The GNU* Project Debugger - GDB
BTS Instruction Trace

Intel® Atom™ Processor supports Branch Trace Store (BTS) using cache-as-RAM or system DRAM

Set breakpoint in OS signal event handler
Unroll execution flow leading up to stack overflow or segmentation fault
Follow execution backwards to where it deviated from expectation
Rerun to that point and analyze memory accesses

Unroll past execution flow: Where did things start to go wrong?
btrace: h/w supported branch tracing

(gdb) btrace list 1-3
1 in foo () at foo.c:23-28
2 in foo () at foo.c:21-22
3 in bar () at foo.c:18
(gdb) btrace /m 3
foo.c:18: foo (42)
  0x400515 <bar+15>: mov $0x2a, %rax
  0x400519 <bar+19>: call 0x400400 <foo>
(gdb)

• H/W records per-thread branch trace.
• Show compact control flow overview.
• Show detailed execution trace disassembly.

Answers “how did I get here?”
btrace: command line syntax

1. btrace enable/disable [all] [auto] [<num>[<num>]]:

   start/stop recording the branch trace for the current [all] [new] [listed] thread[s]

1. btrace list [/a] [/f] [/l] [/t] [<num>[<num>]]:

   display a list of blocks

1. btrace [/n] [/m] [+,-, <num>[<num>]]:

   display the disassembly of one block

“help branchtracing “ for syntax details
btrace: use cases

Debug internal state corruption.

Debug stack corruption (broken backtrace).

Quick control flow overview.
(gdb) btrace enable auto

program crashed and back trace is not much help:

(gdb) run
Starting program: ../gdb/trace/examples/function_pointer/stack64   Program received signal SIGSEGV, Segmentation fault. 0x000000000000002a in ?? ()
(gdb) bt
#0 0x000000000000002a in ?? ()
#1 0x0000000000000017 in ?? ()
#2 0x00000000000040050e in fun_B (arg=0x4005be) at src/stack.c:32
#3 0x0000000000000000 in ?? ()

Look at the branch trace.
List of blocks starts from the most recent block (ending at the current pc) and continues towards older blocks such that control flows from block n+1 to block n.

(gdb) btrace list 1-7
1    in ?? ()
2    in fun_B () at src/stack.c:36-37
3    in fun_B () at src/stack.c:32-34
4    in main () at src/stack.c:57
5    in fun_A () at src/stack.c:22-25
6    in fun_A () at src/stack.c:18-20
7    in main () at src/stack.c:51-56

from main(), we called first fun_A() and then fun_B(). The call to fun_A() returned, and we crashed somewhere in fun_B().
btrace: Example

Look at the disassembly of the last 3 blocks in original control flow (i.e. reverse trace) order, starting from the call to fun_B() from main().

/m interleaves source info

(gdb) btrace /m 1-3
src/stack.c:32  static long fun_B(void* arg) {
  0x000000000040050e <fun_B+1>:  mov  %rsp,%rbp
  0x0000000000400511 <fun_B+4>:  mov  %rdi,-0x18(%rbp)
src/stack.c:33  struct B_arg* myarg = arg;
  0x0000000000400515 <fun_B+8>:  mov  -0x18(%rbp),%rax
  0x0000000000400519 <fun_B+12>: mov  %rax,-0x8(%rbp)
src/stack.c:34  if (!myarg) return -1;
  0x000000000040051d <fun_B+16>: cmpq  $0x0,-0x8(%rbp)
  0x0000000000400522 <fun_B+21>: jne  0x40052d <fun_B+32>
src/stack.c:36  return myarg->arg1 + myarg->arg2;
  0x000000000040052d <fun_B+32>: mov  -0x8(%rbp),%rax
  0x0000000000400531 <fun_B+36>: mov  (%rax),%rdx
  0x0000000000400534 <fun_B+39>: mov  -0x8(%rbp),%rax
  0x0000000000400538 <fun_B+43>: mov  0x8(%rax),%rax
  0x000000000040053c <fun_B+47>: lea  (%rdx,%rax,1),%rax
src/stack.c:37  }
  0x0000000000400540 <fun_B+51>:  leaveq
  0x0000000000400541 <fun_B+52>:  retq
⇒0x000000000000002a: Cannot access memory at address 0x2a

fun_B() is executed and returns to an invalid address suggesting a corrupted stack. fun_B() leaves but that there was no corresponding push on entry to fun_B() => the function pointer comp that was called in main() had been corrupted.
Data Race Detection

Compile with –debug parallel (icc/icpc/ifort only)
Debugger breaks when race has been detected

(gdb) pdbx enable
(gdb) c
data race detected
1: write shared, 4 bytes from foo.c:36
3: read shared, 4 bytes from foo.c:40

Breakpoint -11, 0x401515 in L_test__..._21 () at foo.c:36
36*var = 42; /* bp.write */

Stop in the context of the racing access
Data Race Detection: Filters

Filters and filter sets to fine-tune the analysis
• Suppress: ignore specified regions
• Focus: ignore non-specified regions

(gdb) pdbx filter line foo.c:36
(gdb) pdbx filter code 0x40518..0x40524
(gdb) pdbx filter var shared
(gdb) pdbx filter data 0x60f48..0x60f50
(gdb) pdbx fset list
focus filter set bug0815, 1 filters
focus filter set bug42, 2 filters
suppress filter set default, 0 filters

Filter all read accesses
(gdb) pdbx filter reads

Lots of useful filter operations
Date Race Detection: Manage Overhead

Race detection is expensive – very expensive
• Both in performance and memory consumption

Manage overhead effectively through
• Selective enabling
• Focus filter sets
• Global filter on reads

It’s an interactive debug tool – use it that way!

Effective filter management is key to fast data race debugging.
Intel® Inspector and GDB* work hand-in-hand

• Two-step approach for debugging data races
  - Step 1: whole-program analysis using Intel® Inspector XE
    - Gives a list of all data races in the program
  - Step 2: reproduce individual races in GDB*
    - Select race to debug
    - Start a new focus filter set
    - For each source line in the race report:
      - Add a filter for that line

• GDB* will now break at each instance of the selected data race with very low overhead
Pointer Checker in Compiler

Pointer checking
• Checks before any memory access through a pointer that the pointer address is inside the object pointed to.

Dangling pointer checking
• Checks for accesses through pointers that have been freed.

Enabled via compile time switches.

Implemented mostly in runtime library code (library is automatically linked in via icl / icc command line)

A user API allows control over what happens when a violation is detected.

Intrinsics allow user to create or destroy bounds for a pointer.
Example

void main()
{
    char a[5];
    foo(a);
}
void foo(char *a)
{
    int i;
    for (i=0; i<100; i++) {
        a[i] = 0;
    }
}
Compiling and Running

icc main.c foo.c -check-pointers=write -g
main
A
B
C
D
E

CHKP: Bounds check error
Traceback:
foo [0x4010E0]
main [0x40104D]
__tmainCRTStartup [0x4014A6]
BaseThreadInitThunk [0x760E3677]
RtlInitializeExceptionChain [0x77869F02]
RtlInitializeExceptionChain [0x77869ED5]
What is Pointer Checker (details)

C / C++ pointers have well defined semantics that determine what range of memory they are allowed to access.

Compilers typically do not enforce this.

Point Checker is a compiler option that provides full checking of all memory accesses through pointers.

• This includes subscripted array accesses since arrays are pointers.

An enabled application will catch any out-of-bounds memory accesses before any memory corruption occurs.

• Well, almost, some C runtime functions catch the error only after it has occurred.

This is done with no change to structure layout or ABIs.

Pointer Checker enabled code and non-enabled code can coexist, with partial loss of checking.
Point Lookout (PL): Pointer Checking in Debugger

```c
int arr[N];

int last(int* arr) {
    return arr[N - 1];
}

void bug() {
    int i = last(arr + 1);
}
```

- Extend pointer with bounds information.
- Check bounds before each access.
- Fast through h/w support on future processors.

Fast detection of common memory bugs
PL: GDB* enhancements

- New gdb features:
  - Violation information display.
  - Command info bounds

```c
(gdb) c
Out of bounds access at 0xa10f4, bounds {0xa10000, 0xa10f0}.
int i = last(arr + 1);
(gdb) p arr
(int *) 0xa10000 <arr>
(gdb) info bounds &arr
{0xa10000, 0xa10f0}
```

- Cooperate with s/w PL run-time to diagnose bounds violations.
- Info bounds associated with a pointer.

Debug if SegV caused by bounds violations
