Building Linux* Kernel with Intel® C++ Compiler for Linux*

White Paper
Feilong Huang
Developer Products Division
Introduction

Intel® C++ Compilers have been in the market for over ten years. More and more software developers are interested in using Intel® C++ compilers to optimize their applications on Windows*, Linux* and Mac OS* X.

As the most essential part of a Linux operating system, the Linux kernel is highly-optimized by kernel developers. Additionally there are many GNU C Language extensions, programming tricks and inline assembly code in it. This makes it challenging for compilers other than GNU C compiler, to compile and optimize the kernel. Building the Linux kernel with the Intel C++ Compiler (icc) is an ongoing project at Intel. The goal is to improve gcc source compatibility with the Intel C++ Compiler and to find opportunities to improve kernel performance.

Red Flag* Software Co., Ltd started to use the Intel C++ Compiler for Linux to compile the Linux kernel in its commercial version of Linux operating system in 2004¹. While this is not a how-to guide, this document provides extensive hints for the readers to build the Linux kernel using the Intel C++ Compiler.

Compiler Options Compatibility

icc supports most gcc options, but not all of them, therefore, unsupported options must either be replaced with icc equivalent options, or removed. Most of them are not critical and can be removed without breaking the Linux kernel. For example, the following unsupported options can be removed without any risks.

-ffreestanding
-fno-unit-at-a-time
-msoft-float
-mfloat-abi
-gstabs

Ignoring the following options may break the Linux kernel. Replacing them with icc equivalent options is a must.

-mno-mmx
-mno-sse2
-mno-sse3

Table 1 summarizes some gcc options and support in Intel C++ Compiler 11.1, 12.x and 13.0.¹

Table 1. Some GCC Options and Support in Intel® C++ Compiler for Linux*

<table>
<thead>
<tr>
<th>GCC Options</th>
<th>Intel C++ Compiler 11.1</th>
<th>Intel C++ Compiler 12.x</th>
<th>Intel C++ Compiler 13.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>-ffreestanding</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The Intel C++ Compiler is stricter with syntax checking and reports more warnings than the GNU compiler. As a result, the -Werror option may cause the compilation to stop due syntax errors, and therefore should be removed.

To compile the Linux kernel with icc, setting environment variables HOSTCC and CC to icc is required.

```
make menuconfig
make HOSTCC=icc CC=icc
make modules_install
```

Optionally, user may create a simple wrapper script to remove unsupported compiler options or replace them with equivalent icc options and then invoke icc. In this case, environment variables HOSTCC and CC need to be set to the name of the wrapper script.

```
make menuconfig
make HOSTCC=<name_of_wrapper> CC=<name_of_wrapper>
make modules_install
```

For an example of wrapper script, see Appendix A.

**Source Compatibility**

The Intel C++ Compiler does not support a few gcc’s builtin functions and IA-64 inline assembly code. Workarounds are needed.

- Inline assembly code

The Intel C++ Compiler supports inline assembly code on IA-32 and Intel 64. IA-64 compilers do not support inline assembly. Instead intrinsics that are C-like functions are recommended. Assembly code on IA-64 needs to be rewritten using corresponding intrinsics. The Intel C++ Compiler documentation includes a mapping of assembly instructions to intrinsics. Most of these changes have been checked into the Linux kernel source tree.
Linux Kernel Source Defects
Some Linux kernel source defects were observed during compilation of the Linux kernel with the Intel C++ Compiler. These defects may have been fixed in the newer Linux kernel already.

- **volatile attribute**

Look at the following code snippet from include/asm-ia64/spinlock.h

```c
#define _raw_spin_lock(x) \
do {
  __u32 *ia64_spinlock_ptr = (__u32 *) (x); \
  __u64 ia64_spinlock_val;
  ... 
  if (unlikely(ia64_spinlock_val)) {
    do { 
      while (*ia64_spinlock_ptr) 
      ia64_barrier(); 
      ... 
    } while (ia64_spinlock_val);
  } while (0)
}
```

In the above code snippet, `ia64_spinlock_ptr` points to a 32-bit volatile data in memory. Without a `volatile` keyword here, the compiler may generate the following asm code (shown in pseudo code) for the while loop when optimization option is turned on:

```asm
load ia64_spinlock_ptr, register
label: test register
jump-if-not-zero label
```

Unfortunately, the above code results in a dead lock of the Linux kernel because the 32-bit data pointed to by `ia64_spinlock_ptr` is not reloaded. The GNU compiler happens to generate the “right” code, which is what kernel developers want:

```asm
label: load ia64_spinlock_ptr, register
test register
jump-if-not-zero label
```

In this case, a “volatile” attribute is needed for the variable `ia64_spinlock_ptr`, to make sure other compilers do not fail.

- **inline keyword**

The `inline` keyword is just a hint to the compiler. Compilers may or may not inline a function declared as inline. For example, in some applications `gettimeofday()` is
done very often like when the kernel is timestamping all transactions. It would help performance if it could be implemented with very low overhead.

One way of obtaining a fast `gettimeofday()` is by writing the current time in a fixed place on a page mapped into the memory of all applications and updating this location on each clock interrupt. These applications could then read this fixed location with a single instruction - no system call required.

There might be other data that the kernel could make available in a read-only way to the process, like perhaps the current process ID. A `vsyscall` is a "system" call that avoids crossing the userspace-kernel boundary.

`vsyscall()` and `do_vgettimeofday()` are in a special page, which can be accessed in user mode.

The Intel C++ Compiler doesn't inline the function `sync_core()`, which is marked as an inline function in `include/asm-x86_64/processor.h`. Thus, the function is compiled as a separate function in the kernel image. `vsyscall()` calls `do_vgettimeofday()` and `do_vgettimeofday()` calls `sync_core()`. The first two functions are called by user applications while `sync_core()` is a kernel function. This will cause a page fault. The following illustrates the call-graph of these 3 functions.

```
   vsyscall( )
    |               user space
   do_vgettimeofday( )               --------------
    |                     kernel space
     sync_core( )
```

gcc inlines `sync_core`. As a result, gcc avoids the page fault. To fix this source defect, adding a `always_inline` attribute to `sync_core()`.

**Conclusion**

Intel® C++ Compiler is highly compatible with the GNU Compiler. With a small wrapper script and a limited number of temporary source patches, we’ve successfully compiled Linux kernels 2.4.21, 2.6.9, 2.6.18 and 2.6.32 with the Intel C++ Compilers on IA-32, Intel® 64 and IA-64. Since newer Linux kernels may have fewer source compatibility issues, we recommend that you build newer Linux kernels with the latest Intel C++ Compiler.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
