With the Intel® RealSense™ SDK, you have access to robust, natural human-computer interaction (HCI) algorithms such as face tracking, finger tracking, gesture recognition, speech recognition and synthesis, fully textured 3D scanning and enhanced depth augmented reality.

With the SDK you can create Windows® desktop applications that offer innovative user experiences.

This tutorial shows how to enable the hand tracking module of the SDK and enable its features, such as hand and finger tracking, robust 22-point skeletal joint tracking, and gesture recognition.

The module can also display event alert notifications in your application, and a basic rendering utility is provided to view the output data.

Overview

The Intel RealSense SDK contains input/output modules and algorithm modules. In this tutorial, you'll see how to use one of the algorithm modules in particular the hand tracking module. To learn more about I/O modules, see the Capturing Raw Streams tutorial.

The hand module handles the tracking of hands in the scene, allowing you to reconstruct the 3D skeleton of the hands, recognize various hand gestures and get notifications for interesting events. The PXCHandModule interface is used to set up the configuration and output data of up to two hands. The PXCHandConfiguration can be used to set up different tracking options, enable gesture and alert notification and select the required outputs.

Hand Tracking Data

Applications can locate and return a hand data for up to two hands through the PXCHandData interface.

The hand data is exposed to the application through the iHand interface that provides the following data:

Mass Center: Image and world coordinates of the calculated hand image mass center.

Extremity Points: Special tracking points such as the closest, left-most, top-most, right-most, bottom-most and center points which form the boundaries of the mask of the hand silhouette.

Body Side: Whether it is a left or right hand.

Palm Orientation: Estimation of where the hand is facing.

Tracked Joints: Position and rotations of the user's hand in world and image coordinates.

Normalized Joints: Posture of user's hand without changing dimensions of the hand, i.e., the distances between each joint (bone-length) are always the same.

Finger Data: Degree of foldedness and the radius of a particular fingertip.
**Segmentation Image:** A mask of the hand silhouette allowing to separate a hand from the background image.

**Hand Openness:** (0-100 value) indicating if all fingers are completely folded to all fingers fully spread.

**Gesture Tracking**

Using the `PXCHandData` interface, you can also access gesture information. Certain defined hand movements, also known as hand-gestures, can be enabled for detection.

<table>
<thead>

</tr>
<tr>
<td>v_sign</td>
<td></td>
<td>Index and middle fingers extended in upwards direction.</td>
</tr>
</tbody>
</table>
**full_pinch**

All fingers extended and touching the thumb. The pinched fingers should be pointing to the screen.

---

**swipe**

Swipe to the left with the right hand or swipe to the right with the left hand.
The palm is facing the side and fingers are more or less towards the camera.
The hand swiping must be inside the camera's field of view.

---

**wave**

Move the hand to the left and then the right.
Repeat the action if necessary.
**Hand Alert Notification**

This module helps notify your application of certain useful information:

- **Hand detection and tracking**: Inform the application that a hand is detected and is tracked.
- **Hand calibration**: Inform the application that hand calibration data is available.
- **Tracking Boundaries**: Inform the application when the tracked hand goes out or is about to go out of the tracking boundaries.

**Blob Extractor**

The [blob extractor](#) provides information about image blobs within certain depth value range. The blob extractor does not handle joint tracking or gesture tracking.

**Contour Extractor**

The [contour extractor](#) provides information about the contour of the image blobs. Just like the blob extractor, contour extractor does not handle joint tracking or gesture tracking.

**Data Smoothing Utility**

The data smoothing utility can be used to reduce data noise. The utility interface enables data types for 1D, 2D, 3D data points with support for [Stabilizer smoother](#), [Weighted smoother](#), [Quadratic smoother](#) and [Spring smoother](#) algorithms.
Code Sample Files

You can use either procedural calls or event callbacks to capture hand data, and relevant code samples showing both are listed in Table 1. Using event callbacks is usually preferred when developing console applications; procedural calls are often used for GUI applications. This tutorial's code samples use procedural calls.

The handtracking_render.cpp file, provided with the tutorial code samples, contains the **HandRender** utility class that renders an image sample that contains hand tracking data. It is provided with this tutorial so that you do not have to create your own hand rendering algorithm.

Executable files (.exe) are provided in the Release subfolder in the code sample directory.

Table 1: Hand Tracking Code Samples
Creating a Session for Hand Tracking

The SDK core is represented by two interfaces:

- **PXCSession**: manages all of the modules of the SDK
- **PXC SenseManager**: organizes a pipeline by starting, stopping, and pausing the operations of its various modalities.

The first step when creating an application that uses the Intel RealSense SDK is to create a session. A session can be created explicitly by creating an instance of **PXCSession**. Each session maintains its own pipeline that contains the I/O and algorithm modules.

Another way of creating a session is by creating an instance of the **PXC SenseManager** using **CreateInstance**. The PXCSenseManager implicitly creates a session internally.

1. Initialize an instance of the **HandRender** utility class so that you can render the captured image samples.
2. Create a session and instance of the **PXC SenseManager** to add the functionality of the Intel RealSense SDK to your application.

```c
#include "handanalysis_render.h"
{
    // initialize the UtilRender instances
    HandRender *renderer = new HandRender(L"Procedural Hand Tracking");

    // create the PXCSenseManager
    PXCSenseManager *psm=0;
    psm = PXCSenseManager::CreateInstance();
    if (!psm) {
        wprintf_s(L"Unable to create the PXCSenseManager\n");
        return 1;
    }
}
```
Initializing the Pipeline

Hand Tracking

Create an instance of type `pxcStatus` for error checking throughout the application.

1. Enable the hand analysis using `EnableHand`.
2. Retrieve an instance of hand module using `QueryHand` on the instance of PXCSenseManager.
3. Initialize the pipeline using `Init` and retrieve an instance of handData using `CreateOutput` on the hand module.

```c
// error checking Status
pxcStatus sts;

// enable hand analysis in the multimodal pipeline
sts = psm->EnableHand();
if (sts < PXC_STATUS_NO_ERROR) {
    wprintf_s(L"Unable to enable Hand Tracking\n");
    return 2;
}

// retrieve hand results if ready
PXCHandModule* handAnalyzer = psm->QueryHand();
if (!handAnalyzer) {
    wprintf_s(L"Unable to retrieve hand results\n");
    return 2;
}

// initialize the PXCSenseManager
if (psm->Init() < PXC_STATUS_NO_ERROR) return 3;

PXCHandData* outputData = handAnalyzer->CreateOutput();
```
Create an instance of **PXCHandConfiguration** using the hand module to configure the hand.

```cpp
PXCHandConfiguration* config = handAnalyzer->CreateActiveConfiguration();
```

**Gesture Tracking Configuration**

Enable all the gestures using **EnableAllGestures** on the PXCHandConfiguration instance. You can also enable specific gestures using **EnableGesture**.

```cpp
config->EnableAllGestures();
```

**Alert Event Notification Configuration**

Similarly, enable specific alerts using **EnableAlert**. Refer to **EnableAllAlerts** to enable all alerts for the hand module.

```cpp
config->EnableAlert(PXCHandData::AlertType::ALERT_HAND not DETECTED);
config->EnableAlert(PXCHandData::AlertType::ALERT_HAND NOT DETECTED);
```

After configuring the hand module, apply the changes to the active configuration using **ApplyChanges**.

```cpp
config->ApplyChanges();
```
Streaming the Hand Tracking Data

1. Acquire Frames in a loop using `AcquireFrame(true)`:
   a. TRUE to wait for all processing modules to be ready in a given frame; else
   b. FALSE whenever any of the processing modules signal.
2. In every iteration of the frame loop first use `Update()` on the hand data instance to update the hand data.
3. Create the required data structures for the renderer class provided in the tutorial such as the two-dimensional `PXCHandData::JointData` array.
4. At the end of every iteration of the frame loop make sure to release the acquired frame using `ReleaseFrame` to process the next frame.

```c++
//Stream data
while (psm->AcquireFrame(true)>PXC_STATUS_NO_ERROR)
{
    //update the output data to the latest available
    outputData->Update();

    // create data structs for storing required data
    PXCHandData::JointData nodes[2][PXCHandData::NUMBER_OF_JOINTS]={};

    //refer to upcoming sections to learn how to retrieve and render joint data
    //also gesture notifications, handSide and alerts

    // release or unlock the current frame to go fetch the next frame
    psm->ReleaseFrame();
}
```
Joint data

1. Retrieve the number of detected hands in the current frame using `QueryNumberOfHands` on the updated hand data instance.
2. Loop through the total number of detected hands.
3. Use `QueryHandData` to populate the `PXCHandData::iHand` instance, with appropriate access order type.
4. On a given instance of `iHand` you can loop through and `QueryTrackedJoint` with a specific `JointType` to extract individual joints.

Use the render utility `DrawJoints()` provided in the tutorial to render the joints.

```cpp
//while loop: AcquireFrame
{
    pxCU16 numOfHands = outputData->QueryNumberOfHands();
    for(pxcU16 i = 0 ; i < numOfHands ; i++)
    {
        // get hand joints by time of appearence
        PXCHandData::IHand* handData;
        if(outputData->QueryHandData(PXCHandData::ACCESS_ORDER_BY_TIME,i,handData) == PXC_STATUS_NO_ERROR)
        {
            PXCHandData::JointData jointData;
            // iterate through Joints
            for(int j = 0; j < PXCHandData::NUMBER_OF_JOINTS ; j++)
            {
                handData->QueryTrackedJoint((PXCHandData::JointType)j,jointData);
                nodes[i][j] = jointData;
            }
        }
    }
    renderer->DrawJoints(nodes);
    //ReleaseFrame
}
```
**Gesture Data**

1. Iterate through all the fired gestures using `QueryFiredGesturesNumber` and populate the gesture data using `QueryFiredGestureData`.

2. Access an `iHand` instance associated with a gesture using `QueryHandDataById` on a hand data instance.

3. Use `QueryBodySide` on the retrieved `iHand` instance to detect whether the gesture was fired by a right or left hand.

Use the render utility `NotifyGestures()` provided in the tutorial to display the gestures.

```c++
//while loop: AcquireFrame
{
    // iterate through fired gestures
    int numOfGestures = outputData->QueryFiredGesturesNumber();
    if(numOfGestures>0){
        // iterate through fired gestures
        for(int i = 0; i < numOfGestures; i++){
            // initialize data
            PXCHandData::GestureData gestureData;
            // get fired gesture data
            if(outputData->QueryFiredGestureData(i,gestureData) == PXC_STATUS_NO_ERROR){
                // get hand data related to fired gesture
                PXCHandData::IHand* handData;
                if(outputData->QueryHandDataById(gestureData.handId,handData) == PXC_STATUS_NO_ERROR){
                    // save gesture only if you know that its right/left hand
                    if(handData->QueryBodySide() != PXCHandData::BodySideType::BODY_SIDE_UNKNOWN)
                        renderer->NotifyGestures(handData->QueryBodySide(),gestureData.name);
                }
            }
        }
    }
    //ReleaseFrame
}
```
Alert Event Notification Data

1. Iterate through fired alerts in the current frame using \texttt{QueryFiredAlertsNumber} and populate the alert data using \texttt{QueryFiredAlertData}.

2. Using \texttt{alerData.label} you can compare in a switch statement all available alerts under the \texttt{PXCFaceData} alert type.

Use the render utility \texttt{NotifyAlerts()} provided in the tutorial to display the alerts.

```c
//while loop: AcquireFrame
{
    // iterate through Alerts
    PXCHandData::AlertData alertData;
    for(int i = 0 ; i < outputData->QueryFiredAlertsNumber(); i++)
    {
        sts = outputData->QueryFiredAlertData(i,alertData);
        if(sts==PXC_STATUS_NO_ERROR)
        {
            // Display last alert - see AlertData::Label for all available alerts
            renderer->NotifyAlerts(alertData.label);
        }
    }
} //ReleaseFrame
```
Rendering the Frame

1. Create an image instance for the depth sample used to stream the data.
2. Retrieve a hand sample using `QueryHandSample`.
3. Retrieve the specific frame type from the sample, by saving it in a variable of type `PXCIImage`.
   - Use the `RenderFrame` method provided in the custom renderer to render the depth image as the background.

```c
PXCIImage *depthim = NULL;
//while loop per frame
{
    // retrieve all available image samples
    PXCCapture::Sample *sample = psm->QueryHandSample();

    // retrieve the image or frame by type
    depthim = sample->depth;

    // render the frame
    if (!renderer->RenderFrame(depthIm)) break;

    //ReleaseFrame
}
```
Cleaning up the Pipeline

1. Make sure to delete the `HandRenderer` instance using `delete`.
2. If used, also release any instance of `PXCHandConfiguration` using `Release` on it.
3. It is very important to close the last opened session, in this case the instance of `PXCSenseManager` by using `Release` to indicate the camera to stop streaming.

```cpp
//In Main
{
    //while loop per frame
    {
    }
    //End of while loop per frame

    // delete the HandRender instance
delte renderer;

    // close the Hand Configuration instance
config->Release();

    // close the last opened stream and release any session
    // and processing module instances
psm->Release();
    return 0;
}
//End of Main
```
Running the Code Sample

You can run the code sample two ways:

1. Build and Run the 3_Hands_Tracking sample in Visual Studio®.
2. Run the executables in the “Release” subfolder of the tutorial code sample directory.

Figure 1 shows a rendered depth image frame that displays the hand tracking data as the 22 tracked joints, Alert data, and Gesture Data along with the Body side of each gesture.

![Rendered Depth Sample with Hand Tracking data, Alert data, and Gesture data](image)
