in1)
  for (i=0; i<iter; i++) {
    if (i%2 == 0) {
      #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in2 : length(count)
      alloc_if(0) free_if(0) ) signal(in2)
      #pragma offload target(mic:0) nocopy(in1) wait(in1) out(out1 : length(count)
      alloc_if(0) free_if(0) )
      compute(in1, out1);
    } else {
      #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in1 : length(count)
      alloc_if(0) free_if(0) ) signal(in1)
      #pragma offload target(mic:0) nocopy(in2) wait(in2) out(out2 : length(count)
      alloc_if(0) free_if(0) )
      compute(in2, out2);
    }
  }
}
```

Example of pointer array with special alignment on target

```
#define ARRAY_SIZE 4
#define DATA_ELEMS 100

__declspec(target(mic)) int start[ARRAY_SIZE];
__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) int align[ARRAY_SIZE];
__declspec(target(mic)) float *p[ARRAY_SIZE];
float *q[ARRAY_SIZE];

int main() {
  int i, j;
  bool failed = false;
```
Example of pointer array with special alignment on target

```c
bool align_failed = false;

for (i=0; i<ARRAY_SIZE; i++) {
    // Alloc ptr array elements; assume memory is available
    p[i] = (float *)malloc(sizeof(float)*DATA_ELEMS);
    q[i] = (float *)malloc(sizeof(float)*DATA_ELEMS);
    p[i][0:DATA_ELEMS] = i;
    q[i][0:DATA_ELEMS] = p[i][0:DATA_ELEMS];
}

start[0] = 0;
start[1] = 1;
start[2] = 1;
start[3] = 0;
len[0] = DATA_ELEMS;
len[1] = DATA_ELEMS - 2;
len[2] = DATA_ELEMS - 2;
len[3] = DATA_ELEMS;
align[0] = 2048;
align[1] = 4096;
align[2] = 8192;
align[3] = 8;

// Start is a section and length is also a section
// Default values of alloc_if, free_if
// Special alignment
// Array allocations will start at element 0, but transfers will not
// Update some elements and get them from MIC
// .UUUUUUUUUUUUU
// .UUUUUUUUUUUUU.
// .UUUUUUUUUUUUU.
// .UUUUUUUUUUUUU.

#pragma offload target(mic) \
  inout(p[0:ARRAY_SIZE]) : \ 
  extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \ 
  align(align[0:ARRAY_SIZE]) ) {
    for (i=0; i<ARRAY_SIZE; i++) {
        if (((long long)&p[i][0] & (align[i]-1)) != 0) {
            align_failed = true;
            printf("p[%d] failed alignment\n", i);
            fflush(0);
        }
        p[i][start[i]:len[i]] += 1.0;
    }
}
```

...
```c
#define ARRAY_SIZE 4
#define DATA_ELEMS 100
__declspec(target(mic)) int start[ARRAY_SIZE];
__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) int allocif[ARRAY_SIZE];
__declspec(target(mic)) int freeif[ARRAY_SIZE];
__declspec(target(mic)) int *p[ARRAY_SIZE];

int main() {
    int i, j;
    bool failed = false;

    for (i=0; i<ARRAY_SIZE; i++) {
        // Alloc ptr array elements; assume memory is available
        p[i] = (int *)malloc(sizeof(int)*DATA_ELEMS);
        p[i][0:DATA_ELEMS] = i;
    }

    start[:] = 1;
    len[:] = 98;

    // Start is a section and length is also a section
    // Default values of free_if and align
    // alloc_if uses a vector and free_if a scalar that is expanded
    // Allocate only
    allocif[:] = 1;
    #pragma offload_transfer target(mic) \
        nocopy( p[0:ARRAY_SIZE] : \
                extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \
                alloc_if(allocif[0:ARRAY_SIZE]) \
                free_if(0) )

    // Do the offload reusing memory
    #pragma offload_transfer target(mic) \
        inout( p[0:ARRAY_SIZE] : \
               extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \
               alloc_if(0) \
               free_if(0) ) { 
        for (i=0; i<ARRAY_SIZE; i++) { p[i][start[i]:len[i]] += 1; } 
    }

    // Free the memory
    // alloc_if uses a scalar, free_if a vector
    freeif[:] = 1;
    #pragma offload_transfer target(mic) \
        nocopy( p[0:ARRAY_SIZE] : \
               extent(start[0:ARRAY_SIZE]:len[0:ARRAY_SIZE]) \
               alloc_if(0) \
               free_if(freeif[0:ARRAY_SIZE]) )

    ... 
    return 0;
}
```

Example of pointer array and alloc_if and free_if using array sections
Example of pointer array with into, into_extent and alloc_extent

```c
#define ARRAY_SIZE 4
#define DATA_ELEMS 100
#define SEND_ROWS 2
#define SEND_COLS 50
#define P_OFFSET_IN 2
#define P_OFFSET_OUT 0
#define Q_OFFSET 0
#define COL_OFFSET 50

__declspec(target(mic)) int len[ARRAY_SIZE];
__declspec(target(mic)) short int *p[ARRAY_SIZE];
__declspec(target(mic)) short int *q[ARRAY_SIZE*2];

#ifdef RUN_ON_CPU
bool run_on_cpu = true;
#else
__declspec(target(mic)) bool run_on_cpu = false;
#endif

int main() {
    int i, j;
    bool failed = false;

    for (i=0; i<ARRAY_SIZE; i++) {
        // Alloc ptr array elements; assume memory is available
        p[i] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        q[i] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        q[i+ARRAY_SIZE] = (short int *)malloc(sizeof(short int)*DATA_ELEMS);
        p[i][0:DATA_ELEMS] = i;
    }

    len[:] = SEND_COLS;

    // scalars used for extent start and extent length
    // Default values of alloc_if, free_if and align
    // Data sent to MIC and fetched from MIC
    // p[2][50:50] -> q[0][50:50] allocate only those 50 elements
    // p[3][50:50] -> q[1][50:50] allocate only those 50 elements
    // compute
    // p[0][50:50] <- q[0][50:50]
    // p[1][50:50] <- q[1][50:50]

    #pragma offload target(mic) \
        in (p[P_OFFSET_IN:SEND_ROWS] : extent(COL_OFFSET:SEND_COLS) \ 
            into(q[Q_OFFSET:SEND_ROWS]) into_extent(COL_OFFSET:SEND_COLS) \ 
            alloc_extent(COL_OFFSET:len[0:SEND_ROWS]) ) \
        out(q[Q_OFFSET:SEND_ROWS] : extent(COL_OFFSET:SEND_COLS) \ 
            into(p[P_OFFSET_OUT:SEND_ROWS]) into_extent(COL_OFFSET:SEND_COLS) )
    {
        for (i=0; i<SEND_ROWS; i++) {
            // If running on CPU, mimic the "in into"
            if (run_on_cpu) {
                q[Q_OFFSET+i][COL_OFFSET:SEND_COLS] = p[P_OFFSET_IN+i][COL_OFFSET:SEND_COLS];
            }
            q[Q_OFFSET+i][COL_OFFSET:SEND_COLS] += i*2;
        }
    }
```

offload_wait
Specifies a wait for a previously initiated asynchronous data transfer. This pragma only applies to Intel® MIC Architecture.

Syntax
#pragma offload_wait clause[, clause ...]

Required Clauses
• target ( target-name [:target-number ] )
• wait ( tag[, tag,...] )

Optional Clause
• if ( if-clause )
• status ( statusvarname )
• stream ( handle )

Arguments

Required Clauses

<table>
<thead>
<tr>
<th>target-name [:target-number]</th>
<th>target-name represents the target. Use mic for Intel® Xeon Phi™ products.</th>
</tr>
</thead>
<tbody>
<tr>
<td>target-number</td>
<td>target-number is an integer expression whose value is interpreted as follows:</td>
</tr>
<tr>
<td>&gt;=0</td>
<td>Executes the statement on a specified target according to the following formula:</td>
</tr>
<tr>
<td></td>
<td>target = target-number % number_of_targets</td>
</tr>
</tbody>
</table>

For example, in a system with four targets:
• Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 % 4 and 6 % 4 is 2.
• Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 % 4 is 0.

wait( tag [, tag, ...] )

Specifies a wait until a previously initiated asynchronous data transfer or asynchronous computation is completed.

tag is an expression that is a pointer-size value in the baseline language. This expression serves as a handle on a previously initiated asynchronous activity which used the same expression value in a signal clause. The activity could be an asynchronous computation or asynchronous data transfer.

This clause refers to a specific target device, so you must specify a target-number in the target clause that is greater than or equal to zero.

The signal associated with the handle is cleared following completion of the previously initiated asynchronous data transfer or asynchronous computation. Querying a signal before the signal has been initiated results in undefined behavior and a runtime abort of the application. For example, querying a signal on target:0 that was initiated for target:1 results in a runtime abort of the application because the signal was initiated for target:1, so there is no signal associated with target:0.

Optional Clauses

if (if-clause)

A Boolean expression.

<table>
<thead>
<tr>
<th>If the expression evaluates to ...</th>
<th>... then the following occurs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The runtime will wait until the tags are signaled.</td>
</tr>
<tr>
<td>false</td>
<td>The clause is ignored.</td>
</tr>
</tbody>
</table>

Use the same expression that you used to start the asynchronous computation or data transfer with offload or offload_transfer.

NOTE
Use this clause to control whether offload is enabled. A set of related pragmas should use this clause in a coordinated fashion, so that either all or none of the related offload statements are enabled.

status( statusvarname )

Determines the status of the execution of an offloading construct. The statusvarname variable contains the value that explains the status of the execution. The Description section below explains how to initialize a status variable and the possible values for this variable.

stream( handle )

Causes a wait for all offloads to the stream specified by handle to complete.
If handle is 0 and the target clause specifies a generic Intel® MIC Architecture device, then a wait occurs for all offloads on all devices to complete; for example, target(mic).

If handle is 0 but the target clause specifies a specific Intel® MIC Architecture device, then a wait occurs for all streams on that device to complete. For example, if target(mic:1) is specified, then a wait occurs for all offloads to device 1 to complete.

For more information about streams, see Offload Using Streams.

**Description**

This pragma specifies a wait for the completion of a previously initiated asynchronous data transfer done by offload_transfer, or an asynchronous computation and return data transfer, if any, done by offload.

The status clause requires a statusvarname variable. Initialize the statusvarname variable by using the OFFLOAD_STATUS_INIT(statusvarname) macro. The values of the status variables are defined in offload.h and can be the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD_SUCCESS = 0</td>
<td>The statements were successfully executed on the target.</td>
</tr>
<tr>
<td>OFFLOAD_DISABLED</td>
<td>The statements were not executed were not executed on the target. If you specified if-clause and the value of this clause is false, the statements were successfully executed on the host.</td>
</tr>
<tr>
<td>OFFLOAD_UNAVAILABLE</td>
<td>The statements were not executed on the target because the target was unavailable.</td>
</tr>
<tr>
<td>OFFLOAD_OUT_OF_MEMORY</td>
<td>The statements were not executed on the target because there was not enough memory available for offload-parameter.</td>
</tr>
<tr>
<td>OFFLOAD_PROCESS_DIED</td>
<td>The statements were not executed on the target because a runtime error occurred on the target that caused in the target process to terminate.</td>
</tr>
<tr>
<td>OFFLOAD_ERROR</td>
<td>The statements were not executed on the target because of an error.</td>
</tr>
</tbody>
</table>

**Examples**

**Example: Double buffer inputs to an offload**

```c
#pragma offload_attribute(push, target(mic))
int count = 25000000;
int iter = 10;
float *in1, *out1;
float *in2, *out2;
#pragma offload_attribute(pop)

void do_async_in() {
  int i;
```
Example: Double buffer inputs to an offload

```c
#pragma offload_transfer target(mic:0) in(in1 : length(count) alloc_if(0) free_if(0) )
signal(in1)
for (i=0; i<iter; i++) {
   if (i%2 == 0) {
      #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in2 : length(count) alloc_if(0)
free_if(0) ) signal(in2)
      #pragma offload target(mic:0) nocopy(in1) wait(in1) out(out1 : length(count) alloc_if(0)
free_if(0) )
      compute(in1, out1);
   } else {
      #pragma offload_transfer target(mic:0) if(i!=iter-1) in(in1 : length(count) alloc_if(0)
free_if(0) ) signal(in1)
      #pragma offload target(mic:0) nocopy(in2) wait(in2) out(out2 : length(count) alloc_if(0)
free_if(0) )
      compute(in2, out2);
   }
}
```

Example: Output double-buffered results of an offload

```c
#pragma offload_attribute(push, target(mic))
int count = 25000000;
int iter = 10;
float *in1, *out1;
float *in2, *out2;
#pragma offload_attribute(pop)
void do_async_out() {
   int i;
   for (i=0; i<iter+1; i++) {
      if (i%2 == 0) {
         if (i<iter) {
            #pragma offload target(mic:0) in(in1 : length(count) alloc_if(0) free_if(0) )
nocopy(out1)
            compute(in1, out1);
            #pragma offload_transfer target(mic:0) out(out1 : length(count) alloc_if(0)
free_if(0) ) signal(out1)
         }
      } else {
         if (i<iter) {
            #pragma offload target(mic:0) in(in2 : length(count) alloc_if(0) free_if(0) )
nocopy(out2)
            compute(in2, out2);
            #pragma offload_transfer target(mic:0) out(out2 : length(count) alloc_if(0)
free_if(0) ) signal(out2)
         }
      }
   }
   #pragma offload_wait target(mic:0) wait(out1)
   use_result(out1);
   #pragma offload_wait target(mic:0) wait(out2)
   use_result(out2);
}
```
Example: Output double-buffered results of an offload

```c
}
}

optimize
Enables or disables optimizations for code after this pragma until another optimize pragma or end of the translation unit.

Syntax
#pragma optimize("", on|off)

Arguments
The compiler ignores first argument values. Valid second arguments for optimize are:

- off: Disables optimization
- on: Enables optimization

Description
The `optimize` pragma is used to enable or disable optimizations.

Specifying `#pragma optimize("", off)` disables optimization until either the compiler finds a matching `#pragma optimize("", on)` statement or until the compiler reaches the end of the translation unit.

Examples

Example: Disabling optimization for a single function using the optimize pragma

```c
#pragma optimize("", off)
 alpha() { ... }

#pragma optimize("", on)
 omega() { ... }
```

In this example, optimizations are disabled for the `alpha()` function but not for the `omega()` function.

Example: Disabling optimization for all functions using the optimize pragma

```c
#pragma optimize("", off)
 alpha() { ... }
 omega() { ... }
```

In this example, optimizations are disabled for both the `alpha()` and `omega()` functions.
optimization_level
Controls optimization for one function or all functions after its first occurrence.

Syntax
#pragma [intel|GCC] optimization_level n

Arguments

<table>
<thead>
<tr>
<th>intel</th>
<th>GCC</th>
<th>Indicates the interpretation to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>An integer value specifying an optimization level; valid values are:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 0: same optimizations as option -O0 (Linux* and macOS*) or /Od (Windows*)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 1: same optimizations as option O1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 2: same optimizations as option O2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 3: same optimizations as option O3</td>
<td></td>
</tr>
</tbody>
</table>

Description

The optimization_level pragma is used to restrict optimization for a specific function while optimizing the remaining application using a different, higher optimization level. For example, if you specify option level O3 for the application and specify #pragma optimization_level 1, the marked function will be optimized at option level O1, while the remaining application will be optimized at the higher level.

In general, the pragma optimizes the function at the level specified as n; however, certain compiler optimizations, like Inter-procedural Optimization (IPO), are not enabled or disabled during translation unit compilation. For example, if you enable IPO and a specific optimization level, IPO is enabled even for the function targeted by this pragma; however, IPO might not be fully implemented regardless of the optimization level specified at the command line. The reverse is also true.

Scope of optimization restriction

On Linux* and macOS* systems, the scope of the optimization restriction can be affected by arguments passed to the -pragma-optimization-level compiler option as explained in the following table.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>#pragma Intel optimization_level n</td>
<td>Applies the pragma only to the next function, using the specified optimization level, regardless of the argument passed to the -pragma-optimization-level option.</td>
</tr>
<tr>
<td>#pragma GCC optimization_level n or #pragma GCC optimization_level reset</td>
<td>Applies the pragma to all subsequent functions, using the specified optimization level, regardless of the argument passed to the -pragma-optimization-level option. Specifying reset reverses the effect of the most recent #pragma GCC optimization_level statement, by returning to the optimization level previously specified.</td>
</tr>
<tr>
<td>#pragma optimization_level n</td>
<td>Applies either the Intel® C++ Compiler implementation or the GCC* interpretation. Interpretation depends on the argument passed to the -pragma-optimization-level option.</td>
</tr>
</tbody>
</table>
NOTE
On Windows* systems, the pragma always uses the intel interpretation; the pragma is applied only to the next function.

Examples
Place the pragma immediately before the function being affected.

**Example: intel interpretation of the optimization_level pragma**

```c
#pragma intel optimization_level 1
gamma() { ... }
```

**Example: GCC* interpretation of the optimization_level pragma**

```c
#pragma GCC optimization_level 1
gamma() { ... }
```

**optimization_parameter**

*Passes certain information about a function to the optimizer.*

**Syntax**

Linux* and macOS*:

```c
#pragma intel optimization_parameter target_arch=<CPU>
#pragma intel optimization_parameter inline-max-total-size=n
#pragma intel optimization_parameter inline-max-per-routine=n
```

Windows*:

```c
#pragma [intel] optimization_parameter target_arch=<CPU>
#pragma [intel] optimization_parameter inline-max-total-size=n
#pragma [intel] optimization_parameter inline-max-per-routine=n
```

**Arguments**

- `target_arch=<CPU>`
  - for the list of CPUs, see compiler options `-m (/arch)` and `[Q]x`.

- `inline-max-per-routine=n`
  - Specifies the maximum number of times the inliner may inline into the routine. `n` is one of the following:
    - A non-negative integer constant that specifies the maximum number of times the inliner may inline into the function. If you specify zero, no inlining is done into the function.
    - The keyword unlimited, which means that there is no limit to the number of times the inliner may inline into the function.
  - For more information, see option `[Q]inline-max-per-routine`.

- `inline-max-total-size=n`
  - Specifies how much larger a function can normally grow when inline expansion is performed. `n` is one of the following:
o A non-negative integer constant that specifies the permitted increase in the function's size when inline expansion is performed. If you specify zero, no inlining is done into the function.

o The keyword unlimited, which means that there is no limit to the size a function may grow when inline expansion is performed.

For more information, see option [Q]inline-max-total-size.

Description

The `intell optimization_parameter target_arch` pragma controls the `-m(/arch)` option settings at the function level, overriding the option values specified at the command-line.

Place `#pragma intell optimization_parameter target_arch=<CPU>` at the head of a function to get the compiler to target that function for a specified instruction set. The pragma works like the `-m(/arch)` and [Q]x options, but applies only to the function before which it is placed.

The `intell optimization_parameter inline-max-total-size=n` and `intell optimization_parameter inline-max-per-routine=n` specify information used during inlining into a function.

Examples

```
Example: Targeting code for Intel® Advanced Vector Extensions (Intel® AVX) processors

icc -mAVX foo.c // on Linux* and macOS*
```

The following code targets just the function `bar` for Intel® AVX processors, regardless of the command line options used.

```
Example: Targeting a function for Intel® Advanced Vector Extensions (Intel® AVX) processors

#pragma intel optimization_parameter target_arch=AVX
void bar() { ... }
```

**parallel/noparallel**

Resolves dependencies to facilitate auto-parallelization of the immediately following loop (parallel) or prevents auto-parallelization of the immediately following loop (noparallel).

Syntax

```
#pragma parallel [clause[ [,]clause]...]
```
#pragma noparallel

**Arguments**

clause

Can be any of the following:

**always [assert]** Overrides compiler heuristics that estimate whether parallelizing a loop would increase performance. Using this clause on a loop that the compiler finds to be parallelizable tells the compiler to parallelize the loop even if doing so might not improve performance.

If `assert` is added, the compiler will generate an error-level assertion test to display a message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized.

**firstprivate( var [ :expr ] ... )** Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `firstprivate` list are subject to `private` clause semantics. In addition, its initial value is broadcast to all private instances upon entering the parallel loop.

**lastprivate( var [ :expr ] ... )** Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `lastprivate` list are subject to `private` clause semantics. In addition, when the parallel region is exited, each variable has the value that results from the sequentially last iteration of the loop up exiting the parallel loop.

**num_threads(n)** Parallelizes the loop across `n` threads, where `n` is an integer.

**private( var [ :expr ] ... )** Specifies a list of scalar and array variables (`var`) to privatize. An array or pointer variable can take an optional argument (`expr`) which is an int32 or int64 expression denoting the number of array elements to privatize.

Like the `private` clause, both the `firstprivate` and the `lastprivate` clauses specify a list of scalar and array variables (`var`) to privatize. An array or pointer variable can take an optional argument (`expr`) which is an int32 or int64 expression denoting the number of array elements to privatize.

The same `var` is not allowed to appear in both the `private` and the `firstprivate` clauses for the same loop.

The same `var` is not allowed to appear in both the `private` and the `lastprivate` clauses for the same loop.

When `expr` is absent, the rules on `var` are the same as with OpenMP. A summary of rules to be observed is as follows:
• var must not be part of another variable (as an array or structure element)
• var must not have a const-qualified type unless it is of class type with a mutable member
• var must not have an incomplete type or a reference type
• if var is of class type (or array thereof), then it requires an accessible, unambiguous default constructor for the class type. Furthermore, if this var is in a lastprivate clause, then it also requires an accessible, unambiguous copy assignment operator for the class type.

When expr is present, the same rules apply, but var must be an array or a pointer variable.
• If var is an array, then only its first expr elements are privatized. Without expr, the entire array is privatized.
• If var is a pointer, then the first expr elements are privatized (element size given by the pointer’s target type). Without expr, only the pointer variable itself is privatized.
• Program behavior is undefined if expr evaluates to a non-positive value, or if it exceeds the array size.

Description
The parallel pragma instructs the compiler to ignore potential dependencies that it assumes could exist and which would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored.

The noparallel pragma prevents autoparallelization of the immediately following loop.

These pragmas take effect only if autoparallelization is enabled by the [Q]parallel compiler option. Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as the arch, m, or [Q]x compiler options.

Caution
Use this pragma with care. If a loop has cross-iteration dependencies, annotating it with this pragma can lead to incorrect program behavior.

Only use the parallel pragma if it is known that parallelizing the annotated loop will improve its performance.

Example: Using the parallel pragma

```c
void example(double *A, double *B, double *C, double *D) {
    int i;
    #pragma parallel
    for (i=0; i<10000; i++) {
        A[i] += B[i] + C[i];
        C[i] += A[i] + D[i];
    }
}
```

See Also
arch
Invites the compiler to issue or disable requests to prefetch data from memory. This pragma applies only to Intel® MIC Architecture and Intel® Advanced Vector Extensions 512 (Intel® AVX-512).

Syntax

```c
#pragma prefetch
#pragma prefetch *:hint[:distance]
#pragma prefetch [var1 [:hint1 [:distance1]] [, var2 [:hint2 [:distance2]]]...
#pragma noprefetch [var1 [, var2]...]
```

Arguments

- **var**: An optional memory reference (data to be prefetched)
- **hint**: An optional hint to the compiler to specify the type of prefetch. Possible values:
  - 1: For integer data that will be reused
  - 2: For integer and floating point data that will be reused from L2 cache
  - 3: For data that will be reused from L3 cache
  - 4: For data that will not be reused

To use this argument, you must also specify `var`.

- **distance**: An optional integer argument with a value greater than 0. It indicates the number of loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify `var` and `hint`.

Description

This pragma hints to the compiler to generate data prefetches for some memory references. These hints affect the heuristics used in the compiler. Prefetching data can minimize the effects of memory latency.

If you specify the `prefetch` pragma with no arguments, all arrays accessed in the immediately following loop are prefetched.

If the loop includes the expression `A(j)`, placing `#pragma prefetch A in front of the loop instructs the compiler to insert prefetches for `A(j + d)` within the loop. Here, `d` is the number of iterations ahead of which to prefetch the data, and is determined by the compiler.

If you specify `#pragma prefetch *`, then `hint` and `distance` prefetches all array accesses in the loop.

To use these pragmas, compiler option `[Q]opt-prefetch` must be set (it is turned on by default if the compiler general optimization level is set at option `O2` or higher).

The `noprefetch` pragma hints to the compiler not to generate data prefetches for some memory references. This affects the heuristics used in the compiler.

Examples
Example: Using the `prefetch` pragma

```c
#pragma prefetch htab_p:1:30
#pragma prefetch htab_p:0:6

// Issue vprefetch1 for htab_p with a distance of 30 vectorized iterations ahead
// Issue vprefetch0 for htab_p with a distance of 6 vectorized iterations ahead
// If pragmas are not present, compiler chooses both distance values

for (j=0; j<2*N; j++) { htab_p[i*m1 + j] = -1; }
```

Example: Using `noprefetch` and `prefetch` pragmas together

```c
#pragma noprefetch b
#pragma prefetch a

for(i=0; i<m; i++) { a[i]=b[i]+1; }
```

Example: Using `noprefetch` and `prefetch` pragmas together

```c
for (i=i0; i!=i1; i+=is) {
    float sum = b[i];
    int ip = srow[i];
    int c = col[ip];

#pragma noprefetch col
#pragma prefetch value:1:80
#pragma prefetch x:1:40

    for(; ip<srow[i+1]; c=col[++ip])
        sum -= value[ip] * x[c];
    y[i] = sum;
}
```

**simd**

*Enforces vectorization of loops.*

**Syntax**

```c
#pragma simd [clause[ [,] clause]...]
```

**Arguments**

`clause` Can be any of the following:

`vectorlength(n1[, n2]...)` Where `n` is a vector length (VL). It must be an integer that is a power of 2; the value must be 2, 4, 8, or 16. If you specify more than one `n`, the vectorizer will choose the VL from the values specified.
Causes each iteration in the vector loop to execute the computation equivalent to \( n \) iterations of scalar loop execution. Multiple `vectorlength` clauses are merged as a union.

**vectorlengthfor(data type)**

Where `data type` must be one of built-in integer types (8, 16, 32, or 64bit), pointer types (treated as pointer-sized integer), floating point types (32 or 64bit), or complex types (64bit or 128bit). Otherwise, behavior is undefined.

Causes each iteration in the vector loop to execute the computation equivalent to \( n \) iterations of scalar loop execution where \( n \) is computed from `size_of_vector_register/sizeof(data_type)`.

For example, `vectorlengthfor(float)` results in \( n=4 \) for Intel® Streaming SIMD Extensions (Intel® SSE2) to Intel SSE4.2 targets (packed float operations available on 128bit XMM registers) and \( n=8 \) for an Intel® Advanced Vector Extensions (Intel® AVX) target (packed float operations available on 256bit YMM registers). `vectorlengthfor(int)` results in \( n=4 \) for Intel SSE2 to Intel AVX targets.

`vectorlength()` and `vectorlengthfor()` clauses are mutually exclusive. In other words, the `vectorlengthfor()` clause may not be used with the `vectorlength()` clause, and vice versa.

Behavior for multiple `vectorlengthfor` clauses is undefined.

**private(var1[, var2]...)**

Where `var` is a scalar variable.

Causes each variable to be private to each iteration of a loop. Unless the variable appears in `firstprivate` clause, the initial value of the variable for the particular iteration is undefined. Unless the variable appears in `lastprivate` clause, the value of the variable upon exit of the loop is undefined. Multiple `private` clauses are merged as a union.

---

**NOTE**

Execution of the SIMD loop with `firstprivate/lastprivate` clauses may be different from serial execution of the same code even if the loop fails to vectorize.

A variable in a `private` clause cannot appear in a `linear`, `reduction`, `firstprivate`, or `lastprivate` clause.
**firstprivate**(var1[, var2]...) Provides a superset of the functionality provided by the private clause. Variables that appear in a firstprivate list are subject to private clause semantics. In addition, its initial value is broadcast to all private instances for each iteration upon entering the SIMD loop.

A variable in a firstprivate clause can appear in a lastprivate clause.

A variable in a firstprivate clause cannot appear in a linear, reduction, or private clause.

**lastprivate**(var1[, var2]...) Provides a superset of the functionality provided by the private clause. Variables that appear in a lastprivate list are subject to private clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable).

A variable in a lastprivate clause can appear in a firstprivate clause.

A variable in a lastprivate clause cannot appear in a linear, reduction, or private clause.

**linear**(var1:step1 [,var2:step2]...) Where var is a scalar variable and step is a compile-time positive, integer constant expression.

For each iteration of a scalar loop, var1 is incremented by step1, var2 is incremented by step2, and so on. Therefore, every iteration of the vector loop increments the variables by VL*step1, VL*step2, ..., to VL*stepN, respectively. If more than one step is specified for a var, a compile-time error occurs. Multiple linear clauses are merged as a union.

A variable in a linear clause cannot appear in a reduction, private, firstprivate, or lastprivate clause.

**reduction**(oper:var1 [,var2]...) Where oper is a reduction operator and var is a scalar variable.

Applies the vector reduction indicated by oper to var1, var2, ..., varN. The simd pragma may have multiple reduction clauses with the same or different operators. If more than one reduction operator is associated with a var, a compile-time error occurs.

A variable in a reduction clause cannot appear in a linear, private, firstprivate, or lastprivate clause.
[no]assert  
Directs the compiler to assert or not to assert when the vectorization fails. The default is noassert. If this clause is specified more than once, a compile-time error occurs.

[no]vecremainder  
Instrcutes the compiler to vectorize or not to vectorize the remainder loop when the original loop is vectorized. See the description of the vector pragma for more information.

Description

The simd pragma is used to guide the compiler to vectorize more loops. Vectorization using the simd pragma complements (but does not replace) the fully automatic approach.

The simd pragma can be used on a cilk_for loop. See the documentation on cilk_for for a discussion of how they are best used together.

Without explicit vectorlength() and vectorlengthfor() clauses, the compiler will choose a vectorlength using its own cost model. Misclassification of variables into private, firstprivate, lastprivate, linear, and reduction, or lack of appropriate classification of variables may cause unintended consequences such as runtime failures and/or incorrect result.

You can only specify a particular variable in at most one instance of a private, linear, or reduction clause.

If the compiler is unable to vectorize a loop, a warning will be emitted (use the assert clause to make it an error).

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

The vectorization performed on this loop by the simd pragma overrides any setting you may specify for options -fp-model (Linux* and macOS*) and /fp (Windows*) for this loop.

Note that the simd pragma may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the simd pragma:

- The countable loop for the simd pragma has to conform to the for-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating point numbers, or single or double-precision complex numbers.
- A SIMD loop may contain another loop (for, while, do-while) in it. Goto out of such inner loops are not supported. Break and continue are supported. Note that inlining can create such an inner loop, which may not be obvious at the source level.
- A SIMD loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable transformations that enables more vectorization, specify the -vec -no-simd (Linux* and macOS*) or /Qvec /Qno-simd (Windows*) options.

User-mandated vectorization, also called SIMD vectorization can assert or not assert an error if a #pragma simd annotated loop fails to vectorize. By default, the simd pragma is set to noassert, and the compiler will issue a warning if the loop fails to vectorize. To direct the compiler to assert an error when the #pragma simd annotated loop fails to vectorize, add the assert clause to the simd pragma. If a simd pragma annotated loop is not vectorized by the compiler, the loop holds its serial semantics.
**Example: Using the simd pragma**

```c
void add_floats(float *a, float *b, float *c, float *d, float *e, int n){
    int i;
    #pragma simd
    for (i=0; i<n; i++){
        a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
    }
}
```

In the example above, the function `add_floats()` uses too many unknown pointers for the compiler's automatic runtime independence check optimization to kick-in. The programmer can enforce the vectorization of this loop by using the `simd` pragma to avoid the overhead of runtime check.

**simdoff**

Specifies a block of code in the SIMD loop or SIMD-enabled function that should be executed serially, in a logical order of SIMD lanes.

**Syntax**

```
#pragma simdoff
structured-block
```

**Arguments**

None.

**Description**

The `simdoff` block will use a single SIMD lane to execute operations in the order of the loop iterations, or logical lanes of a SIMD-enabled function. This preserves ordering of operations in the block with respect to each other, and correlates with iteration space of the enclosing SIMD construct. The ordered `simd` block is executed in order, with respect to each SIMD lane or each loop iteration. The operations within the ordered `simd` or `simdoff` block can be re-ordered by optimizations, as long as the original execution semantics are preserved.

`simdoff` blocks allow the isolation and resolution of situations prohibited from SIMD execution. This includes cross-iteration data dependencies, function calls with side effects, such as OpenMP, TBB and native thread synchronization primitives.

`simdoff` sections are useful for resolving cross-iteration data dependencies in otherwise data-parallel computations. For example, the section may handle histogram updates as shown below:
Example

```c
#pragma simd
for (int i = 0; i < N; i++)
{
    float amount = compute_amount(i);
    int cluster = compute_cluster(i);
#pragma simdoff
    { 
        totals[cluster] += amount; // Requires ordering to process multiple updates for the same cluster
    }
}
```

**unroll/nounroll**

*Indicates to the compiler to unroll or not to unroll a counted loop.*

**Syntax**

- `#pragma unroll`
- `#pragma unroll(n)`
- `#pragma nounroll`

**Arguments**

- `n` The unrolling factor representing the number of times to unroll a loop; it must be an integer constant from 0 through 255.

**Description**

The `unroll[n]` pragma tells the compiler how many times to unroll a counted loop.

The `unroll` pragma must precede the `for` statement for each `for` loop it affects. If `n` is specified, the optimizer unrolls the loop `n` times. If `n` is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop.

This pragma is supported only when option `O3` is set. The `unroll` pragma overrides any setting of loop unrolling from the command line.

The pragma can be applied for the innermost loop nest as well as for the outer loop nest. If applied to outer loop nests, the current implementation supports complete outer loop unrolling. The loops inside the loop nest are either not unrolled at all or completely unrolled. The compiler generates correct code by comparing `n` and the loop count.

When unrolling a loop increases register pressure and code size it may be necessary to prevent unrolling of a loop. In such cases, use the `nounroll` pragma. The `nounroll` pragma instructs the compiler not to unroll a specified loop.
### Examples

#### Example: Using the unroll pragma for innermost loop unrolling

```c
void unroll(int a[], int b[], int c[], int d[]) {
    #pragma unroll(4)
    for (int i = 1; i < 100; i++) {
        b[i] = a[i] + 1;
        d[i] = c[i] + 1;
    }
}
```

#### Example: Using the unroll pragma for outer loop unrolling

```c
int m = 0;
int dir[4]= {1,2,3,4};
int data[10];
#pragma unroll (4) // outer loop unrolling
for (int i = 0; i < 4; i++) {
    for (int j = dir[i]; data[j]==N ; j+=dir[i])
        m++;
}
```

By placing the `unroll` pragma before the first `for` loop causes the compiler to unroll the outer loop completely. If an `unroll` pragma is placed before the inner `for` loop as well as before the outer `for` loop, the compiler ignores the inner `for` loop `unroll` pragma. If the `unroll` pragma is placed only for the innermost loop, the compiler unrolls the innermost loop according to some factor.

### unroll_and_jam/nounroll_and_jam

Enables or disables loop unrolling and jamming. These pragmas can only be applied to iterative for loops.

#### Syntax

```
#pragma unroll_and_jam
#pragma unroll_and_jam (n)
#pragma nounroll_and_jam
```

#### Arguments

- `n` The unrolling factor representing the number of times to unroll a loop; it must be an integer constant from 0 through 255

#### Description

The `unroll_and_jam` pragma partially unrolls one or more loops higher in the nest than the innermost loop and fuses/jams the resulting loops back together. This transformation allows more reuses in the loop.

This pragma is not effective on innermost loops. Ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this pragma is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler enables this transformation whenever possible.
**The unroll_and_jam pragma** must precede the `for` statement for each `for` loop it affects. If `n` is specified, the optimizer unrolls the loop `n` times. If `n` is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop. The compiler generates correct code by comparing `n` and the loop count.

This pragma is supported only when compiler option `O3` is set. The `unroll_and_jam` pragma overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size it may be necessary to prevent unrolling of a nested loop or an imperfect nested loop. In such cases, use the `nounroll_and_jam` pragma. The `nounroll_and_jam` pragma hints to the compiler not to unroll a specified loop.

</tbody>
</table>
**unused**
Describes variables that are unused (warnings not generated).

**Syntax**

```
#pragma unused
```

**Arguments**
None

**Description**
The `unused` pragma is implemented for compatibility with Apple* implementation of GCC.

**vector**
Indicates to the compiler that the loop should be vectorized according to the argument keywords.

**Syntax**

```
#pragma vector {always[assert]|aligned|unaligned|dynamic_align[(var)]|nodynamic_align|
temporal|nontemporal|[no]vecremainder|[no]mask_readwrite|vectorlength(n1[, n2]...)}
#pragma vector nontemporal[(var1[, var2, ...])]}
```
Arguments

always
Instructs the compiler to override any efficiency heuristic during the decision to vectorize or not, and vectorize non-unit strides or very unaligned memory accesses; controls the vectorization of the subsequent loop in the program; optionally takes the keyword assert

aligned
Instructs the compiler to use aligned data movement instructions for all array references when vectorizing

unaligned
Instructs the compiler to use unaligned data movement instructions for all array references when vectorizing

dynamic_align[(var)]
Instructs the compiler to perform dynamic alignment optimization for the loop with an optionally specified variable to perform alignment on

nodynamic_align
Disables dynamic alignment optimization for the loop

nontemporal
Instructs the compiler to use non-temporal (that is, streaming) stores on systems based on all supported architectures, unless otherwise specified; optionally takes a comma-separated list of variables.

When this pragma is specified, it is your responsibility to also insert any fences as required to ensure correct memory ordering within a thread or across threads. One typical way to do this is to insert a _mm_sfence intrinsic call just after the loops (such as the initialization loop) where the compiler may insert streaming store instructions.

On systems based on Intel® MIC Architecture, directs the compiler to generate clevict (cache-line-evict) instructions after the stores based on the non-temporal pragma when the compiler knows that the store addresses are aligned; optionally takes a comma separated list of variables.

temporal
Instructs the compiler to use temporal (that is, non-streaming) stores on systems based on all supported architectures, unless otherwise specified

vecremainder
Instructs the compiler to vectorize the remainder loop when the original loop is vectorized

novecremainerder
Instructs the compiler not to vectorize the remainder loop when the original loop is vectorized

mask_readwrite
Enables memory speculation causing the generate of non-masked loads and stores within conditions

nomask_readwrite
Disables memory speculation causing the generation of masked load and store operations within conditions

vectorlength(n1[,n2]...)
Instructs the vectorizer which vector length/factor to use when generating the main vector loop.

Description

The vector pragma indicates that the loop should be vectorized, if it is legal to do so, ignoring normal heuristic decisions about profitability. The vector pragma takes several argument keywords to specify the kind of loop vectorization required. These keywords are aligned, unaligned, always, temporal, and nontemporal. The compiler does not apply the vector pragma to nested loops, each nested loop needs a preceding pragma statement. Place the pragma before the loop control statement.

Using the aligned/unaligned keywords
When the **aligned/unaligned** argument keyword is used with this pragma, it indicates that the loop should be vectorized using aligned/unaligned data movement instructions for all array references. Specify only one argument keyword: **aligned** or **unaligned**.

**Caution**
If you specify **aligned** as an argument, you must be sure that the loop is vectorizable using this pragma. Otherwise, the compiler generates incorrect code.

**Using the always keyword**
When the **always** argument keyword is used, the pragma controls the vectorization of the subsequent loop in the program. If **assert** is added, the compiler will generate an error-level assertion test to display a message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized.

**Using the dynamic_align/nodynamic_align keywords**
Dynamic alignment is an optimization the compiler attempts to perform by default. It involves peeling iterations from the vector loop into a scalar loop before the vector loop so that the vector loop aligns with a particular memory reference. The **dynamic_align(var)** form of the directive allows the user to provide a scalar or array variable name to align on. Specifying **nodynamic_align** with or without **var** does not guarantee the optimization is performed; the compiler still uses heuristics to determine feasibility of the operation.

**Using the nontemporal/temporal keywords**
The **nontemporal** and **temporal** argument keywords are used to control how the "stores" of register contents to storage are performed (streaming versus non-streaming) on systems based on IA-32 and Intel® 64 architectures.

On systems based on Intel® MIC Architecture, **#pragma vector nontemporal** directs the compiler to generate **clevict** (cache-line-evict) instructions after the stores based on the non-temporal pragma when the compiler knows that the store addresses are aligned; optionally takes a comma separated list of variables.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

**Using the [no]vecremainder keyword**
If the **vector always** pragma and keyword are specified, the following occurs:

- If the vecremainder clause is specified, the compiler vectorizes both the main and remainder loops.
- If the novecremainder clause is specified, the compiler vectorizes the main loop, but it does not vectorize the remainder loop.

**Using the [no]mask_readwrite keyword**
If the **vector** pragma and **mask_readwrite** or **nomask_readwrite** keyword are specified, the following occurs:

- If the mask_readwrite clause is specified, the compiler generates masked loads and stores within all conditions in the loop.
- If the nomask_readwrite clause is specified, the compiler generates unmasked loads and stores for increased performance.

**Using the vectorlength keyword**
n is an integer power of 2; the value must be 2, 4, 6, 8, 16, 32, or 64. If more than one value is specified, the vectorizer will choose one of the specified vector lengths based on a cost model decision.

**NOTE**
The pragma `vector(always|aligned|unaligned)` should be used with care.

Overriding the efficiency heuristics of the compiler should only be done if the programmer is absolutely sure that vectorization will improve performance. Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a run-time exception in case some of the access patterns are actually unaligned.

**Examples**

In the following example, the `aligned` argument keyword is used to request that the loop be vectorized with aligned instructions.

Note that the arrays are declared in such a way that the compiler could not normally prove this would be safe to vectorize.

**Example: Using the vector aligned pragma**

```c
void vec_aligned(float *a, int m, int c) {
    int i;
    // Instruct compiler to ignore assumed vector dependencies.
    #pragma vector aligned
    for (i = 0; i < m; i++)
        a[i] = a[i] * c;
    // Alignment unknown but compiler can still align.
    for (i = 0; i < 100; i++)
        a[i] = a[i] + 1.0f;
}
```

**Example: Using the vector always pragma**

```c
void vec_always(int *a, int *b, int m) {
    #pragma vector always
    for(int i = 0; i <= m; i++)
        a[32*i] = b[99*i];
}
```

**Example: Using vector nontemporal pragma**

```c
float a[1000];
void foo(int N){
    int i;
    // #pragma vector nontemporal
    for (i = 0; i < N; i++) {
        a[i] = 1;
    }
}
```

A float-type loop together with the generated assembly is shown in the following example. For large N, significant performance improvements result on systems with Intel® Pentium® 4 processors over non-streaming implementations.
Example: Using ASM code for the loop body

```asm
.B1.2:
movntps XMMWORD PTR _a[eax], xmm0
movntps XMMWORD PTR _a[eax+16], xmm0
add eax, 32
cmp eax, 4096
jl .B1.2
```

Example: Using pragma vector nontemporal with variables for implementing streaming stores

```c
double A[1000];
double B[1000];
void foo(int n){
    int i;
    #pragma vector nontemporal (A, B)
    for (i=0; i<n; i++){
        A[i] = 0;
        B[i] = i;
    }
}
```

**Intel-supported Pragma Reference**

The Intel® C++ Compiler supports the following pragmas to ensure compatibility with other compilers.

**Pragmas Compatible with the Microsoft* Compiler**

The following pragmas are compatible with the Microsoft* compiler. For more information about these pragmas, go to the Microsoft* Developer Network (http://msdn.microsoft.com).

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alloc_text</td>
<td>Names the code section where the specified function definitions are to reside.</td>
</tr>
<tr>
<td>auto_inline</td>
<td>Excludes any function defined within the range where off is specified from being considered as candidates for automatic inline expansion.</td>
</tr>
<tr>
<td>bss_seg</td>
<td>Indicates to the compiler the segment where uninitialized variables are stored in the .obj file.</td>
</tr>
<tr>
<td>check_stack</td>
<td>The on argument indicates that stack checking should be enabled for functions that follow and the off argument indicates that stack checking should be disabled for functions that follow.</td>
</tr>
<tr>
<td>code_seg</td>
<td>Specifies a code section where functions are to be allocated.</td>
</tr>
<tr>
<td>comment</td>
<td>Places a comment record into an object file or executable file.</td>
</tr>
<tr>
<td>component</td>
<td>Controls collecting of browse information or dependency information from within source files.</td>
</tr>
<tr>
<td>Pragma</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>conform</td>
<td>Specifies the run-time behavior of the /Zc:forScope compiler option.</td>
</tr>
<tr>
<td>const_seg</td>
<td>Specifies the segment where functions are stored in the .obj file.</td>
</tr>
<tr>
<td>data_seg</td>
<td>Specifies the default section for initialized data.</td>
</tr>
<tr>
<td>deprecated</td>
<td>Indicates that a function, type, or any other identifier may not be supported in a future release or indicates that a function, type, or any other identifier should not be used any more.</td>
</tr>
<tr>
<td>fenv_access</td>
<td>Informs an implementation that a program may test status flags or run under a non-default control mode.</td>
</tr>
<tr>
<td>float_control</td>
<td>Specifies floating-point behavior for a function.</td>
</tr>
<tr>
<td>fp_contract</td>
<td>Allows or disallows the implementation to contract expressions.</td>
</tr>
<tr>
<td>loop</td>
<td>Controls how the loop code will be considered or excluded from consideration by the auto-vectorizer.</td>
</tr>
<tr>
<td>init_seg</td>
<td>Specifies the section to contain C++ initialization code for the translation unit.</td>
</tr>
<tr>
<td>message</td>
<td>Displays the specified string literal to the standard output device (stdout).</td>
</tr>
<tr>
<td>optimize</td>
<td>Specifies optimizations to be performed on functions below the pragma or until the next optimize pragma; implemented to partly support the Microsoft* implementation of same pragma; for the Intel® C++ Compiler implementation, see the optimize reference page.</td>
</tr>
<tr>
<td>pointers_to_members</td>
<td>Specifies whether a pointer to a class member can be declared before its associated class definition and is used to control the pointer size and the code required to interpret the pointer.</td>
</tr>
<tr>
<td>pop_macro</td>
<td>Sets the value of the specified macro to the value on the top of the stack.</td>
</tr>
<tr>
<td>push_macro</td>
<td>Saves the value of the specified macro on the top of the stack.</td>
</tr>
<tr>
<td>region/endregion</td>
<td>Specifies a code segment in the Microsoft* Visual Studio* Code Editor that expands and contracts by using the outlining feature.</td>
</tr>
<tr>
<td>section</td>
<td>Creates a section in an .obj file. Once a section is defined, it remains valid for the remainder of the compilation.</td>
</tr>
<tr>
<td>vtordisp</td>
<td>The on argument enables the generation of hidden vtordisp members and the off disables them.</td>
</tr>
<tr>
<td></td>
<td>push argument pushes the current vtordisp setting to the internal compiler stack. pop argument removes the top record from the compiler stack and restores the removed value of vtordisp.</td>
</tr>
<tr>
<td>warning</td>
<td>Allows selective modification of the behavior of compiler warning messages.</td>
</tr>
<tr>
<td>weak</td>
<td>Declares symbol you enter to be weak.</td>
</tr>

OpenMP® Standard Pragmas

The Intel® C++ Compiler currently supports OpenMP® TR4: Version 5.0 pragmas, as listed below. For more information about these pragmas, reference the OpenMP® TR4: Version 5.0 specification.

Intel-specific clauses are noted in the affected pragma description.

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>omp atomic</td>
<td>Specifies a computation that must be executed atomically.</td>
</tr>
<tr>
<td>omp barrier</td>
<td>Specifies a point in the code where each thread must wait until all threads in the team arrive.</td>
</tr>
<tr>
<td>omp cancel</td>
<td>Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering task to proceed to the end of the cancelled construct.</td>
</tr>
<tr>
<td>omp cancellation point</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.</td>
</tr>
<tr>
<td>omp critical</td>
<td>Specifies a code block that is restricted to access by only one thread at a time.</td>
</tr>
<tr>
<td>omp declare reduction</td>
<td>Declares User-Defined Reduction (UDR) functions (reduction identifiers) that can be used as reduction operators in a reduction clause.</td>
</tr>
<tr>
<td>omp declare simd</td>
<td>Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.</td>
</tr>
<tr>
<td>omp declare target</td>
<td>Specifies functions and variables that are created or mapped to a device. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp distribute</td>
<td>Specifies that the iterations of one or more loops should be distributed among the master threads of all thread teams in a league.</td>
</tr>
<tr>
<td>omp distribute parallel for</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>omp distribute parallel for simd</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp distribute simd</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp flush</td>
<td>Identifies a point at which the view of the memory by the thread becomes consistent with the memory.</td>
</tr>
<tr>
<td>omp for</td>
<td>Specifies a parallel loop. Each iteration of the loop is executed by one of the threads in the team.</td>
</tr>
<tr>
<td>omp for simd</td>
<td>Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp inclusive_scan</td>
<td>Specifies a boundary between definitions and uses. This pragma should be used with the scan clause and must not be used in nested loops.</td>
</tr>

<td>omp target update</td>
<td>Makes the items listed in the device data environment consistent between the device and host, in accordance with the motion clauses on the pragma. This pragma only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>omp task</td>
<td>Specifies the beginning of a code block whose execution may be deferred.</td>
</tr>
<tr>
<td>omp taskgroup</td>
<td>Causes the program to wait until the completion of all enclosed and descendant tasks.</td>
</tr>
<tr>
<td>omp taskwait</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>omp taskyield</td>
<td>Specifies that the current task can be suspended at this point in favor of execution of a different task.</td>
</tr>
<tr>
<td>Pragma</td>
<td>Description</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>omp teams</td>
<td>Creates a league of thread teams inside a target region to execute a structured block in the master thread of each team.</td>
</tr>
<tr>
<td>omp teams distribute</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a teams construct.</td>
</tr>
<tr>
<td>omp teams distribute parallel for</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>omp teams distribute parallel for simd</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>omp teams distribute simd</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams.</td>
</tr>
<tr>
<td>omp threadprivate</td>
<td>Specifies a list of globally-visible variables that will be allocated private to each thread.</td>
</tr>

**Error Handling**
Remarks, Warnings, and Errors

This topic describes compiler remarks, warnings, and errors. The Intel® C++ Compiler sends these messages, along with the erroneous source line, to stderr.

Remarks

Remark messages report common but sometimes unconventional use of C or C++. Remarks do not stop translation or linking. Remarks do not interfere with any output files. The following are some representative remark messages:

- function declared implicitly.
- type qualifiers are meaningless in this declaration.
- controlling expression is constant.

Warnings

Warning messages report legal but questionable use of C or C++. The compiler displays warnings by default. You can suppress warning messages by specifying an appropriate compiler option. Warnings do not stop translation or linking. Warnings do not interfere with any output files. The following are some representative warning messages:

- declaration does not declare anything.
- pointless comparison of unsigned integer with zero.
- possible use of = where == was intended.

Additional Warnings

The following Linux* and macOS* options produce additional warnings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>-W[no-]missing-prototypes</td>
<td>Warn for missing prototypes.</td>
</tr>
<tr>
<td>-W[no-]missing-declarations</td>
<td>Warn for missing declarations.</td>
</tr>
<tr>
<td>-W[no-]unused-variable</td>
<td>Warn for unused variable.</td>
</tr>
<tr>
<td>-W[no-]pointer-arith</td>
<td>Warn for questionable pointer arithmetic.</td>
</tr>
<tr>
<td>-W[no-]uninitialized</td>
<td>Warn if a variable is used before being initialized.</td>
</tr>
<tr>
<td>-W[no-]deprecated</td>
<td>Display warnings related to deprecated features.</td>
</tr>
<tr>
<td>-W[no-]abi</td>
<td>Warn if generated code is not C++ ABI compliant.</td>
</tr>
<tr>
<td>-W[no-]unused-function</td>
<td>Warn if declared function is not used.</td>
</tr>
<tr>
<td>-W[no-]unknown-pragmas</td>
<td>Warn if an unknown #pragma directive is used.</td>
</tr>
<tr>
<td>-W[no-]main</td>
<td>Warn if return type of main is not expected.</td>
</tr>
<tr>
<td>-W[no-]comment[s]</td>
<td>Warn when /* appears in the middle of a /* */ comment.</td>
</tr>
<tr>
<td>-W[no-]return-type</td>
<td>Warn when a function uses the default int return type</td>
</tr>
<tr>
<td></td>
<td>Warn when a return statement is used in a void function.</td>
</tr>
</tbody>
</table>
Errors

These messages report syntactic or semantic misuse of C or C++. The compiler always displays error messages. Errors suppress object code for the module containing the error and prevent linking, but they allow parsing to continue to detect other possible errors. Some representative error messages are:

- missing closing quote.
- expression must have arithmetic type.
- expected a ";".

Some remarks, warnings, and errors are numbered and can be disabled using option -diag-disable=list or /Qdiag-disable:list.

Example

<table>
<thead>
<tr>
<th>// Windows*</th>
</tr>
</thead>
<tbody>
<tr>
<td>/Qdiag-disable:117,230,450</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>// Linux* and macOS*</th>
</tr>
</thead>
<tbody>
<tr>
<td>-diag-disable=117,230,450</td>
</tr>
</tbody>
</table>

Option Summary

Use the following compiler options to control remarks, warnings, and errors (Note: options with a '-' prefix supported on Linux* and macOS* and options with a '/' prefix supported on Windows*):

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>-w, /W0</td>
<td>Enables diagnostics for errors; disables diagnostics for warnings.</td>
</tr>
<tr>
<td>-w1, /W1, /W2</td>
<td>Enables diagnostics for warnings and errors.</td>
</tr>
<tr>
<td>-w2</td>
<td>Enables diagnostics for verbose warnings, warnings, and errors.</td>
</tr>
<tr>
<td>-w3, /W3</td>
<td>Enables diagnostics for remarks, warnings, and errors. Additional</td>
</tr>
<tr>
<td></td>
<td>warnings are also enabled above level 2 warnings.</td>
</tr>
<tr>
<td>/W4, /Wall</td>
<td>Enables diagnostics for all level 3 warnings, plus informational warnings</td>
</tr>
<tr>
<td></td>
<td>and remarks, which, in most cases, can be safely ignored.</td>
</tr>
<tr>
<td>/W5</td>
<td>Enables diagnostics for all remarks, warnings, and errors. This option</td>
</tr>
<tr>
<td></td>
<td>produces the most diagnostic messages.</td>
</tr>
<tr>
<td>-Wremarks</td>
<td>Display remarks and comments.</td>
</tr>
<tr>
<td>-Wbrief, /WL</td>
<td>Display brief one-line diagnostics.</td>
</tr>
<tr>
<td>-Wcheck</td>
<td>Enable more strict diagnostics.</td>
</tr>
<tr>
<td>-Werror-all</td>
<td>Change all warnings and remarks to errors.</td>
</tr>
<tr>
<td>-Werror, /WX</td>
<td>Change all warnings to errors.</td>
</tr>
<tr>
<td>/Wp64</td>
<td>Display diagnostics for 64-bit porting.</td>
</tr>
</tbody>
</table>

You can also control the display of diagnostic information with variations of the [Q]diag compiler option. This compiler option accepts numerous arguments and values, allowing you wide control over displayed diagnostic messages and reports.

Some of the most common variations include the following:
<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>`[Q]diag-enable&lt;:</td>
<td>= list`</td>
</tr>
<tr>
<td>`[Q]diag-disable&lt;:</td>
<td>= list`</td>
</tr>
<tr>
<td>`[Q]diag-warning&lt;:</td>
<td>= list`</td>
</tr>
<tr>
<td>`[Q]diag-error&lt;:</td>
<td>= list`</td>
</tr>
<tr>
<td>`[Q]diag-remark&lt;:</td>
<td>= list`</td>
</tr>
</tbody>
</table>

The `list` items can be specific diagnostic IDs, one of the keywords `warn`, `remark`, or `error`, or a keyword specifying a certain group (`par`, `vec`, `driver`, `thread`, `port-linux` (available on Windows* systems), `port-win` (available on Linux* and macOS* systems), `openmp`). For more information, see `[Q]diag`

Other diagnostic-related options include the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[Q]diag-dump</code></td>
<td>Tells the compiler to print all enabled diagnostic messages and stop compilation.</td>
</tr>
<tr>
<td>`[Q]diag-file&lt;:</td>
<td>= file`</td>
</tr>
<tr>
<td>`[Q]diag-file-append&lt;:</td>
<td>= file`</td>
</tr>
<tr>
<td>`[Q]diag-error-limit&lt;:</td>
<td>= n`</td>
</tr>
</tbody>
</table>
## Supported Environment Variables

You can customize your system environment by specifying paths where the compiler searches for certain files such as libraries, include files, configuration files, and certain settings.

### Compiler Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the compiler:

<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CILK_NWORKERS (Windows*, Linux*)</td>
<td>Specifies the number of worker threads to use in an Intel® Cilk™ Plus program. Intel® Cilk™ Plus is a deprecated feature. See the section Set Worker Count on Debugging an Intel® Cilk™ Plus Program.</td>
</tr>
<tr>
<td>CL (Windows)</td>
<td>Define the files and options you use most often with the CL variable. Note: You cannot set the CL environment variable to a string that contains an equal sign. You can use the pound sign instead. In the following example, the pound sign (#) is used as a substitute for an equal sign in the assigned string: <code>SET CL=/Dtest#100</code></td>
</tr>
<tr>
<td><em>CL</em> (Windows)</td>
<td>Same as PROF_DIR.</td>
</tr>
<tr>
<td>COV_DIR (Windows)</td>
<td>Same as PROF_DPI.</td>
</tr>
<tr>
<td>COV_DPI (Windows)</td>
<td>Points to the directories containing the include and library files for a non-standard installation structure.</td>
</tr>
<tr>
<td>IA32ROOT (IA-32 architecture and Intel® 64 architecture)</td>
<td><strong>NOTE</strong> IA-32 architecture is no longer supported on macOS*.</td>
</tr>
<tr>
<td>ICCCFG</td>
<td>Specifies the configuration file for customizing compilations when invoking the compiler using <code>icc</code>.</td>
</tr>
<tr>
<td>Compile-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>ICPCCFG</td>
<td>Specifies the configuration file for customizing compilations when invoking the compiler using <code>icpc</code>.</td>
</tr>
<tr>
<td>ICLCFG (Windows)</td>
<td>Specifies a configuration file, which the compiler should use instead of the default configuration file.</td>
</tr>
<tr>
<td>INTEL_LICENSE_FILE</td>
<td>Specifies the location for the Intel license file.</td>
</tr>
</tbody>
</table>

**NOTE**

On Windows* operating systems, this environment variable cannot be set from Visual Studio.

| __INTEL_PRE_CFLAGS               | Specifies a set of compiler options to add to the compile line. |
|                                   | This is an extension to the facility already provided in the compiler configuration file `icl.cfg`. |

**NOTE**

By default, a configuration file named `icl.cfg` (Windows*), `icc.cfg` (Linux*, macOS*), or `icpc.cfg` (Linux*, macOS*) is used. This file is in the same directory as the compiler executable. To use another configuration file in another location, you can use the `ICLCFG` (Windows*), `ICCCFG` (Linux*, macOS*), or `ICPCCFG` (Linux*, macOS*) environment variable to assign the directory and file name for the configuration file.

You can insert command line options in the prefix position using `__INTEL_PRE_CFLAGS`, or in the suffix position using `__INTEL_POST_CFLAGS`. The command line is built as follows:

**Syntax:** (On Windows, use `icl`. On Linux or macOS* use `icc`) `icl/icc <PRE flags> <flags from configuration file> <flags from the compiler invocation> <POST flags>`

**NOTE**

The driver issues a warning that the compiler is overriding an option because of an environment variable, but only when you include the option `/W5` (Windows*) or `-w3` (Linux* and macOS*).

<p>| INTEL_TARGET_ARCH                | Set this environment variable to target 32-bit compilations for all associated tools (this includes the compiler and Intel-specific linker tools). Without this environment variable, you will be required to use the explicit command line options, <code>/Qm32</code> on Windows* and <code>-m32</code> on Linux*, for each compiler invocation. |
| CH_IA32 (Linux* and Windows*)    | <strong>NOTE</strong> IA-32 architecture is no longer supported on macOS*. |
| PATH                             | Specifies the directories the system searches for binary executable files. |</p>
<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong> On Windows* this also affects the search for Dynamic Link Libraries (DLLs).</td>
<td></td>
</tr>
<tr>
<td><strong>TMP</strong></td>
<td>Specifies the location for temporary files. If none of these are specified, or writeable, or found, the compiler stores temporary files in /tmp (Linux, macOS*) or the current directory (Windows).</td>
</tr>
<tr>
<td><strong>TMPDIR</strong></td>
<td></td>
</tr>
<tr>
<td><strong>TEMP</strong></td>
<td>The compiler searches for these variables in the following order: TMP, TMPDIR, and TEMP.</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>On Windows* operating systems, these environment variables cannot be set from Visual Studio.</td>
</tr>
<tr>
<td><strong>LD_LIBRARY_PATH</strong> (Linux*)</td>
<td>Specifies the location for shared objects (.so files).</td>
</tr>
<tr>
<td><strong>DYLD_LIBRARY_PATH</strong> (macOS*)</td>
<td>Specifies the path for dynamic libraries.</td>
</tr>
<tr>
<td><strong>INCLUDE</strong> (Windows*)</td>
<td>Specifies the directories for the source header files (include files).</td>
</tr>
<tr>
<td><strong>LIB</strong> (Windows*)</td>
<td>Specifies the directories for all libraries used by the compiler and linker.</td>
</tr>
</tbody>
</table>

**Intel® MIC Architecture Environment Variables**

**GNU Environment Variables and Extensions**

| **CPATH** (Linux* and macOS*) | Specifies the path to include directory for C/C++ compilations. |
| **C_INCLUDE_PATH** (Linux* and macOS*) | Specifies path to include directory for C compilations. |
| **CPLUS_INCLUDE_PATH** (Linux* and macOS*) | Specifies path to include directory for C++ compilations. |
| **DEPENDENCIES_OUTPUT** (Linux* and macOS*) | Specifies how to output dependencies for make based on the non-system header files processed by the compiler. System header files are ignored in the dependency output. |
| **GCC_EXEC_PREFIX** (Linux*) | Specifies alternative names for the linker (ld) and assembler (as). |
| **GCCROOT** (Linux*) | Specifies the location of the gcc* binaries. Set this variable only when the compiler cannot locate the gcc binaries when using the -gcc-name option. |
Compile-Time Environment Variable | Description
--- | ---
**GXX_INCLUDE** *(Linux*) | Specifies the location of the gcc headers. Set this variable to specify the locations of the gcc installed files when the compiler does not find the needed values as specified by the use of `-gcc-name=directory-name/gcc` or `-gxx-name=directory-name/g++`.

**GXX_ROOT** *(Linux*) | Specifies the location of the gcc binaries. Set this variable to specify the locations of the gcc installed files when the compiler does not find the needed values as specified by the use of `-gcc-name=directory-name/gcc` or `-gxx-name=directory-name/g++`.

**LIBRARY_PATH** *(Linux* and macOS*) | Specifies the path for libraries to be used during the link phase.

**SUNPRO_DEPENDENCIES** *(Linux*) | This variable is the same as `DEPENDENCIES_OUTPUT`, except that system header files are not ignored.

---

Compiler Run-Time Environment Variables

The following table summarizes compiler environment variables that are recognized at run time.

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **INTEL_CHKPO_REPORT_MODE** *(Linux*) | Changes the pointer checker reporting mode at runtime.  
See Finding and Reporting Out-of-Bounds Errors. |

**GNU extensions (recognized by the Intel OpenMP* compatibility library)**

**GOMP_CPU_AFFINITY** *(Linux*) | GNU extension recognized by the intel OpenMP* compatibility library. Specifies a list of OS processor IDs.  
You must set this environment variable before the first parallel region or before certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls.  
For detailed information on this environment variable, see *Thread Affinity Interface*.  
**Default:** Affinity is disabled |

**GOMP_STACKSIZE** *(Linux*) | GNU extension recognized by the Intel OpenMP compatibility library. Same as `OMP_STACKSIZE.KMP_STACKSIZE overrides GOMP_STACKSIZE`, which overrides `OMP_STACKSIZE`.  
**Default:** See the description for `OMP_STACKSIZE`. |

OpenMP* Environment Variables (OMP__) and Extensions (KMP__)
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_CANCELLATION</td>
<td>Activates cancellation of the innermost enclosing region of the type specified. If set to <strong>TRUE</strong>, the effects of the cancel construct and of cancellation points are enabled and cancellation is activated. If set to <strong>FALSE</strong>, cancellation is disabled and the cancel construct and cancellation points are effectively ignored.</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>Internal barrier code will work differently depending on whether the cancellation is enabled. Barrier code should repeatedly check the global flag to figure out if the cancellation had been triggered. If a thread observes the cancellation it should leave the barrier prematurely with the return value 1 (may wake up other threads). Otherwise, it should leave the barrier with the return value 0.</td>
</tr>
<tr>
<td></td>
<td>Enables (<strong>TRUE</strong>) or disables (<strong>FALSE</strong>) cancellation of the innermost enclosing region of the type specified.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> <strong>FALSE</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> OMP_CANCELLATION=TRUE</td>
</tr>
<tr>
<td>OMP_DISPLAY_ENV</td>
<td>Enables (<strong>TRUE</strong>) or disables (<strong>FALSE</strong>) the printing to stderr of the OpenMP version number and the values associated with the OpenMP environment variable.</td>
</tr>
<tr>
<td></td>
<td>Possible values are: <strong>TRUE</strong>, <strong>FALSE</strong>, or <strong>VERBOSE</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> <strong>FALSE</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> OMP_DISPLAY_ENV=TRUE</td>
</tr>
<tr>
<td>OMP_DEFAULT_DEVICE</td>
<td>Sets the device that will be used in a target region. The OpenMP routine <em>omp_set_default_device</em> or a <em>device</em> clause in a <em>parallel</em> pragma can override this variable.</td>
</tr>
<tr>
<td></td>
<td>If no device with the specified device number exists, the code is executed on the host. If this environment variable is not set, device number 0 is used.</td>
</tr>
<tr>
<td></td>
<td>Enables (<strong>TRUE</strong>) or disables (<strong>FALSE</strong>) the dynamic adjustment of the number of threads.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> <strong>FALSE</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> OMP_DYNAMIC=TRUE</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| OMP_MAX_ACTIVE_LEVELS         | The maximum number of levels of parallel nesting for the program.  
**Default:** 1  
**Syntax:** OMP_MAX_ACTIVE_LEVELS=TRUE |
| OMP_NESTED                    | Enables (TRUE) or disables (FALSE) nested parallelism.  
**Default:** FALSE  
**Example:** OMP_NESTED=TRUE |
| OMP_NUM_THREADS               | Sets the maximum number of threads to use for OpenMP* parallel regions if no other value is specified in the application.  
The value can be a single integer, in which case it specifies the number of threads for all parallel regions. The value can also be a comma-separated list of integers, in which case each integer specifies the number of threads for a parallel region at a nesting level.  
The first position in the list represents the outer-most parallel nesting level, the second position represents the next-inner parallel nesting level, and so on. At any level, the integer can be left out of the list. If the first integer in a list is left out, it implies the normal default value for threads is used at the outer-most level. If the integer is left out of any other level, the number of threads for that level is inherited from the previous level.  
This environment variable applies to the options Qopenmp (Windows) or qopenmp (Linux and macOS*), or Qparallel (Windows) or parallel (Linux and macOS*).  
**Default:** The number of processors visible to the operating system on which the program is executed.  
**Syntax:** OMP_NUM_THREADS=value[,value]* |
| OMP_PLACES                    | Specifies an explicit ordered list of places, either as an abstract name describing a set of places or as an explicit list of places described by nonnegative numbers. An exclusion operator “!” can also be used to exclude the number or place immediately following the operator.  
For **explicit lists**, the meaning of the numbers and how the numbering is done for a list of nonnegative numbers are implementation defined. Generally, |
Run-Time Environment Variable | Description
---|---
| the numbers represent the smallest unit of execution exposed by the execution environment, typically a hardware thread.

Intervals can be specified using the `<lower-bound>:<length>:<stride>` notation to represent the following list of numbers:

```
"<lower-bound>, <lower-bound> + <stride>, ..., <lower-bound> +(<length>-1)*<stride>.
```

When `<stride>` is omitted, a unit stride is assumed. Intervals can specify numbers within a place as well as sequences of places.

# EXPLICIT LIST EXAMPLE
```
setenv OMP_PLACES "{0,1,2,3},{4,5,6,7},
{8,9,10,11},{12,13,14,15}"
setenv OMP_PLACES "{0:4},{4:4},{8:4},{12:4}"
setenv OMP_PLACES "{0:4}:4:4"
```

The **abstract names** listed below should be understood by the execution and runtime environment:

- **threads**: Each place corresponds to a single hardware thread on the target machine.
- **cores**: Each place corresponds to a single core (having one or more hardware threads) on the target machine.
- **sockets**: Each place corresponds to a single socket (consisting of one or more cores) on the target machine.

When requesting fewer places or more resources than available on the system, the determination of which resources of type `abstract_name` are to be included in the place list is implementation-defined. The precise definitions of the abstract names are implementation defined. An implementation may also add abstract names as appropriate for the target platform. The abstract name may be appended by a positive number in parentheses to denote the length of the place list to be created, that is `abstract_name(num-places)`.

# ABSTRACT NAMES EXAMPLE
```
setenv OMP_PLACES threads
setenv OMP_PLACES threads(4)
```
### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong></td>
<td>If any numerical values cannot be mapped to a processor on the target platform the behavior is implementation-defined. The behavior is also implementation-defined when the <code>OMP_PLACES</code> environment variable is defined using an abstract name.</td>
</tr>
</tbody>
</table>

**OMP_PROC_BIND (Windows, Linux)**

Sets the thread affinity policy to be used for parallel regions at the corresponding nested level. Enables (`TRUE`) or disables (`FALSE`) the binding of threads to processor contexts. If enabled, this is the same as specifying `KMP_AFFINITY=scatter`. If disabled, this is the same as specifying `KMP_AFFINITY=none`.

**Acceptable values:** `TRUE`, `FALSE`, or a comma separated list, each element of which is one of the following values: `MASTER`, `CLOSE`, `SPREAD`.

**Default:** `FALSE`

If set to `FALSE`, the execution environment may move OpenMP* threads between OpenMP* places, thread affinity is disabled, and proc_bind clauses on parallel constructs are ignored. Otherwise, the execution environment should not move OpenMP* threads between OpenMP* places, thread affinity is enabled, and the initial thread is bound to the first place in the OpenMP* place list.

If set to `MASTER`, all threads are bound to the same place as the master thread. If set to `CLOSE`, threads are bound to successive places, close to where the master thread is bound. If set to `SPREAD`, the master thread’s partition is subdivided and threads are bound to single place successive sub-partitions.

**NOTE**

`KMP_AFFINITY` takes precedence over `GOMP_CPU_AFFINITY` and `OMP_PROC_BIND`.

`GOMP_CPU_AFFINITY` takes precedence over `OMP_PROC_BIND`.

**OMP_SCHEDULE**

Sets the run-time schedule type and an optional chunk size.

**Default:** `STATIC`, no chunk size specified

**Example syntax:** `OMP_SCHEDULE="kind[,chunk_size]"`
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong></td>
<td>Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.</td>
</tr>
<tr>
<td><strong>OMP_STACKSIZE</strong></td>
<td>Sets the number of bytes to allocate for each OpenMP* thread to use as the private stack for the thread. Recommended size is 16M. Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes). This variable does not affect the native operating system threads created by the user program, or the thread executing the sequential part of an OpenMP* program or parallel programs created using the option Qparallel (Windows) or parallel (Linux and macOS*). The kmp_{set,get}_stacksize_s() routines set/retrieve the value. The kmp_set_stacksize_s() routine must be called from sequential part, before first parallel region is created. Otherwise, calling kmp_set_stacksize_s() has no effect. <strong>Default (IA-32 architecture):</strong> 2M <strong>Default (Intel® 64 architecture):</strong> 4M <strong>Default (Intel® MIC architecture):</strong> 4M (on supported OSes) <strong>NOTE</strong> IA-32 architecture is no longer supported on macOS*.</td>
</tr>
<tr>
<td><strong>OMP_THREAD_LIMIT</strong></td>
<td>Limits the number of simultaneously-executing threads in an OpenMP* program. If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP* parallel region begins, a one-time warning message</td>

### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong></td>
<td>On Windows* with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows*). Otherwise, the respect affinity modifier is used.</td>
</tr>
<tr>
<td><strong>KMP_ALL_THREADS</strong></td>
<td>Limits the number of simultaneously-executing threads in an OpenMP* program. If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, then the program may abort with an error message. If this limit is reached at the time an OpenMP* parallel region begins, a one-time warning message may be generated indicating that the number of threads in the team was reduced, but the program will continue execution. This environment variable is only used for programs compiled with the <code>qopenmp</code> (Windows) or <code>qopenmp</code> (Linux and macOS*) option.</td>
</tr>
<tr>
<td><strong>Default:</strong></td>
<td>No enforced limit.</td>
</tr>
<tr>
<td><strong>KMP_BLOCKTIME</strong></td>
<td>Sets the time, in milliseconds, that a thread should wait, after completing the execution of a parallel region, before sleeping. Use the optional character suffixes: <code>s</code> (seconds), <code>m</code> (minutes), <code>h</code> (hours), or <code>d</code> (days) to specify the units. Specify <code>infinite</code> for an unlimited wait time.</td>
</tr>
<tr>
<td><strong>Default:</strong></td>
<td>200 milliseconds</td>
</tr>
<tr>
<td><strong>Related Environment Variable:</strong></td>
<td><code>KMP_LIBRARY</code> environment variable.</td>
</tr>
<tr>
<td><strong>KMP_CPUINFO_FILE</strong></td>
<td>Specifies an alternate file name for a file containing the machine topology description. The file must be in the same format as <code>/proc/cpuinfo</code>.</td>
</tr>
<tr>
<td><strong>KMP_DETERMINISTIC_REDUCTION</strong></td>
<td>Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) the use of a specific ordering of the reduction operations for implementing the reduction clause for an OpenMP* parallel region. This has the effect that, for a given number of threads, in a given parallel region, for a given data set and reduction operation, a floating point reduction done for an OpenMP* reduction clause has a consistent floating point result from run to run, since round-off errors are identical.</td>
</tr>
</tbody>
</table>

*Intel® C++ Compiler 19.0 Developer Guide and Reference*
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **KMP_DYNAMIC_MODE**        | Default: FALSE  
Selects the method used to determine the number of threads to use for a parallel region when OMP_DYNAMIC=TRUE. Possible values: (asat | load_balance | thread_limit), where,  
- asat: estimates number of threads based on parallel start time;  

**NOTE**  
Support for **asat** (automatic self-allocating threads) is now deprecated and will be removed in a future release.  
- load_balance: tries to avoid using more threads than available execution units on the machine;  
- thread_limit: tries to avoid using more threads than total execution units on the machine.  

**Default (IA-32 architecture):** load_balance (on all supported OSes)  
**Default (Intel® 64 architecture):** load_balance (on all supported OSes)  
**Default (Intel® MIC architecture):**  
thread_limit (on supported OSes)  

**NOTE** IA-32 architecture is no longer supported on macOS*. |
| **KMP_HOT_TEAMS_MAX_LEVEL** | Sets the maximum nested level to which teams of threads will be hot.  

**NOTE**  
A hot team is a team of threads optimized for faster reuse by subsequent parallel regions. In a hot team, threads are kept ready for execution of the next parallel region, in contrast to the cold team, which is freed after each parallel region, with its threads going into a common pool of threads.  

For values of 2 and above, nested parallelism should be enabled.  
**Default:** 1 |
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_HOT_TEAMS_MODE</td>
<td>Specifies the run-time behavior when the number of threads in a hot team is reduced.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: Extra threads are freed and put into a common pool of threads.</td>
</tr>
<tr>
<td></td>
<td>• 1: Extra threads are kept in the team in reserve, for faster reuse in subsequent parallel regions.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 0</td>
</tr>
<tr>
<td>KMP_HW_SUBSET</td>
<td>Specifies the number of sockets, cores per socket, and the number of threads per core, to use with an OpenMP* application, as an alternative to writing explicit affinity settings or a process affinity mask. You can also specify an offset value to set which resources to use.</td>
</tr>
<tr>
<td></td>
<td>An extended syntax is available when KMP_TOPOLOGY_METHOD=hwloc. Depending on what resources are detected, you may be able to specify additional resources, such as NUMA nodes and groups of hardware resources that share certain cache levels. For example, <em>tiles</em> are sets of cores that share an L2 cache on some processors in the Intel® Xeon Phi™ family.</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>socketsS[@offset], numasN[@offset], tilesL2[@offset], coresC[@offset], threadsT</td>
</tr>
<tr>
<td></td>
<td>S, N, L2, C and T are not case-sensitive. Some designators are aliases on some machines. Specifying duplicate or multiple alias designators for the same resource type is not allowed.</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>numas</code></td>
<td>If detectable, the number of NUMA nodes to use per socket, where available.</td>
</tr>
<tr>
<td><code>tiles</code></td>
<td>If detectable, the number of tiles to use per NUMA node, where available, otherwise per socket.</td>
</tr>
<tr>
<td><code>cores</code></td>
<td>The number of cores to use per socket, where available, otherwise per NUMA node, or per socket.</td>
</tr>
<tr>
<td><code>threads</code></td>
<td>The number of threads to use per core.</td>
</tr>
<tr>
<td><code>offset</code></td>
<td>(Optional) The number of sockets or cores to skip.</td>
</tr>
</tbody>
</table>

**NOTE**
If you don’t specify one or more types of resource, sockets, cores or threads, all available resources of that type are used.

**NOTE**
If a particular type of resource is specified, but detection of that resource is not supported by the chosen topology detection method, the setting of `KMP_HW_SUBSET` is ignored.

**NOTE**
This variable does not work if the OpenMP* affinity is set to disabled.

**Default:** If omitted, the default value is to use all the available hardware resources.

**Examples:**
- `2s, 4c, 2t`: Use the first 2 sockets (s0 and s1), the first 4 cores on each socket (c0 - c3), and 2 threads per core.
- `2s@2, 4c@8, 2t`: Skip the first 2 sockets (s0 and s1) and use 2 sockets (s2-s3), skip the first 8 cores (c0-c7) and use 4 cores on each socket (c8-c11), and use 2 threads per core.
- `5c@1, 3T`: Use all available sockets, skip the first core and use 5 cores, and use 3 threads per core.
- `2T`: Use all cores on all sockets, 2 threads per core.
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_INHERIT_FP_CONTROL</td>
<td>Enables (TRUE) or disables (FALSE) the copying of the floating-point control settings of the master thread to the floating-point control settings of the OpenMP* worker threads at the start of each parallel region. <strong>Default:</strong> TRUE</td>
</tr>
<tr>
<td>KMP_LIBRARY</td>
<td>Selects the OpenMP* run-time library execution mode. The values for this variable are serial, turnaround, or throughput. <strong>Default:</strong> throughput</td>
</tr>
<tr>
<td>KMP_PLACE_THREADS</td>
<td>Deprecated; use KMP_HW_SUBSET instead.</td>
</tr>
<tr>
<td>KMP_SETTINGS</td>
<td>Enables (TRUE) or disables (FALSE) the printing of OpenMP* run-time library environment variables during program execution. Two lists of variables are printed: user-defined environment variables settings and effective values of variables used by OpenMP* run-time library. <strong>Default:</strong> FALSE</td>
</tr>
<tr>
<td>KMP_STACKSIZE</td>
<td>Sets the number of bytes to allocate for each OpenMP* thread to use as its private stack. Recommended size is 16m. Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes). This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP* program or parallel programs created using the option Qparallel (Windows) or parallel (Linux and macOS*). KMP_STACKSIZE overrides GOMP_STACKSIZE, which overrides OMP_STACKSIZE. <strong>Default (IA-32 architecture):</strong> 2m <strong>Default (Intel® 64 architecture):</strong> 4m <strong>Default (Intel® MIC architecture):</strong> 4M (on supported OSes)</td>

### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **NOTE** | IA-32 architecture is no longer supported on macOS*.
| **KMP_TOPOLOGY_METHOD** | Forces OpenMP* to use a particular machine topology modeling method. Possible values are:
- *cpuid_leaf11*
  Decodes the APIC identifiers as specified by leaf 11 of the `cpuid` instruction.
- *cpuid_leaf4*
  Decodes the APIC identifiers as specified in leaf 4 of the `cpuid` instruction.
- *cpuinfo*
  If `KMP_CPUINFO_FILE` is not specified, forces OpenMP* to parse `/proc/cpuinfo` to determine the topology (Linux* only).
  If `KMP_CPUINFO_FILE` is specified as described above, uses it (Windows* or Linux*).
- *group*
  Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows* 64-bit only).
- *flat*
  Models the machine as a flat (linear) list of processors.
- *hwloc*
  Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows* processor groups.
| **KMP_VERSION** | Enables (TRUE) or disables (FALSE) the printing of OpenMP* run-time library version information during program execution.
**Default:** FALSE
| **KMP_WARNINGS** | Enables (TRUE) or disables (FALSE) displaying warnings from the OpenMP* run-time library during program execution.
**Default:** TRUE

---

**Intel® Many Integrated Core (Intel® MIC) Environment Variables**
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIC_ENV_PREFIX</td>
<td>Controls environment variables passed to the target. By default, all environment variables set on the host are passed to the target. Setting MIC_ENV_PREFIX passes only environment variables that have a prefix of the value of this variable. For example, setting MIC_ENV_PREFIX=ABC passes only environment variables that have a prefix of ABC.</td>
</tr>
</tbody>
</table>

**NOTE**
Because the MIC_LD_LIBRARY_PATH variable is not stripped and passed to the target, you cannot use MIC_ENV_PREFIX=MIC to change the LD_LIBRARY_PATH on the target.

To change LD_LIBRARY_PATH on the target:
1. Set MIC_ENV_PREFIX to any prefix other than MIC.
2. Create an additional pre-fixed environment variable on the host set to the desired value for LD_LIBRARY_PATH for the target.

For example, setting these two environment variables on the host sets LD_LIBRARY_PATH on the target to /tmp/mylibs.

```
MIC_ENV_PREFIX=ABC
ABC_LD_LIBRARY_PATH=/tmp/mylibs
```

For information on passing environment variables to a particular coprocessor, and on passing multiple environment variables to one or all coprocessors, see Setting Environment Variables on the CPU to Modify the Coprocessor's Execution Environment.

<table>
<thead>
<tr>
<th>MIC_PROXY_IO</th>
<th>Enables (1) or disables (0) the proxy of stderr and stdout, and specifies whether the process wants I/O proxy support between the host and target. <strong>Default:</strong> 1 <strong>Example:</strong> MIC_PROXY_IO=0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIC_SEP_MONITOR</td>
<td>Enables (1) or disables (0) SEP at offload regions. <strong>Default:</strong> 0 <strong>Example:</strong> MIC_SEP_MONITOR=1</td>
</tr>
<tr>
<td>MIC_STACKSIZE</td>
<td>Specifies the stack size of the main thread for the offload. This value is typically much larger than the stack size for individual threads. It corresponds to</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| **MIC_STACKSIZE**            | what you would set with `ulimit-s` (BASH shell) or `limit stacksize` (C shell) if you were running natively on either the target or the host.  
Set this variable to `integerB|K|M|G|T`, where:  
- `B` = bytes  
- `K` = kilobytes  
- `M` = megabytes  
- `G` = gigabytes  
- `T` = terabytes  
**Default:** 12M  
**Example:** `MIC_STACKSIZE=16M` |
| **MIC_USE_2MB_BUFFERS**      | Use 2M pages for `(size > MIC_USE_2MB_BUFFERS)`. Pointer-based variables whose runtime length exceeds the value of this environment variable are allocated in large pages.  
Set this variable to `integerB|K|M|G|T`, where:  
- `B` = Bytes  
- `K` = Kilobytes  
- `M` = Megabytes  
- `G` = Gigabytes  
- `T` = Terabytes  
**Example:** `MIC_USE_2MB_BUFFERS=64K` |
| **OFFLOAD_DEVICES**          | Restricts the offload process to use only the coprocessors specified as the value of the variable.  
Set this variable to a comma-separated list of target device numbers in the range 0 to `(number_of_devices_in_the_system -1)`, where 0 is the first coprocessor in the system, and `(number_of_devices_in_the_system -1)` is the last coprocessor in the system.  
Coprocessors available for offloading are numbered logically. The function `_Offload_number_of_devices()` returns the number of available coprocessors. Coprocessor indices that you use in the target specifier of the offload pragmas are mapped to coprocessors specified in `OFFLOAD_DEVICES`.  
**Default:** The offload process uses all devices.  
**Example:** `OFFLOAD_DEVICES = 1,2`  
On a system with more than two coprocessors installed, this setting enables the application to use only coprocessors 1 and 2. Offloads to coprocessors 0 or 1 are performed on the second and third physical coprocessors. Offloads to target numbers |
### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| _Offload_number_of_devices()_ | higher than 1 wrap around, and all offloads remain within coprocessors 0 and 1. The function _Offload_number_of_devices()_, executed on a coprocessor, returns 0 or 1 when the offload is running on coprocessor 1 or 2 as specified in OFFLOAD_DEVICES. Setting this variable to an empty value (export OFFLOAD_DEVICES= ) has no effect. Setting this variable to value none (set OFFLOAD_DEVICES=none) impacts the execution of offloaded code within your program as follows:  
  - When you use optional offloading, the code executes on the host CPU.  
  - When you use mandatory offloading, the program terminates with an offload error, reporting that a device is not available, when it reaches a point in the execution where the coprocessor requires initialization for offloading.  
You can specify optional and mandatory offloading using the optional and mandatory clauses in either of the following:  
  - The compiler option qoffload (Linux) or Qoffload (Windows)  
  - The offload pragma |

#### OFFLOAD_NODES

Defines a subset of a cluster (group of servers or nodes) that is available for offloading from the host system. When offloading within a cluster, this environment variable must be set to specify the available offload-able nodes.  
The value of the environment variable is a comma-separated list of machine specifiers. A machine specifier is either a machine name or an IP address. The machine specifier may be optionally followed by a specification of the node type and fabric type in square brackets. The default node type is currently x200 and the default fabric type is OFI. More node and fabric types may be supported in the future.  
The offloadable machines in OFFLOAD_NODES are assigned device numbers 0, 1, 2 and so on, in the order specified. These device numbers are available for offloading through #pragma offload target(mic:<number>). The OFFLOAD_DEVICES environment variable may be used to restrict offloading to a subset of the available cluster machines.
<table>

---

## Compilation Phases

The Intel® C++ Compiler processes C and C++ language source files. Compilation can be divided into these major phases:

- Preprocessing
- Semantic parsing
- Optimization
- Code generation
- Linking

The first four phases are performed by the compiler:

### Example

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td># Linux* and macOS*icc, icpc</td>
</tr>
<tr>
<td># Windows* icl.exe</td>
</tr>
</tbody>
</table>

By default, the compiler automatically invokes the linker to generate the final executable binary:

### Example

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td># Linux* and macOS*xild</td>
</tr>
</tbody>
</table>
If you specify the \texttt{c} option at compilation time, the compiler will generate only object files. You will need to explicitly invoke linker in order to generate the executable.

If you are compiling for a 32-bit target, you may either set the environment variable, \texttt{INTEL\_TARGET\_ARCH\_IA32}, or use the \texttt{[Q]m32} option. If you used the \texttt{c} option you will need to pass the \texttt{[Q]m32} option to the linker as well.

If you specify the \texttt{E} and \texttt{P} options when calling the compiler, the compiler will only generate the preprocessed file with an .i extension.

If you specify the \texttt{[Q]ipo} option to use multi-file interprocedural optimization (also called Whole Program Optimization), the optimization is done at link time. Similarly, when you specify option \texttt{[Q]prof-gen} to use Profile Guided Optimization, the optimization is done at link time.

In both cases, the Intel® C++ compiler will generate mock object files that only the linker (\texttt{xilink.exe} and \texttt{xild}) can understand. You can also use the compiler driver to perform the link step (\texttt{icl.exe}, \texttt{icc} and \texttt{icpc}).

\item \texttt{E} compiler option
\item \texttt{P} compiler option
\end{itemize}

\textbf{Passing Options to the Linker}

\textbf{Specifying Linker Options}

This topic describes the options that let you control and customize linking with tools and libraries and define the output of the linker.

\textbf{Windows*}

This section describes options specified at compile-time that take effect at link-time.

You can use the \texttt{link} option to pass options specifically to the linker at compile time. For example:

\begin{verbatim}
icl a.cpp libfoo.lib /link -delayload:comct132.dll
\end{verbatim}

In this example, the compiler recognizes that \texttt{libfoo.lib} is a library that should be linked with \texttt{a.cpp}, so it does not need to follow the \texttt{link} option on the command line. The compiler does not recognize \texttt{-delayload:comct132.dll}, so the \texttt{link} option is used to direct the option to the linking phase. You can use the \texttt{Qoption} option to pass options to various tools, including the linker. You can also use \texttt{#pragma comment} to pass options to the linker. For example:

\begin{verbatim}
#pragma comment(linker, "/defaultlib:mylib.lib")
\end{verbatim}

OR

\begin{verbatim}
#pragma comment(lib, "mylib.lib")
\end{verbatim}
Both examples instruct the compiler to link mylib.lib at link time.

**Linux* and macOS***

This section describes options specified at compile-time that take effect at link-time to define the output of the ld linker. See the ld man page for more information on the linker.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-L directory</code></td>
<td>Instruct the linker to search directory for libraries.</td>
</tr>
<tr>
<td><code>-Qoption,tool,list</code></td>
<td>Passes an argument list to another program in the compilation sequence, such as the assembler or linker.</td>
</tr>
<tr>
<td><code>-shared</code></td>
<td>Instructs the compiler to build a Dynamic Shared Object (DSO) instead of an executable.</td>
</tr>
<tr>
<td><code>-shared-libgcc</code></td>
<td><code>-shared-libgcc</code> has the opposite effect of <code>-static-libgcc</code>. When it is used, the GNU standard libraries are linked in dynamically, allowing the user to override the static linking behavior when the <code>-static</code> option is used.</td>
</tr>
</tbody>
</table>

**NOTE**

Note: By default, all C++ standard and support libraries are linked dynamically.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-shared-intel</code></td>
<td>Specifies that all Intel-provided libraries should be linked dynamically.</td>

<td></td>
</tr>
<tr>
<td><code>-static-intel</code></td>
<td>This option causes Intel-provided libraries to be linked in statically. It is the opposite of <code>-shared-intel</code>.</td>
</tr>
<tr>
<td><code>-Wl,optlist</code></td>
<td>This option passes a comma-separated list (optlist) of options to the linker.</td>
</tr>
<tr>
<td><code>-Xlinker val</code></td>
<td>This option passes a value (val), such as a linker option, an object, or a library, directly to the linker.</td>
</tr>
</tbody>
</table>
Linking Tools and Options

This topic describes how to use the Intel® linking tools, xild (Linux* and macOS*) and xilink (Windows*).

The Intel® linking tools behave differently on different platforms. The following sections summarize the primary differences between linking behavior.

**Linux* and macOS* Linking Behavior Summary**

The linking tool invokes the Intel® C++ Compiler to perform IPO if objects containing IR (intermediate representation) are found. These are mock objects. The tool invokes GNU ld to link the application.

The command-line syntax for xild is the same as that of the GNU linker:

```
xild [options>] <normal command-line>
```

where:

- **[options]>**: One or more options supported only by xild (optional).
- **<normal command-line>**: Linker command line containing a set of valid arguments for ld.

To create the file app using IPO, use the option o[filename] as shown in the following example:

```
xild -qipo-fas-oapp a.o b.o c.o
```

The linking tool calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker then calls ld to link the object files that are specified in the new list and produce the application with the name specified by the o option. The linker supports the ipo[n] and ipo-separate options.

To display a list of the supported link options from xild, use the following command:

```
$ xild -qhelp
```

**Windows* Linking Behavior Summary**

The linking tool invokes the Intel® C++ Compiler to perform multi-file IPO if objects containing IR (intermediate representation) is found. These are mock objects. It invokes the Microsoft linker link.exe to link the application.

The command-line syntax for the Intel® linker is the same as that of the Microsoft linker:

```
xilink [options>] <normal command-line>
```

where:

- **[options]>**: One or more options supported only by xilink (optional).
- **<normal command-line>**: Linker command line containing a set of valid arguments for the Microsoft linker.

To place the multifile IPO executable in ipo_file.exe, use the linker option out:[filename], for example:

```
xilink -qipo-fas/out:ipo_file.exe a.obj b.obj c.obj
```

The linker calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker calls Microsoft link.exe to link the object files that are specified in the new list and produce the application with the name specified by the out:[filename] linker option.
Windows* Linking Behavior Summary

To display a list of support link options from xilink, use the following command:

```
>> xilink /qhelp
```

xilink.exe accepts all the options of link.exe and will pass them on to link.exe at the final linking stage.

Using the Linking Tools

You must use the Intel® linking tools to link your application if the following conditions apply:

- Your source files were compiled with multi-file IPO enabled. Multi-file IPO is enabled by specifying compiler option 

  compiler option \[Q\]ipo.

- You would normally invoke the GNU linker (ld) to link your application.
- You would normally invoke the Microsoft linker (link.exe) to link your application.

Linker Options

The following table provides information on linking options.

<table>
<thead>
<tr>
<th>Linking Tools Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| qdiag-
  [type]=
  [diag-list] | Controls the display of diagnostic information. The type is an action to perform on diagnostics. Possible values are: |
|                     | Enable: Enables a diagnostic message or a group of messages. |
|                     | Disable: Disables a diagnostic message or a group of messages. |
|                     | The diag-list is a diagnostic group or ID value. Possible values are: |
|                     | thread: Specifies diagnostic messages that help in thread-enabling a program. |
|                     | vec: Specifies diagnostic messages issued by the vectorizer. |
|                     | par: Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer). |
|                     | openmp: Specifies diagnostic messages issued by the OpenMP* parallelizer. |
|                     | warn: Specifies diagnostic messages that have a "warning" severity level. |
|                     | error: Specifies diagnostic messages that have an "error" severity level. |
|                     | remark: Specifies diagnostic messages that are remarks or comments. |
|                     | cpu-dispatch: Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. |
|                     | id[,id,...]: Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each "id". |
|                     | tag[,tag,...]: Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each "tag". |

**NOTE**

Diagnostic messages generated by this option can be affected by other options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.
### Linking Tools

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m32 (Linux* only), m64 (Linux* and macOS*)</td>
<td>![m32](Linux* only), ![m64](Linux* and macOS*) generates code for Intel® 64 architecture. Option -m32 is only available on Linux* systems.</td>
</tr>
<tr>
<td>Qm32, Qm64 (Windows*)</td>
<td><img src="Windows*" alt="Qm32" />, <img src="Windows*" alt="Qm64" /> generates code for IA-32 architecture. For example, when your compilation environment is configured for Intel® 64 architecture, and you use [Q]m32 with the compiler, you also need to use qm32 on the linker command line to make sure the proper compilation target is set up for any IPO compilations or the final link.</td>
</tr>
</tbody>

## Specifying Alternate Tools and Paths

Use the `Qlocation` option to specify an alternate path for a tool. This option accepts two arguments using the following syntax:

### Qlocation Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td># (Linux* and macOS*)</td>
</tr>
<tr>
<td># (Windows*)</td>
</tr>
</tbody>
</table>

where `tool` designates which compilation tool is associated with the alternate `path`.

<table>
<thead>
<tr>
<th>tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpp</td>
<td>Specifies the compiler front-end preprocessor.</td>
</tr>
<tr>
<td>c</td>
<td>Specifies the C++ compiler.</td>
</tr>
<tr>
<td>asm</td>
<td>Specifies the assembler.</td>
</tr>
<tr>
<td>link</td>
<td>Specifies the linker.</td>
</tr>
</tbody>
</table>

Use the `Qoption` option to pass an option specified by `optlist` to a `tool`, where `optlist` is a comma-separated list of options. The syntax for this command is:

### Qoption Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td># (Linux* and macOS*)</td>
</tr>
<tr>
<td># (Windows*)</td>
</tr>
</tbody>
</table>

where `tool` designates which compilation tool receives the `optlist`.  

2032
## Using Configuration Files

You can decrease the time you spend entering command-line options by using the configuration file to automate command-line entries. Configuration files are automatically processed every time you run the Intel® C++ Compiler. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the specified command-line options when the compiler is invoked.

**NOTE**
Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use Using Response Files.

### Sample Configuration Files

The default configuration files icc.cfg and icpc.cfg (Linux* and macOS*) or or icl.cfg (Windows*), are located in the same directory as the compiler executable file. If you want to use a different configuration file than the default, you can use the ICCCFG/ICPCCFG (for Linux* and macOS*) or ICLCFG (for Windows) environment variables to specify the location of another configuration file.

**NOTE**
Anytime you instruct the compiler to use a different configuration file, the default configuration file(s) are ignored.

The following examples illustrate basic configuration files. The pound (#) character indicates that the rest of the line is a comment.

In the Windows* examples, the compiler reads the configuration file and invokes the I option every time you run the compiler, along with any options specified on the command line.

### Example

```
## Sample icpc.cfg file
-I/my_headers

## Sample icl.cfg file
/Ic:\my_headers
```

**See Also**
Supported Environment Variables

## Using Response Files

You can use response files to:

- Specify options used during particular compilations or projects.
- Save this information in individual files.

Response files are invoked as options on the command line. Options in response files are inserted in the command line at the point where the response file is invoked. Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file without specifying it on the command line, it will not be invoked.

### Sample Response Files

#### Example

```bash
# (Linux* and macOS*)
# response file: response1.txt
# compile with these options
-w0
# end of response1 file

# response file: response2.txt
# compile with these options
-O0
# end of response2 file

# (Windows*)
# response file: response1.txt
# compile with these options
/W0
# end of response1 file

# response file: response2.txt
# compile with these options
/Od
# end of response2 file
```

Use response files to decrease the time spent entering command-line options and to ensure consistency by automating command-line entries. Use individual response files to maintain options for specific projects.

Any number of options or file names can be placed on a line in a response file. Several response files can be referenced in the same command line. The following example shows how to specify a response file on the command line:

#### Example

```bash
# (Linux*)
icpc @response1.txt prog1.cpp @response2.txt prog2.cpp

# (macOS*)
icpc @response1.txt prog1.cpp @response2.txt prog2.cpp
```
Global Symbols and Visibility Attributes (Linux* and macOS*)

Example

```
# (Windows*)
icl @response1.txt prog1.cpp @response2.txt prog2.cpp
```

**NOTE**

An "at" sign (@) must precede the name of the response file on the command line.

Using Configuration Files

Global Symbols and Visibility Attributes (Linux* and macOS*)

This topic applies to C/C++ applications for Linux* and macOS* only.

A global symbol is one that is visible outside the compilation unit (single source file and its include files) in which it is declared. In C/C++, this means anything declared at file level without the `static` keyword. For example:

```c
int x = 5;        // global data definition
extern int y;     // global data reference
int five()        // global function definition
{ return 5; }
extern int four(); // global function reference
```

A complete program consists of a main program file and possibly one or more shareable object (.so) files that contain the definitions for data or functions referenced by the main program. Similarly, shareable objects might reference data or functions defined in other shareable objects. Shareable objects are so called because if more than one simultaneously executing process has the shareable object mapped into its virtual memory, there is only one copy of the read-only portion of the object resident in physical memory. The main program file and any shareable objects that it references are collectively called the components of the program.

Each global symbol definition or reference in a compilation unit has a visibility attribute that controls how (or if) it may be referenced from outside the component in which it is defined. There are five possible values for visibility:

- **EXTERNAL** – The compiler must treat the symbol as though it is defined in another component. For a definition, this means that the compiler must assume that the symbol will be overridden (preempted) by a definition of the same name in another component. See Symbol Preemption. If a function symbol has external visibility, the compiler knows that it must be called indirectly and can inline the indirect call stub.
- **DEFAULT** – Other components can reference the symbol. Furthermore, the symbol definition may be overridden (preempted) by a definition of the same name in another component.
- **PROTECTED** – Other components can reference the symbol, but it cannot be preempted by a definition of the same name in another component.
- **HIDDEN** – Other components cannot directly reference the symbol. However, its address might be passed to other components indirectly (for example, as an argument to a call to a function in another component, or by having its address stored in a data item reference by a function in another component).
- **INTERNAL** – The symbol cannot be referenced outside its defining component, either directly or indirectly.

Static local symbols (in C/C++, declared at file scope or elsewhere with the keyword `static`) usually have `HIDDEN` visibility— they cannot be referenced directly by other components (or, for that matter, other compilation units within the same component), but they might be referenced indirectly.
Visibility applies to references as well as definitions. A symbol reference’s visibility attribute is an assertion that the corresponding definition will have that visibility.

**Specifying Symbol Visibility Explicitly (Linux* and macOS*)**

This topic applies to C/C++ applications for Linux* and macOS* only.

You can explicitly set the visibility of an individual symbol using the `visibility` attribute on a data or function declaration. For example:

```c
int i __attribute__((visibility("default")));
void __attribute__((visibility("hidden"))) x() {...}
extern void y() __attribute__((visibility("protected")));
```

The `visibility` declaration attribute accepts one of the five keywords:

- `external`
- `default`
- `protected`
- `hidden`
- `internal`

The value of the `visibility` declaration attribute overrides the default set by the options `-fvisibility`, `-fpic`, or `-fno-common` attributes.

If you have a number of symbols for which you wish to specify the same `visibility` attribute, you can set the visibility using one of the five command line options:

- `-fvisibility-external=file`
- `-fvisibility-default=file`
- `-fvisibility-protected=file`
- `-fvisibility-hidden=file`
- `-fvisibility-internal=file`

where `file` is the pathname of a file containing a list of the symbol names whose visibility you wish to set.

The symbol names in the file are separated by white space (blanks, TAB characters, or newlines). For example, the command line option: `-fvisibility-protected=prot.txt`, where file `prot.txt` contains:

```
a  
b cd
e
```

This sets protected visibility for symbols `a`, `b`, `c`, `d`, and `e`.

This has the same effect as `__attribute__((visibility("protected")))` on the declaration for each of the symbols.

**NOTE**

These two ways to explicitly set visibility are mutually exclusive— you may use `__attribute__((visibility()))` on the declaration or specify the symbol name in a file, but not both.

You can set the default visibility for symbols using one of the command line options:
This option sets the visibility for symbols not specified in a visibility list file and that do not have `__attribute__((visibility=()))` in their declaration. For example, the command line options: `-fvisibility=protected -fvisibility-default=prot.txt`, where file `prot.txt` is as previously described, will cause all global symbols except `a`, `b`, `c`, `d`, and `e` to have protected visibility. Those five symbols, however, will have default visibility, and thus will be preemptable.

### Saving Compiler Information in Your Executable

If you want to save information about the compiler in your executable, use the `[Q]sox` option to save:

- Compiler version number and options used to produce the executable.
- Profile data and inlining information (if optional arguments were specified).

**On Linux**

To view the information stored in the object file, use the following command:

```
objdump -sj comment a.out
strings -a a.out | grep comment:
```

**On Windows**

To view the linker directives stored in string format in the object file, use the following command:

```
link /dump /directives filename.obj
```

In the output, the `-comment` linker directive displays the compiler version information. To search your executable for compiler information, use the following command:

```
findstr "Compiler" filename.exe
```

This searches for any strings that have the substring "Compiler" in them.

### Linking Debug Information

**Windows**

Use option `Z7` at compile time or option `debug` at link time to tell the compiler to generate symbolic debugging information in the object file. Alternately, use option `Zi` at link time to generate executables with debug information in the `.pdb` file.

**Linux**

Use option `g` at compile time to tell the compiler to generate symbolic debugging information in the object file.
Use option `gsplit-dwarf` to create a separate object file containing DWARF debug information. Because the DWARF object file is not used by the linker, this reduces the amount of debug information the linker must process and it results in a smaller executable file. See `gsplit-dwarf` for detailed information.

**macOS**

You can link the DWARF debug information from the object files for an executable using `dsymutil`, a utility included with Xcode*. By linking the debug information in an executable, you eliminate the need to retain object files specifically for debugging purposes.

The utility runs automatically in the following cases:

- When you use the Intel® C++ Compiler to compile directly from source to executable using the command line with option `g`. For example:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icc -g myprogram.c</code></td>
</tr>
</tbody>
</table>

- When you compile using Xcode*.

In other cases, you must explicitly run `dsymutil`, such as when you compile using a make file that builds `.o` files and subsequently links the program.
OpenMP* Support

The Intel® compiler supports most of OpenMP* Version Technical Report 4: Version 5.0 Preview 1. For the complete OpenMP specification, see the OpenMP* Application Program Interface Version TR4: Version 5.0 specification, which is available from the OpenMP* web site (http://www.openmp.org; see OpenMP Specifications on that site). The descriptions of OpenMP* language characteristics in this documentation often use terms defined in that specification.

The OpenMP* API provides symmetric multiprocessing (SMP) with the following major features:

- Relieves you from implementing the low-level details of iteration space partitioning, data sharing, thread creation, scheduling, or synchronization.
- Provides the benefit of performance available from shared memory multiprocessor and multi-core processor systems on all supported Intel architectures, including those processors with Intel® Hyper-Threading Technology (Intel® HT Technology).
- Provides support for the Intel® Xeon Phi™ coprocessor.

The compiler performs transformations to generate multithreaded code based on your placement of OpenMP* pragmas in the source program, making it simple to add threading to existing software. The Intel compiler compiles parallel programs and supports the industry-standard OpenMP* pragmas.

The compiler provides Intel-specific extensions to the OpenMP* specification including run-time library routines and environment variables. A summary of the compiler options appear in the OpenMP* Options Quick Reference.

Parallel Processing with OpenMP*

To compile with the OpenMP* API, add the pragmas to your code. The compiler processes the code and internally produces a multithreaded version which is then compiled into an executable with the parallelism implemented by threads that execute parallel regions or constructs.

Using Other Compilers

The OpenMP* specification does not define interoperability of multiple implementations, so the OpenMP* implementation supported by other compilers and OpenMP* support in the Intel compiler might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP* source compatibility that enable you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

The Intel compiler includes two sets of OpenMP* libraries, as described in OpenMP* Source Compatibility and Interoperability with Other Compilers.

OpenMP* Source Compatibility and Interoperability with Other Compilers

The Intel® C++ Compiler includes OpenMP* libraries that are object-level compatible with OpenMP* support provided by certain versions of the following compilers:
• Microsoft* Visual C++* compiler on Windows*
• GCC* on Linux*
• Intel® C++ Compiler version 10.x (and later)

The term object-level interoperability refers to the ability to link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, such that the resulting executable runs successfully. In contrast, source compatibility means that the entire application is compiled and linked by one compiler, and you do not need to modify the sources to get the resulting executable to run successfully.

Different compilers support different versions of the OpenMP* specification. Based on the OpenMP* features your application uses, determine what version of the OpenMP* specification your application requires. If your application uses an OpenMP* specification level equal or less than the OpenMP* specification level supported by all the compilers, your application should have source compatibility with all compilers, but you need to link all object files and libraries with the same compiler's OpenMP* libraries.

The Intel OpenMP* run-time libraries provide source compatibility and object-level interoperability with the OpenMP* support provided by:

• Certain versions of Microsoft* Visual C++* libraries that support OpenMP*, starting with Visual C++ 2013.
• Certain versions of GCC that support OpenMP*, starting with GCC version 4.4.2.
• The Intel® C++ Compiler versions 10.0 and later and their supplied OpenMP* compatibility libraries.

Guidelines for Using Different Intel® Compiler Versions

To avoid possible linking or run-time problems, follow these guidelines:

• Object modules produced by current Intel compilers are not compatible with object modules compiled by the Intel® C++ Compiler prior to version 10.0.
• Object modules produced by current versions of the Intel® C++ Compiler are compatible with object modules produced by the compatibility libraries, for the Intel® C++ Compiler versions 10.0 and later.
• Use dynamic instead of static OpenMP* libraries to avoid linking multiple copies of the libraries into a single program.

Guidelines for Using the Intel® C++ Compiler with non-Intel Compilers

To avoid possible linking or run-time problems, follow these guidelines:

• Always link using the Intel® C++ Compiler OpenMP* libraries. This avoids linking multiple copies of the OpenMP* runtime libraries from different compilers. It is easiest if you use the Intel compiler command (driver) to link the application, but it is possible to link with the Intel® C++ Compiler OpenMP* libraries when linking the application using GCC or the Visual C++* compiler (or linker) commands.
• If possible, compile all the OpenMP* sources with the same compiler. If you compile (not link) using multiple compilers such as the Microsoft* Visual C++* or GNU* compilers that provide object-level interoperability with the libraries, see the instructions in Using the OpenMP* Libraries.
• Use dynamic instead of static OpenMP* libraries to avoid linking multiple copies of the libraries into a single program.

Limitations When Using OpenMP* Libraries with Other Compilers

Limitations of threadprivate objects on object-level interoperability:

• On Windows* systems, the Intel® C++ Compiler by default (/Qopenmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than does the Microsoft* Visual C++* compiler. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® C++ Compiler and the Visual C++* Compiler, the code compiled by the Intel® C++ Compiler and the code compiled by the Visual C++* Compiler reference different locations for the variable even when referenced by the same thread. Use the /Qopenmp-threadprivate:compat compiler option when compiling with the Intel® C++ Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by Microsoft* Visual C++*.
• On Linux* systems, the Intel® C++ Compiler by default (-qopenmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than GCC*. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® C++ Compiler and GCC* compiler, the code compiled by the Intel® C++ Compiler and the code compiled by the gcc reference different locations for the variable even when referenced by the same thread. Use the
-openmp-threadprivate:compat compiler option when compiling with the Intel® C++ Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by GCC.

Using the OpenMP* Libraries

Adding OpenMP* Support to your Application

To add OpenMP* support to your application, do the following:

1. Add the appropriate OpenMP* pragmas to your source code.
2. Compile the application with the Qopenmp (Windows) or qopenmp (Linux* and macOS*) option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at run-time. In addition, you may need to increase the stack allocated to individual threads by using the OMP_STACKSIZE environment variable or by setting the corresponding library routines.

You can set other environment variables to control multi-threaded code execution.

OpenMP Pragma Syntax

To add OpenMP* support to your application, first declare the OpenMP* header and then add appropriate OpenMP* pragmas to your source code.

To declare the OpenMP* header, add the following in your code:

```c
#include <omp.h>
```

OpenMP* pragmas use a specific format and syntax. Intel Extension Routines to OpenMP* describes the OpenMP* extensions to the specification that have been added to the Intel® C++ Compiler.

The following syntax illustrates using the pragmas in your source.

```c
<prefix> <pragma> [<clause>, ...] <newline>
```

where:

- `<prefix>` - Required for all OpenMP* pragmas. The prefix must be #pragma omp.
- `<pragma>` - A valid OpenMP* pragma. Must immediately follow the prefix.
- `<clause>` - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
- `<newline>` - A required component of pragma syntax. It precedes the structured block which is enclosed by this pragma.

The pragmas are interpreted as comments if you omit the Qopenmp (Windows) or qopenmp (Linux* and macOS*) option.

The following example demonstrates one way of using an OpenMP* pragma to parallelize a loop.

```c
#include <omp.h>
void simple_omp(int *a){
  int i;
```
Example

```c
#pragma omp parallel for
for (i=0; i<1024; i++)
    a[i] = i*2;
```  

Compile the Application

The `qopenmp` (Windows) or `qopenmp` (Linux* and macOS*) option enables the parallelizer to generate multi-threaded code based on the OpenMP* pragmas in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

The `qopenmp` (Windows) or `qopenmp` (Linux* and macOS*) option works with both `-O0` (Linux* and macOS*) and `/Od` (Windows*) and with any optimization level of `O1`, `O2` and `O3`.

Specifying `-O0` (Linux* and macOS*) or `/Od` (Windows*) with the `qopenmp` (Windows) or `qopenmp` (Linux* and macOS*) option helps to debug OpenMP* applications.

Compile your application using commands similar to those shown below:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>icc -qopenmp source_file</td>
</tr>
<tr>
<td>macOS*</td>
<td>icc -qopenmp source_file</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /Qopenmp source_file</td>
</tr>
</tbody>
</table>

Assume that you compile the sample above, using commands similar to the following, where the `c` option instructs the compiler to compile the code without generating an executable:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Extended Syntax Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>icc -qopenmp -c parallel.cpp</td>
</tr>
<tr>
<td>macOS*</td>
<td>icc -qopenmp -c parallel.cpp</td>
</tr>
<tr>
<td>Windows*</td>
<td>icl /Qopenmp /c parallel.cpp</td>
</tr>
</tbody>
</table>

The compiler might return a message similar to the following:

Example

```
parallel.cpp(20) : (col. 3) remark: OpenMP DEFINED LOOP WAS PARALLELIZED.
```  

Configure the OpenMP* Environment

Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP* environment variable, `OMP_NUM_THREADS`.

Supported Environment Variables
Parallel Processing Model

A program containing OpenMP* API compiler pragmas begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

In the OpenMP* API, the **omp parallel** pragma defines the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the master of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the master thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP* constructs. The comments in the code explain the structure of each construct or section.

### Example

```c
main() {                     // Begin serial execution.
  ...                        // Only the initial thread executes
  #pragma omp parallel {     // Begin a parallel construct and form a team.
    #pragma omp sections {   // Begin a worksharing construct.
      #pragma omp section   // One unit of work.
        {...}              // Wait until both units of work complete.
    }                        // End of worksharing construct.
    #pragma omp critical    // Begin a critical section.
      {...}                // Only one thread executes at a time.
    }                        // End of Parallel Construct
  #pragma omp barrier       // Wait for all team members to arrive.
  ...                      // This code is executed by each team member.
}                            // End serial execution.
```

### Using Orphaned Pragmas

In routines called from within parallel constructs, you can also use pragmas. Pragmas that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned pragmas. Orphaned pragmas allow you to execute portions of your program in parallel with only minimal changes to the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:
Example

```c
int main(void) {
    #pragma omp parallel {
        phase1();
    }
}

void phase1(void) {
    #pragma omp for // This is an orphaned pragma.
    for(i=0; i < n; i++) { some_work(i); }
}
```

This is an orphaned `omp for` loop pragma since the parallel region is not lexically present in routine `phase1`.

Data Environment Controls

You can control the data environment within parallel and worksharing constructs. Using directives and data environment clauses on directives, you can privatize named global-lifetime objects by using `threadprivate` pragma, or control data scope attributes by using the data environment clauses for directives that support them.

The data scope attribute clauses are:
- `default`
- `private`
- `firstprivate`
- `lastprivate`
- `reduction`
- `shared`
- `linear`
- `map`
- `defaultmap`
- `is_device_ptr`
- `use_device_ptr`

The data copying clauses are:
- `copyin`
- `copyprivate`
- `to`
- `from`
- `tofrom`
- `alloc`
- `release`
- `delete`

You can use several pragma clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a pragma, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP* API specification, for the variables affected by the directive.
Determining How Many Threads to Use

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/video size and resolution, depth/breadth/bushiness of tree-based structures, and size of list-based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer the number of threads to employ until application run-time when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex threads on the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has higher-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the num_threads clause on parallel regions to control the number of threads employed and use the if clause on parallel regions to decide whether to employ multiple threads at all. The omp_set_num_threads routine can also be used, but it also affects parallel regions created by the calling thread. The num_threads clause is local in its effect, so it does not impact other parallel regions. The disadvantages of explicitly setting a number of threads are:

1. In a system with a large number of processors, your application will use some but not all of the processors.
2. In a system with a small number of processors, your application may force over subscription that results in poor performance.

The Intel OpenMP runtime will create the same number of threads as the available number of logical processors unless you use the omp_set_num_threads routine. To determine the actual limits, use omp_get_thread_limit() and omp_get_max_active_levels(). Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The OMP_THREAD_LIMIT environment variable limits the number of OpenMP* threads to use for the whole OpenMP* program. The OMP_MAX_ACTIVE_LEVELS environment variable limits the number of active nested parallel regions.

Binding Sets

The various binding sets describe which OpenMP constructs can be nested in which other OpenMP constructs and what effect that nesting has.

The binding region for an OpenMP construct is the enclosing region that determines the execution context and the scope of the effects of the directive:

- The binding region for an omp ordered construct is the innermost enclosing omp for loop region.
- The binding region for a omp taskwait construct is the innermost enclosing omp task region.
- For all other constructs for which the binding thread set is the current team or the binding task set is the current team tasks, the binding region is the innermost enclosing region.
- For constructs for which the binding task set is the generating task, the binding region is the region of the generating task.
- A omp parallel construct need not be active nor explicit to be a binding region.
- A construct need not be explicit to be a binding region.
- A region never binds to any region outside of the innermost enclosing parallel region.
The binding task set for an OpenMP construct is the set of tasks that are affected by, or provide the context for, the execution of a region. The binding task set for a given construct can be all tasks, the current team tasks, or the generating task.

The binding thread set for an OpenMP construct is the set of threads that are affected by, or provide the context for, the execution of a region. The binding thread set for a given construct can be all threads on a device, all threads in a contention group, the current team, or the encountering thread.

**Worksharing Using OpenMP**

To get the maximum performance benefit from a processor with multi-core and Intel® Hyper-Threading Technology (Intel® HT Technology), an application needs to be executed in parallel. Parallel execution requires threads, and threading an application is not a simple thing to do; using OpenMP* can make the process a lot easier. Using the OpenMP* pragmas, most loops with no loop-carried dependencies can be threaded with one simple statement. This topic explains how to start using OpenMP* to parallelize loops, which is also called worksharing.

Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Most loops can be threaded by inserting one pragma immediately prior to the loop. Further, by leaving the details to the Intel® C++ Compiler and OpenMP*, you can spend more time determining which loops should be threaded and how to best restructure the algorithms for maximum performance. The maximum performance of OpenMP* is realized when it is used to thread hotspots, the most time-consuming loops in your application.

The power and simplicity of OpenMP* is demonstrated by looking at an example. The following loop converts a 32-bit RGB (red, green, blue) pixel to an 8-bit gray-scale pixel. One pragma, which has been inserted immediately before the loop, is all that is needed for parallel execution.

**Example**

```cpp
#pragma omp parallel for
for (i=0; i < numPixels; i++) {
    pGrayScaleBitmap[i] = (unsigned BYTE)
    (pRGBBitmap[i].red * 0.299 +
     pRGBBitmap[i].green * 0.587 +
     pRGBBitmap[i].blue * 0.114);
}
```

First, the example uses worksharing, which is the general term used in OpenMP* to describe distribution of work across threads. When worksharing is used with the `for` construct, as shown in the example, the iterations of the loop are distributed among multiple threads so that each loop iteration is executed exactly once with different iterations executing if there is more than one available thread. Since there is no explicit `numthreads` clause, OpenMP* determines the number of threads to create and how to best create, synchronize, and destroy them. OpenMP* places the following five restrictions on which loops can be threaded:

- The loop variable must be of type signed or unsigned integer, random access iterator, or pointer.
- The comparison operation must be in the form `loop_variable <, <=, >, or >= loop_invariant_expression` of a compatible type.
- The third expression or increment portion of the `for` loop must be either addition or subtraction by a loop invariant value.
- If the comparison operation is `< or `<=`, the loop variable must increment on every iteration; conversely, if the comparison operation is `> or `>=`, the loop variable must decrement on every iteration.
• The loop body must be single-entry-single-exit, meaning no jumps are permitted from inside to outside the loop, with the exception of the exit statement that terminates the whole application. If the statements goto or break are used, the statements must jump within the loop, not outside it. Similarly, for exception handling, exceptions must be caught within the loop.

Although these restrictions might sound somewhat limiting, non-conforming loops can frequently be rewritten to follow these restrictions.

Basics of Compilation
Using the OpenMP* pragmas requires an OpenMP-compatible compiler and thread-safe libraries. Adding the [Q]openmp option to the compiler instructs the compiler to pay attention to the OpenMP* pragmas and to insert threads. If you omit the [Q]openmp option, the compiler will ignore OpenMP* pragmas, which provides a very simple way to generate a single-threaded version without changing any source code.

For conditional compilation, the compiler defines the _OPENMP macro. If needed, the macro can be tested as shown in the following example.

### Example

```c
#ifdef _OPENMP
  fn();
#endif
```

A Few Simple Examples
The following examples illustrate how simple OpenMP* is to use. In common practice, additional issues need to be addressed, but these examples illustrate a good starting point.

In the first example, the following loop clips an array to the range from 0 to 255.

### Example

```c
// clip an array to 0 <= x <= 255
for (i=0; i < numElements; i++) {
  if (array[i] < 0)
    array[i] = 0;
  else if (array[i] > 255)
    array[i] = 255;
}
```

You can thread it using a single OpenMP* pragma; insert the pragma immediately prior to the loop:

### Example

```c
#pragma omp parallel for
for (i=0; i < numElements; i++) {
  if (array[i] < 0)
    array[i] = 0;
  else if (array[i] > 255)
    array[i] = 255;
}
```

In the second example, the loop generates a table of square roots for the numbers from 0 to 100.
Thread the loop by changing the loop variable to a signed integer or unsigned integer and inserting a `#pragma omp parallel` pragma.

```
int value;
double roots[100];
#pragma omp parallel for
for (value = 0; value < 100; value ++) { roots[value] = sqrt((double)value); }
```

### Avoiding Data Dependencies and Race Conditions

When a loop meets all five loop restrictions (listed above) and the compiler threads the loop, the loop still might not work correctly due to the existence of data dependencies.

Data dependencies exist when different iterations of a loop (more specifically a loop iteration that is executed on a different thread) read or write the same location in shared memory. Consider the following example that calculates factorials.

```
// Each loop iteration writes a value that a different iteration reads.
#pragma omp parallel for
for (i=2; i < 10; i++) { factorial[i] = i * factorial[i-1]; }
```

The compiler will thread this loop, but the threading will fail because at least one of the loop iterations is data-dependent upon a different iteration. This situation is referred to as a race condition. Race conditions can only occur when using shared resources (like memory) and parallel execution. To address this problem either rewrite the loop or pick a different algorithm, one that does not contain the race condition.

Race conditions are difficult to detect because, for a given case or system, the threads might win the race in the order that happens to make the program function correctly. Because a program works once does not mean that the program will work under all conditions. Testing your program on various machines, some with Intel® Hyper-Threading Technology and some with multiple physical processors, is a good starting point to help identify race conditions.

Traditional debuggers are useless for detecting race conditions because they cause one thread to stop the race while the other threads continue to significantly change the runtime behavior; however, thread checking tools can help.

### Managing Shared and Private Data

Nearly every loop (in real applications) reads from or writes to memory; it's your responsibility, as the developer, to instruct the compiler what memory should be shared among the threads and what memory should be kept private. When memory is identified as shared, all threads access the same memory location. When memory is identified as private, however, a separate copy of the variable is made for each thread to access in private. When the loop ends, the private copies are destroyed. By default, all variables are shared except for the loop variable, which is private.

Memory can be declared as private in two ways:

- Declare the variable inside the loop—really inside the parallel OpenMP* pragma—without the static keyword.
• Specify the private clause on an OpenMP* pragma.

The following loop fails to function correctly because the variable `temp` is shared. It should be private.

```
Example

// Variable temp is shared among all threads, so while one thread
// is reading variable temp another thread might be writing to it
#pragma omp parallel for
for (i=0; i < 100; i++) {
    temp = array[i];
    array[i] = do_something(temp);
}
```

The following two examples both declare the variable `temp` as private memory, which solves the problem.

```
Example

#pragma omp parallel for
for (i=0; i < 100; i++) {
    int temp; // variables declared within a parallel construct
    // are, by definition, private
    temp = array[i];
    array[i] = do_something(temp);
}
```

The `temp` variable can also be made private in the following way:

```
Example

#pragma omp parallel for private(temp)
for (i=0; i < 100; i++) {
    temp = array[i];
    array[i] = do_something(temp);
}
```

Every time you use OpenMP* to parallelize a loop, you should carefully examine all memory references, including the references made by called functions. Variables declared within a parallel construct are defined as private except when they are declared with the `static` declarator, because static variables are not allocated on the stack.

**Reductions**

Loops that accumulate a value are fairly common, and OpenMP* has a specific clause to accommodate them. Consider the following loop that calculates the sum of an array of integers.

```
Example

sum = 0;
for (i=0; i < 100; i++) {
    sum += array[i]; // this variable needs to be shared to generate
    // the correct results, but private to avoid
    // race conditions from parallel execution
}
```
The variable sum in the previous loop must be shared to generate the correct result, but it also must be private to permit access by multiple threads. OpenMP* provides the reduction clause that is used to efficiently combine the mathematical reduction of one or more variables in a loop. The following example demonstrates how the loop can use the reduction clause to generate the correct results.

Example

```c
sum = 0;
#pragma omp parallel for reduction(+:sum)
for (i=0; i < 100; i++) { sum += array[i]; }
```

In the case of the example listed above, the reduction provides private copies of the variable sum for each thread, and when the threads exit, it adds the values together and places the result in the one global copy of the variable.

The following table lists the possible reduction operations, along with their initial values (mathematical identity values).

<table>
<thead>
<tr>
<th>Operation</th>
<th>private Variable Initialization Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ (addition)</td>
<td>0</td>
</tr>
<tr>
<td>- (subtraction)</td>
<td>0</td>
</tr>
<tr>
<td>* (multiplication)</td>
<td>1</td>
</tr>
<tr>
<td>&amp; (bitwise and)</td>
<td>~0</td>
</tr>
<tr>
<td></td>
<td>(bitwise or)</td>
</tr>
<tr>
<td>^ (bitwise exclusive or)</td>
<td>0</td>
</tr>
<tr>
<td>&amp;&amp; (conditional and)</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Multiple reductions in a loop are possible by specifying comma-separated variables and operations on a given parallel construct. Reduction variables must meet the following requirements:

- can be listed in just one reduction.
- cannot be declared constant.
- cannot be declared private in the parallel construct.

Load Balancing and Loop Scheduling

Load balancing, the equal division of work among threads, is among the most important attributes for parallel application performance. Load balancing is extremely important, because it ensures that the processors are busy most, if not all, of the time. Without a balanced load, some threads may finish significantly before others, leaving processor resources idle and wasting performance opportunities.

Within loop constructs, poor load balancing is often caused by variations in compute time among loop iterations. It is usually easy to determine the variability of loop iteration compute time by examining the source code. In most cases, you will see that loop iterations consume a uniform amount of time. When that is not true, it may be possible to find a set of iterations that consume similar amounts of time. For example, sometimes the set of all even iterations consumes about as much time as the set of all odd iterations. Similarly, it might be the case that the set of the first half of the loop consumes about as much time as the second half. In contrast, it might be impossible to find sets of loop iterations that have a uniform execution
time. Regardless of the case, you should provide this extra loop scheduling information to OpenMP* so it can better distribute the iterations of the loop across the threads (and therefore processors) for optimum load balancing.

If you know that all loop iterations consume roughly the same amount of time, the OpenMP* schedule clause should be used to distribute the iterations of the loop among the threads in roughly equal amounts via the scheduling policy. In addition, you need to minimize the chances of memory conflicts that may arise because of false sharing due to using large chunks. This behavior is possible because loops generally touch memory sequentially, so splitting up the loop in large chunks—like the first half and second half when using two threads—will result in the least chance for overlapping memory. While this may be the best choice for memory issues, it may be bad for load balancing. Unfortunately, the reverse is also true; what might be best for load balancing may be bad for memory performance. You must strike a balance between optimal memory usage and optimal load balancing by measuring the performance to see what method produces the best results.

Use the following general form on the parallel construct to schedule an OpenMP* loop:

```
#pragma omp parallel for schedule(kind [, chunk size])
```

Four different loop scheduling types (kinds) can be provided to OpenMP*, as shown in the following table. The optional parameter (chunk), when specified, must be a positive integer.

<table>
<thead>
<tr>
<th>Kind</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static</td>
<td>Divide the loop into equal-sized chunks or as equal as possible in the case where the number of loop iterations is not evenly divisible by the number of threads multiplied by the chunk size. By default, chunk size is $\text{loop_count}/\text{number_of_threads}$. Set chunk to 1 to interleave the iterations.</td>
</tr>
<tr>
<td>dynamic</td>
<td>Use the internal work queue to give a chunk-sized block of loop iterations to each thread. When a thread is finished, it retrieves the next block of loop iterations from the top of the work queue. By default, the chunk size is 1. Be careful when using this scheduling type because of the extra overhead involved.</td>
</tr>
<tr>
<td>guided</td>
<td>Similar to dynamic scheduling, but the chunk size starts off large and decreases to better handle load imbalance between iterations. The optional chunk parameter specifies them minimum size chunk to use. By default the chunk size is approximately $\text{loop_count}/\text{number_of_threads}$.</td>
</tr>
<tr>
<td>auto</td>
<td>When schedule (auto) is specified, the decision regarding scheduling is delegated to the compiler. The programmer gives the compiler the freedom to choose any possible mapping of iterations to threads in the team.</td>
</tr>
<tr>
<td>runtime</td>
<td>Uses the <code>OMP_SCHEDULE</code> environment variable to specify which one of the three loop-scheduling types should be used. <code>OMP_SCHEDULE</code> is a string formatted exactly the same as would appear on the parallel construct.</td>
</tr>
</tbody>
</table>

Assume that you want to parallelize the following loop.
As written, the loop contains a data dependency, making it impossible to parallelize without a change. The new loop, shown below, fills the array in the same manner, but without data dependencies. The new loop benefits from using the SIMD instructions generated by the compiler.

Observe that the code is not 100% identical because the value of variable `StartVal` is not incremented. As a result, when the parallel loop is finished, the variable will have a value different from the one produced by the serial version. If the value of `StartVal` is needed after the loop, the additional statement, shown below, is needed.

**OpenMP** Tasking Model

The OpenMP** tasking model enables you to parallelize a large range of applications. You can use several OpenMP** pragmas for tasking.

**The `omp task` Pragma**

The **omp task** pragma has the following syntax:

```
#pragma omp task [clause[[,] clause] ...] new-line
structured-block
```

where clause is one of the following:

- `if(scalar-expression)`
- `final (scalar expression)`
- `untied`
- `default(shared | none)`
- `mergeable`
- `private(list)`
- `firstprivate(list)`
- `in_reduction(reduction-identifier : list)`
- `shared(list)`
• depend (dependence-type : list)
• priority (priority-value)

The 
#pragma omp task
defines an explicit task region as shown in the following example:

**Example**

```c
void test1(LIST *head) {
    #pragma intel omp parallel shared(head)
    {
        #pragma omp single
        {
            LIST *p = head;
            while (p != NULL) {
                #pragma omp task firstprivate(p)
                {
                    do_work1(p);
                }
                p = p->next;
            }
        }
    }
}
```

The binding thread set of the task region is the current parallel team. A task region binds to the innermost enclosing PARALLEL region. When a thread encounters a task construct, a task is generated from the structured block enclosed in the construct. The encountering thread may immediately execute the task, or defer its execution. A task construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

**Using #pragma omp task clauses**

The 
#pragma omp task
takes an optional comma-separated list of clauses. The data environment of the task is created according to the data-sharing attribute clauses on the task construct and any defaults that apply. The example below shows a way to generate N tasks with one thread and execute them with the threads in the parallel team:

**Example**

```c
#pragma omp parallel shared(data)
{
    #pragma omp single private(i)
    {
        for (i=0, i<N; i++)
        {
            #pragma omp task firstprivate(i shared(data)
            {
                do_work(data(i));
            }
        }
    }
}
```

**Task scheduling**

When a thread reaches a task scheduling point, it may perform a task switch, beginning or resuming execution of a different task bound to the current team. Task scheduling points are implied at the following locations:

• the point immediately following the generation of an explicit task.
• after the last instruction of a task region.
• in a taskwait region.
• in implicit and explicit barrier regions.

When a thread encounters a task scheduling point it may do one of the following:
• begin execution of a tied task bound to the current team.
• resume any suspended task region, bound to the current team, to which it is tied.
• begin execution of an untied task bound to the current team.
• resume any suspended untied task region bound to the current team.

If more than one of the above choices is available, it is unspecified as to which will be chosen.

**Task scheduling constraints**

1. An explicit task whose construct contained an if clause whose if clause expression evaluated to false is executed immediately after generation of the task.
