The Fortran 2018 Standard specifies that the default mode is recursion; previous standards specified the default was no recursion. The default compilation mode will change to recursion in a future release.

If a function is directly recursive and array valued, and if the keyword RESULT is not specified in the FUNCTION statement, the result variable is the function name, and all occurrences of the function name in the executable part of the function are references to the function result variable.

A directly recursive function cannot have a declared type of CHARACTER if the character length is declared as *.

A procedure interface is always explicit within the subprogram that defines the procedure.

The keyword RECURSIVE must be specified if the compilation mode is set to non-recursive by a compiler option and if any of the following applies (directly or indirectly):

- The subprogram invokes itself.
- The subprogram invokes a subprogram defined by an ENTRY statement in the same subprogram.
- An ENTRY procedure in the same subprogram invokes one of the following:
  - Itself
  - Another ENTRY procedure in the same subprogram
  - The subprogram defined by the FUNCTION or SUBROUTINE statement

The keyword NON_RECURSIVE must be specified if the compilation mode is set to recursion by a compiler option and the procedure is not to be compiled for recursion.

Example

```fortran
! RECURS.F90
!
i = 0
CALL Inc (i)
END
RECURSIVE SUBROUTINE Inc (i)
i = i + 1
CALL Out (i)
IF (i.LT.20) CALL Inc (i)    ! This also works in OUT
END SUBROUTINE Inc
```
SUBROUTINE Out (i)
    WRITE (*,*) i
END SUBROUTINE Out

REDUCTION

**Parallel Directive Clause**: Performs a reduction operation on the specified variables.

**Syntax**

REDUCTION (reduction-identifier : list)

- **reduction-identifier**: Is an identifier, user defined operator, or generic name which has appeared in an accessible DECLARE REDUCTION directive, or one of the predefined reduction operators or intrinsic names in the table of predefined reduction-identifiers below.

- **list**: Is the name of one or more variables that are accessible to the scoping unit. Each list item must be definable. Each name must be separated by a comma. The type of each variable must be compatible with a type for which the reduction-identifier has an accessible definition.

Assumed-size arrays, procedure pointers, and dummy arguments that are pointers with the INTENT (IN) attribute are not allowed. Array sections are allowed.

For each list item, the number of copies is unspecified.

The same list item cannot appear in both a REDUCTION and an IN_REDUCTION clause.

Variables that appear in a REDUCTION clause must be SHARED in the enclosing context. A private copy of each variable in list is created for each thread as if the PRIVATE clause had been used. The private copy is initialized according to the initializer-clause of the reduction-identifier. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a REDUCTION clause.

At the end of the REDUCTION, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the combiner specified for the reduction-identifier. Reduction operations should all be associative (except for subtraction), and the compiler can freely reassociate the computation of the final value; the partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the construct containing the REDUCTION clause.

However, if the REDUCTION clause is used in a construct to which NOWAIT is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all the threads complete the REDUCTION clause.
Any list item copies associated with the reduction must be initialized before they are accessed by the tasks participating in the reduction. After the end of the region, the original list item contains the result of the reduction.

An original list item with the POINTER attribute, or any pointer component of an original list item that is referenced, must be associated at entry to the construct that contains the REDUCTION clause. Also, the list item, or the pointer component of the list item, must not be deallocated, allocated, or pointer assigned within the region.

An original list item with the ALLOCATABLE attribute, or any allocatable component of an original list item that is referenced, must be in the allocated state at entry to the construct that contains the REDUCTION clause. Also, the list item, or the allocatable component of the list item, must be neither deallocated nor allocated within the region.

Any number of REDUCTION clauses can be specified on the directive, but a list item can appear only once in REDUCTION clauses for that directive.

If a list item is an array section, the following applies:

- The array section must specify contiguous storage and it cannot be a zero-length array section.
- Accesses to the elements of the array outside the specified array section result in unspecified behavior.
- The reduction clause will be applied to each separate element of the array section.
- Access to the elements of the array outside the specified array section result in unspecified behavior.

The following table lists predefined reduction-identifiers. These reduction-identifiers are implicitly defined and cannot be redefined in a DECLARE REDUCTION directive for the types shown here. The actual initialization value will be consistent with the data type of the reduction variable.

### Predefined reduction-identifiers

<table>
<thead>
<tr>
<th>reduction-identifier</th>
<th>Type</th>
<th>Combiner</th>
<th>Initializer</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out + omp_in</td>
<td>omp_priv = 0</td>
</tr>
<tr>
<td>*</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out * omp_in</td>
<td>omp_priv = 1</td>
</tr>
<tr>
<td>-</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out + omp_in</td>
<td>omp_priv = 0</td>
</tr>
<tr>
<td>.AND.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .AND. omp_in</td>
<td>omp_priv = .TRUE.</td>
</tr>
<tr>
<td>.OR.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .OR. omp_in</td>
<td>omp_priv = .FALSE.</td>
</tr>
<tr>
<td>.EQV.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .EQV. omp_in</td>
<td>omp_priv = .TRUE.</td>
</tr>
<tr>
<td>.NEQV.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .NEQV.omp_in</td>
<td>omp_priv = .FALSE.</td>
</tr>
<tr>
<td>MAX</td>
<td>INTEGER, REAL</td>
<td>omp_out = max (omp_out, omp_in)</td>
<td>omp_priv = Smallest</td>
</tr>
<tr>
<td>MIN</td>
<td>INTEGER, REAL</td>
<td>omp_out = min (omp_out, omp_in)</td>
<td>omp_priv = Largest</td>
</tr>
<tr>
<td>IAND</td>
<td>INTEGER</td>
<td>omp_out = iand (omp_out, omp_in)</td>
<td>omp_priv = All bits set</td>
</tr>
</tbody>
</table>
If a directive allows REDUCTION clauses, the number you can specify is not limited. However, each variable name can appear only once in only one of the clauses.

**NOTE**
If a variable appears in a REDUCTION clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a map-type of TOFROM.

### Example
In the following program fragment, time will be the sum of the time spent in the do loop across all threads:

```fortran
use omp_lib
integer i
double precision t1, time
call omp_set_num_threads(4)
...
!$omp do reduction(+:time)
do i = 1, omp_get_num_threads()
t1 = omp_get_wtime()
  time = omp_get_wtime() - t1
end do
!here time is equal to the total time across all threads
...
```

### See Also

TASK_REDUCTION

### %REF
**Built-in Function:** Changes the form of an actual argument. Passes the argument by reference. In Intel® Fortran, passing by reference is the default.

**Syntax**

```fortran
%REF (a)
```

- **a**
  
  (Input) An expression, record name, procedure name, array, character array section, or array element.

You must specify %REF in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following table lists the Intel® Fortran defaults for argument passing, and the allowed uses of %REF:

<table>
<thead>
<tr>
<th>reduction-identifier</th>
<th>Type</th>
<th>Combiner</th>
<th>Initializer</th>
</tr>
</thead>
<tbody>
<tr>
<td>IOR</td>
<td>INTEGER</td>
<td>omp_out = ior (omp_out, omp_in)</td>
<td>omp_priv = 0</td>
</tr>
<tr>
<td>IEOR</td>
<td>INTEGER</td>
<td>omp_out = ieor (omp_out, omp_in)</td>
<td>omp_priv = 0</td>
</tr>
</tbody>
</table>

The table above shows the reduction identifiers, types, combinators, and initializers for both IOR and IEOR operations.

</tr>
</tbody>
</table>

¹A character argument is passed by address and hidden length.
²In Intel® Fortran record structures

The %REF and %VAL functions override related !DIR$ ATTRIBUTE settings.

### Example

```fortran
CHARACTER(LEN=10) A, B
CALL SUB(A, %REF(B))
```

Variable A is passed by address and hidden length. Variable B is passed by reference.

Note that on Windows* systems, compiler option iface determines how the character argument for variable B is passed.

**REGISTERMOUSEEVENT (W*S)**

QuickWin Function: Registers the application-supplied callback routine to be called when a specified mouse event occurs in a specified window.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = REGISTERMOUSEEVENT (unit, mouseevents, callbackroutine)
```

- **unit** (Input) INTEGER(4). Unit number of the window whose callback routine on mouse events is to be registered.
- **mouseevents** (Input) INTEGER(4). One or more mouse events to be handled by the callback routine to be registered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:
  - MOUSE$LBUTTONDOWN - Left mouse button down
  - MOUSE$LBUTTONUP - Left mouse button up
  - MOUSE$LBUTTONDBLCLK - Left mouse button double-click
  - MOUSE$RBUTTONDOWN - Right mouse button down
  - MOUSE$RBUTTONUP - Right mouse button up
  - MOUSE$RBUTTONDBLCLK - Right mouse button double-click
  - MOUSE$MOVE - Mouse moved
- **callbackroutine** (Input) Routine to be called on the specified mouse event in the specified window. It must be declared EXTERNAL.

**Results**

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE$BADEVENT - The event specified is not supported.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system’s CONTROL PANEL/MOUSE.

**Example**

The following example registers the routine CALCULATE, to be called when the user double-clicks the left mouse button while the mouse cursor is in the child window opened as unit 4:

```fortran
USE IFQWIN
INTEGER(4) result
OPEN (4, FILE= 'USER')
...
result = REGISTERMOUSEEVENT (4, MOUSE$LBUTTONDBLCLK, CALCULATE)
```
REMAPPALLETERGB, REMAPPALLETERGB (W*S)

**Graphics Functions:** REMAPALLPALETTEGB remaps a set of Red-Green-Blue (RGB) color values to indexes recognized by the video hardware. REMAPPALETTEGB remaps one color index to an RGB color value.

**Module**
USE IFQWIN

**Syntax**

result = REMAPALLPALETTEGB (colors)
result = REMAPPALETTEGB (index, colors)

- **colors** (Input) INTEGER(4). Ordered array of RGB color values to be mapped in order to indexes. Must hold 0-255 elements.
- **index** (Input) INTEGER(4). Color index to be reassigned an RGB color.
- **color** (Input) INTEGER(4). RGB color value to assign to a color index.

**Results**

The result type is INTEGER(4). REMAPALLPALETTEGB returns 0 if successful; otherwise, -1. REMAPPALETTEGB returns the previous color assigned to the index.

The REMAPALLPALETTEGB function remaps all of the available color indexes simultaneously (up to 236; 20 indexes are reserved by the operating system). The colors argument points to an array of RGB color values. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in IFQWIN.F90.

<table>
<thead>
<tr>
<th>Index</th>
<th>Color</th>
<th>Index</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$BLACK</td>
<td>8</td>
<td>$GRAY</td>
</tr>
<tr>
<td>1</td>
<td>$BLUE</td>
<td>9</td>
<td>$LIGHTBLUE</td>
</tr>
<tr>
<td>2</td>
<td>$GREEN</td>
<td>10</td>
<td>$LIGHTGREEN</td>
</tr>
<tr>
<td>3</td>
<td>$CYAN</td>
<td>11</td>
<td>$LIGHTCYAN</td>
</tr>
<tr>
<td>4</td>
<td>$RED</td>
<td>12</td>
<td>$LIGHTRED</td>
</tr>
<tr>
<td>5</td>
<td>$MAGENTA</td>
<td>13</td>
<td>$LIGHTMAGENTA</td>
</tr>
<tr>
<td>6</td>
<td>$BROWN</td>
<td>14</td>
<td>$YELLOW</td>
</tr>
<tr>
<td>7</td>
<td>$WHITE</td>
<td>15</td>
<td>$BRIGHTWHITE</td>
</tr>
</tbody>
</table>
The number of colors mapped can be fewer than 236 if the number of colors supported by the current video mode is fewer, but at most 236 colors can be mapped by REMAPALLPALETTERGB. Most Windows* graphics drivers support a palette of 256K colors or more, of which only a few can be mapped into the 236 palette indexes at a time. To access and use all colors on the system, bypass the palette and use direct RGB color functions such as SETCOLORRGB and SETPIXELSRGB.

Any RGB colors can be mapped into the 236 palette indexes. Thus, you could specify a palette with 236 shades of red.

In each RGB color value, each of the three colors, red, green and blue, is represented by an eight-bit value (2 hex digits). In the values you specify with REMAPALLPALETTERGB or REMAPPALETTERGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'008080' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

Example

```
! Build as QuickWin or Standard Graphics App.

USE IFQWIN
INTEGER(4) colors(3)
INTEGER(2) status
colors(1) = Z'00FFFF' ! yellow
colors(2) = Z'FFFFFF' ! bright white
colors(3) = 0 ! black
status = REMAPALLPALETTERGB(colors)
status = REMAPPALETTERGB(INT2(47), Z'45A315')
END
```

SETCOLOR

RENAME

*Portability Function: Renames a file.*

Module
USE IFPORT

Syntax

```
result = RENAME (from, to)
```

*from* (Input) Character/*.*/. Path of an existing file.

*to* (Input) Character/*.*/. The new path for the file (see Caution note below).
Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

- EACCES - The file or directory specified by to could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
- ENOENT - The file or path specified by from could not be found.
- EXDEV - Attempt to move a file to a different device.

Caution
This routine can cause data to be lost. If the file specified in to already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.

The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).

Example
use IFPORT
integer(4) istatus
character*12 old_name, new_name
print *, "Enter file to rename: ", old_name
read *, old_name
print *, "Enter new name: ", new_name
read *, new_name
ISTATUS = RENAME (old_name, new_name)

See Also
RENAMEFILEQQ

RENAMEFILEQQ
Portability Function: Renames a file or directory.

Module
USE IFPORT

Syntax
result = RENAMEFILEQQ (oldname, newname)

oldname (Input) Character*(*) Character. Current name of the file or directory to be renamed.

newname (Input) Character*(*) Character. New name of the file or directory.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the newname parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$ACCES - Permission denied. The file's or directory's permission setting does not allow the specified access.
• ERR$EXIST - The file or directory already exists.
• ERR$NOENT - File or directory or path specified by oldname not found.
• ERR$XDEV - Attempt to move a file or directory to a different device.

Example

```
USE IFPORT
USE IPCORE
INTEGER(4) len
CHARACTER(80) oldname, newname
LOGICAL(4) result

WRITE(*,'(A, \)') ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,'(A, \)') ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END
```

See Also
FINDFILEQQ
RENAME
GETLASTERRORQQ

**REPEAT**

*Transformational Intrinsic Function (Generic):*
*Concatenates several copies of a string.*

**Syntax**

```
result = REPEAT (string,ncopies)
```

- `string` (Input) Must be scalar and of type character.
- `ncopies` (Input) Must be scalar and of type integer. It must not be negative.

**Results**

The result is a scalar of type character and length `ncopies x LEN(string)`. The kind parameter is the same as `string`. The value of the result is the concatenation of `ncopies` copies of `string`.

**Example**

REPEAT ('S', 3) has the value SSS.
REPEAT ('ABC', 0) has the value of a zero-length string.

The following shows another example:

```
CHARACTER(6) str
str = REPEAT('HO', 3) ! returns HOHOHO
```

See Also
SPREAD
**RESHAPE**

**Transformational Intrinsic Function (Generic):**
Constructs an array with a different shape from the argument array.

**Syntax**

\[
\text{result} = \text{RESHAPE} \left( \text{source}, \text{shape}, \text{pad} \right) \left[ , \text{order} \right]
\]

- **source**
  (Input) Must be an array. It may be of any data type. It supplies the elements for the result array. Its size must be greater than or equal to \(\text{PRODUCT(} \text{shape} \text{)}\) if \(\text{pad}\) is omitted or has size zero.

- **shape**
  (Input) Must be an integer array of up to 31 elements, with rank one and constant size. It defines the shape of the result array. Its size must be positive; its elements must not have negative values.

- **pad**
  (Input; optional) Must be an array with the same type and kind parameters as \(\text{source}\). It is used to fill in extra values if the result array is larger than \(\text{source}\).

- **order**
  (Input; optional) Must be an integer array with the same shape as \(\text{shape}\). Its elements must be a permutation of \((1, 2, \ldots, n)\), where \(n\) is the size of \(\text{shape}\). If \(\text{order}\) is omitted, it is assumed to be \((1, 2, \ldots, n)\).

**Results**

The result is an array of shape \(\text{shape}\) with the same type and kind parameters as \(\text{source}\). The size of the result is the product of the values of the elements of \(\text{shape}\).

In the result array, the array elements of \(\text{source}\) are placed in the order of dimensions specified by \(\text{order}\). If \(\text{order}\) is omitted, the array elements are placed in normal array element order.

The array elements of \(\text{source}\) are followed (if necessary) by the array elements of \(\text{pad}\) in array element order. If necessary, additional copies of \(\text{pad}\) follow until all the elements of the result array have values.

**NOTE**

In standard Fortran array element order, the first dimension varies fastest. For example, element order in a two-dimensional array would be \((1,1), (2,1), (3,1)\) and so on. In a three-dimensional array, each dimension having two elements, the array element order would be \((1,1,1), (2, 1, 1), (1, 2, 1), (2, 2, 1), (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2)\).

RESHAPE can be used to reorder a Fortran array to match C array ordering before the array is passed from a Fortran to a C procedure.

**Example**

RESHAPE \(((3, 4, 5, 6, 7, 8/), (2, 3/))\) has the value

\[
\begin{bmatrix}
3 & 5 & 7 \\
4 & 6 & 8
\end{bmatrix}.
\]

RESHAPE \(((3, 4, 5, 6, 7, 8/), (2, 4/), (1, 1/), (2, 1/))\) has the value

\[
\begin{bmatrix}
3 & 4 & 5 & 6 \\
7 & 8 & 1 & 1
\end{bmatrix}.
\]
The following shows another example:

```fortran
INTEGER AR1(2, 5)
REAL F(5, 3, 8)
REAL C(8, 3, 5)
AR1 = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 5/), (/0, 0/), (/2, 1/))
! returns 1 2 3 4 5
! 6 0 0 0 0
!
! Change Fortran array order to C array order
C = RESHAPE(F, (/8, 3, 5/), ORDER = (/3, 2, 1/))
END
```

Array Assignment Statements

**RESULT**

**Keyword:** Specifies a name for a function result.

**Description**

Normally, a function result is returned in the function's name, and all references to the function name are references to the function result.

However, if you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. In this case, all references to the function name are recursive calls, and the function name must not appear in specification statements.

The RESULT name must be different from the name of the function.

**Example**

The following shows an example of a recursive function specifying a RESULT variable:

```fortran
RECURSIVE FUNCTION FACTORIAL(P) RESULT(L)
  INTEGER, INTENT(IN) :: P
  INTEGER L
  IF (P == 1) THEN
    L = 1
  ELSE
    L = P * FACTORIAL(P - 1)
  END IF
END FUNCTION
```

The following shows another example:

```fortran
recursive function FindSame(Aindex, Last, Used) &
  result(FindSameResult)
  type(card) Last
  integer Aindex, i
  logical matched, used(5), FindSameResult
  if( Aindex > 5 ) then
    FindSameResult = .true.
    return
  endif
  ...
```

Program Units and Procedures

RETURN
Statement: Transfers control from a subprogram to the calling program unit.

Syntax
RETURN [expr]

expr Is a scalar expression that is converted to an integer value if necessary.

The expr is only allowed in subroutines; it indicates an alternate return. (An alternate return is an obsolescent feature in Standard Fortran.)

Description
When a RETURN statement is executed in a function subprogram, control is transferred to the referencing statement in the calling program unit.

When a RETURN statement is executed in a subroutine subprogram, control is transferred to the first executable statement following the CALL statement that invoked the subroutine, or to the alternate return (if one is specified).

Example
The following shows how alternate returns can be used in a subroutine:

```
CALL CHECK(A, B, *10, *20, C)
...
10 ...
20 ...
SUBROUTINE CHECK(X, Y, *, *, C)
...
50 IF (X) 60, 70, 80
60 RETURN
70 RETURN 1
80 RETURN 2
END
```

The value of X determines the return, as follows:

- If X < 0, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the calling program.
- If X = 0, the first alternate return (RETURN 1) occurs and control is transferred to the statement identified with label 10.
- If X > 0, the second alternate return (RETURN 2) occurs and control is transferred to the statement identified with label 20.

Note that an asterisk (*) specifies the alternate return. An ampersand (&) can also specify an alternate return in a CALL statement, but not in a subroutine’s dummy argument list.
The following shows another example:

```fortran
SUBROUTINE Loop
  CHARACTER in
  10 READ (*, '(A)') in
      IF (in .EQ. 'Y') RETURN
      GOTO 10
  ! RETURN implied by the following statement:
  END

! The following example shows alternate returns:
CALL AltRet (i, *10, *20, *30)
WRITE (*, *) 'normal return'
GOTO 40
10 WRITE (*, *) 'I = 10'
   GOTO 40
20 WRITE (*, *) 'I = 20'
   GOTO 40
30 WRITE (*, *) 'I = 30'
40 CONTINUE
END

SUBROUTINE AltRet (i, *, *, *)
  IF (i .EQ. 10) RETURN 1
  IF (i .EQ. 20) RETURN 2
  IF (i .EQ. 30) RETURN 3
END
```

In the above example, RETURN 1 specifies the list's first alternate-return label, which is a symbol for the actual argument *10 in the CALL statement. RETURN 2 specifies the second alternate-return label, and RETURN 3 specifies the third alternate-return label.

CALL
CASE

REWIND

**Statement:** Positions a sequential or direct access file at the beginning of the file (the initial point). It takes one of the following forms:

**Syntax**

REWIND ([UNIT=] io-unit[, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])

REWIND io-unit

- **io-unit** (Input) Is an external unit specifier.
- **label** (Output) Is the label of the branch target statement that receives control if an error occurs.
- **msg-var** (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
- **i-var** (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.
Description

The unit number must refer to a file on disk or magnetic tape, and the file must be open for sequential, direct, or append access.

If a REWIND is done on a direct access file, the NEXTREC specifier is assigned a value of 1.

If a file is already positioned at the initial point, a REWIND statement has no effect.

If a REWIND statement is specified for a unit that is not open, it has no effect.

Example

The following statement repositions the file connected to I/O unit 3 to the beginning of the file:

REWIND 3

Consider the following statement:

REWIND (UNIT=9, IOSTAT=IOS, ERR=10)

This statement positions the file connected to unit 9 at the beginning of the file. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

The following shows another example:

```
WRITE (7, '(I10)') int
REWIND (7)
READ (7, '(I10)') int
```

OPEN
READ
WRITE
Data Transfer I/O Statements
Branch Specifiers

REWRITE

**Statement:** Rewrites the current record.

**Syntax**

**Formatted:**

REWRITE (eunit, format[, iostat] [, err]) [io-list]

**Unformatted:**

REWRITE (eunit[, iostat][, err]) [io-list]

eunit
  Is an external unit specifier ([UNIT=]io-unit).

format
  Is a format specifier ([FMT=]format).

iostat
  Is a status specifier (IOSTAT=i-var).

err
  Is a branch specifier (ERR=label) if an error condition occurs.

io-list
  Is an I/O list.

**Description**

In the REWRITE statement, data (translated if formatted; untranslated if unformatted) is written to the current (existing) record in a file with direct access.
The current record is the last record accessed by a preceding, successful sequential or direct-access READ statement.

Between a READ and REWRITE statement, you should not specify any other I/O statement (except INQUIRE) on that logical unit. Execution of any other I/O statement on the logical unit destroys the current-record context and causes the current record to become undefined.

Only one record can be rewritten in a single REWRITE statement operation.

The output list (and format specification, if any) must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the number of characters specified by the I/O list (and format, if any) do not fill a record, blank characters are added to fill the record.

**Example**

In the following example, the current record (contained in the relative organization file connected to logical unit 3) is updated with the values represented by NAME, AGE, and BIRTH:

```plaintext
REWRI TE (3, 10, ERR=99) NAME, ,AGE, BIRTH
10 FORMAT (A16, I2, A8)
```

**RGBTOINTEGER (W*S)**

*QuickWin Function:* Converts three integers specifying red, green, and blue color intensities into a four-byte RGB integer for use with RGB functions and subroutines.

**Module**

`USE IFQWIN`

**Syntax**

```plaintext
result = RGBTOINTEGER (red, green, blue)
```

- `red` (Input) INTEGER(4). Intensity of the red component of the RGB color value. Only the lower 8 bits of `red` are used.
- `green` (Input) INTEGER(4). Intensity of the green component of the RGB color value. Only the lower 8 bits of `green` are used.
- `blue` (Input) INTEGER(4). Intensity of the blue component of the RGB color value. Only the lower 8 bits of `blue` are used.

**Results**

The result type is INTEGER(4). The result is the combined RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value returned with RGBTOINTEGER, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.
Example

! Build as a QuickWin App.
USE IFQWIN
INTEGER r, g, b, rgb, result
INTEGER(2) status
r = Z'F0'
g = Z'F0'
b = 0
rgb = RGBTOINTEGER(r, g, b)
result = SETCOLORRGB(rgb)
status = ELLIPSE($GFILLINTERIOR,INT2(40), INT2(55), &
             INT2(90), INT2(85))
END

RINDEX

Portability Function: Locates the index of the last occurrence of a substring within a string.

Module
USE IFPORT

Syntax
result = RINDEX (string, substr)

string (Input) Character*(*). Original string to search.
substr (Input) Character*(*) String to search for.

Results
The result type is INTEGER(4). The result is the starting position of the final occurrence of substr in string. The result is zero if substring does not occur in string.

Example
USE IFPORT
character*80 mainstring
character*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring,shortstr)
! where is 19

See Also
INDEX
**RNUM**

**Elemental Intrinsic Function (Specific):** Converts a character string to a REAL(4) value. This function cannot be passed as an actual argument.

**Syntax**

```
result = RNUM (i)
```

`i` (Input) Must be of type character.

**Results**

The result type is REAL(4). The result value is the real value represented by the character string `i`.

**Example**

RNUM ("821.003") has the value 821.003 of type REAL(4).

**RRSPACING**

**Elemental Intrinsic Function (Generic):** Returns the reciprocal of the relative spacing of model numbers near the argument value.

**Syntax**

```
result = RRSPACING (x)
```

`x` (Input) Must be of type real.

**Results**

The result type and kind are the same as `x`. The result has the value `|x* b^-e| * b^p`. Parameters `b`, `e`, `p` are defined in Model for Real Data.

**Example**

If -3.0 is a REAL(4) value, RRSPACING (-3.0) has the value 0.75 x 2^{24}.

The following shows another example:

```
REAL(4) res4
REAL(8) res8, r2
res4 = RRSPACING(3.0) ! returns 1.258291E+07
res4 = RRSPACING(-3.0) ! returns 1.258291E+07
r2 = 487923.3
res8 = RRSPACING(r2) ! returns 8.382458680573952E+015
END
```

**See Also**

SPACING  
Data Representation Models
RSHIFT

**Elemental Intrinsic Function (Generic):** Shifts the bits in an integer right by a specified number of positions. This is the same as specifying **ISHFT** with a negative shift.

**See Also**
See **ISHFT**.

RTC

**Portability Function:** Returns the number of seconds elapsed since a specific Greenwich mean time.

**Module**
USE IFPORT

**Syntax**

result = RTC( )

**Results**

The result type is REAL(8). The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

**Example**

```fortran
USE IFPORT
real(8) s, s1, time_spent
INTEGER(4) i, j
s = RTC( )
call sleep(4)
s1 = RTC( )
time_spent = s1 - s
PRINT *, 'It took ', time_spent, 'seconds to run.'
```

**See Also**
DATE_AND_TIME

TIME portability routine

RUNQQ

**Portability Function:** Executes another program and waits for it to complete.

**Module**
USE IFPORT

**Syntax**

result = RUNQQ (filename,commandline)

filename (Input) Character*(*) File name of a program to be executed.
commandline (Input) Character*(*) Character*(*). Command-line arguments passed to the program to be executed.

Results

The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the exit code of that program is returned to the program that launched it. If the program fails, -1 is returned.

The RUNQQ function executes a new process for the operating system using the same path, environment, and resources as the process that launched it. The launching process is suspended until execution of the launched process is complete.

Example

```
USE IFPORT
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END
```

See also the example in NARGS.

NARGS

SAME_TYPE_AS

**Inquiry Intrinsic Function (Generic):** Inquires whether the dynamic type of one object is the same as the dynamic type of another object.

Syntax

```
result = SAME_TYPE_AS (a, b)
```

- **a** (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.
- **b** (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

Results

The result type is default logical scalar. The result is true only if the dynamic type of `a` is the same as the dynamic type of `b`.

SAVE

**Statement and Attribute:** Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.
Syntax
The SAVE attribute can be specified in a type declaration statement or a SAVE statement, and takes one of the following forms:

Type Declaration Statement:
```fortran
type,[att-ls,] SAVE [ , att-ls ] :: entity[, entity ] ...
```
Statement:
```fortran
SAVE [::]entity [, entity ] ...
```

- `type` is a data type specifier.
- `att-ls` is an optional list of attribute specifiers.
- `entity` is the name of an object, the name of a procedure pointer, or the name of a common block enclosed in slashes (`/common-block-name/`).

Description
In Intel® Fortran, certain variables are given the SAVE attribute, or not, by default:

- The following variables are not saved by default:
  - Scalar local variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL without default initialization
  - Variables that are declared AUTOMATIC
  - Local variables that are allocatable arrays
  - Derived-type variables that are data initialized by default initialization of any of their components
  - RECORD variables that are data initialized by default initialization specified in its STRUCTURE declaration

- The following variables are saved by default:
  - COMMON variables
  - Scalar local variables not of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL of non-recursive subprograms
  - Non-scalar local variables of non-recursive subprograms
  - Module or submodule variables
  - Data initialized by DATA statements
  - Local variables that are not described in the preceding two lists are saved by default.

**NOTE**
Certain compiler options (such as options `Qsave` and `automatic`) and the use of OpenMP* features can change the defaults.

To enhance portability and avoid possible compiler warning messages, Intel recommends that you use the SAVE statement to name variables whose values you want to preserve between subprogram invocations.

When a SAVE statement does not explicitly contain a list, all allowable items in the scoping unit are saved.

A SAVE statement cannot specify the following (their values cannot be saved):

- A blank common
- An object in a common block
- A procedure
- A dummy argument
- A function result
- An automatic object
A PARAMETER (named) constant

Even though a common block can be included in a SAVE statement, individual variables within the common block can become undefined (or redefined) in another scoping unit.

If a common block is saved in any scoping unit of a program (other than the main program), it must be saved in every scoping unit in which the common block appears.

A SAVE statement has no effect in a main program.

Example

The following example shows a type declaration statement specifying the SAVE attribute:

```fortran
SUBROUTINE TEST()
  REAL, SAVE :: X, Y
END SUBROUTINE TEST
```

The following is an example of the SAVE statement:

```fortran
SAVE A, /BLOCK_B/, C, /BLOCK_D/, E
```

The following shows another example:

```fortran
SUBROUTINE MySub
  COMMON /z/ da, in, a, idum(10)
  REAL(8) x, y
  ...
  SAVE x, y, /z/
  ! alternate declaration
  REAL(8), SAVE :: x, y
  SAVE /z/
END SUBROUTINE MySub
```

SAVEIMAGE, SAVEIMAGE_W (W*S)

**Graphics Functions:** Save an image from a specified portion of the screen into a Windows bitmap file.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SAVEIMAGE (filename, ulxcoord, ulycoord, lrxcoord, lrycoord)
result = SAVEIMAGE_W (filename, ulwxcoord, ulwycoord, lrxcoord, lrwycoord)
```

*filename* (Input) Character*(*). Path of the bitmap file.
ulxcoord, ulycoord  
(Input) INTEGER(4). Viewport coordinates for upper-left corner of the screen image to be captured.

lrxcoord, lrycoord  
(Input) INTEGER(4). Viewport coordinates for lower-right corner of the screen image to be captured.

ulwxcoord, ulwycoord  
(Input) REAL(8). Window coordinates for upper-left corner of the screen image to be captured.

lrwxcoord, lrwycoord  
(Input) REAL(8). Window coordinates for lower-right corner of the screen image to be captured.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The SAVEIMAGE function captures the screen image within a rectangle defined by the upper-left and lower-right screen coordinates and stores the image as a Windows bitmap file specified by filename. The image is stored with a palette containing the colors displayed on the screen.

SAVEIMAGE defines the bounding rectangle in viewport coordinates. SAVEIMAGE_W defines the bounding rectangle in window coordinates.

SCALE

Elemental Intrinsic Function (Generic): Returns the value of the exponent part (of the model for the argument) changed by a specified value.

Syntax

result = SCALE (x, i)

x  
(Input) Must be of type real.

i  
(Input) Must be of type integer.

Results

The result type and kind are the same as x. The result has the value $x \times b^i$. Parameter $b$ is defined in Model for Real Data.

Example

If 3.0 is a REAL(4) value, SCALE (3.0, 2) has the value 12.0 and SCALE (3.0, 3) has the value 24.0.

The following shows another example:

```
REAL r
r = SCALE(5.2, 2)  ! returns 20.8
```

See Also

LSHIFT

Data Representation Models
SCAN

**Elemental Intrinsic Function (Generic):** Scans a string for any character in a set of characters.

**Syntax**

```fortran
result = SCAN (string, set [, back] [, kind])
```

- **string** (Input) Must be of type character.
- **set** (Input) Must be of type character with the same kind parameter as `string`.
- **back** (Input; optional) Must be of type logical.
- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `back` is omitted (or is present with the value false) and `string` has at least one character that is in `set`, the value of the result is the position of the leftmost character of `string` that is in `set`.

If `back` is present with the value true and `string` has at least one character that is in `set`, the value of the result is the position of the rightmost character of `string` that is in `set`.

If no character of `string` is in `set` or the length of `string` or `set` is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

SCAN ("ASTRING", 'ST') has the value 2.

SCAN ("ASTRING", 'ST', BACK=.TRUE.) has the value 3.

SCAN ("ASTRING", 'CD') has the value zero.

The following shows another example:

```fortran
INTEGER i
INTEGER array(2)
i = SCAN ('FORTRAN', 'TR') ! returns 3
i = SCAN ('FORTRAN', 'TR', BACK = .TRUE.) ! returns 5
i = SCAN ('FORTRAN', 'GHA') ! returns 6
i = SCAN ('FORTRAN', 'ora') ! returns 0
array = SCAN ((/'FORTRAN','VISUALC'/),(/'A', 'A'/))
! returns (6, 5)

! Note that when using SCAN with arrays, the string
! elements must be the same length. When using string
! constants, blank pad to make strings the same length.
! For example:

array = SCAN ((/'FORTRAN','MASM '/),(/'A', 'A'/))
! returns (6, 2)
END
```
See Also
VERIFY

SCANENV

**Portability Subroutine:** Scans the environment for the value of an environment variable.

**Module**
USE IFPORT

**Syntax**
CALL SCANENV (envname,envtext,envvalue)

- **envname** *(Input)* Character(*(*). Contains the name of an environment variable you need to find the value for.
- **envtext** *(Output)* Character(*(*). Set to the full text of the environment variable if found, or to '' if nothing is found.
- **envvalue** *(Output)* Character(*(*). Set to the value associated with the environment variable if found or to '' if nothing is found.

SCANENV scans for an environment variable that matches envname and returns the value or string it is set to.

SCROLLTEXTWINDOW (W*S)

**Graphics Subroutine:** Scrolls the contents of a text window.

**Module**
USE IFQWIN

**Syntax**
CALL SCROLLTEXTWINDOW (rows)

- **rows** *(Input)* INTEGER(2). Number of rows to scroll.

The SCROLLTEXTWINDOW subroutine scrolls the text in a text window (previously defined by SETTEXTWINDOW). The default text window is the entire window.

The rows argument specifies the number of lines to scroll. A positive value for rows scrolls the window up (the usual direction); a negative value scrolls the window down. Specifying a number larger than the height of the current text window is equivalent to calling CLEARSCREEN ($GWINDOW). A value of 0 for rows has no effect.

**Example**

```plaintext
! Build as QuickWin or Standard Graphics app.
USE IFQWIN INTEGER(2) row, istat
CHARACTER(18) string
TYPE (rccoord) oldpos

CALL SETTEXTWINDOW (INT2(1), INT2(0), &
                   INT2(25), INT2(80))
CALL CLEARSCREEN ( $GCLEARSCREEN )
```
CALL SETTEXTPOSITION (INT2(1), INT2(1), oldpos)
DO row = 1, 6
    string = 'Hello, World # '
    CALL SETTEXTPOSITION( row, INT2(1), oldpos )
    WRITE(string(15:16), '(I2)') row
    CALL OUTTEXT( string )
END DO
istat  = displaycursor($GCURSORON)
WRITE(*,'(1x,A")') 'Hit ENTER'
READ (*,*)
   ! wait for ENTER
   ! Scroll window down 4 lines
CALL SCROLLTEXTWINDOW(INT2( -4) )
CALL SETTEXTPOSITION (INT2(10), INT2(18), oldpos)
WRITE(*,'(2X,A")') "Hit ENTER"
READ( *,*)
   ! wait for ENTER
   ! Scroll window up 5 lines
CALL SCROLLTEXTWINDOW( INT2(5 ) )
END

SCWRQQ

Portability Subroutine: Returns the floating-point processor control word.

Module
USE IFPORT

Syntax
CALL SCWRQQ (control)

control  (Output) INTEGER(2). Floating-point processor control word.

SCWRQQ performs the same function as the run-time subroutine GETCONTROLFPQQ, and is provided for compatibility.

Example
See the example in LCWRQQ.

See Also
GETCONTROLFPQQ
LCWRQQ
SECNDS Intrinsic Procedure

Elemental Intrinsic Function (Generic): Provides the system time of day, or elapsed time, as a floating-point value in seconds. SECNDS can be used as an intrinsic function or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

Syntax

This function must not be passed as an actual argument. It is not a pure function, so it cannot be referenced inside a FORALL construct.

\[ \text{result} = \text{SECNDS}(x) \]

\( (\text{Input}) \text{ Must be of type real.} \)

Results

The result type and kind are the same as \( x \).

If \( x \) is zero, the result value is the time in seconds since the most recent midnight (in local time).

If \( x \) is not zero, it is compared to \( \text{now} \): the value that would be returned if \( x \) had been zero. If \( x \) is less than \( \text{now} \), then the result value is \( \text{now} - x \). If \( x \) is more than \( \text{now} \), the function assumes that \( x \) is the result of a call to SECONDS made the previous day and returns the value between that time and \( \text{now} \).

This function cannot detect a delay of more than one day between calls. For timing intervals longer than 24 hours, use DCLOCK.

This function does not account for daylight savings changes in either direction.

The value of SECNDS is accurate to 0.01 second, which is the resolution of the system clock.

The 24 bits of precision provide accuracy to the resolution of the system clock for about one day. However, loss of significance can occur if you attempt to compute very small elapsed times late in the day.

Example

The following shows how to use SECNDS to perform elapsed-time computations:

```c
C    START OF TIMED SEQUENCE
T1 = SECNDS(0.0)
C    CODE TO BE TIMED
...
DELTA = SECNDS(T1)   ! DELTA gives the elapsed time
```

See Also

DATE_AND_TIME

RTC

SYSTEM_CLOCK

TIME intrinsic procedure

SECNDS portability routine

DCLOCK
SECNDS Portability Routine

**Portability Function:** Returns the number of seconds that have elapsed since midnight, less the value of its argument. SECNDS can be used as a portability function or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SECNDS (time)
```

where:

- `time` (Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.

**Results**

The result type is REAL(4). The result value is the number of seconds that have elapsed since midnight, minus `time`, with a precision of a hundredth of a second (0.01).

To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

**Example**

```fortran
USE IFPORT
REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
   J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ', s, ' seconds to run.'
```

**SECTIONS**

*OpenMP* Fortran Compiler Directive: Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.
**Syntax**

```
!$OMP SECTIONS [clause[, clause] ... ]

[$!$OMP SECTION]

block

[!]$OMP SECTION

block...

!$OMP END SECTIONS[NOWAIT]
```

*clause*  
Is one of the following:
- FIRSTPRIVATE (list)
- LASTPRIVATE ([CONDITIONAL:] list)
- PRIVATE (list)
- REDUCTION (reduction-identifier : list)

*block*  
Is a structured block (section) of statements or constructs. Any constituent section must also be a structured block.

You cannot branch into or out of the block.

The binding thread set for a SECTIONS construct is the current team. A SECTIONS region binds to the innermost enclosing parallel region.

Each section of code is preceded by a SECTION directive, although the directive is optional for the first section. The SECTION directives must appear within the lexical extent of the SECTIONS and END SECTIONS directive pair.

The last section ends at the END SECTIONS directive. Threads that complete execution of their SECTIONs encounter an implied barrier at the END SECTIONS directive unless NOWAIT is specified.

SECTIONS directives must be encountered by all threads in a team or by none at all.

**Example**

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```
!$OMP PARALLEL
!$OMP SECTIONS
  !$OMP SECTION
    CALL XAXIS
  !$OMP SECTION
    CALL YAXIS
  !$OMP SECTION
    CALL ZAXIS
!$OMP END SECTIONS
!$OMP END PARALLEL
```

**See Also**

OpenMP Fortran Compiler Directives  
Syntax Rules for Compiler Directives  
Parallel Processing Model for information about Binding Sets

**SEED**

*Portability Subroutine: Changes the starting point of the pseudorandom number generator.*
Module
USE IFPORT

Syntax
CALL SEED (iseed)

(iseed) (Input) INTEGER(4). Starting point for RANDOM.

SEED uses iseed to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.

This routine is not thread-safe.

Example
USE IFPORT
REAL myrand
CALL SEED(7531)
CALL RANDOM(myrand)

See Also
RANDOM
RANDOM_SEED
RANDOM_NUMBER

SELECT CASE and END SELECT
Statement: Transfers program control to a selected block of statements according to the value of a controlling expression.

Example
CHARACTER*1 cmdchar
... Files: SELECT CASE (cmdchar)
  CASE ('0')
    WRITE (*, *) "Must retrieve one to nine files"
  CASE ('1':'9')
    CALL RetrieveNumFiles (cmdchar)
  CASE ('A', 'a')
    CALL AddEntry
  CASE ('D', 'd')
    CALL DeleteEntry
  CASE ('H', 'h')
    CALL Help
  CASE DEFAULT
    WRITE (*, *) "Command not recognized; please re-enter"
END SELECT Files

See Also
See CASE.
SELECT TYPE

Statement: Marks the beginning of a SELECT TYPE construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the dynamic type of a specified expression.

Syntax

\[
\text{name:} \text{SELECT TYPE } \{\text{assoc-name => } \} \text{selector}
\]

\[
\text{[type-guard-stmt block]}...
\]

\[
\text{END SELECT [name]}
\]

(name: Optional) Is the name of the SELECT TYPE construct.

assoc-name

(Optional) Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct. If selector is not a named variable, assoc-name => must appear.

selector

Is an expression or variable. It must be polymorphic. It is evaluated when the SELECT TYPE statement is executed.

type-guard-stmt

(Optional) Is one of the following:

- TYPE IS (type) [name]
- CLASS IS (type) [name]
- CLASS DEFAULT [name]

CLASS DEFAULT can be specified only once in the construct. The same type and kind parameter values can only be specified in one TYPE IS statement and one CLASS IS statement.

type

Is an intrinsic type specifier or a derived-type specifier. It must specify that each length type parameter is assumed. It cannot be a sequence derived type or a type with the BIND attribute.

block

(Optional) Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of a SELECT TYPE statement, the same name must appear in the corresponding END SELECT statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT TYPE statement, you cannot specify one following the END SELECT statement or any type-guard-stmt. If a type-guard-stmt specifies a construct name, it must match the construct name on the corresponding SELECT TYPE statement.

A branch to the END SELECT statement is allowed from within the SELECT TYPE construct, but it is not allowed from anywhere outside the construct.

Execution of a SELECT TYPE construct whose selector is not a variable causes the selector expression to be evaluated.
A SELECT TYPE construct selects at most one block to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector. The entity associated with the associate name has the declared type and type parameters of the selector. The entity is polymorphic only if the selector is polymorphic.

The following steps determine which block is selected for execution:

1. If a TYPE IS statement matches the selector, the block following that statement is executed. A TYPE IS statement matches the selector if the dynamic type and type parameter values of the selector are the same as those specified by the statement.
2. Otherwise, if exactly one CLASS IS statement matches the selector, the block following that statement is executed. A CLASS IS statement matches the selector if the dynamic type of the selector is an extension of the type specified by the statement and the kind type parameters specified by the statement are the same as the corresponding type parameters of the dynamic type of the selector.
3. Otherwise, if several CLASS IS statements match the selector, one of these statements must specify a type that is an extension of all the types specified in the others. In this case, the block following that statement is executed.
4. Otherwise, if there is a CLASS DEFAULT statement, the block following that statement is executed.

Within the block following a TYPE IS statement, the associating entity is not polymorphic, it has the type named in the TYPE IS statement, and has the type parameters of the selector.

Within the block following a CLASS IS statement, the associating entity is polymorphic and has the declared type named in the CLASS IS statement. The type parameters of the associating entity are the corresponding type parameters of the selector.

Within the block following a CLASS DEFAULT statement, the associating entity is polymorphic and has the same declared type as the selector. The type parameters of the associating entity are those of the declared type of the selector.

If the declared type of the selector is M, specifying CLASS DEFAULT has the same effect as specifying CLASS IS (M).

Within a SELECT TYPE construct, each associating entity has the same rank as its associated selector.

A type-guard-stmt cannot be a branch target statement. You can branch to an END SELECT statement only from within its SELECT TYPE construct.

Example

The following example shows a SELECT TYPE construct:

```fortran
TYPE POINT
  REAL :: X, Y
END TYPE POINT

TYPE, EXTENDS(POINT) :: POINT_3D
  REAL :: Z
END TYPE POINT_3D

TYPE, EXTENDS(POINT) :: COLOR_POINT
  INTEGER :: COLOR
END TYPE COLOR_POINT

TYPE(POINT), TARGET :: P
TYPE(POINT_3D), TARGET :: P3D
TYPE(COLOR_POINT), TARGET :: CP
CLASS(POINT), POINTER :: P_OR_CP
P_OR_CP=> CP
SELECT TYPE ( AN => P_OR_CP )
CLASS IS ( POINT )
  ! "CLASS ( POINT ) :: AN" is implied here
PRINT *, AN%X, AN%Y ! This block gets executed
```
TYPE IS ( POINT_3D )
   ! "TYPE ( POINT_3D ) :: AN" is implied here
   PRINT *, AN%X, AN%Y, AN%Z
END SELECT

The following example uses declarations from the above example, but it omits the associate name AN:

P_OR_CP => P3D
SELECT TYPE ( P_OR_CP )
CLASS IS ( POINT )
   ! "CLASS ( POINT ) :: P_OR_CP" is implied here
   PRINT *, P_OR_CP%X, P_OR_CP%Y
TYPE IS ( POINT_3D )
   ! "TYPE ( POINT_3D ) :: P_OR_CP" is implied here
   PRINT *, P_OR_CP%X, P_OR_CP%Y, P_OR_CP%Z   ! This block gets executed
END SELECT

Construct Association

SELECTED_CHAR_KIND
Transformational Intrinsic Function (Generic):
Returns the value of the kind type parameter of the character set named by the argument.

Syntax
result = SELECTED_CHAR_KIND(name)

name (Input) Must be scalar and of type default character. Its value must be 'DEFAULT' or 'ASCII'.

Results
The result is a scalar of type default integer.
The result is a scalar of type default integer. The result value is 1 if NAME has the value 'DEFAULT' or 'ASCII'; otherwise, the result value is -1.

SELECTED_INT_KIND
Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of an integer data type.

Syntax
result = SELECTED_INT_KIND (r)

r (Input) Must be scalar and of type integer.

Results
The result is a scalar of type default integer. The result has a value equal to the value of the kind parameter of the integer data type that represents all values \( n \) in the range of values \( n \) with \(-10^r < n < 10^r\).

If no such kind type parameter is available on the processor, the result is -1. If more than one kind type parameter meets the criteria, the value returned is the one with the smallest decimal exponent range. For more information, see Model for Integer Data.
Example

SELECTED_INT_KIND (6) = 4

The following shows another example:

```fortran
i = SELECTED_INT_KIND(8)  ! returns 4
i = SELECTED_INT_KIND(3)  ! returns 2
i = SELECTED_INT_KIND(10) ! returns 8
i = SELECTED_INT_KIND(20) ! returns -1 because 10**20
      ! is bigger than 2**63
```

See Also

SELECTED_REAL_KIND

**SELECTED_REAL_KIND**

*Transformational Intrinsic Function (Generic):*

*Returns the value of the kind parameter of a real data type.*

**Syntax**

```fortran
result = SELECTED_REAL_KIND ([p] [,r] [,radix])
```

- **p** (Input; optional) Must be scalar and of type integer.
- **r** (Input; optional) Must be scalar and of type integer.
- **radix** (Input; optional) Must be scalar and of type integer.

At least argument p or r must be present.

**Results**

If p or r is absent, the result is as if the argument was present with the value zero. If radix is absent, there is no requirement on the radix of the selected kind.

The result is a scalar of type default integer. If both arguments are absent, the result is zero. Otherwise, the result has a value equal to a value of the kind parameter of a real data type with decimal precision, as returned by the function PRECISION, of at least \( p \) digits, a decimal exponent range, as returned by the function RANGE, of at least \( r \), and a radix, as returned by the function RADIX, of \( \text{radix} \).

If no such kind type parameter is available on the processor, the result is as follows:

-1 if the precision is not available but the range is available
-2 if the exponent range is not available but the precision is available
-3 if neither is available
-4 if real types for the precision and the range are available separately but not together
-5 if no real type of the specified radix is available

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision. **Intel® Fortran currently does not return -4 for any combination of \( p \) and \( r \), and supports only a radix of 2. For more information, see Model for Real Data.**

Example

SELECTED_REAL_KIND (6, 70) = 8

The following shows another example:

```fortran
i = SELECTED_REAL_KIND(r=200, radix=2)  ! returns 8
i = SELECTED_REAL_KIND(13)    ! returns 8
i = SELECTED_REAL_KIND (100, 200)  ! returns -1
```
The following example gives a compile-time error:

```fortran
i = SELECTED_REAL_KIND ()
```

SEQUENCE

Statement: Preserves the storage order of a derived-type definition.

Syntax

SEQUENCE

Description

The SEQUENCE statement allows derived types to be used in common blocks and to be equivalenced. The SEQUENCE statement appears only as part of derived-type definitions. It causes the components of the derived type to be stored in the same sequence they are listed in the type definition. If you do not specify SEQUENCE, the physical storage order is not necessarily the same as the order of components in the type definition.

If a derived type is a sequence derived type, then any other derived type that includes it must also be a sequence type.

Example

```fortran
!DIR$ PACK:1
TYPE NUM1_SEQ
  SEQUENCE
  INTEGER(2)::int_val
  REAL(4)::real_val
  LOGICAL(2)::log_val
END TYPE NUM1_SEQ
TYPE num2_seq
  SEQUENCE
  logical(2)::log_val
  integer(2)::int_val
  real(4)::real_val
end type num2_seq
type (num1_seq) num1
type (num2_seq) num2
character*8 t, t1
equivalence (num1,t)
equivalence (num2,t1)
num1%int_val=2
num1%real_val=3.5
num1%log_val=.TRUE.
t1(1:2)=t(7:8)
t1(3:4)=t(1:2)
t1(5:8)=t(3:6)
print *, num2%int_val, num2%real_val, num2%log_val
end
```

**SETACTIVEQQ (W*S)**

*QuickWin Function:* Makes a child window active, but does not give it focus.

**Module**
USE IFQWIN

**Syntax**

```
result = SETACTIVEQQ (unit)
```

- **unit** (Input) INTEGER(4). Unit number of the child window to be made active.

**Results**

The result type is INTEGER(4). The result is 1 if successful; otherwise, 0.

When a window is made active, it receives graphics output (from ARC, LINETO and OUTGTEXT, for example) but is not brought to the foreground and does not have the focus. If a window needs to be brought to the foreground, it must be given the focus. A window is given focus with FOCUSQQ, by clicking it with the mouse, or by performing I/O other than graphics on it, unless the window was opened with IOFOCUS='FALSE'. By default, IOFOCUS='TRUE', except for child windows opened as unit '*'.

The window that has the focus is always on top, and all other windows have their title bars grayed out. A window can have the focus and yet not be active and not have graphics output directed to it. Graphical output is independent of focus.

If IOFOCUS='TRUE', the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**SETBKCOLOR (W*S)**

*Graphics Function:* Sets the current background color index for both text and graphics.

**Module**
USE IFQWIN

**Syntax**

```
result = SETBKCOLOR (color)
```

- **color** (Input) INTEGER(4). Color index to set the background color to.

**Results**

The result type is INTEGER(4). The result is the previous background color index.
SETBKCOLOR changes the background color index for both text and graphics. The color index of text over the background color is set with SETTEXTCOLOR. The color index of graphics over the background color (used by drawing functions such as FLOODFILL and ELLIPSE) is set with SETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Changing the background color index does not change the screen immediately. The change becomes effective when CLEARSCREEN is executed or when doing text input or output, such as with READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background color index is 0, which is associated with black unless the user remaps the palette with REMAPPALLETTERGB.

**NOTE**
The SETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetBkColor.

**Example**
```plaintext
USE IFQWIN
INTEGER(4) i
i = SETBKCOLOR(14)
```

**See Also**
SETBKCOLORRGB
GETBKCOLOR
REMAPALLPALETTERGB, REMAPPALLETTERGB
SETCOLOR
SETTEXTCOLOR

**SETBKCOLORRGB (W*S)**

*Graphics Function:* Sets the current background color to the given Red-Green-Blue (RGB) value.

**Module**
USE IFQWIN

**Syntax**
```plaintext
result = SETBKCOLORRGB (color)
```

| color | (Input) INTEGER(4). RGB color value to set the background color to. Range and result depend on the system's display adapter. |

**Results**
The result type is INTEGER(4). The result is the previous background RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:
Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

The default background color is value 0, which is black. Changing the background color value does not change the screen immediately, but becomes effective when CLEARSCREEN is executed or when doing text input or output such as READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETBKCOLORRGB(Z'FF0000') !blue
oldcolor = SETCOLORRGB(Z'FF') ! red
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

SETCLIPRGN (W*S)

* Graphics Subroutine: Limits graphics output to part of the screen.

Module
USE IFQWIN
Syntax

CALL SETCLIPRGN (x1, y1, x2, y2)

x1, y1  (Input) INTEGER(2). Physical coordinates for upper-left corner of clipping region.

x2, y2  (Input) INTEGER(2). Physical coordinates for lower-right corner of clipping region.

The SETCLIPRGN function limits the display of subsequent graphics output and font text output to that which fits within a designated area of the screen (the "clipping region"). The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangle that defines the clipping region. The SETCLIPRGN function does not change the viewport-coordinate system; it merely masks graphics output to the screen.

SETCLIPRGN affects graphics and font text output only, such as OUTGTEXT. To mask the screen for text output using OUTTEXT, use SETTEXTWINDOW.

Example

This program draws an ellipse lying partly within a clipping region, as shown below.

! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2
INTEGER(4) oldcolor
x1 = 10;  y1 = 50
x2 = 170; y2 = 150
! Draw full ellipse in white
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
oldcolor = SETCOLORRGB(Z'FF0000') !blue
WRITE(*,*) "Hit enter"
READ(*,*)
CALL CLEARSCREEN($GCLEARSCREEN) ! clear screen
CALL SETCLIPRGN( INT2(0), INT2(0), &
                  INT2(150), INT2(125))
! only part of ellipse inside clip region drawn now
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

The following shows the output of this program.

[Bounding rectangle]

[Clip region]

[Arc of clipped ellipse]

SETWINDOW

**SETCOLOR (W*S)**

*Graphics Function:* Sets the current graphics color index.

**Module**

USE IFQWIN

**Syntax**

```
result = SETCOLOR (color)
```

*color* (Input) INTEGER(2). Color index to set the current graphics color to.

**Results**

The result type is INTEGER(2). The result is the previous color index if successful; otherwise, -1.

The SETCOLOR function sets the current graphics color index, which is used by graphics functions such as ELLIPSE. The background color index is set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

**Example**

```
USE IFQWIN
INTEGER(2) color, oldcolor
LOGICAL status
TYPE (windowconfig) wc

status = GETWINDOWCONFIG(wc)
color = wc%numcolors - 1
oldcolor = SETCOLOR(color)
END
```

**See Also**

SETCOLORRGB
GETCOLOR
REMAPPALETTERGB
SETBKCOLOR
SETTEXTCOLOR
SETPIXEL
SETPIXELS

**SETCOLORRGB (W*S)**

*Graphics Function:* Sets the current graphics color to the specified Red-Green-Blue (RGB) value.

**Module**

USE IFQWIN
Syntax

result = SETCOLORRGB (color)

(Input) INTEGER(4). RGB color value to set the current graphics color to. Range and result depend on the system’s display adapter.

Results

The result type is INTEGER(4). The result is the previous RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
| Bit | 31 (MSB) | 24 | 23 | 16 | 15 | 8 | 7 | 0 |
--- | ------- | --- | --- | --- | --- | - | - | - |
RGB | 0 0 0 0 0 0 0 0 | B B B B B B B G G G G G G G R R R R R R R
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FFFF00’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

SETCOLORRGB sets the RGB color value of graphics over the background color, used by the following graphics functions: ARC, ELLIPSE, FLOODFILL, LINETO, OUTGTEXT, PIE, POLYGON, RECTANGLE, and SETPIXEL. SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETTEXTCOLORRGB sets the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT).

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) oldcolor
TYPE (xycoord) xy
numfonts = INITIALIZEFONTS( ) ! red
oldcolor = SETCOLORRGB(Z'0000FF') ! green
oldcolor = SETBKCOLORRGB(Z'00FF00')
CALL MOVETO(INT2(200), INT2(100), xy)
CALL OUTGTEXT("hello, world")
END
```

SETCONTROLFPQQ

Portability Subroutine: Sets the value of the floating-point processor control word.

Module

USE IFPORT

Syntax

CALL SETCONTROLFPQQ (controlword)

controlword (Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math processor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z'1000'</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z'1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z'0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z'0300'</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z'0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z'0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z'0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z'0C00'</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z'0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z'0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z'0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z'0000'</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z'003F'</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>Z'0001'</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Hex value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>FPCW$DENORMAL</td>
<td>Z'0002'</td>
<td>Allow denormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZERODIVIDE</td>
<td>Z'0004'</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>Z'0008'</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>Z'0010'</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z'0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.

Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.

**NOTE**
The Intel® Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Intel Fortran with another compiler.

**Example**

```fortran
USE IFPORT
INTEGER(2) status, control, controlo
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
!     Save old control word
controlo = control
!     Clear all flags
control = control .AND. Z'0000'
!     Set new control to round up
control = control .OR. FPCW$UP
CALL SETCONTROLFPQQ(control)
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END
```

SETDAT

**Portability Function:** Sets the system date. This function is only available on Windows* and Linux* systems.

**Module**

USE IFPORT

**Syntax**

result = SETDAT (iyr, imon, iday)

- **iyr** (Input) INTEGER(2) or INTEGER(4). Year (xxxxAD).
- **imon** (Input) INTEGER(2) or INTEGER(4). Month (1-12).
- **iday** (Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.

Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Refer to your operating system documentation for the range of permitted dates.

---

**NOTE**

On Linux systems, you must have root privileges to execute this function.

---

**Example**

```
USE IFPORT
LOGICAL(4) success
success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))
END
```

**See Also**

GETDAT
GETTIM
SETTIM

SETENVQQ

**Portability Function:** Sets the value of an existing environment variable, or adds and sets a new environment variable.

**Module**

USE IFPORT
Syntax

\[
\text{result} = \text{SETENVQQ (varname=value)}
\]

\[
\text{varname=value}
\]  
(Input) Character*. String containing both the name and the value of the variable to be added or modified. Must be in the form: \text{varname = value}, where \text{varname} is the name of an environment variable and \text{value} is the value being assigned to it.

Results

The result is of type LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate \text{value} so that trailing blanks are preserved. For example, the string \text{PATH=} =sets \text{value} to ''. You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, LIB= removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

SETENVQQ and GETENVQQ will not work properly with the Windows* APIs SetEnvironmentVariable and GetEnvironmentVariable.

Example

```fortran
USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END
```

*Portability Subroutine: Sets the prompt mode for critical errors that by default generate system prompts.*
Module
USE IFPORT

Syntax
CALL SETERRORMODEQQ (pmode)

pmode (Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (pmode= .TRUE.). You can also enable system error prompts by calling SETERRORMODEQQ with pmode set to ERR$HARDPROMPT (defined in IFPORT.F90).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting pmode to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).

Note that SETERRORMODEQQ affects only errors that generate a system prompt. It does not affect other I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with STATUS='OLD'.

Example

!PROGRAM 1
! DRIVE B door open
OPEN (10, FILE = 'B:\Nofile.DAT', ERR = 100)
! Generates a system prompt error here and waits for the user
! to respond to the prompt before continuing
100   WRITE(*,*) ' Continuing'
END

! PROGRAM 2
! DRIVE B door open
USE IFPORT
CALL SETERRORMODEQQ(.FALSE.)
OPEN (10, FILE = 'B:\Nofile.DAT', ERR = 100)
! Causes the statement at label 100 to execute
! without system prompt
100   WRITE(*,*) ' Drive B: not available, opening &
   &alternative drive.'
   OPEN (10, FILE = 'C:\Nofile.DAT')
END

SETEXITQQ

QuickWin Function: Sets a QuickWin application's exit behavior.

Module
USE IFQWIN
Syntax

result = SETEXITQQ (exitmode)  

(exitmode) INTEGER(4). Determines the program exit behavior. The following exit parameters are defined in IFQWIN.F90:

- QWIN$EXITPROMPT - Displays the following message box:
  "Program exited with exit status X. Exit Window?"
  where X is the exit status from the program.
  If Yes is entered, the application closes the window and terminates. If No is entered, the dialog box disappears and you can manipulate the windows as usual. You must then close the window manually.
- QWIN$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN$EXITPERSIST - Leaves the application open without displaying a message box.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The default for both QuickWin and Standard Graphics applications is QWIN$EXITPROMPT.

Example

! Build as QuickWin Ap
USE IFQWIN
INTEGER(4) exmode, result

WRITE(*,'(1X,A,/)') 'Please enter the exit mode 1, 2 &
or 3 '
READ(*,*) exmode
SELECT CASE (exmode)
CASE (1)
  result = SETEXITQQ(QWIN$EXITPROMPT)
CASE (2)
  result = SETEXITQQ(QWIN$EXITNOPERSIST)
CASE (3)
  result = SETEXITQQ(QWIN$EXITPERSIST)
CASE DEFAULT
  WRITE(*,*) 'Invalid option - checking for bad &
  return'
  IF(SETEXITQQ( exmode ) .NE. -1) THEN
    WRITE(*,*) 'Error not returned'
  ELSE
    WRITE(*,*) 'Error code returned'
  ENDIF
END SELECT
END

See Also
GETEXITQQ
**SET_EXPONENT**

_Elemental Intrinsic Function (Generic): Returns the value of the exponent part (of the model for the argument) set to a specified value._

**Syntax**

```fortran
result = SET_EXPONENT (x, i)
```

- `x` (Input) Must be of type real.
- `i` (Input) Must be of type integer.

**Results**

The result type and kind are the same as `x`. The result has the value `x * b^i`. Parameters `b` and `e` are defined in Model for Real Data. If `x` has the value zero, the result is zero.

**Example**

If 3.0 is a REAL(4) value, `SET_EXPONENT (3.0, 1)` has the value 1.5.

**See Also**

EXPONENT
Data Representation Models

---

**SETFILEACCESSQQ**

_Portability Function: Sets the file access mode for a specified file._

**Module**

USE IFPORT

**Syntax**

```fortran
result = SETFILEACCESSQQ (filename, access)
```

- `filename` (Input) Character*(*)). Name of a file to set access for.
- `access` (Input) INTEGER(4). Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such asIOR or OR):
  - FILE$ARCHIVE - Marked as having been copied to a backup device.
  - FILE$HIDDEN - Hidden. The file does not appear in the directory list that you can request from the command console.
  - FILE$NORMAL - No special attributes (default).
  - FILE$READONLY - Write-protected. You can read the file, but you cannot make changes to it.
  - FILE$SYSTEM - Used by the operating system.

The flags are defined in module IFPORT.F90.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.. To set the access value for a file, add the constants representing the appropriate access.
Example

USE IFPORT
INTEGER(4) permit
LOGICAL(4) result

permit = 0   ! clear permit
permit = IOR(FILE$READONLY, FILE$HIDDEN)
result = SETFILEACCESSQQ ('formula.f90', permit)
END

See Also
GETFILEINFOQQ

SETFILETIMEQQ

Portability Function: Sets the modification time for a specified file.

Module
USE IFPORT

Syntax

result = SETFILETIMEQQ (filename, timedate)

timedate     (Input) INTEGER(4) . Time and date information, as packed by PACKTIMEQQ.

Results

The result type is LOGICAL(4) . The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of different versions of the file. The process that calls SETFILETIMEQQ must have write access to the file; otherwise, the time cannot be changed. If you set timedate to FILE$CURTIME (defined in IFPORT.F90), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the following:

• ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
• ERR$INVAL - Invalid argument; the timedate argument is invalid.
• ERR$MFILE - Too many open files (the file must be opened to change its modification time).
• ERR$NOENT - File or path not found.
• ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

Example

USE IFPORT
INTEGER(2) day, month, year
INTEGER(2) hour, minute, second, hund
INTEGER(4) timedate
LOGICAL(4) result

CALL GETDAT(year, month, day)
CALL GETTIM(hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, &
    hour, minute, second)
result = SETFILETIMEQQ('myfile.dat', timedate)
END

PACKTIMEQQ
UNPACKTIMEQQ
GETLASTERRORQQ

SETFILLMASK (W*S)

Graphics Subroutine: Sets the current fill mask to a new pattern.

Module
USE IFQWIN

Syntax
CALL SETFILLMASK (mask)

mask (Input) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in mask, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of mask becomes the top 8 bits of the pattern, and the eighth element (byte) of mask becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of zero are set to the current background color. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

To change the current fill mask, determine the array of bytes that corresponds to the desired bit pattern and set the pattern with SETFILLMASK, as in the following example.

<table>
<thead>
<tr>
<th>Bit pattern</th>
<th>Value In mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(1) = Z'93'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(2) = Z'C9'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(3) = Z'64'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(4) = Z'B2'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(5) = Z'59'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(6) = Z'2C'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(7) = Z'96'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(8) = Z'4B'</td>
</tr>
</tbody>
</table>
Example

This program draws six rectangles, each with a different fill mask, as shown below.

```
USE IFQWIN

INTEGER(1), TARGET :: style1(8) &
  /Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18'/
INTEGER(1), TARGET :: style2(8) &
  /Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08'/
INTEGER(1), TARGET :: style3(8) &
  /Z'18',Z'00',Z'18',Z'18',Z'00',Z'18',Z'18',Z'18'/
INTEGER(1), TARGET :: style4(8) &
  /Z'00',Z'08',Z'00',Z'08',Z'08',Z'08',Z'08',Z'08'/
INTEGER(1), TARGET :: style5(8) &
  /Z'18',Z'18',Z'00',Z'18',Z'18',Z'00',Z'18',Z'18'/
INTEGER(1), TARGET :: style6(8) &
  /Z'08',Z'00',Z'08',Z'00',Z'08',Z'00',Z'08',Z'00'/
INTEGER(1) oldstyle(8) ! Placeholder for old style

INTEGER loop
INTEGER(1), POINTER :: ptr(:)

CALL GETFILLMASK( oldstyle )
! Make 6 rectangles, each with a different fill
DO loop = 1, 6
  SELECT CASE (loop)
    CASE (1)
      ptr => style1
    CASE (2)
      ptr => style2
    CASE (3)
      ptr => style3
    CASE (4)
      ptr => style4
    CASE (5)
      ptr => style5
    CASE (6)
      ptr => style6
  END SELECT
  CALL SETFILLMASK( ptr )
  status = RECTANGLE($GFILLINTERIOR,INT2(loop*40+5), &
                    INT2(90),INT2((loop+1)*40), INT2(110))
  CALL SETFILLMASK( oldstyle )  ! Restore old style
END DO

CALL SETFILLMASK( oldstyle ) ! Restore old style
READ (*,*) ! Wait for ENTER to be pressed

END
```

The following shows the output of this program.

![Typical fill masks for rectangle](image-url)
SETFONT (W*S)

**Graphics Function:** Finds a single font that matches a specified set of characteristics and makes it the current font used by the OUTGTEXT function.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETFONT (options)
```

- **options** *(Input) Character*(*). String describing font characteristics (see below for details).

**Results**

The result type is INTEGER(2). The result is the index number (x as used in the nx option) of the font if successful; otherwise, -1.

The SETFONT function searches the list of available fonts for a font matching the characteristics specified in `options`. If a font matching the characteristics is found, it becomes the current font. The current font is used in all subsequent calls to the OUTGTEXT function. There can be only one current font.

The `options` argument consists of letter codes, as follows, that describe the desired font. The argument is neither case sensitive nor position sensitive.

- `'t' fontname'` Name of the desired typeface. It can be any installed font.
- `'h' y` Character height, where y is the number of pixels.
- `'w' x` Select character width, where x is the number of pixels.
- `'f'` Select only a fixed-space font (do not use with the p characteristic).
- `'p'` Select only a proportional-space font (do not use with the f characteristic).
- `'v'` Select only a vector-mapped font (do not use with the r characteristic). Roman, Modern, and Script are examples of vector-mapped fonts, also called plotter fonts. True Type fonts (for example, Arial, Symbol, and Times New Roman) are not vector-mapped.
Select only a raster-mapped (bitmapped) font (do not use with the v characteristic). Courier, Helvetica, and Palatino are examples of raster-mapped fonts, also called screen fonts. True Type fonts are not raster-mapped.

Select the bold text format. This parameter is ignored if the font does not allow the bold format.

Select the underline text format. This parameter is ignored if the font does not allow underlining.

Select the italic text format. This parameter is ignored if the font does not allow italics.

Select the font that best fits the other parameters specified.

Select font number x, where x is less than or equal to the value returned by the INITIALIZEFONTS function.

You can specify as many options as you want, except with nx, which should be used alone. If you specify options that are mutually exclusive (such as the pairs e/p or r/v), the SETFONT function ignores them. There is no error detection for incompatible parameters used with nx.

If the b option is specified and at least one font is initialized, SETFONT sets a font and returns 0 to indicate success.

In selecting a font, the SETFONT routine uses the following criteria, rated from highest precedence to lowest:

1. Pixel height
2. Typeface
3. Pixel width
4. Fixed or proportional font

You can also specify a pixel width and height for fonts. If you choose a nonexistent value for either and specify the b option, SETFONT chooses the closest match.

A smaller font size has precedence over a larger size. If you request Arial 12 with best fit, and only Arial 10 and Arial 14 are available, SETFONT selects Arial 10.

If you choose a nonexistent value for pixel height and width, the SETFONT function applies a magnification factor to a vector-mapped font to obtain a suitable font size. This automatic magnification does not apply if you specify the r option (raster-mapped font), or if you request a specific typeface and do not specify the b option (best-fit).

If you specify the nx parameter, SETFONT ignores any other specified options and supplies only the font number corresponding to x.

If a height is given, but not a width, SETFONT computes the width to preserve the correct font proportions.

If a width is given, but not a height, SETFONT uses a default height, which may vary from font type to font type. This may lead to characters that appear distorted, particularly when a very wide width is specified. This behavior is the same as that of the Windows* API CreateFontIndirect. A sample program is provided below showing you how to calculate the correct height for a given width.

The font functions affect only OUTGTEXT and the current graphics position; no other Fortran Graphics Library output functions are affected by font usage.
For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

**Example**

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
! Set typeface to Arial, character height to 18, 
! character width to 10, and italic
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Demo text')
END

Another example follows:

! The following program shows you how to compute 
! an appropriate font height for a given font width
! 
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
TYPE (rccoord) rcc
TYPE (FONTINFO) info
CHARACTER*11 str, str1
CHARACTER*22 str2
real rh
integer h, inw
str = "t'Arial'bih"
strl= " "
numfonts = INITIALIZEFONTS ( )
! Default both height and width. This seems to work
! properly. From this setting get the ratio between
! height and width.
fontnum = SETFONT ("t'Arial'")
ireturn = GETFONTINFO(info)
rh = real(info%pixheight)/real(info%avgwidth)

! Now calculate the height for a width of 40
write(*,*) 'Input desired width:'
read(*,*) inw
h =int(inw*rh)
write(strl,'(I3.3)') h
str2 = str//strl
print *,str2,fontnum = SETFONT (str2)
CALL MOVETO (INT2(10), INT2(50), pos)
CALL OUTGTEXT('ABCDEFGabcdefg12345!@#$%')
CALL MOVETO (INT2(10), INT2(50+10+rh), pos)
CALL OUTGTEXT('123456789012345678901234')
ireturn = GETFONTINFO(info)
CALL SETTEXTPosition(4, 1, rcc)
PRINT *, info%avgwidth, info%pixheight
END

GETGTEXTEXTENT
GRSTATUS
OUTGTEXT
INITIALIZEFONTS
SETGTEXTROTATION

SETGTEXTROTATION (W*S)

Graphics Subroutine: Sets the orientation angle of
the font text output in degrees. The current
orientation is used in calls to OUTGTEXT.

Module
USE IFQWIN

Syntax
CALL SETGTEXTROTATION (degree-tenths)

degree-tenths
   (Input) INTEGER(4). Angle of orientation, in tenths of degrees, of the
   font text output.

The orientation of the font text output is set in tenths of degrees. Horizontal is 0°, and angles increase
counterclockwise so that 900 (90°) is straight up, 1800 (180°) is upside down and left, 2700 (270°) is
straight down, and so forth. If the user specifies a value greater than 3600 (360°), the subroutine takes a
value equal to:

MODULO (user-specified tenths of degrees, 3600)

Although SETGTEXTROTATION accepts arguments in tenths of degrees, only increments of one full degree
differ visually from each other on the screen.

Bitmap fonts cannot be rotated; TruType fonts should be used instead.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
INTEGER(4) oldcolor, deg
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Straight text')
deg = -1370
CALL SETGTEXTROTATION(deg)
oldcolor = SETCOLORRGB(Z'008080')
CALL OUTGTEXT('Slanted text')
END
SETLINESTYLE (W*S)

Graphics Subroutine: Sets the current line style to a new line style.

Module

USE IFQWIN

Syntax

CALL SETLINESTYLE(mask)

mask (Input) INTEGER(2). Desired Quickwin line-style mask. (See the table below.)

The mask is mapped to the style that most closely equivalences the percentage of the bits in the mask that are set. The style produces lines that cover a certain percentage of the pixels in that line.

SETLINESTYLE sets the style used in drawing a line. You can choose from the following styles:

<table>
<thead>
<tr>
<th>QuickWin Mask</th>
<th>Internal Windows* Style</th>
<th>Selection Criteria</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFF</td>
<td>PS_SOLID</td>
<td>16 bits on</td>
<td></td>
</tr>
<tr>
<td>0xEEEE</td>
<td>PS_DASH</td>
<td>11 to 15 bits on</td>
<td></td>
</tr>
<tr>
<td>0xECEC</td>
<td>PS_DASHDOT</td>
<td>10 bits on</td>
<td>-.-.-.-.-.-.</td>
</tr>
<tr>
<td>0xECCC</td>
<td>PS_DASHDOTDOT</td>
<td>9 bits on</td>
<td>-.-.-.-.-.-.</td>
</tr>
<tr>
<td>0xAAAA</td>
<td>PS_DOT</td>
<td>1 to 8 bits on</td>
<td></td>
</tr>
<tr>
<td>0x0000</td>
<td>PS_NULL</td>
<td>0 bits on</td>
<td></td>
</tr>
</tbody>
</table>

SETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON, and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE, or PIE.

The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, style
TYPE (xycoord) xy

style = Z'FFFF'
CALL SETLINESTYLE(style)
CALL MOVETO(INT2(50), INT2(50), xy )
status = LINETO(INT2(300), INT2(300))
END

GRSTATUS

Inte! Fortran Compiler 19.0 Developer Guide and Reference
**SETLINEWIDTHQQ (W*S)**

*Graphics Subroutine:* Sets the width of a solid line drawn using any of the supported graphics functions.

**Module**

USE IFQWIN

**Syntax**

CALL SETLINEWIDTHQQ (x)

x (Input) INTEGER(4). It can be any non-negative integer.

This subroutine sets the line width in pixels using the value that is passed as the argument.

SETLINEWIDTHQQ affects the drawing of straight lines using functions such as LINETO, POLYGON, LINETOAR, LINETOAREX, RECTANGLE, and it affects the drawing of curved lines using functions such as ARC, ELLIPSE, or PIE.

---

**NOTE**

The nWidth argument in the Windows* API CreatePen() is the width used to draw the lines or borders of a closed shape. A cosmetic pen can only have a width of 1 pixel. If you specify a higher width, it is ignored. A geometric pen can have a width of 1 or more pixels, but the line can only be solid or null. This means that if you specify the style as PS_DASH, PS_DOT, PS_DASHDOT, or PS_DASHDOTDOT, but set a width higher than 1 pixel, the line is drawn as PS_SOLID.

---

</tbody>
</table>

QWIN$MSG_FILEOPENDLG and QWIN$MSG_BMPSAVEDLG control the text in file choosing dialog boxes and have the following syntax:

"file description, file designation"
You can change any string produced by QuickWin by calling SETMESSAGEQQ with the appropriate \textit{id}. This includes status messages displayed at the bottom of a QuickWin application, state messages (such as "Paused"), and dialog box messages. These messages can include multibyte characters. To change menu messages, use MODIFYMENUSTRINGQQ.

\textbf{Example}

\begin{verbatim}
USE IFQWIN
print*, "Hello"
CALL SETMESSAGEQQ('Changed exit text', QWIN$MSG_EXITQ)
\end{verbatim}

\textbf{See Also}

MODIFYMENUSTRINGQQ

\textbf{SETMOUSECURSOR (W*S)}

\textit{Quickwin Function:} Sets the shape of the mouse cursor for the window in focus.

\textbf{Module}

USE IFQWIN
USE IFWIN

\textbf{Syntax}

\begin{verbatim}
oldcursor = SETMOUSECURSOR (newcursor)
\end{verbatim}

\textbf{newcursor} (Input) INTEGER(4). A Windows HCURSOR value. For many predefined shapes, LoadCursor(0, shape) is a convenient way to get a legitimate value. See the list of predefined shapes below. A value of zero prevents the cursor from being displayed.

\textbf{Results}

The result type is INTEGER(4). This is also an HCURSOR Value. The result is the previous cursor value.

The window in focus at the time SETMOUSECURSOR is called has its cursor changed to the specified value. Once changed, the cursor retains its shape until another call to SETMOUSECURSOR.

In Standard Graphics applications, units 5 and 6 (the default screen input and output units) are always considered to be in focus.

The following predefined values for cursor shapes are available:

<table>
<thead>
<tr>
<th>Predefined Value</th>
<th>Cursor Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDC_APPSTARTING</td>
<td>Standard arrow and small hourglass</td>
</tr>
<tr>
<td>IDC_ARROW</td>
<td>Standard arrow</td>
</tr>
<tr>
<td>IDC_CROSS</td>
<td>Crosshair</td>
</tr>
<tr>
<td>IDC_IBEAM</td>
<td>Text I-beam</td>
</tr>
<tr>
<td>IDC_ICON</td>
<td>Obsolete value</td>
</tr>
<tr>
<td>IDC_NO</td>
<td>Slashed circle</td>
</tr>
<tr>
<td>IDC_SIZE</td>
<td>Obsolete value; use IDC_SIZEALL</td>
</tr>
</tbody>
</table>
### Predefined Value | Cursor Shape
---|---
IDC_SIZEALL | Four-pointed arrow
IDC_SIZENESW | Double-pointed arrow pointing northeast and southwest
IDC_SIZENS | Double-pointed arrow pointing north and south
IDC_SIZENWSE | Double-pointed arrow pointing northwest and southeast
IDC_SIZEWE | Double-pointed arrow pointing west and east
IDC_UPARROW | Vertical arrow
IDC_WAIT | Hour glass

A LoadCursor must be done on these values before they can be used by SETMOUSECURSOR.

**Example**

```fortran
! Build as Standard Graphics or QuickWin
use ifqwin
use ifwin

oldcursor = SetMouseCursor(oldcursor)
read(5,*)
stop
end
```

**SETPIXEL, SETPIXEL_W (W*S)**

**Graphics Functions:** Set a pixel at a specified location to the current graphics color index.

**Module**

USE IFQWIN
Syntax

result = SETPIXEL (x, y)
result = SETPIXEL_W (wx, wy)

x, y      (Input) INTEGER(2). Viewport coordinates for target pixel.
wx, wy    (Input) REAL(8). Window coordinates for target pixel.

Results

The result type is INTEGER(2). The result is the previous color index of the target pixel if successful; otherwise, -1 (for example, if the pixel lies outside the clipping region).

SETPIXEL sets the specified pixel to the current graphics color index. The current graphics color index is set with SETCOLOR and retrieved with GETCOLOR. The non-RGB color functions (such as SETCOLOR and SETPIXELS) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function. SETPIXELRGB and SETPIXELRGB_W give access to the full color capacity of the system by using direct color values rather than indexes to a palette.

NOTE

The SETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetPixel.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
status = SETCOLOR(INT2(2))
x = 10
! Draw pixels.
DO y = 50, 389, 3
   status = SETPIXEL( x, y )
x = x + 2
END DO
READ (*,*)! Wait for ENTER to be pressed
END

See Also

SETPIXELRGB
GETPIXEL
SETPIXELS
GETPIXELS
GETCOLOR
SETCOLOR
SETPIXELRGB, SETPIXELRGB_W (W*S)

**Graphics Functions:** Set a pixel at a specified location to the specified Red-Green-Blue (RGB) color value.

**Module**

USE IFQWIN

**Syntax**

result = SETPIXELRGB (x, y, color)
result = SETPIXELRGB_W (x, y, color)

- **x, y** (Input) INTEGER(2). Viewport coordinates for target pixel.
- **wx, wy** (Input) REAL(8). Window coordinates for target pixel.
- **color** (Input) INTEGER(4). RGB color value to set the pixel to. Range and result depend on the system's display adapter.

**Results**

The result type is INTEGER(4). The result is the previous RGB color value of the pixel.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETPIXELRGB or SETPIXELRGB_W, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>R</th>
<th>G</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B B B</td>
<td>G G G G G G G G</td>
<td>R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

If any of the pixels are outside the clipping region, those pixels are ignored.

SETPIXELRGB (and the other RGB color selection functions such as SETPIXELSRGB, SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) x, y
INTEGER(4) color
DO i = 10, 30, 10
   SELECT CASE (i)
      CASE(10)
         color = Z'0000FF'
      CASE(20)
```

2038
color = Z'00FF00'
CASE (30)
  color = Z'FF0000'
END SELECT
! Draw pixels.
DO y = 50, 180, 2
  status = SETPIXELRGB( x, y, color )
  x      = x + 2
END DO
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

GETPIXELRGB
GETPIXELSRGB
SETCOLORRGB
SETPIXELSRGB

SETPIXELS (W*S)

Graphics Subroutine: Sets the color indexes of multiple pixels.

Module
USE IFQWIN

Syntax
CALL SETPIXELS ( n, x, y, color)

n  (Input) INTEGER(4). Number of pixels to set. Sets the number of elements in the other arguments.

x, y  (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to set.

color  (Input) INTEGER(2). Array containing color indexes to set the pixels to.

SETPIXELS sets the pixels specified in the arrays x and y to the color indexes in color. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELS with n less than 1 are also ignored. SETPIXELS is a much faster way to set multiple pixel color indexes than individual calls to SETPIXEL.

Unlike SETPIXELS, SETPIXELSRGB gives access to the full color capacity of the system by using direct color values rather than indexes to a palette. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.
Example

! Build as a Graphics ap.
USE IFQWIN
  INTEGER(2) color(9)
  INTEGER(2) x(9), y(9), i
  DO i = 1, 9
    x(i) = 20 * i
    y(i) = 10 * i
    color(i) = INT2(i)
  END DO
  CALL SETPIXELS(9, x, y, color)
END

See Also
GETPIXELS
SETPIXEL
SETPIXELSRGB

SETPIXELSRGB (W*S)

Graphics Subroutine: Sets multiple pixels to the given Red-Green-Blue (RGB) color.

Module
USE IFQWIN

Syntax
CALL SETPIXELSRGB (n, x, y, color)

n (Input) INTEGER(4). Number of pixels to be changed. Determines the number of elements in arrays x and y.

x, y (Input) INTEGER(2). Parallel arrays containing viewport coordinates of the pixels to set.

color (Input) INTEGER(4). Array containing the RGB color values to set the pixels to. Range and result depend on the system's display adapter.

SETPIXELSRGB sets the pixels specified in the arrays x and y to the RGB color values in color. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three color values, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you set with SETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B B G G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

A good use for SETPIXELSRGB is as a buffering form of SETPIXELRGB, which can improve performance substantially. The example code shows how to do this.
If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELSRGB with $n$ less than 1 are also ignored.

SETPIXELSRGB (and the other RGB color selection functions such as SETPIXELRGB and SETCOLORRGB) sets colors to values chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

```fortran
! Buffering replacement for SetPixelRGB and
! SetPixelRGB_W. This can improve performance by
! doing batches of pixels together.

USE IFQWIN

PARAMETER (I$SIZE = 200)
INTEGER(4) bn, bc(I$SIZE), status
INTEGER(2) bx(I$SIZE), by(I$SIZE)

bn = 0
DO i = 1, I$SIZE
   bn = bn + 1
   bx(bn) = i
   by(bn) = i
   bc(bn) = GETCOLORRGB()
   status = SETCOLORRGB(bc(bn)+1)
END DO
CALL SETPIXELSRGB(bn,bx,by,bc)
END
```

See Also

SETTEXTCOLOR (W*S)

**Graphics Function:** Sets the current text color index.

Module
USE IFQWIN

Syntax

```
result = SETTEXTCOLOR (index)
```

*index* (Input) INTEGER(2). Color index to set the text color to.

Results

The result type is INTEGER(2). The result is the previous text color index.
SETTEXTCOLOR sets the current text color index. The default value is 15, which is associated with white unless the user remaps the palette. GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT.

The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

**NOTE**
The SETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetTextColor.

### Example

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) oldtc
oldtc = SETTEXTCOLOR(INT2(2)) ! green
WRITE(*,*) "hello, world"
END
```

### See Also

GETTEXTCOLOR
REMAPPALETTERGB
SETCOLOR
SETTEXTCOLORRGB

### SETTEXTCOLORRGB (W*S)
**Graphics Function:** Sets the current text color to the specified Red-Green-Blue (RGB) value.

**Module**
USE IFQWIN

**Syntax**

```fortran
result = SETTEXTCOLORRGB (color)
```

**color** (Input) INTEGER(4). RGB color value to set the text color to. Range and result depend on the system's display adapter.

**Results**

The result type is INTEGER(4). The result is the previous text RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>[00000000]</td>
<td>[BBBBBB]</td>
<td>[GGGGGG]</td>
<td>[GGGGGG]</td>
<td>[RRRRRR]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FFF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

`SETTEXTCOLORRGB` sets the current text RGB color. The default value is Z'00FFFFFF', which is full-intensity white. `SETTEXTCOLORRGB` sets the color used by `OUTTEXT`, `WRITE`, and `PRINT`. It does not affect the color of text output with the `OUTGTEXT` font routine. Use `SETCOLORRGB` to change the color of font output.

`SETBKCOLORRGB` sets the RGB color value of the current background for both text and graphics. `SETCOLORRGB` sets the RGB color value of graphics over the background color, used by the graphics functions such as `ARC`, `FLOODFILLRGB`, and `OUTGTEXT`.

`SETTEXTCOLORRGB` (and the other RGB color selection functions `SETBKCOLORRGB` and `SETCOLORRGB`) sets the color to a value chosen from the entire available range. The non-RGB color functions (`SETTEXTCOLOR`, `SETBKCOLOR`, and `SETCOLOR`) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(4) oldtc

oldtc = SETTEXTCOLORRGB(Z'000000FF')
WRITE(*,*) 'I am red'
oldtc = SETTEXTCOLORRGB(Z'0000FF00')
CALL OUTTEXT ('I am green'//CHAR(13)//CHAR(10))
oldtc = SETTEXTCOLORRGB(Z'00FF0000')
PRINT *, 'I am blue'
END
```

**See Also**

- `SETBKCOLORRGB`
- `SETCOLORRGB`
- `GETTEXTCOLORRGB`
- `GETWINDOWCONFIG`
- `OUTTEXT`

**SETTEXTCURSOR (W*S)**

*Graphics Function:* Sets the height and width of the text cursor (the caret) for the window in focus.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETTEXTCURSOR (newcursor)
```

`newcursor` (Input) INTEGER(2). The leftmost 8 bits specify the width of the cursor, and the rightmost 8 bits specify the height of the cursor. These dimensions can range from 1 to 8, and represent a fraction of the current character cell size. For example:
• Z'0808' - Specifies the full character cell; this is the default size.
• Z'0108' - Specifies 1/8th of the character cell width, and 8/8th (or all) of the character cell height.

If either of these dimensions is outside the range 1 to 8, it is forced to 8.

Results
The result type is INTEGER(2); it is the previous text cursor value in the same format as newcursor.

NOTE
After calling SETTEXTCURSOR, you must call DISPLAYCURSOR($GCURSORON) to actually see the cursor.

Example

```
use IFQWIN
integer(2) oldcur
integer(2) istat
type(rccoord) rc
open(10, file='user')
istat = displaycursor($GCURSORON)
write(10,*) 'Text cursor is now character cell size, the default.'
read(10,*)
write(10,*) 'Setting text cursor to wide and low.'
oldcur = settextcursor(Z'0801')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to high and narrow.'
oldcur = settextcursor(Z'0108')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to a dot.'
oldcur = settextcursor(Z'0101')
istat = displaycursor($GCURSORON)
read(10,*)
end
```

See Also
DISPLAYCURSOR

SETTEXTPOSITION (W*S)

**Graphics Subroutine:** Sets the current text position to a specified position relative to the current text window.

Module
USE IFQWIN

Syntax

```
CALL SETTEXTPOSITION (row, column, t)
```

row (Input) INTEGER(2). New text row position.
column (Input) INTEGER(2). New text column position.

rccoord (Output) Derived type rccoord. Previous text position. The derived type rccoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE rccoord
  INTEGER(2) row ! Row coordinate
  INTEGER(2) col ! Column coordinate
END TYPE rccoord
```

Subsequent text output with the OUTTEXT function (as well as standard console I/O statements, such as PRINT and WRITE) begins at the point (row, column).

Example

```fortran
USE IFQWIN
TYPE (rccoord) curpos
WRITE(*,*) "Original text position"
CALL SETTEXTPOSITION (INT2(6), INT2(5), curpos)
WRITE (*,*) 'New text position'
END
```

See Also
CLEARSCREEN
GETTEXTPOSITION
OUTTEXT

SETTEXTWINDOW
WRAPON

SETTEXTWINDOW (W*S)

**Graphics Subroutine:** Sets the current text window.

Module

USE IFQWIN

Syntax

```fortran
CALL SETTEXTWINDOW (r1,c1,r2,c2)
```

r1, c1 (Input) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

r2, c2 (Input) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

SETTEXTWINDOW specifies a window in row and column coordinates where text output to the screen using OUTTEXT, WRITE, or PRINT will be displayed. You set the text location within this window with SETTEXTPOSITION.

Text is output from the top of the window down. When the window is full, successive lines overwrite the last line.

SETTEXTWINDOW does not affect the output of the graphics text routine OUTGTEXT. Use the SETVIEWPORT function to control the display area for graphics output.
Example

```fortran
USE IFQWIN
TYPE (rccoord) curpos
CALL SETTEXTWINDOW(INT2(5), INT2(1), INT2(7), &
INT2(40))
CALL SETTEXTPOSITION (INT2(5), INT2(5), curpos)
WRITE(*,*) 'Only two lines in this text window'
WRITE(*,*) 'so this line will be overwritten'
WRITE(*,*) 'by this line'
END
```

SETTIM

**Portability Function:** Sets the system time in your programs. This function is only available on Windows* and Linux* systems.

Module

USE IFPORT

Syntax

```fortran
result = SETTIM (ihr, imin, isec, i100th)
```

- `ihr` (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
- `imin` (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
- `isec` (Output) INTEGER(4) or INTEGER(2). Second (0-59).
- `i100th` (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

Results

The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.

**NOTE**

On Linux systems, you must have root privileges to execute this function.
Example

```
USE IFPORT
LOGICAL(4) success
success = SETTIM(INT2(21),INT2(53+3),&
          INT2(14*2),INT2(88))
END
```

See Also
GETDAT
GETTIM
SETDAT

SETVIEWORG (W*S)

**Graphics Subroutine:** Moves the viewport-coordinate origin (0, 0) to the specified physical point.

Module
USE IFQWIN

Syntax
CALL SETVIEWORG (x, y, s)

x, y

(Input) INTEGER(2). Physical coordinates of new viewport origin.

s

(Output) Derived type xycoord. Physical coordinates of the previous viewport origin. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
   INTEGER(2) xcoord ! x-coordinate
   INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord
```

The xycoord type variable s, defined in IFQWIN.F90, returns the physical coordinates of the previous viewport origin.

Example

```
USE IFQWIN
TYPE (xycoord) xy
CALL SETVIEWORG(INT2(30), INT2(30), xy)
```

See Also
GETCURRENTPOSITION
GETPHYSCOORD
GETVIEWCOORD
GETWINDOWCOORD
GRSTATUS
SETCLIPRGN
SETVIEWPORT
SETVIEWPORT (W*S)

**Graphics Subroutine:** Redefines the graphics viewport by defining a clipping region in the same manner as SETCLIPRGN and then setting the viewport-coordinate origin to the upper-left corner of the region.

**Module**

USE IFQWIN

**Syntax**

CALL SETVIEWPORT (x1,y1,x2,y2)

- **x1, y1** (Input) INTEGER(2). Physical coordinates for upper-left corner of viewport.
- **x2, y2** (Input) INTEGER(2). Physical coordinates for lower-right corner of viewport.

The physical coordinates \((x1, y1)\) and \((x2, y2)\) are the upper-left and lower-right corners of the rectangular clipping region. Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

**Example**

```
USE IFQWIN
INTEGER(2) upx, upy
INTEGER(2) downx, downy
upx = 0
upy = 30
downx= 250
downy = 100
CALL SETVIEWPORT(upx, upy, downx, downy)
```

**See Also**

GETVIEWCOORD
GETPHYSCOORD
GRSTATUS
SETCLIPRGN
SETVIEWORG
SETWINDOW

SETWINDOW (W*S)

**Graphics Function:** Defines a window bound by the specified coordinates.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETWINDOW (finvert,wx1,wy1,wx2,wy2)
```
finvert

(Input) LOGICAL(2). Direction of increase of the y-axis. If finvert is .TRUE., the y-axis increases from the window bottom to the window top (as Cartesian coordinates). If finvert is .FALSE., the y-axis increases from the window top to the window bottom (as pixel coordinates).

wx1, wy1

(Input) REAL(8). Window coordinates for upper-left corner of window.

wx2, wy2

(Input) REAL(8). Window coordinates for lower-right corner of window.

Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0 (for example, if the program that calls SETWINDOW is not in a graphics mode).

The SETWINDOW function determines the coordinate system used by all window-relative graphics routines. Any graphics routines that end in _W (such as ARC_W, RECTANGLE_W, and LINETO_W) use the coordinate system set by SETWINDOW.

Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

An arc drawn using inverted window coordinates is not an upside-down version of an arc drawn with the same parameters in a noninverted window. The arc is still drawn counterclockwise, but the points that define where the arc begins and ends are inverted.

If wx1 equals wx2 or wy1 equals wy2, SETWINDOW fails.

Example

USE IFQWIN
INTEGER(2) status
LOGICAL(2) invert /.TRUE./
REAL(8) upx /0.0/, upy /0.0/
REAL(8) downx /1000.0/, downy /1000.0/
status = SETWINDOW(invert, upx, upy, downx, downy)

SETWINDOWCONFIG (W*S)

QuickWin Function: Sets the properties of a child window.
Module
USE IFQWIN

Syntax
result = SETWINDOWCONFIG (wc)

(Input) Derived type windowconfig. Contains window properties. The
windowconfig derived type is defined in IFQWIN.F90 as follows:

```
TYPE windowconfig
  INTEGER(2) numxpixels         ! Number of pixels on x-axis.
  INTEGER(2) numypixels         ! Number of pixels on y-axis.
  INTEGER(2) numtextcols        ! Number of text columns
  INTEGER(2) numtextrows        ! Number of text rows available.
  INTEGER(2) numcolors          ! Number of color indexes.
  INTEGER(4) fontsize           ! Size of default font. Set to
                                 !   QWIN$EXTENDFONT when specifying
  CHARACTER(80) title               ! The window title.
  INTEGER(2) bitsperpixel       ! The number of bits per pixel.
  INTEGER(2) numvideopages          ! Unused.
  INTEGER(2) mode               ! Controls scrolling mode.
  INTEGER(2) adapter                ! Unused.
  INTEGER(2) monitor                ! Unused.
  INTEGER(2) memory                 ! Unused.
  INTEGER(2) environment            ! Unused.
  CHARACTER(32) extendfontname      ! The name of the desired font.
  INTEGER(4) extendfontsize     ! Takes the same values as fontsize,
                                 ! when fontsize is set to
                                 !   QWIN$EXTENDFONT.
  INTEGER(4) extendfontattributes   ! Font attributes such as bold
                                 !   and italic.
END TYPE windowconfig
```

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The following value can be used to configure a QuickWin window so that it will show the last line written and
the text cursor (if it is on):

```
wc%mode = QWIN$SCROLLDOWN
```

Note that if you scroll the window to another position, you will have to scroll back to the last line to see your input.
The following values can be used with SETWINDOWCONFIG extended fonts:

**Style:**

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_NORMAL</td>
<td>No underline, no italic, and a font weight of 400 out of 1000.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_UNDERLINE</td>
<td>Underlined characters.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_BOLD</td>
<td>A font weight of 700 out of 1000.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_ITALIC</td>
<td>Italic characters.</td>
</tr>
</tbody>
</table>

**Pitch:**

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FIXED_PITCH</td>
<td>QuickWin default. Equal character widths.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_VARIABLE_PITCH</td>
<td>Variable character widths.</td>
</tr>
</tbody>
</table>

**Font Families:**

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FF_ROMAN</td>
<td>Variable stroke width, serifed. Times Roman, Century Schoolbook, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SWISS</td>
<td>Variable stroke width, sans-serifed. Helvetica, Swiss, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_MODERN</td>
<td>QuickWin default. Constant stroke width, serifed or sans-serifed. Pica, Elite, Courier, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SCRIPT</td>
<td>Cursive, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_DECORATIVE</td>
<td>Old English, etc.</td>
</tr>
</tbody>
</table>

**Character Sets:**

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_ANSI_CHARSET</td>
<td>QuickWin default.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_OEM_CHARSET</td>
<td>Use this to get Microsoft* LineDraw.</td>
</tr>
</tbody>
</table>

Using QWIN$EXTENDFONT_OEM_CHARSET with the font name 'MS LineDraw'C will get the old DOS-style character set with symbols that can be used to draw lines and boxes. The pitch and font family items can be specified to help guide the font matching algorithms used by CreateFontIndirect, the Windows* API used by SETWINDOWCONFIG.

If you use SETWINDOWCONFIG to set the variables in windowconfig to -1, the function sets the highest resolution possible for your system, given the other fields you specify, if any. You can set the actual size of the window by specifying parameters that influence the window size: the number of x and y pixels, the number of rows and columns, and the font size. If you do not call SETWINDOWCONFIG, the window defaults to the best possible resolution and a font size of 8x16. The number of colors available depends on the video driver used.

If you use SETWINDOWCONFIG, you should specify a value for each field (-1 or your own value for the numeric fields and a C string for the title, for example, "words of text")C). Using SETWINDOWCONFIG with only some fields specified can result in useless values for the unspecified fields.

If you request a configuration that cannot be set, SETWINDOWCONFIG returns .FALSE. and calculates parameter values that will work and are as close as possible to the requested configuration. A second call to SETWINDOWCONFIG establishes the adjusted values; for example:

```plaintext
status = SETWINDOWCONFIG(wc)
if (.NOT. status) status = SETWINDOWCONFIG(wc)
```
If you specify values for all four of the size parameters, `numxpixels`, `numypixels`, `numtextcols`, and `numtextrows`, the font size is calculated by dividing these values. The default font is Courier New and the default font size is 8x16. There is no restriction on font size, except that the window must be large enough to hold it.

Under Standard Graphics, the application attempts to start in Full Screen mode with no window decoration (window decoration includes scroll bars, menu bar, title bar, and message bar) so that the maximum resolution can be fully used. Otherwise, the application starts in a window. You can use ALT+ENTER at any time to toggle between the two modes.

If you are in Full Screen mode and the resolution of the window does not match the resolution of the video driver, graphics output will be slow compared to drawing in a window.

**NOTE**
You must call `DISPLAYCURSOR($GCURSORON)` to make the cursor visible after calling `SETWINDOWCONFIG`.

**Example**

```fortran
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL status /.FALSE./
! Set the x & y pixels to 800X600 and font size to 8x12
wc%numxpixels  = 800
wc%numypixels  = 600
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors   = -1
wc%title= "This is a test"C
wc%fontsize = Z'0008000C'
status = SETWINDOWCONFIG(wc)  ! attempt to set configuration with above values
if (.NOT.status) status = SETWINDOWCONFIG(wc)
```

**See Also**

`DISPLAYCURSOR`

`GETWINDOWCONFIG`

**SETWINDOWMENUQQ (W*S)**

**QuickWin Function:** Sets a top-level menu as the menu to which a list of current child window names is appended.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETWINDOWMENUQQ (menuID)
```

**menuID** (Input) INTEGER(4). Identifies the menu to hold the child window names, starting with 1 as the leftmost menu.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
The list of current child window names can appear in only one menu at a time. If the list of windows is currently in a menu, it is removed from that menu. By default, the list of child windows appears at the end of the Window menu.

Example

```fortran
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL(4) result, status /.FALSE./
! Set title for child window
wc%numxpixels = -1
wc%numypixels = -1
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors   = -1
wc%fontsize    = -1
wc%title= "I am child window name"C
if (.NOT.status) status = SETWINDOWCONFIG(wc)

! put child window list under menu 3 (View)
result = SETWINDOWMENUQQ(3)
END
```

See Also

APPENDMENUQQ

SETWRITEMODE (W*S)

*Graphics Function:* Sets the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions.

**Module**

USE IFQWIN

**Syntax**

```
result = SETWRITEMODE (wmode)
```

**wmode** (Input) INTEGER(2). Write mode to be set. One of the following symbolic constants (defined in IFQWIN.F90):

- **$GPSET** - Causes lines to be drawn in the current graphics color. (Default)
- **$GAND** - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- **$GOR** - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- **$GPRESET** - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- **$GXOR** - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

In addition, one of the following binary raster operation constants can be used (described in the online documentation for the Windows* API SetROP2):
Results

The result type is INTEGER(2). The result is the previous write mode if successful; otherwise, -1.

The current graphics color is set with SETCOLORRGB (or SETCOLOR) and the current background color is set with SETBKCOLORRGB (or SETBKCOLOR). As an example, suppose you set the background color to yellow (Z'00FFFF') and the graphics color to purple (Z'FF00FF') with the following commands:

```fortran
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
```

If you then set the write mode with the $GAND option, lines are drawn in red (Z'0000FF'); with the $GOR option, lines are drawn in white (Z'FFFFFF'); with the $GXOR option, lines are drawn in turquoise (Z'FFFF00'); and with the $GPRESET option, lines are drawn in green (Z'00FF00'). Setting the write mode to $GPSET causes lines to be drawn in the graphics color.

Example

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) result, oldmode
INTEGER(4) oldcolor
TYPE (xycoord) xy

oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
CALL MOVETO(INT2(0), INT2(0), xy)
result = LINETO(INT2(200), INT2(200)) ! purple

oldmode = SETWRITEMODE($GAND)
CALL MOVETO(INT2(50), INT2(0), xy)
result = LINETO(INT2(250), INT2(200)) ! red
END
```

POLYGON
**SETWSIZEQQ (W*S)**

*QuickWin Function:* Sets the size and position of a window.

**Module**
USE IFQWIN

**Syntax**

result = SETWSIZEQQ (unit, winfo)

unit

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5, and 6 refer to the default startup window only if the program does not explicitly open them with the OPEN statement. To set the size of the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW (defined in IFQWIN.F90).

When called from INITIALSETTINGS, SETWSIZEQQ behaves slightly differently than when called from a user routine after initialization. See below under Results.

winfo

(Input) Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

```plaintext
TYPE QWINFO
  INTEGER(2) TYPE   ! request type
  INTEGER(2) X     ! x coordinate for upper left
  INTEGER(2) Y     ! y coordinate for upper left
  INTEGER(2) H     ! window height
  INTEGER(2) W     ! window width
END TYPE QWINFO
```

This function's behavior depends on the value of QWIN$TYPE, which can be any of the following:

- QWIN$MIN - Minimizes the window.
- QWIN$MAX - Maximizes the window.
- QWIN$RESTORE - Restores the minimized window to its previous size.
- QWIN$SET - Sets the window's position and size according to the other values in qwinfo.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero (unless called from INITIALSETTINGS). If called from INITIALSETTINGS, the following occurs:

- SETWSIZEQQ always returns -1.
- Only QWIN$SET will work.
The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width specified for a frame window reflects the actual size in pixels of the frame window including any borders, menus, and status bar at the bottom.

Example

```
USE IFQWIN
INTEGER(4) result
INTEGER(2) numfonts, fontnum
TYPE (qwinfo) winfo
TYPE (xycoord) pos
! Maximize frame window
winfo%TYPE = QWIN$MAX
result = SETWSIZEQQ(QWIN$FRAMEWINDOW, winfo)
! Maximize child window
result = SETWSIZEQQ(0, winfo)
numfonts = INITIALIZEFONTS( )
fontnum = SETFONT ('t''Arial''h50w34i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT("BIG Window")
END
```

See Also
GETWSIZEQQ
INITIALSETTINGS

SHAPE

_Inquiry Intrinsic Function (Generic):_ Returns the shape of an array or scalar argument.

**Syntax**

```
result = SHAPE (source [, kind])
```

*source* (Input) Is a scalar or array. It may be of any data type. It must not be an assumed-size array, a disassociated pointer, or an allocatable array that is not allocated. It cannot be an assumed-size array.

*kind* (Input; optional) Must be a scalar integer constant expression.

**Results**

The result is a rank-one integer array whose size is equal to the rank of *source*. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is the shape of *source*, unless *source* is assumed-rank and is associated with an assumed-size array. In that case, the last element of the value returned by SHAPE is -1.

The setting of compiler options specifying integer size can affect this function.

**Example**

SHAPE (2) has the value of a rank-one array of size zero.

If B is declared as B(2:4, -3:1), then SHAPE (B) has the value (3, 5).
The following shows another example:

```fortran
INTEGER VEC(2)
REAL array(3:10, -1:3)
VEC = SHAPE(array)
WRITE(*,*), VEC ! prints 8 5
END
!
! Check if a mask is conformal with an array
REAL, ALLOCATABLE :: A(:,:,)
LOGICAL, ALLOCATABLE :: MASK(:,:,)
INTEGER B(3), C(3)
LOGICAL conform
ALLOCATE (A(5, 4, 3))
ALLOCATE (MASK(3, 4, 5))
! Check if MASK and A allocated. If they are, check
! that they have the same shape (conform).
IF(ALLOCATED(A) .AND. ALLOCATED(MASK)) THEN
  B = SHAPE(A); C = SHAPE(MASK)
  IF ((B(1) .EQ. C(1)) .AND. (B(2) .EQ. C(2)) .AND. (B(3) .EQ. C(3))) THEN
    conform = .TRUE.
  ELSE
    conform = .FALSE.
  END IF
END IF
WRITE(*,*), conform ! prints F
END
```

See Also
SIZE

**SHARED Clause**

*Parallel Directive Clause:* Specifies variables that will be shared by all the threads in a team.

**Syntax**

```
SHARED (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

All threads within a team access the same storage area for SHARED data.

**SHIFTA**

*Elemental Intrinsic Function (Specific):* Performs a right shift with fill. This function cannot be passed as an actual argument.

**Syntax**

```
result = SHIFTA (i,shift)
```
\( i \)

(Input) Must be of type integer. This is the value to be shifted.

\( \text{shift} \)

(Input) Must be of type integer. It must be nonnegative and \( \leq \text{BIT\_SIZE}(i) \). This value is the number of positions to shift.

**Results**

The result type and kind are the same as \( i \).

The result has the value obtained by shifting the bits of \( i \) to the right \( \text{shift} \) bits and replicating the leftmost bit of \( i \) in the left \( \text{shift} \) bits.

If \( \text{shift} \) is zero the result is \( i \). Bits shifted off the right end are lost.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

\[
\text{SHIFTA} \left( \text{IBSET} \left( 0, \text{BIT\_SIZE} \left( 0 \right) - 1 \right), 2 \right) \text{ is equal to SHIFTL} \left( 7, \text{BIT\_SIZE} \left( 0 \right) - 3 \right).
\]

**SHIFTL**

*Elemental Intrinsic Function (Specific):* Logically shifts an integer left by a specified number of bits. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{SHIFTL} \left( i, \text{shift} \right)
\]

\( i \)

(Input) Must be of type integer. This is the value to be shifted.

\( \text{shift} \)

(Input) Must be of type integer. The value must be nonnegative and \( \leq \text{BIT\_SIZE}(i) \). This value is the number of positions to shift.

**Results**

The result type and kind are the same as \( i \). The result is the value of \( i \) shifted left by \( \text{shift} \) bit positions. Bits shifted off the left end are lost; zeros are shifted in from the opposite end.

\[
\text{SHIFTL} \left( i, j \right) \text{ is the same as ISHFT} \left( i, j \right).
\]

**See Also**

ISHFT

**SHIFTR**

*Elemental Intrinsic Function (Specific):* Logically shifts an integer right by a specified number of bits. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{SHIFTR} \left( i, \text{shift} \right)
\]

\( i \)

(Input) Must be of type integer. This is the value to be shifted.

\( \text{shift} \)

(Input) Must be of type integer. The value must be nonnegative and \( \leq \text{BIT\_SIZE}(i) \). This value is the number of positions to shift.
**Results**

The result type and kind are the same as \( i \). The result is the value of \( i \) shifted right by \( shift \) bit positions. Bits shifted off the right end are lost; zeros are shifted in from the opposite end.

\( \text{SHIFTR} \ (i, \ j) \) is the same as \( \text{ISHFT} \ (i, \ -j) \).

**See Also**

ISHFT

**SHORT**

*Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SHORT} \ (\text{int4})
\]

\( \text{int4} \)

(Input) INTEGER(4). Value to be converted.

**Results**

The result type is INTEGER(2). The result is equal to the lower 16 bits of \( \text{int4} \). If the \( \text{int4} \) value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

**Example**

```fortran
USE IFPORT
INTEGER(4) this_one
INTEGER(2) that_one
READ(*,*) this_one
THAT_ONE = SHORT(THIS_ONE)
WRITE(*,10) THIS_ONE, THAT_ONE
END
```

**See Also**

INT

Type Declarations

**SIGN**

*Elemental Intrinsic Function (Generic):* Returns the absolute value of the first argument times the sign of the second argument.

**Syntax**

\[
\text{result} = \text{SIGN} \ (a, \ b)
\]

\( a \)

(Input) Must be of type integer or real.

\( b \)

(Input) Must have the same type as \( a \).
Results
The result type and kind are the same as $a$. The value of the result is as follows:

- $|a|$ if $b > 0$ and $-|a|$ if $b < 0$.
- $|a|$ if $b$ is of type integer and is zero.
- If $b$ is of type real and zero and compiler option assume minus0 is not specified, the value of the result is $|a|$.
- If $b$ is of type real and zero and compiler option assume minus0 is specified, the processor can distinguish between positive and negative real zero and the following occurs:
  - If $b$ is positive real zero, the value of the result is $|a|$.
  - If $b$ is negative real zero, the value of the result is $-|a|$.

The specific named versions of the function require that the arguments have the same kind parameters.

<table>
<thead>
<tr>

</tbody>
</table>

\(^1\) Or HSIGN.
\(^2\) Or JISIGN. For compatibility with older versions of Fortran, ISIGN is treated as a generic function.
\(^3\) The setting of compiler options specifying real size can affect SIGN and DSIGN.
\(^4\) The setting of compiler options specifying double size can affect DSIGN.

Example
SIGN (4.0, -6.0) has the value -4.0.
SIGN (-5.0, 2.0) has the value 5.0.

The following shows another example:

```
c = SIGN (5.2, -3.1) ! returns -5.2
```

See Also
ABS
assume minus0 compiler option

SIGNAL

*Portability Function:* Controls interrupt signal handling and changes the action for a specified signal.

Module
USE IFPORT
Syntax

result = SIGNAL (signum, proc, flag)

signum  (Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names are listed in a table below.

proc  (Input) Name of a signal-handler routine. It must be declared EXTERNAL and INTEGER(4). This routine is called only if flag is negative.

flag  (Input) INTEGER(4). If negative, the user's proc routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the previous value of proc associated with the specified signal. For example, if the previous value of proc was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is invalid, if the flag value is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINVAL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns -(EINVAL) and a call to IERRNO returns EINVAL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C's signal function, nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

The signal-handler argument proc accepts a single INTEGER(4) argument, which is the number of the signal to be handled. The function must use the compiler's default calling conventions. If you have used compiler options, such as option iface, to change the default conventions, add the following directive to the signal handler function to reset the calling conventions:

!DIR$ ATTRIBUTES DEFAULT :: the-routine-specified-in-proc

The signal-handler function returns an INTEGER(4) value. If the function has handled the signal, the value returned is an integer, but the value is not used.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

- Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
- Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
- Functions that generate a system call (such as TIME).

The following table lists signals, their names and values:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABRT</td>
<td>6</td>
<td>Abnormal termination</td>
</tr>
<tr>
<td>SIGFPE</td>
<td>8</td>
<td>Floating-point error</td>
</tr>
</tbody>
</table>
Symbolic name | Number | Description
--- | --- | ---
SIGKILL | 9 | Kill process
SIGILL | 4 | Illegal instruction
SIGINT | 2 | CTRL+C signal
SIGSEGV | 11 | Illegal storage access
SIGTERM | 15 | Termination request

1SIGKILL can be neither caught nor ignored.

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

Example

```
USE IFPORT
EXTERNAL h_abort
INTEGER(4) :: h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler #1. Return = ', iret1

procnum = getpid( )
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END

! Signal-handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
!DIR$ ATTRIBUTES DEFAULT :: h_abort
WRITE(*,*) 'In signal handler function h_abort for SIG$ABORT'
WRITE(*,*) 'signum = ', sig_num
h_abort = 1
END
```

See Also
SIGNALQQ

**SIGNALQQ**

*Portability Function:* Registers the function to be called if an interrupt signal occurs.

**Module**
USE IFPORT

**Syntax**
```
result = SIGNALQQ (sig, func)
```
sig (Input) INTEGER(2). Interrupt type. One of the following constants, defined in IFPORT.F90:
• SIG$ABORT - Abnormal termination
• SIG$FPE - Floating-point error
• SIG$ILL - Illegal instruction
• SIG$INT - CTRL+CSIGNAL
• SIG$SEGV - Illegal storage access
• SIG$TERM - Termination request

func (Input) Function to be executed on interrupt. It must be declared EXTERNAL.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a positive integer if successful; otherwise, -1 (SIG$ERR).
SIGNALQQ installs the function func as the handler for a signal of the type specified by sig. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.
The argument func is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

NOTE
All signal-handler functions must be declared with the directive !DIR$ ATTRIBUTES C.

When an interrupt occurs, except a SIG$FPE interrupt, the sig argument SIG$INT is passed to func, and then func is executed.
When a SIG$FPE interrupt occurs, the function func is passed two arguments: SIG$FPE and the floating-point error code (for example, FPE$ZERODIVIDE or FPE$OVERFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPE$ and are defined in IFPORT.F90.
If func returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode.
Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).
To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.
The example below shows a signal handler for SIG$ABORT.

Example

! This program shows a signal handler for
! SIG$ABORT
USE IFPORT
INTERFACE
FUNCTION h_abort (signum)
!DIR$ ATTRIBUTES C :: h_abort
INTEGER(4) h_abort
INTEGER(2) signum
END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret

i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret

i2ret = RAISEQQ(SIG$ABORT)
WRITE(*,*) 'Raised signal. Return = ', i2ret

END

! Signal handler routine
!
INTEGER(4) FUNCTION h_abort (signum)
!DIR$ ATTRIBUTES C :: h_abort
INTEGER(2) signum
WRITE(*,*) 'In signal handler for SIG$ABORT'
WRITE(*,*) 'signum = ', signum
h_abort = 1
END

SIMD Directive (OpenMP* API)

OpenMP* Fortran Compiler Directive: Transforms a loop into a loop that will be executed concurrently using Single Instruction Multiple Data (SIMD) instructions.

Syntax
!$OMP SIMD [clause[,... clause]... ]
do-loop
[!$OMP END SIMD]

clause

Is one of the following:

- ALIGNED (list [:n])
- [NO]ASSERT
  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.
- COLLAPSE (n)
- EARLY_EXIT
Allows vectorization of multiple exit loops. When this clause is specified the following occurs:

- Each operation before the last lexical early exit of the loop may be executed as if the early exit were not triggered within the SIMD chunk.
- After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
- The last value for LINEARs and conditional LASTPRIVATEs are preserved with respect to scalar execution.
- The last value for REDUCTIONs are computed as if the last iteration in the last SIMD chunk was executed upon exiting the loop.
- The shared memory state may not be preserved with regard to scalar execution.
- Exceptions are not allowed.

When a SIMD loop is specified with the EARLY_EXIT clause, each list item specified in the LINEAR clause is computed based on the last iteration number upon exiting the loop.

- LASTPRIVATE ([CONDITIONAL:] list)
- LINEAR (var-list[: linear-step])
- PRIVATE (list)
- REDUCTION (reduction-identifier : list)
- SAFELEN($m$)

Limits the number of iterations in a SIMD chunk (set of concurrent iterations).

The $m$ must be a constant positive integer expression; it indicates the number of iterations allowed in a SIMD chunk.

When this clause is used, no two iterations executed concurrently with SIMD instructions can have a greater distance in the logical iteration space than $m$.

The number of iterations that are executed concurrently at any given time is defined by the implementation. Each concurrent iteration is executed by a different SIMD vector lane.

At most one SAFELEN clause can appear in a SIMD directive.

- SIMDLEN($n$)

Specifies the preferred number of iterations to be executed concurrently. $n$ must be a positive scalar integer constant. The number of iterations that are executed concurrently at any given time is implementation defined. Each concurrent iteration will be executed by a different SIMD lane.

If both SIMDLEN ($n$) and SAFELEN ($m$) are specified, the value of the $n$ must be less than or equal to the value of $m$.

At most one SIMDLEN clause can appear in a SIMD directive.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a SIMD directive.

A SIMD construct binds to the current task region. The binding thread set of the SIMD region is the current team.

If used, the END SIMD directive must appear immediately after the end of the loop. If you do not specify an END SIMD directive, an END SIMD directive is assumed at the end of do-loop.

The SIMD construct enables the execution of multiple iterations of the associated loops concurrently by means of SIMD instructions. No other OpenMP* Fortran construct can appear in a SIMD directive.

A SIMD region binds to the current task region. The binding thread set of the SIMD region is the current team.

When any thread encounters a SIMD construct, the iterations of the loop associated with the construct may be executed concurrently using the SIMD lanes that are available to the thread.

If an ORDERED directive with the SIMD clause is specified inside the SIMD region, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

**Example**

The following is an example using the SIMD directive:

```fortran
subroutine subr(a, b, c, n)
  implicit none
  real(kind=kind(0.0d0)),dimension(*) :: a, b, c
  integer :: n, i

  !$omp simd
  do i = 1, n
    a(i) = a(i) * b(i) + c(i)
  end do
end subroutine
```

The following example demonstrates the EARLY_EXIT clause:

```fortran
  !$omp simd early_exit
  do i = 1, n
    if (a(i) == i) exit
  enddo
```

**SIMD Loop Directive**

*General Compiler Directive:* Requires and controls SIMD vectorization of loops.

### Syntax

```bash
!DIR$ SIMD [clause[,,] clause]...
```

`clause` is an optional vectorization clause. It can be one or more of the following:

- **[NO]ASSERT**
  
  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.

- **FIRSTPRIVATE(list)**

  *list* is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, each variable has its initial value broadcast to all private instances for each iteration upon entering the SIMD loop.

  A variable in a FIRSTPRIVATE clause can appear in a LASTPRIVATE clause.

  A variable in a FIRSTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LASTPRIVATE(list)**

  *list* is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable).

  A variable in a LASTPRIVATE clause can appear in a FIRSTPRIVATE clause.

  A variable in a LASTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LINEAR(var1:step1 [, var2:step2]...)**

  *var* is a scalar variable.

  *step* is a positive, integer, scalar expression.
For each iteration of a scalar loop, \textit{var1} is incremented by \textit{step1}, \textit{var2} is incremented by \textit{step2}, and so on. Therefore, every iteration of the vector loop increments the variables by \(VL \times \text{step1}, VL \times \text{step2}, \ldots\), to \(VL \times \text{stepN}\), respectively. If more than one step is specified for a \textit{var}, a compile-time error occurs. Multiple LINEAR clauses are merged as a union.

A variable in a LINEAR clause cannot appear in a REDUCTION, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

- **PRIVATE** \((\text{list})\)

  \text{list}

  Is a list of names of one or more variables or common blocks that are accessible to the scoping unit. A variable that is part of another variable (for example, subobjects such as an array or structure element) cannot appear. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

  Causes each variable to be private to each iteration of a loop. Its initial and last values are undefined upon entering and exiting the SIMD loop. Multiple PRIVATE clauses are merged as a union.

  A variable in a PRIVATE clause cannot appear in a LINEAR, REDUCTION, FIRSTPRIVATE, or LASTPRIVATE clause.

- **REDUCTION** \((\text{reduction-identifier} : \text{var1} [, \text{var2}]...)\)

  \text{reduction-identifier}

  Is a predefined reduction identifier ( +, *, -, .AND., .OR., .EQV., or .NEQV.), or an accessible user-defined reduction identifier declared in a DECLARE REDUCTION directive.

  \text{var}

  Is a scalar variable.

  Applies the vector reduction indicated by \text{reduction-identifier} to \textit{var1}, \textit{var2}, ..., \textit{varN}. A SIMD directive can have multiple REDUCTION clauses using the same or different operators. If more than one reduction operator is associated with a \textit{var}, a compile-time error occurs.

  A variable in a REDUCTION clause cannot appear in a LINEAR, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

- **[NO]VECREMAINDER**

- **VECTORLENGTH** \((n1 [, n2]...)\)

  \text{n}

  Is a vector length (VL). It must be an integer that is a power of 2; the value must be 2, 4, 8, 16, 32 or 64. If you specify more than one \text{n}, the vectorizer will choose the VL from the values specified.

  Causes each iteration in the vector loop to execute the computation equivalent to \text{n} iterations of scalar loop execution.
The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- **VECTORLENGTHFOR** *(data-type)*

  *data-type* is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
<tr>
<td>REAL</td>
<td>Default REAL</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>REAL (KIND=4)</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>REAL (KIND=8)</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Default COMPLEX</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>COMPLEX (KIND=4)</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>COMPLEX (KIND=8)</td>
</tr>
</tbody>
</table>

Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution where *n* is computed from \[ \frac{\text{size of vector register}}{\text{sizeof(data_type)}} \].

For example, VECTORLENGTHFOR (REAL (KIND=4)) results in *n*=4 for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and *n*=8 for AVX target (packed float operations available on 256-bit YMM registers).

VECTORLENGTHFOR(INTEGER (KIND=4)) results in *n*=4 for SSE2 to AVX targets.

The VECTORLENGTHFOR and VECTORLENGTH clauses are mutually exclusive. You cannot use the VECTORLENGTHFOR clause with the VECTORLENGTH clause, and vice versa.

Multiple VECTORLENGTHFOR clauses cause a syntax error.
Without explicit VECTORLENGTH and VECTORLENGTHFOR clauses, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

If you specify the SIMD directive with no clause, default rules are in effect for variable attributes, vector length, and so forth.

If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

You can only specify a particular variable in at most one instance of a PRIVATE, LINEAR, or REDUCTION clause.

If the compiler is unable to vectorize a loop, a warning occurs by default. However, if ASSERT is specified, an error occurs instead.

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

A SIMD loop may contain one or more nested loops or be contained in a loop nest. Only the loop preceded by the SIMD directive is processed for SIMD vectorization.

The vectorization performed on this loop by the SIMD directive overrides any setting you may specify for options -fp-model (Linux* and macOS*) and /fp (Windows*) for this loop.

Note that the SIMD directive may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the SIMD directive:

- The countable loop for the SIMD directive has to conform to the DO-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating-point numbers, or single- or double-precision complex numbers.
- A SIMD directive loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable the SIMD transformations for vectorization, specify option -no-simd (Linux* and macOS*) or /Qsimd- (Windows*).

To disable transformations that enable more vectorization, specify options -no-vec-no-simd (Linux and macOS*) or /Qvec-/Qsimd- (Windows).

**Example**

Consider the following:

```fortran
... subroutine add(A, N, X)
   integer N, X
   real    A(N)
cDIR$ SIMD
   DO I=X+1, N
       A(I) = A(I) + A(I-X)
   END DO
end subroutine add
```
When the program containing this subroutine is compiled, the DO loop will be vectorized.

Because no optional clause was specified for the directive, default rules will apply for variable attributes, vector length, and so forth.

**SIN**

*Elemental Intrinsic Function (Generic): Produces the sine of an argument.*

**Syntax**

result = SIN (x)

x  

(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

**Results**

The result type and kind are the same as x.
If x is of type real, the result is a value in radians.
If x is of type complex, the real part of the result is a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSIN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSIN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CSIN ¹</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>CDSIN ²</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSIN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying real size can affect CSIN.
²This function can also be specified as ZSIN.

**Example**

SIN (2.0) has the value 0.9092974.
SIN (0.8) has the value 0.7173561.
**SIND**

*Elemental Intrinsic Function (Generic): Produces the sine of an argument.*

**Syntax**

\[ \text{result} = \text{SIND} \,(x) \]

\( x \) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIND</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSIND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSIND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

SIND (2.0) has the value 3.4899496E-02.

SIND (0.8) has the value 1.3962180E-02.

---

**SINGLE**

*OpenMP* Fortran Compiler Directive: Specifies that a block of code is to be executed by only one thread in the team at a time.

**Syntax**

\[ \text{!$OMP SINGLE [clause[, ] clause] ... ] block} \]

\[ \text{!$OMP END SINGLE [modifier]} \]

clause Is one of the following:
- FIRSTPRIVATE (list)
- PRIVATE (list)

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

modifier Is one of the following:
- COPYPRIVATE (list)
- NOWAIT

The binding thread set for a SINGLE construct is the current team. A SINGLE region binds to the innermost enclosing parallel region.

Threads in the team that are not executing this directive wait at the END SINGLE directive unless NOWAIT is specified.
SINGLE directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

**Example**

In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
  CALL WORK(X)
!$OMP BARRIER
!$OMP SINGLE
  CALL OUTPUT(X)
  CALL INPUT(Y)
!$OMP END SINGLE
  CALL WORK(Y)
!$OMP END PARALLEL
```

You should not make assumptions as to which thread executes the SINGLE section. All other threads skip the SINGLE section and stop at the barrier at the END SINGLE construct. If other threads can proceed without waiting for the thread executing the SINGLE section, you can specify NOWAIT in the END SINGLE directive.

**See Also**

- OpenMP Fortran Compiler Directives
- Syntax Rules for Compiler Directives
- Parallel Processing Model for information about Binding Sets

**SINH**

*Elemental Intrinsic Function (Generic): Produces a hyperbolic sine.*

**Syntax**

```fortran
result = SINH (x)
```

x (Input) Must be of type real or complex.

**Results**

The result type and kind are the same as x.

If x is of type complex, the imaginary part of the result is in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSINH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSINH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

SINH (2.0) has the value 3.626860.
SINH (0.8) has the value 0.8881060.
SIZE Function

Inquiry Intrinsic Function (Generic): Returns the total number of elements in an array, or the extent of an array along a specified dimension.

Syntax

result = SIZE (array [, dim] [, kind])

array
  (Input) Must be an array; it can be assumed-rank. It can be of any data type. It must not be a disassociated pointer or an allocatable array that is not allocated. It can be an assumed-size array if dim is present with a value less than the rank of array.

dim
  (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.

kind
  (Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

In general, if dim is present, the result is the extent of dimension dim in array; otherwise, the result is the total number of elements in array. However, the following exceptions apply:

- If array is assumed-rank and associated with an assumed-size array and dim is present with a value equal to the rank of ARRAY, the result has a value of -1.
- If dim is absent and array is assumed-rank, the result has a value equal to \( \text{PRODUCT(SHAPE(ARRAY, KIND))} \).

The setting of compiler options specifying integer size can affect this function.

Example

If B is declared as B(2:4, -3:1), then SIZE (B, DIM=2) has the value 5 and SIZE (B) has the value 15.

The following shows another example:

```fortran
REAL(8) array (3:10, -1:3)
INTEGER i
i = SIZE(array, DIM = 2) ! returns 5
i = SIZE(array)          ! returns 40
```

See Also

SHAPE
Character Count Specifier

SIZEOF

Inquiry Intrinsic Function (Generic): Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.

Syntax

result = SIZEOF (x)
x

(Input) Can be a scalar or array. It may be of any data type. It must not be an assumed-size array.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result value is the number of bytes of storage used by x. If x is of derived type, the result includes storage used by padding and descriptors for pointer or allocatable components, if any, but not the storage used for the data of pointer or allocatable components.

Example

```
SIZEOF (3.44)         ! has the value 4
SIZEOF ('SIZE')       ! has the value 4
```

See Also

C_SIZEOF

SLEEP

**Portability Subroutine:** Suspends the execution of a process for a specified interval.

Module

USE IFPORT

Syntax

```
CALL SLEEP (time)
```

*time*  

(Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.

Example

```
USE IFPORT
integer(4) hold_time
hold_time = 1    ! lets the loop execute
DO WHILE (hold_time .NE. 0)
   write(*,'(A)') "Enter the number of seconds to suspend"
   read(*,*) hold_time
   CALL SLEEP (hold_time)
END DO
END
```

See Also

SLEEPQQ

SLEEPQQ

**Portability Subroutine:** Delays execution of the program for a specified duration.
**Module**

USE IFPORT

**Syntax**

CALL SLEEPQQ (duration)

*duration* (Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).

**Example**

```
USE IFPORT
INTEGER(4) delay, freq, duration
delay = 2000
freq = 4000
duration = 1000
CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)
END
```

**SNGL**

*Converts a REAL value to a default REAL result.*

**See Also**

See REAL function.

**SORTQQ**

*Portability Subroutine: Sorts a one-dimensional array. The array elements cannot be derived types or record structures.*

**Module**

USE IFPORT

**Syntax**

CALL SORTQQ (adrarray,count,size)

*adrarray* (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

*count* (Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. On input, number of elements in the array to be sorted. On output, number of elements actually sorted.

To be certain that SORTQQ is successful, compare the value returned in *count* to the value you provided. If they are the same, then SORTQQ sorted the correct number of elements.

*size* (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:
<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**Caution**
The location of the array must be passed by address using the LOC function. This defeats Fortran type-checking, so you must make certain that the `count` and `size` arguments are correct.

If you pass invalid arguments, SORTQQ attempts to sort random parts of memory. If the memory it attempts to sort is allocated to the current process, that memory is sorted; otherwise, the operating system intervenes, the program is halted, and you get a General Protection Violation message.

**Example**

```fortran
! Sort a 1-D array
! USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 2223, 67/
! Sort the array
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)
! Display the sorted array
DO i = 1, 10
   WRITE (*, 9000) i, array (i) 9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END
```

**See Also**
BSEARCHQQ
LOC

**SPACING**

*Elemental Intrinsic Function (Generic):* Returns the absolute spacing of model numbers near the argument value.

**Syntax**

```fortran
result = SPACING (x)
```

*x* (Input) Must be of type real.
**Results**

The result type and kind are the same as \( x \). The result has the value \( b \times 10^e \). Parameters \( b \), \( e \), and \( p \) are defined in Model for Real Data. If the result value is outside of the real model range, the result is \( \text{TINY}(x) \).

**Example**

If 3.0 is a REAL(4) value, \( \text{SPACING}(3.0) \) has the value \( 2^{-22} \).

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = SPACING(3.0) ! returns 2.384186E-07
res4 = SPACING(-3.0) ! returns 2.384186E-07
r2   = 487923.3
res8 = SPACING(r2) ! returns 5.820766091346741E-011
```

**See Also**

- \( \text{TINY} \)
- \( \text{RRSPACING} \)
- Data Representation Models

**SPLITPATHQQ**

*Portability Function*: Breaks a file path or directory path into its components.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPLITPATHQQ(path, drive, dir, name, ext)
```

- **path**
  - (Input) Character*(*). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in `path`.

- **drive**
  - (Output) Character*(*). Drive letter followed by a colon.

- **dir**
  - (Output) Character*(*). Path of directories, including the trailing slash.

- **name**
  - (Output) Character*(*). Name of file or, if no file is specified in `path`, name of the lowest directory. A file name must not include an extension.

- **ext**
  - (Output) Character*(*). File name extension, if any, including the leading period (\).

**Results**

The result type is INTEGER(4). The result is the length of `dir`.

The `path` parameter can be a complete or partial file specification.

\( \$\text{MAXPATH} \) is a symbolic constant defined in module `IFPORT.F90` as 260.
Example

USE IFPORT
CHARACTER($MAXPATH) buf
CHARACTER(3)        drive
CHARACTER(256)      dir
CHARACTER(256)      name
CHARACTER(256)      ext
CHARACTER(256)      file
INTEGER(4)          length

buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
END

See Also
FULLPATHQQ

SPORT_CANCEL_IO (W*S)

Serial Port I/O Function: Cancels any I/O in progress to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_CANCEL_IO (port)

port  (Input) Integer. The port number.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE
This call also kills the thread that keeps an outstanding read operation to the serial port. This call must be done before any of the port characteristics are modified.

Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CANCEL_IO( 2 )
END

See Also
Communications and Communications Functions in the Microsoft* Platform SDK
**SPORT_CONNECT (W*S)**

*Serial Port I/O Function:* Establishes the connection to a serial port and defines certain usage parameters.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_CONNECT (port [,options])
```

*port* (Input) Integer. The port number of connection. The routine will open COM \( n \), where \( n \) is the port number specified.

*options* (Input; optional) Integer. Defines the connection options. These options define how the `nnn_LINE` routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator `.OR.` should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>DL TERM_LF</td>
<td>Causes SPORT_READ_LINE to terminate READ when a LF is encountered.</td>
</tr>
<tr>
<td>DL TERM_CRLF</td>
<td>Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If *options* is not specified, the following occurs by default:

```fortran
```

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

**Results**

The result type is `INTEGER(4)`. The result is zero if successful; otherwise, a Windows* error value.
Example

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT( 2 )
END
```

SPORT_RELEASE

Communications and Communications Functions in the Microsoft* Platform SDK

**SPORT_CONNECT_EX (W*S)**

*Serial Port I/O Function:* Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_CONNECT_EX (port [,options] [,BufferSize])
```

- **port** (Input) Integer. The port number of connection. The routine will open COM n, where n is the port number specified.
- **options** (Input; optional) Integer. Defines the connection options. These options define how the nnn_LINE routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>DL_TERM_LF</td>
<td>Causes SPORT_READ_LINE to terminate READ when a LF is encountered.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TERM_CRLF</td>
<td>Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If `options` is not specified, the following occurs by default:

```
(DL_OUT_CR .OR. DL_TERM_CR .OR. DL_TOSS_CR .OR. DL_TOSS_LF)
```

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

**BufferSize**

(Input; optional) Integer. Size of the internal buffer for data reception. If `BufferSize` is not specified, the size of the buffer is 16384 bytes (the default).

The size of the buffer must be 4096 bytes or larger. If you try to specify a size smaller than 4096 bytes, your specification will be ignored and the buffer size will be set to 4096 bytes.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT_EX( 2, BufferSize = 8196 )
END
```

**See Also**

SPORT_CONNECT
SPORT_RELEASE
Communications and Communications Functions in the Microsoft* Platform SDK

**SPORT_GET_HANDLE (W*S)**

**Serial Port I/O Function:** Returns the Windows* handle associated with the communications port. This is the handle that was returned by the Windows API `CreateFile`.

**Module**

USE IFPORT

**Syntax**

```
result = SPORT_GET_HANDLE (port, handle)
```

- **port**
  - (Input) Integer. The port number.

- **handle**
  - (Output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This is the Windows handle that was returned from `CreateFile( )` on the serial port.
Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Example

USE IFPORT
INTEGER(4) iresult
INTEGER(KIND=INT_PTR_KIND( )) handle
iresult = SPORT_GET_HANDLE( 2, handle )
END

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_GET_STATE (W*S)
Serial Port I/O Function: Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module
USE IFPORT

Syntax

result = SPORT_GET_STATE (port [,baud] [,parity] [,dbits] [,sbits])

port
(Input) Integer. The port number.

baud
(Output; optional) Integer. The baud rate of the port.

parity
(Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits
(Output; optional) Integer. The data bits for the port.

sbits
(Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example

USE IFPORT
INTEGER(4) iresult
INTEGER baud
INTEGER parity
INTEGER dbits
INTEGER sbits
iresult =  SPORT_GET_STATE( 2, baud, parity, dbits, sbits )
END

See Also
SPORT_SET_STATE
Communications and Communications Functions in the Microsoft* Platform SDK
SPORT_GET_STATE_EX (W*S)

Serial Port I/O Function: Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.

Module

USE IFPORT

Syntax

port (Input) Integer. The port number.

baud (Input; optional) Integer. The baud rate of the port.

parity (Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits (Output; optional) Integer. The data bits for the port.

sbits (Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Binmode (Output; optional) Integer. 1 if binary mode is enabled; otherwise, 0. Currently, the value of this parameter is always 1.

DTRcntrl (Output; optional) Integer. 1 if DTR (data-terminal-ready) flow control is used; otherwise, 0.

RTScntrl (Output; optional) Integer. 1 if RTS (request-to-send) flow control is used; otherwise, 0.

OutCTSFlow (Output; optional) Integer. 1 if the CTS (clear-to-send) signal is monitored for output flow control; otherwise, 0.

OutDSRFlow (Output; optional) Integer. 1 if the DSR (data-set-ready) signal is monitored for output flow control; otherwise, 0.

DSRSense (Output; optional) Integer. 1 if the communications driver is sensitive to the state of the DSR signal; otherwise, 0.

OutXonOff (Output; optional) Integer. 1 if XON/XOFF flow control is used during transmission; otherwise, 0.

InXonOff (Output; optional) Integer. 1 if XON/XOFF flow control is used during reception; otherwise, 0.

XonLim (Output; optional) Integer. The minimum number of bytes accepted in the input buffer before the XON character is set.
XoffLim (Output; optional) Integer. The maximum number of bytes accepted in the input buffer before the XOFF character is set.

TXContOnXoff (Output; optional) Integer. 1 if transmission stops when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

ErrAbort (Output; optional) Integer. 1 if read and write operations are terminated when an error occurs; otherwise, 0.

ErrCharEnbl (Output; optional) Integer. 1 if bytes received with parity errors are replaced with the ErrChar character; otherwise, 0.

NullStrip (Output; optional) Integer. 1 if null bytes are discarded; otherwise, 0.

XonChar (Output; optional) Character. The value of the XON character that is used for both transmission and reception.

XoffChar (Output; optional) Character. The value of the XOFF character that is used for both transmission and reception.

ErrChar (Output; optional) Character. The value of the character that is used to replace bytes received with parity errors.

EofChar (Output; optional) Character. The value of the character that is used to signal the end of data.

EvtChar (Output; optional) Character. The value of the character that is used to signal an event.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example
USE IFPORT
INTEGER(4) iresult
INTEGER(4) port, baud, parity, dbits, sbits
INTEGER(4) OutXonOff, InXonOff, OutDSRFlow
INTEGER(4) OutCTSFlow, DTRcntrl, RTScntrl
INTEGER(4) DSRSense, XonLim, XoffLim
CHARACTER(1) XonChar, XoffChar
iresult = SPORT_GET_STATE_EX(port, baud, parity, dbits, sbits, &
OutXonOff=OutXonOff, InXonOff=InXonOff, OutDSRFlow=OutDSRFlow, &
OutCTSFlow=OutCTSFlow, DTRcntrl=DTRcntrl, RTScntrl=RTScntrl, &
DSRSense = DSRSense, XonLim = XonLim, XoffLim = XoffLim)
END

SPORT_GET_TIMEOUTS (W*S)
Serial Port I/O Function: Returns the user selectable timeouts for the serial port.
Module
USE IFPORT

Syntax
result = SPORT_GET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])

port
(Input) Integer. The port number.

rx_int
(Output; optional) INTEGER(4). The receive interval timeout value.

tx_tot_mult
(Output; optional) INTEGER(4). The transmit multiplier part of the timeout value.

tx_tot_const
(Output; optional) INTEGER(4). The transmit constant part of the timeout value.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example
USE IFPORT
INTEGER(4) iresult
INTEGER*4 rx_int
INTEGER*4 tx_tot_mult
INTEGER*4 tx_tot_const

iresult = SPORT_GET_TIMEOUTS( 2, rx_int, tx_tot_mult, tx_tot_const )
END

See Also
SPORT_SET_TIMEOUTS
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_PEEK_DATA (W*S)
Serial Port I/O Function: Returns information about the availability of input data.

Module
USE IFPORT

Syntax
result = SPORT_PEEK_DATA (port [,present] [,count])

port
(Input) Integer. The port number.

present
(Output; optional) Integer. 1 if data is present, 0 if no data has been read.

count
(Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.
NOTE
CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Example

USE IFPORT
INTEGER(4) iresult
INTEGER    present
INTEGER    count

iresult = SPORT_PEEK_DATA( 2, present, count )
END

SPORT_CONNECT
SPORT_READ_DATA
SPORT_PEEK_LINE

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_PEEK_LINE (W*S)

Serial Port I/O Function: Returns information about the availability of input records.

Module
USE IFPORT

Syntax

result = SPORT_PEEK_LINE (port [,present] [,count])

port  (Input) Integer. The port number.
present  (Output; optional) Integer. 1 if data is present, 0 if no data has been read.
count  (Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.

NOTE
CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Example

USE IFPORT
INTEGER(4) iresult
INTEGER    present

IMAGE
INTEGER count
iresult = SPORT_PEEK_LINE( 2, present, count )
END

SPORT_PURGE (W*S)
Serial Port I/O Function: Executes the Windows* API communications function PurgeComm on the specificed port.

Module
USE IFPORT

Syntax
result = SPORT_PURGE (port,function)
port (Input) Integer. The port number.
function (Input) INTEGER(4). The function for PurgeComm (see the Windows* documentation).

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Example
USE IFWINTY
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_PURGE( 2, (PURGE_TXABORT .or. PURGE_RXABORT) )
END

See Also
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_READ_DATA (W*S)
Serial Port I/O Function: Reads available data from the specified port. This routine stalls until at least one character has been read.

Module
USE IFPORT

Syntax
result = SPORT_READ_DATA (port,buffer[,count])
**port**  
(Input) Integer. The port number.

**buffer**  
(Output) Character*(*) The data that was read.

**count**  
(Output; optional) Integer. The count of bytes read.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

---

**NOTE**

CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

---

**Example**

```
USE IFPORT
INTEGER(4)      iresult
INTEGER         count
CHARACTER*1024   rbuff

iresult = SPORT_READ_DATA( 2, rbuff, count )
END
```

**See Also**

SPORT_READ_LINE  
SPORT_WRITE_DATA

Communications and Communications Functions in the Microsoft* Platform SDK

**SPORT_READ_LINE (W*S)**

**Serial Port I/O Function:** Reads a record from the specified port. This routine stalls until at least one record has been read.

**Module**

USE IFPORT

**Syntax**

```plaintext
result = SPORT_READ_LINE (port, buffer[, count])
```

**port**  
(Input) Integer. The port number.

**buffer**  
(Output) Character*(*) The data that was read.

**count**  
(Output; optional) Integer. The count of bytes read.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.
NOTE
CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Example
USE IFPORT
INTEGER(4) iresult
INTEGER count
CHARACTER*1024 rbuff

iresult = SPORT_READ_LINE( 2, rbuff, count )
END

See Also
SPORT_CONNECT
SPORT_PEEK_LINE
SPORT_READ_DATA
SPORT_WRITE_LINE
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_RELEASE (W*S)
Serial Port I/O Function: Releases a serial port that was previously connected when SPORT_CONNECT was specified.

Module
USE IFPORT

Syntax
result = SPORT_RELEASE (port)

port (Input) Integer. The port number.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_READ_LINE( 2 )
END

See Also
SPORT_CONNECT
Communications and Communications Functions in the Microsoft* Platform SDK
SPORT_SET_STATE (W*S)

Serial Port I/O Function: Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module
USE IFPORT

Syntax

result = SPORT_SET_STATE (port [,baud] [,parity] [,dbits] [,sbits])

port (Input) Integer. The port number.
baud (Input; optional) Integer. The baud rate of the port.
parity (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
dbits (Input; optional) Integer. The data bits for the port.
sbits (Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.
The following restrictions apply:
- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

NOTE
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Example

USE IFPORT
INTEGER(4) iresult
iresult =  SPORT_SET_STATE( 2, 9600, 0, 7, 0 )
END

See Also
SPORTCANCEL_IO
SPORTGET_STATE
Communications, Communications Functions, and SetCommState in the Microsoft* Platform SDK
**SPORT_SET_STATE_EX (WS)**

**Serial Port I/O Function:** Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.

### Module

**USE IFPORT**

### Syntax

```fortran
```

- **port** (Input) Integer. The port number.
- **baud** (Input; optional) Integer. The baud rate of the port.
- **parity** (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
- **dbits** (Input; optional) Integer. The data bits for the port.
- **sbits** (Input; optional) Integer. The stop bits for the port.
- **Binmode** (Input; optional) Integer. 1 if binary mode should be enabled; otherwise, 0. Currently, if this parameter is used, the value must be 1.
- **DTRcntrl** (Input; optional) Integer. 1 if DTR (data-terminal-ready) flow control should be used; otherwise, 0.
- **RTScntrl** (Input; optional) Integer. 1 if RTS (request-to-send) flow control should be used; otherwise, 0.
- **OutCTSFlow** (Input; optional) Integer. 1 if the CTS (clear-to-send) signal should be monitored for output flow control; otherwise, 0.
- **OutDSRFlow** (Input; optional) Integer. 1 if the DSR (data-set-ready) signal should be monitored for output flow control; otherwise, 0.
- **DSRSense** (Input; optional) Integer. 1 if the communications driver should be sensitive to the state of the DSR signal; otherwise, 0.
- **OutXonOff** (Input; optional) Integer. 1 if XON/XOFF flow control should be used during transmission; otherwise, 0.
- **InXonOff** (Input; optional) Integer. 1 if XON/XOFF flow control should be used during reception; otherwise, 0.
- **XonLim** (Input; optional) Integer. The minimum number of bytes that should be accepted in the input buffer before the XON character is set.
**XoffLim**
(Input; optional) Integer. The maximum number of bytes that should be accepted in the input buffer before the XOFF character is set.

**TXContOnXoff**
(Input; optional) Integer. 1 if transmission should be stopped when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

**ErrAbort**
(Input; optional) Integer. 1 if read and write operations should be terminated when an error occurs; otherwise, 0.

**ErrCharEnbl**
(Input; optional) Integer. 1 if bytes received with parity errors should be replaced with the ErrChar character; otherwise, 0.

**NullStrip**
(Input; optional) Integer. 1 if null bytes should be discarded; otherwise, 0.

**XonChar**
(Input; optional) Character. The value of the XON character that should be used for both transmission and reception.

**XoffChar**
(Input; optional) Character. The value of the XOFF character that should be used for both transmission and reception.

**ErrChar**
(Input; optional) Character. The value of the character that should be used to replace bytes received with parity errors.

**EofChar**
(Input; optional) Character. The value of the character that should be used to signal the end of data.

**EvtChar**
(Input; optional) Character. The value of the character that should be used to signal an event.

**fZeroDCB**
(Input; optional) Integer. 1 if all settings of the communications port should be set to zero before parameters are set; otherwise, 0.

**Results**
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

The following restrictions apply:

- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

**NOTE**
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

**Example**

```
USE IPORT
INTEGER(4) iresult
iresult =  SPORT_SET_STATE_EX( 2, 9600, 0, 7, 1, OutXonOff=1, InXonOff=1, &
   XonLim=1024, XoffLim=512, XonChar=CHAR(17), XoffChar=CHAR(19), &
   fZeroDCB=1 )
END
```
SPORT_SET_TIMEOUTS (W*S)

Serial Port I/O Function: Sets the user selectable timeouts for the serial port.

Module
USE IFPORT

Syntax
result = SPORT_SET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>port</td>
<td>(Input) Integer. The port number.</td>
</tr>
<tr>
<td>rx_int</td>
<td>(Input; optional) INTEGER(4). The receive interval timeout value.</td>
</tr>
<tr>
<td>tx_tot_mult</td>
<td>(Input; optional) INTEGER(4). The transmit multiplier part of the timeout value.</td>
</tr>
<tr>
<td>tx_tot_const</td>
<td>(Input; optional) INTEGER(4). The transmit constant part of the timeout value.</td>
</tr>
</tbody>
</table>

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_TIMEOUTS( 2, 100, 0, 1000 )
END

See Also
SPORT_CANCEL_IO
SPORT_GET_TIMEOUTS

SPORT_SHOW_STATE (W*S)

Serial Port I/O Function: Displays the state of a port to standard output.
Module
USE IFPORT

Syntax
result = SPORT_SHOW_STATE (port, level)

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>port</td>
<td>(Input) Integer. The port number.</td>
</tr>
<tr>
<td>level</td>
<td>(Input) Integer. Controls the level of detail displayed as follows:</td>
</tr>
<tr>
<td>0</td>
<td>Basic one line display</td>
</tr>
<tr>
<td>1</td>
<td>Basic information</td>
</tr>
<tr>
<td>2</td>
<td>Add modem signal control flow information</td>
</tr>
<tr>
<td>3</td>
<td>Add XON/XOFF information</td>
</tr>
<tr>
<td>4</td>
<td>Add event character information</td>
</tr>
<tr>
<td>11</td>
<td>Add timeout information</td>
</tr>
<tr>
<td>901</td>
<td>Add debug information</td>
</tr>
</tbody>
</table>

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Example
USE IFPORT
INTEGER(4) iresult
iresult =  SPORT_SHOW_STATE( 2, 0 )
END

See Also
SPORT_CANCEL_IO
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_SPECIAL_FUNC (W*S)
Serial Port I/O Function: Executes the Windows* API communications function EscapeCommFunction on the specified port.

Module
USE IFPORT

Syntax
result = SPORT_SPECIAL_FUNC (port, function)
port  
(Input) Integer. The port number.

function
 INPUT INTEGER(4). The function to perform.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, the result is a Windows* error value.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SPECIAL_FUNC( 2, ? )
END

See Also
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_WRITE_DATA (W*S)
Serial Port I/O Function: Outputs data to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_WRITE_DATA (port, data[, count])

port  
(Input) Integer. The port number.

data  
(Input) Character*(*). The data to be output.

count
(Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE
When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count contains the number of bytes that were really written.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_DATA( 2, 'ATZ'//CHAR(13), 0 )
END
See Also
SPORT_WRITE_LINE
SPORT_READ_DATA

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_WRITE_LINE (W*S)

Serial Port I/O Function: Outputs data, followed by a record terminator, to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_WRITE_LINE (port, data[, count])

port (Input) Integer. The port number.
data (Input) Character*(*). The data to be output.
count (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

After the data is output, a line terminator character is added based on the mode used during the SPORT_CONNECT( ) call.

NOTE
When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count contains the number of bytes that were really written.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_LINE( 2, 'ATZ', 0 )
END

See Also
SPORT_CONNECT
SPORT_WRITE_DATA
SPORT_READ_DATA

Communications and Communications Functions in the Microsoft* Platform SDK
**SPREAD**

**Transformational Intrinsic Function (Generic):**

Creates a replicated array with an added dimension by making copies of existing elements along a specified dimension.

**Syntax**

```
result = SPREAD (source, dim, ncopies)
```

- **source** (Input) Must be a scalar or array. It may be of any data type. The rank must be less than 31.
- **dim** (Input) Must be scalar and of type integer. It must have a value in the range 1 to \( n + 1 \) (inclusive), where \( n \) is the rank of \( source \).
- **ncopies** Must be scalar and of type integer. It becomes the extent of the additional dimension in the result.

**Results**

The result is an array of the same type as \( source \) and of rank that is one greater than \( source \).

If \( source \) is an array, each array element in dimension \( dim \) of the result is equal to the corresponding array element in \( source \).

If \( source \) is a scalar, the result is a rank-one array with \( ncopies \) elements, each with the value \( source \).

If \( ncopies \) less than or equal to zero, the result is an array of size zero.

**Example**

**SPREAD ("B", 1, 4)** is the character array ("B", "B", "B", "B").

\( B \) is the array \([3, 4, 5]\) and \( NC \) has the value 4.

```
SPREAD (B, DIM=1, NCOPIES=NC) produces the array

[ 3 4 5 ]
[ 3 4 5 ]
[ 3 4 5 ]
[ 3 4 5 ].
```

```
SPREAD (B, DIM=2, NCOPIES=NC) produces the array

[3 3 3 3 ]
[4 4 4 4 ]
[5 5 5 5 ].
```

The following shows another example:

```
INTEGER AR1(2,3), AR2(3,2)
AR1 = SPREAD((/1,2,3/),DIM= 1,NCOPIES= 2) ! returns
!  1  2  3
!  1  2  3

AR2 = SPREAD((/1,2,3/), 2, 2) !(returns 1 1
!  2  2
!  3  3
```

PACK
RESHAPE

SQRT
Elemental Intrinsic Function (Generic): Produces
the square root of its argument.

Syntax
result = SQRT (x)

x (Input) must be of type real or complex. If x is type real, its value
must be greater than or equal to zero.

Results
The result type and kind are the same as x. The result has a value equal to the square root of x.
A result of type complex is the principal value, with the real part greater than or equal to zero.
When the real part of the result is zero, the imaginary part of the result has the same sign as the imaginary
part of x, even if the imaginary part of x is a negative real zero.

Specific Name | Argument Type | Result Type
--- | --- | ---
SQRT | REAL(4) | REAL(4)
DSQRT | REAL(8) | REAL(8)
QSQRT | REAL(16) | REAL(16)
CSQRT | COMPLEX(4) | COMPLEX(4)
CDSQRT | COMPLEX(8) | COMPLEX(8)
CQSQRT | COMPLEX(16) | COMPLEX(16)

1The setting of compiler options specifying real size can affect CSQRT.
2This function can also be specified as ZSQRT.

Example
SQRT (16.0) has the value 4.0.
SQRT (3.0) has the value 1.732051.
The following shows another example:

```fortran
! Calculate the hypotenuse of a right triangle
! from the lengths of the other two sides.
REAL sidea, sideb, hyp
sidea = 3.0
sideb = 4.0
hyp = SQRT (sidea**2 + sideb**2)
WRITE (*, 100) hyp
100 FORMAT (/ ' The hypotenuse is ', F10.3)
END
```
SRAND

**Portability Subroutine:** Seeds the random number generator used with IRAND and RAND.

**Module**
USE IFPORT

**Syntax**
CALL SRAND (iseed)

*iseed*  
(Input) INTEGER(4). Any value. The default value is 1.

SRAND seeds the random number generator used with IRAND and RAND. Calling SRAND is equivalent to calling IRAND or RAND with a new seed.

The same value for *iseed* generates the same sequence of random numbers. To vary the sequence, call SRAND with a different *iseed* value each time the program is executed.

**Example**

```fortran
!  How many random numbers out of 100 will be between .5 and .6?
USE IFPORT
ICOUNT = 0
CALL SRAND(123)
DO I = 1, 100
   X = RAND(0)
   IF ((X>.5).AND.(x<.6)) ICOUNT = ICOUNT + 1
END DO
WRITE(*,*) ICOUNT, "numbers between .5 and .6!"
END
```

**See Also**
RAND  
IRAND  
RANDOM_NUMBER  
RANDOM_SEED

SSWRQQ

**Portability Subroutine:** Returns the floating-point processor status word.

**Module**
USE IFPORT

**Syntax**
CALL SSWRQQ (status)

*status*  
(Output) INTEGER(2). Floating-point processor status word.

SSWRQQ performs the same function as the run-time subroutine GETSTATUSFPQQ and is provided for compatibility.
Example

USE IFPORT
INTEGER(2) status
CALL SSWRQQ (status)

See Also

LCWRQQ
GETSTATUSFPQQ

STAT

**Portability Function:** Returns detailed information about a file.

Module

USE IFPORT

Syntax

```
result = STAT (name, statb)
```

(name) Character(*). Name of the file to examine.

(statb) (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of `statb` contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W<em>S: Always 0, L</em>X, M*X: System dependent</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W<em>S: Always 0, L</em>X, M*X: System dependent</td>
</tr>
<tr>
<td>statb(3)</td>
<td>Access mode of the file</td>
<td>See the table in Results</td>
</tr>
<tr>
<td>statb(4)</td>
<td>Number of hard links to the file</td>
<td>W<em>S: Always 1, L</em>X, M*X: System dependent</td>
</tr>
<tr>
<td>statb(5)</td>
<td>User ID of owner</td>
<td>W<em>S: Always 1, L</em>X, M*X: System dependent</td>
</tr>
<tr>
<td>statb(6)</td>
<td>Group ID of owner</td>
<td>W<em>S: Always 1, L</em>X, M*X: System dependent</td>
</tr>
<tr>
<td>statb(7)</td>
<td>Raw device the file resides on</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td><strong>Element</strong></td>
<td><strong>Description</strong></td>
<td><strong>Values or Notes</strong></td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed(^1)</td>
<td>W*S: Only available on non-FAT file systems; undefined on FAT systems</td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified(^1)</td>
<td></td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change(^1)</td>
<td>W*S: Same as stat(10)</td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W*S: Always 1</td>
</tr>
</tbody>
</table>

\(^1\)Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4).

On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code ENOENT (the specified file could not be found). On Linux* and macOS* systems, the file inquired about must be currently connected to a logical unit and must already exist when STAT is called; if STAT fails, errno is set.

For a list of other error codes, see IERRNO.

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th><strong>Symbolic name</strong></th>
<th><strong>Constant</strong></th>
<th><strong>Description</strong></th>
<th><strong>Notes</strong></th>
</tr>
</thead>

<td>Other's execute permission</td>
<td>Same as S_IXUSR on Windows systems</td>
</tr>
</tbody>
</table>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows* systems, LSTAT returns exactly the same information as STAT. On Linux and macOS* systems, if the file denoted by `name` is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

You can also use the INQUIRE statement to get information about file properties.
Example

USE IFPORT
CHARACTER*12 file_name
INTEGER(4) info_array(12)
print *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
  print *, info_array else
  print *, 'Error = ',istatus
end if
end

FSTAT

Statement Function

Statement: Defines a function in a single statement in the same program unit in which the procedure is referenced.

Syntax

fun([d-arg [,.d-arg] ...]) = expr

fun
Is the name of the statement function.

d-arg
Is a dummy argument. A dummy argument can appear only once in any list of dummy arguments, and its scope is local to the statement function.

expr
Is a scalar expression defining the computation to be performed.

Named constants and variables used in the expression must have been declared previously in the specification part of the scoping unit or made accessible by use or host association.

If the expression contains a function or statement function reference, that function must have been defined previously as a function or statement function in the same program unit.

A statement function reference takes the following form:

fun([ a-arg[, a-arg] ...])

fun
Is the name of the statement function.

a-arg
Is an actual argument.

Description

When a statement function reference appears in an expression, the values of the actual arguments are associated with the dummy arguments in the statement function definition. The expression in the definition is then evaluated. The resulting value is used to complete the evaluation of the expression containing the function reference.

The data type of a statement function can be explicitly defined in a type declaration statement. If no type is specified, the type is determined by implicit typing rules in effect for the program unit.
Actual arguments must agree in number, order, and data type with their corresponding dummy arguments. Except for the data type, declarative information associated with an entity is not associated with dummy arguments in the statement function; for example, declaring an entity to be an array or to be in a common block does not affect a dummy argument with the same name.

The name of the statement function cannot be the same as the name of any other entity within the same program unit.

Any reference to a statement function must appear in the same program unit as the definition of that function.

A statement function reference must appear as (or be part of) an expression. The reference cannot appear on the left side of an assignment statement.

A statement function must not be provided as a procedure argument.

**Example**

The following are examples of statement functions:

```plaintext
REAL VOLUME, RADIUS
VOLUME(RADIUS) = 4.189*RADIUS**3

CHARACTER*10 CSF, A, B
CSF(A, B) = A(6:10)//B(1:5)
```

The following example shows a statement function and some references to it:

```plaintext
AVG(A, B, C) = (A+B+C)/3.
...
GRADE = AVG(TEST1, TEST2, XLAB)
IF (AVG(P, D, Q) .LT. AVG(X, Y, Z)) STOP
FINAL = AVG(TEST3, TEST4, LAB2) ! Invalid reference; implicit
... ! type of third argument does not
... ! match implicit type of dummy argument
```

Implicit typing problems can be avoided if all arguments are explicitly typed.

The following statement function definition is invalid because it contains a constant, which cannot be used as a dummy argument:

```plaintext
REAL COMP, C, D, E
COMP(C, D, E, 3.) = (C + D - E)/3.
```

The following shows another example:

```plaintext
Add (a, b) = a + b
REAL(4) y, x(6)
... DO n = 2, 6
   x(n) = Add (y, x(n-1))
END DO
```

FUNCTION
Argument Association
Use and Host Association
STATIC

**Statement and Attribute:** Controls the storage allocation of variables in subprograms (as does AUTOMATIC). Variables declared as STATIC and allocated in memory reside in the static storage area, rather than in the stack storage area.

**Syntax**

The STATIC attribute can be specified in a type declaration statement or a STATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls], STATIC [, att-ls] :: v[, v] ...
```

**Statement:**

```
STATIC[::] v[, v] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `v` Is the name of a variable or an array specification. It can be of any type.

STATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

By default, the compiler allocates local scalar variables of non-recursive subprograms in the static storage area. Local arrays, except for allocatable arrays, are in the static storage area by default.

The compiler may choose to allocate a variable in temporary (stack or register) storage if it notices that the variable is always defined before use. Appropriate use of the SAVE attribute can prevent compiler warnings if a variable is used before it is defined.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

To override any compiler option that may affect variables, explicitly specify the variables as STATIC.

**NOTE**

Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as STATIC more than once in the same scoping unit.

If the variable is a pointer, STATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as STATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
</tbody>
</table>
A variable can be specified with both the STATIC and SAVE attributes.
If a variable is in a module's outer scope, it can be specified as STATIC.

Example
The following example shows a type declaration statement specifying the STATIC attribute:

```
INTEGER, STATIC :: ARRAY_A
```

The following example shows a STATIC statement:

```
... CONTAINS
  INTEGER FUNCTION REDO_FUNC
    INTEGER I, J(10), K
    REAL C, D, E(30)
    AUTOMATIC I, J, K(20)
    STATIC C, D, E
  ...
END FUNCTION
...
INTEGER N1, N2
N1 = -1
DO WHILE (N1)
  N2 = N1*2
  call sub1(N1, N2)
  read *, N1
END DO
CONTAINS
SUBROUTINE sub1 (iold, inew)
  INTEGER, intent(INOUT):: iold
  integer, STATIC ::N3
  integer, intent(IN) :: inew
  if (iold .eq. -1) then
    N3 = iold
  end if
  print *, 'New: ', inew, 'N3: ',N3
END subroutine
!
END
```

See Also
AUTOMATIC
SAVE
Type Declarations

Compatible attributes
STOP and ERROR STOP

**Statements:** The STOP statement initiates normal termination of an image before the execution of an END statement of the main program. The ERROR STOP statement initiates error termination.

**Syntax**

STOP [stop-code]
ERROR STOP [stop-code]

*stop-code* (Optional) A message. It can be any of the following:

- A scalar character constant expression of type default character
- A non-negative integer constant less than or equal to $2^{31}-1$; leading zeros are ignored
- A scalar integer constant expression

An ERROR STOP statement can appear in a PURE procedure, a STOP statement cannot appear.

If *stop-code* is specified, the STOP or ERROR STOP statement does the following:

- Writes the specified message to the standard error device.
- Writes one or more of the following messages to the standard error device indicating which IEEE floating-point exceptions are signaling if *assume fpe-summary* is specified:
  
  - IEEE_DIVIDE_BY_ZERO is signaling
  - IEEE_INVALID is signaling
  - IEEE_OVERFLOW is signaling
  - IEEE_UNDERFLOW is signaling

- STOP initiates normal termination on the image that executes it. ERROR STOP initiates error termination.
  
  If *stop-code* is a character constant, STOP returns a status of zero and ERROR STOP returns a status of non-zero. If *stop-code* is an integer, a status equal to *stop-code* is returned.

If *stop-code* is not specified, the program is terminated, no message is printed, and a status of zero is returned.

When a program is running on multiple images, a STOP statement on one image does not affect the other images; they can continue to reference and define the coarrays located on the stopped image. An ERROR STOP initiates execution termination on all images, which may include flushing of I/O buffers, closing of I/O files, and reporting error status on one or more images.

**Effect on Windows* Systems**

In QuickWin programs, the following is displayed in a message box:

```
Program terminated with Exit Code stop-code
```

If the application has no console window, the stop-code is displayed in a message box.

**Effect on Linux* and macOS* Systems**
Operating system shells (such as bash, sh, csh, dash, etc.) work with a one byte exit status. So, when *stop-code* is an integer, only the lowest byte is significant. For example, consider the following statement:

```
STOP 99999
```

In this case, the program returns a status equal to 159 because integer 99999 = Z'1869F', and the lowest byte is equal to Z'9F', which equals 159.

### Example

The following examples show valid STOP statements:

```
STOP 98
STOP 'END OF RUN'
DO
    READ *, X, Y
    IF (X > Y) STOP 5555
END DO
```

The following shows another example:

```
OPEN(1,FILE='file1.dat', status='OLD', ERR=100)
...
100 STOP 'ERROR DETECTED!'
END
```

*EXIT*  
*Program Termination*

### STORAGE_SIZE

**Inquiry Intrinsic Function (Generic):** Returns the storage size in bits.

**Syntax**

```
result = STORAGE_SIZE (a [, kind])
```

**result**  
(Input) Must be a scalar or array. It can be of any type. If it has any deferred type parameters it must not be an unallocated allocatable variable, or a disassociated, or undefined pointer.

**a**

**kind**

(Input; optional) Must be a scalar integer constant expression.

### Results

The result is a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is the size expressed in bits for an element of an array that has the dynamic type and kind parameters of *a*.

If the type and kind parameters are such that storage association applies, the result is consistent with the named constants defined in the intrinsic module ISO_FORTRAN_ENV.

An array element may take more bits to store than a scalar, since any hardware-imposed alignment requirements for array elements may not apply to a scalar variable.
NOTE
The result is intended to be the size in memory that an object takes when it is stored. This may differ from the size it takes during expression handling (which may be the native register size) or when stored in a file. If an object is never stored in memory but only in a register, this function nonetheless returns the size it would take if it were stored in memory.

Example
STORAGE_SIZE (1.0) has the same value as the named constant NUMERIC_STORAGE_SIZE in the intrinsic module ISO_FORTRAN_ENV.

Storage Association
ISO_FORTRAN_ENV Module

STRICT and NOSTRICT

**General Compiler Directive:** STRICT disables language features not found in the language standard specified on the command line (Fortran 2008, Fortran 2003, Fortran 95, or Fortran 90). NOSTRICT (the default) enables these features.

Syntax

```fortran
!DIR$ STRICT

!DIR$ NOSTRICT
```

If STRICT is specified and no language standard is specified on the command line, the default is to disable features not found in Fortran 2008.

The STRICT and NOSTRICT directives can appear only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. STRICT and NOSTRICT cannot appear between program units, or at the beginning of internal subprograms. They do not affect any modules invoked with the USE statement in the program unit that contains them.

Example

```fortran
! NOSTRICT by default
TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff
TYPE (stuff) examp
DOUBLE COMPLEX cd  ! non-standard data type, no error
cd = (3.0D0, 4.0D0)
examp.k = 4        ! non-standard component designation, ! no error
END
SUBROUTINE STRICTDEMO( )
  !DIR$ STRICT
  TYPE stuff
    INTEGER(4) k
    INTEGER(4) m
    CHARACTER(4) name
  END TYPE stuff
  TYPE (stuff) samp
```
DOUBLE COMPLEX  cd ! ERROR
   cd = (3.0D0, 4.0D0)
samp.k = 4    ! ERROR
END SUBROUTINE

Syntax Rules for Compiler Directives
stand compiler option
Equivalent Compiler Options

STRUCTURE and END STRUCTURE

Statement: Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.

Syntax

\[
\text{STRUCTURE} [\text{/structure-name/}] [\text{field-namelist}] \\
\hspace{1cm} \text{field-declaration} \\
\hspace{2cm} [\text{field-declaration}] \\
\hspace{3cm} \ldots \\
\hspace{4cm} [\text{field-declaration}] \\
\hspace{1cm} \text{END STRUCTURE}
\]

structure-name

Is the name used to identify a structure, enclosed by slashes. Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks.

Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

field-namelist

Is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.

field-declaration

Also called the declaration body. A field-declaration consists of any combination of the following:

- Type declarations
These are ordinary Fortran data type declarations.

- **Substructure declarations**
  A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.

- **Union declarations**
  A union declaration is composed of one or more mapped field declarations.

- **PARAMETER statements**
  PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

  Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

  ```fortran
  INTEGER*4 P
  STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
  END STRUCTURE
  REAL*4 A(P)
  ```

  The Standard Fortran derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

  Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

  Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.

  In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

  By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

  To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.

  A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).

**Example**

An item can be a RECORD statement that references a previously defined structure type:

```fortran
STRUCTURE /full_address/
  RECORD /full_name/ personsname
  RECORD /address/ ship_to
  INTEGER*1 age
  INTEGER*4 phone
END STRUCTURE
```
You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address` structure defined in the previous example:

```plaintext
RECORD /full_address/ shippingaddress
```

In this case, the `age` item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.

In the following example, the declaration defines a structure named `APPOINTMENT`. `APPOINTMENT` contains the structure `DATE` (field `APP_DATE`) as a substructure. It also contains a substructure named `TIME` (field `APP_TIME`, an array), a CHARACTER*20 array named `APP_MEMO`, and a LOGICAL*1 field named `APP_FLAG`.

```plaintext
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/
  RECORD /DATE/    APP_DATE
  STRUCTURE /TIME/ APP_TIME (2)
    INTEGER*1 HOUR, MINUTE
  END STRUCTURE
  CHARACTE*20      APP_MEMO (4)
  LOGICAL*1        APP_FLAG
END STRUCTURE
```

The length of any instance of structure `APPOINTMENT` is 89 bytes.
The following figure shows the memory mapping of any record or record array element with the structure APPOINTMENT.

**Memory Map of Structure APPOINTMENT**

<table>
<thead>

**SUBMODULE**

**Statement:** Marks the beginning of a submodule program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```
SUBMODULE (ancestor-module-name [:parent-submodule-name]) name
  [specification-part]
  [module-subprogram
   [module-subprogram]...]
END [SUBMODULE [name]]
```

- **ancestor-module-name**
  - Must be the name of a nonintrinsic module. It is the name of the module at the root of the module or submodule tree.

- **parent-submodule-name**
  - (Optional) Is the name of the parent submodule, if any. The parent submodule must be a descendant of `ancestor-module-name`.

- **name**
  - Is the name of the submodule.

- **specification-part**
  - Is one or more specification statements, except for the following:
    - ENTRY
    - FORMAT
    - AUTOMATIC (or its equivalent attribute)
    - INTENT (or its equivalent attribute)
    - OPTIONAL (or its equivalent attribute)
    - Statement functions
    - An automatic object must not appear in a specification statement.

- **module-subprogram**
  - Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.
  - A module subprogram can contain internal procedures.

**Description**

If a name follows the END statement, it must be the same as the name specified in the SUBMODULE statement.

Each submodule has exactly one ancestor module and exactly one parent module or submodule. If the parent is a module then it must be the ancestor module. The relationship is tree-like, with the parent module or submodule at the root of the tree, and its descendant submodules as the branches of the tree.

A module or submodule may have one or more descendent submodules.

A submodule can access the entities from its parent module or submodule by host association. Unlike a module, a submodule cannot be referenced in other program units by use association. Entities declared in a submodule are only accessible from the submodule and its descendent submodules. Furthermore, a module procedure can have its interface declared in a module or submodule and its implementation contained in a descendent submodule in a separate file.

Submodules help the modularization of a large module in several ways:
• Internal data can be shared among submodules without being exposed to users of the module. Without
  the submodule feature, when a large module is split into smaller modules, internal data may be forced
to become public in order to be shared among the modules.
• Even if a module procedure implementation in a submodule is changed, as long as the module procedure
  interface declared in the ancestor module remains the same, a recompilation would not be needed for the
  user of the module. This could reduce the rebuilding time for a complex system.
• Separate concepts with circular dependencies can now be implemented in different submodules. It cannot
  be done with just modules.

A submodule is uniquely identified by a submodule identifier which consists of its ancestor-module-name
and the name of the submodule. The name of a submodule can therefore be the same as the name of
another submodule so long as they do not have the same ancestor module.

The following rules also apply to submodules:
• The specification part of a submodule must not contain IMPORT, ENTRY, FORMAT, executable, or statement
  function statements.
• A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute,
  which may be confirmed by explicit specification.
• If a specification or constant expression in the specification-part of a submodule includes a reference to a
genetic entity, there must be no specific procedures of the generic entity defined in the submodule
subsequent to the specification or constant expression.

Unlike a module, the specification part of a submodule must not contain PUBLIC and PRIVATE specifications.
Any executable statements in a module or submodule can only be specified in a module or submodule
subprogram.

A submodule can contain one or more procedure interface blocks, which let you specify an explicit interface
for an external subprogram or dummy subprogram.

Example

Consider the following example of a multilevel submodule system:

| Module M |
| Submodule A | Submodule B | Submodule C |
| Submodule X | Submodule Y | Submodule Z |

In the above example, module M is extended by submodules up to two levels. Module M is the ancestor
module of all the submodules. Entities declared in module M can be shared among all the submodules. A is
the parent submodule of X, Y, and Z. Entities declared in submodule A can be shared among submodules X,
Y, and Z, but not by B or C.

Only public entities declared in M can be available to other program units by use association.

The SUBMODULE declarations for A and X are:

```fortran
SUBMODULE (M) A
  ...
END SUBMODULE A

SUBMODULE (M : A) X
  ...
END SUBMODULE X
```

The following example shows modules and submodules, separate module procedures, and how circular
dependency can be avoided with submodules. There are five parts in the example:

1. module color_points
2. level-1 submodule color_points_a
3. level-2 submodule color_points_b
4. module palette_stuff
5. program main

! part 1
module color_points  ! This is the ancestor module
  type color_point
  private
    real :: x, y
    integer :: color
  end type color_point

! Below is the interface declaration of the separate module procedures.
! No IMPORT statement is used in the interface bodies.
! The separate module procedures are implemented in the two submodules.
interface
  module subroutine color_point_del ( p )
    type(color_point), allocatable :: p
  end subroutine color_point_del

  real module function color_point_dist ( a, b )
    type(color_point), intent(in) :: a, b
  end function color_point_dist

  module subroutine color_point_draw ( p )
    type(color_point), intent(in) :: p
  end subroutine color_point_draw

  module subroutine color_point_new ( p )
    type(color_point), allocatable :: p
  end subroutine color_point_new
end interface
end module color_points

! part 2
submodule ( color_points ) color_points_a  ! submodule of color_points
  integer :: instance_count = 0

  ! Below is the interface declaration of the separate module procedure
  ! inquire_palette, which is implemented in the submodule color_points_b.
  interface
    module subroutine inquire_palette ( pt, pal )
      use palette_stuff
      ! Later you will see that module palette_stuff uses color_points.
      ! This use of palette_stuff however does not cause a circular
      ! dependence because this use is not in the module.
      type(color_point), intent(in) :: pt
      type(palette), intent(out) :: pal
    end subroutine inquire_palette
  end interface
contains
  ! Here are the implementations of three of the four separate module
  ! procedures declared in module color_point.
  module subroutine color_point_del ( p )
    type(color_point), allocatable :: p
instance_count = instance_count - 1
deallocate ( p )
end subroutine color_point_del

real module function color_point_dist ( a, b ) result ( dist )
type(color_point), intent(in) :: a, b
dist = sqrt( (b%x - a%x)**2 + (b%y - a%y)**2 )
end function color_point_dist

module subroutine color_point_new ( p )
type(color_point), allocatable :: p
instance_count = instance_count + 1
allocate ( p )
end subroutine color_point_new

end submodule color_points_a

! part 3
submodule ( color_points:color_points_a ) color_points_b
! submodule of color_point_a
contains
! Implementation of a module procedure declared in the ancestor module
module subroutine color_point_draw ( p )
  use palette_stuff, only: palette
type(color_point), intent(in) :: p
type(palette) :: MyPalette
...; call inquire_palette ( p, MyPalette ); ...
end subroutine color_point_draw

! Implementation of a module procedure declared in the parent submodule
module procedure inquire_palette
...
end procedure inquire_palette

! A procedure only accessible from color_points_b and its submodules
subroutine private_stuff
...
end subroutine private_stuff

end submodule color_points_b

! part 4
module palette_stuff
  type :: palette ; ... ; end type palette
contains
  subroutine test_palette ( p )
    use color_points
    ! This does not cause a circular dependency because the
    ! "use palette_stuff" that is logically within color_points
    ! is in the color_points_a submodule.
    type(palette), intent(in) :: p
    ...
  end subroutine test_palette
end module palette_stuff
! part 5
program main
  use color_points
  ! Only public entities in color_points can be accessed here, not the
  !   entities from its submodules.
  ! The separate module procedure color_point_draw can be a specific
  !   procedure for a generic here. Recall that color_point_draw is
  !   implemented in a submodule, but its interface is public in a module.
  interface draw
    module procedure color_point_draw
  end interface
  type(color_point), allocatable :: c_1, c_2
  real :: rc
  ...
  call color_point_new (c_1)  ! body in color_points_a, interface in
    !   color_points
  ...
  call draw (c_1)             ! body in color_points_b, specific interface
    !   in color_points, generic interface here
  ...
  rc = color_point_dist (c_1, c_2)  ! body in color_points_a, interface in
    !   color_points
  ...
  call color_point_del (c_1)  ! body in color_points_a, interface in
    !   color_points
  ...
end program main

MODULE
FUNCTION
SUBROUTINE
References to Generic Procedures

SUBROUTINE
Statement: The initial statement of a subroutine
subprogram. A subroutine subprogram is invoked in a
CALL statement or by a defined assignment or
operator, and does not return a particular value.

Syntax
[prefix [prefix]] SUBROUTINE name [([d-arg-list]) [lang-binding]]
  [specification-part]
  [execution-part]
[CONTAINS
  [internal-subprogram-part] ]
END [SUBROUTINE [name]]

prefix         (Optional) Is any of the following:
- **ELEMENTAL**
  Acts on one array element at a time. This is a restricted form of pure procedure.
- **IMPURE**
  Asserts that the procedure has side effects.
- **MODULE**
  Indicates a separate module procedure. See separate module procedures.
- **NON_RECURSIVE**
  Indicates a procedure is not recursive.
- **PURE**
  Asserts that the procedure has no side effects.
- **RECURSIVE**
  Permits direct or indirect recursion to occur.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if lang-binding is specified.

**name**
Is the name of the subroutine.

**d-arg-list**
(Optional) Is a list of one or more dummy arguments or alternate return specifiers (*).

**lang-binding**
(Optional) Takes the following form:

```
BIND (C [, NAME=ext-name])
```

- **ext-name**
  Is a character scalar constant expression that can be used to construct the external name.

**specification-part**
Is one or more specification statements.

**execution-part**
Is one or more executable constructs or statements.

**internal-subprogram-part**
Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

A subroutine is invoked by a CALL statement or defined assignment. When a subroutine is invoked, dummy arguments (if present) become associated with the corresponding actual arguments specified in the call.

Execution begins with the first executable construct or statement following the SUBROUTINE statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

A subroutine subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A subroutine can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

You need an interface block for a subroutine when:

- Calling arguments use argument keywords.
• Some arguments are optional.
• A dummy argument is an assumed-shape array, a pointer, or a target.
• The subroutine extends intrinsic assignment.
• The subroutine can be referenced by a generic name.
• The subroutine is in a dynamic-link library.

If the subroutine is in a DLL and is called from your program, use the option DLLEXPORT or DLLIMPORT, which you can specify with the ATTRIBUTES directive.

Note that if you specify lang-binding, you have to use the parentheses even if there are no arguments. For example, without lang-binding you can specify SUBROUTINE F but with lang-binding you have to specify SUBROUTINE F( ) BIND (C).

Example

The following example shows a subroutine:

```
Main Program
CALL HELLO_WORLD
...                  PRINT *, "Hello World"
END

Subroutine
SUBROUTINE HELLO_WORLD
...                   PRINT *, "Hello World"
END SUBROUTINE
```

The following example uses alternate return specifiers to determine where control transfers on completion of the subroutine:

```
Main Program
CALL CHECK(A,B,*10,*20,C)            SUBROUTINE CHECK(X,Y,*,*,Q)
       TYPE *, 'VALUE LESS THAN ZERO'    ...
      10  TYPE*, 'VALUE EQUALS ZERO'     60  RETURN
       GO TO 30                         70  RETURN 1
      20  TYPE*, 'VALUE MORE THAN ZERO'  80  RETURN 2
      30  CONTINUE                      END
      ...
```

The SUBROUTINE statement argument list contains two dummy alternate return arguments corresponding to the actual arguments *10 and *20 in the CALL statement argument list.

The value of Z determines the return, as follows:

• If Z < zero, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the main program.
• If Z = = zero, the return is to statement label 10 in the main program.
• If Z > zero, the return is to statement label 20 in the main program.

Note that an alternate return is an obsolescent feature in the Fortran Standard.

The following shows another example:

```
SUBROUTINE GetNum (num, unit)
   INTEGER num, unit
  10  READ (unit, '(I10)', ERR = 10) num
   END
  ...
```

FUNCTION
INTERFACE
PURE
ELEMENTAL
CALL
SUM

Transformational Intrinsic Function (Generic):
Returns the sum of all the elements in an entire array or in a specified dimension of an array.

Syntax

\[
\text{result} = \text{SUM}(\text{array} [, \text{dim} [, \text{mask}]])
\]

- \text{array} (Input) Must be an array of type integer, real, or complex.
- \text{dim} (Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \text{array}.
- \text{mask} (Input; optional) Must be of type logical and conformable with \text{array}.

Results

The result is an array or a scalar of the same data type as \text{array}.

The result is a scalar if \text{dim} is omitted or \text{array} has rank one.

The following rules apply if \text{dim} is omitted:

- If SUM(\text{array}) is specified, the result is the sum of all elements of \text{array}. If \text{array} has size zero, the result is zero.
- If SUM(\text{array}, \text{MASK= mask}) is specified, the result is the sum of all elements of \text{array} corresponding to true elements of \text{mask}. If \text{array} has size zero, or every element of \text{mask} has the value .FALSE., the result is zero.

The following rules apply if \text{dim} is specified:

- If \text{array} has rank one, the value is the same as SUM(\text{array},\text{MASK= mask}).
- An array result has a rank that is one less than \text{array}, and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \text{array}.
- The value of element \((s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of SUM(\text{array}, \text{dim}=, \text{mask}) is equal to SUM(\text{array}(s_1, s_2, \ldots, s_{\text{dim}-1}, ;, s_{\text{dim}+1}, \ldots, s_n) [,\text{MASK = mask}(s_1, s_2, \ldots, s_{\text{dim}-1}, ;, s_{\text{dim}+1}, \ldots, s_n)]).

Example

SUM ((/2, 3, 4/)) returns the value 9 (sum of 2 + 3 + 4). SUM ((/2, 3, 4/), \text{DIM}=1) returns the same result.

SUM (B, \text{MASK=B .LT. 0.0}) returns the arithmetic sum of the negative elements of B.

C is the array

\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6
\end{bmatrix}
\]

SUM (C, \text{DIM}=1) returns the value (5, 7, 9), which is the sum of all elements in each column. 5 is the sum of 1 + 4 in column 1. 7 is the sum of 2 + 5 in column 2, and so forth.

SUM (C, \text{DIM}=2) returns the value (6, 15), which is the sum of all elements in each row. 6 is the sum of 1 + 2 + 3 in row 1. 15 is the sum of 4 + 5 + 6 in row 2.
The following shows another example:

```fortran
INTEGER array (2, 3), i, j(3)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
!  array is  1 3 5
!            2 4 6
i = SUM((/ 1, 2, 3 /))        ! returns 6
j = SUM(array, DIM = 1)       ! returns [3 7 11]
WRITE(*,*) i, j
END
```

See Also
PRODUCT

**SYNC ALL**

**Statement:** Performs a synchronization of all images.

**Syntax**

```
SYNC ALL([[(STAT=stat-var)[, ERRMSG=err-var]]])
```

- **stat-var**
  Is a scalar integer variable in which the status of the synchronization is stored.

- **err-var**
  Is a scalar default character variable in which an error condition is stored if such a condition occurs.

**STAT=** and **ERRMSG=** can appear in either order, but only once in a SYNC ALL statement.

**Description**

Execution on an image, for example, C, of the segment following the SYNC ALL statement is delayed until each other image has executed a SYNC ALL statement as many times as has image C.

The segments that executed before the SYNC ALL statement on an image, precede the segments that execute after the SYNC ALL statement on another image.

**Example**

In the following example, image 5 reads data and transmits the data to other images:

```fortran
REAL :: W[*]
SYNC ALL
IF (THIS_IMAGE()==5) THEN
   READ (*,*) W
   DO I = 6, NUM_IMAGES()
      W[I] = W
   END DO
END IF
...  
SYNC ALL
```

See Also
Image Control Statements
Coarrays
Using Coarrays
SYNC IMAGES

**Statement:** Performs a synchronization of the image with each of the other images in the image set. It takes the following form:

**Syntax**

```
SYNC IMAGES (image-set[, STAT=stat-var][, ERRMSG=err-var])
```

- `image-set` is an integer expression or *. If it is an integer expression, it must be scalar or of rank one. If it is an array expression, the value of each element must be positive and not greater than the number of images; there must be no repeated values.
  - If it is a scalar expression, the value must be positive and not greater than the number of images.
  - If * is specified, it indicates all images.

- `stat-var` is a scalar integer variable in which the status of the synchronization is stored.

- `err-var` is a scalar default character variable in which an error condition is stored if such a condition occurs.

`STAT=` and `ERRMSG=` can appear in either order, but only once in a SYNC IMAGES statement.

**Description**

When SYNC IMAGES statements are executed on images C and G, they correspond if the number of times image C has executed a SYNC IMAGES statement with G in its image set is the same as the number of times image G has executed a SYNC IMAGES statement with C in its image set. The segments that executed before the SYNC IMAGES statement on either image, precede the segments that execute after the corresponding SYNC IMAGES statement on the other image.

In a program that uses SYNC ALL as its only synchronization mechanism, every SYNC ALL statement can be replaced by a SYNC IMAGES (*) statement. However, SYNC ALL may provide better performance. SYNC IMAGES statements are not required to specify the entire image set, or even the same image set, on all images that participate in the synchronization.

**Example**

In the following example, image 5 waits for each of the other images to complete using the data. The other images wait for image 5 to set up the data, but do not wait for any other image:

```
IF (THIS_IMAGE() == 5) then
  SYNC IMAGES(*)       ! Sets up coarray data for other images
ELSE
  SYNC IMAGES(5)       ! Other images use the data set up by image 5
END IF
```

In the following example, each image synchronizes with its neighbor:

```
INTEGER :: THIS_STEP, TOTAL_STEPS, TOTAL_IMAGES, MY_IMAGE
MY_IMAGE = THIS_IMAGE ()
TOTAL_IMAGES = NUM_IMAGES ()
  ! Set up calculation
SYNC ALL
DO THIS_STEP = 1, TOTAL_STEPS
```
The calculation starts on image 1 since all the others will be waiting on `SYNC IMAGES (TOTAL_IMAGES-1)`. When this is done, image 2 starts and image 1 performs its second calculation. This continues until they are all executing different steps at the same time. Eventually, image 1 finishes and then the others finish one by one.

Image Control Statements
Coarrays
Using Coarrays

**SYNC MEMORY**

**Statement:** Ends one image segment and begins another. Each segment can then be ordered in some way with respect to segments on other images. It takes the following form:

**Syntax**

```
SYNC MEMORY [ ( [STAT=stat-var[, ERRMSG=err-var]] ) ]
```

- `stat-var` is a scalar integer variable in which the status of the synchronization is stored.
- `err-var` is a scalar default character variable in which an error condition is stored if such a condition occurs.

`STAT=` and `ERRMSG=` can appear in either order, but only once in a `SYNC IMAGES` statement.

**Description**

Unlike the other image control statements, this statement does not have any built-in synchronization effect.

The action regarding X on image Q precedes the action regarding Y on image Q if, by execution of statements on image P, the following is true:

- A variable X on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement
- That statement precedes a successful execution of a `SYNC MEMORY` statement
- A variable Y on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement that succeeds execution of that `SYNC MEMORY` statement,

User-defined ordering of segment Pi on image P to precede segment Qj on image Q occurs when the following happens:

- Image P executes an image control statement that ends segment Pi, and then executes statements that initiate a cooperative synchronization between images P and Q
- Image Q executes statements that complete the cooperative synchronization between images P and Q and then executes an image control statement that begins segment Qj
Execution of the cooperative synchronization between images P and Q must include a dependency that forces execution on image P of the statements that initiate the synchronization to precede the execution on image Q of the statements that complete the synchronization. The mechanisms available for creating such a dependency are processor dependent.

NOTE
SYNC MEMORY usually suppresses compiler optimizations that may reorder memory operations across the segment boundary defined by the SYNC MEMORY statement. It ensures that all memory operations initiated in the preceding segments in its image complete before any memory operations in the subsequent segment in its image are started.

Example
The following example should be run on two images:

```fortran
use, intrinsic :: iso_fortran_env
logical (atomic_logical_kind), save :: locked[*] = .true.
logical val
integer :: iam
iam = this_image()
if (iam == 1) then
  sync memory
  call atomic_define(locked[2], .false.)
else if (iam == 2) then
  val = .true.
  do while (val)
    call atomic_ref(val, locked)
  end do
  sync memory
end if
print *, 'success'
end
```

Image Control Statements
Coarrays
Using Coarrays

**SYSTEM**

*Portability Function:* Sends a command to the shell as if it had been typed at the command line.

**Module**

**USE IFPORT**

**Syntax**

```
result = SYSTEM (string)
```

*string*  
(Input) Character*(*)/ Operating system command.
Results

The result type is INTEGER(4). The result is the exit status of the shell command. If -1, use IERRNO to retrieve the error. Errors can be one of the following:

- E2BIG: The argument list is too long.
- ENOENT: The command interpreter cannot be found.
- ENOEXEC: The command interpreter file has an invalid format and is not executable.
- ENOMEM: Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Example

```fortran
USE IFPORT
INTEGER(4) I, errnum
I = SYSTEM("dir > file.lst")
If (I .eq. -1) then
   errnum = ierrno()
   print *, 'Error ', errnum
end if
END
```

See Also
SYSTEMQQ

SYSTEM_CLOCK

*Intrinsic Subroutine*: Returns integer data from a real-time clock. SYSTEM_CLOCK returns the number of seconds from 00:00 Coordinated Universal Time (CUT) on 1 JAN 1970. The number is returned with no bias. To get the elapsed time, you must call SYSTEM_CLOCK twice, and subtract the starting time value from the ending time value.

**Syntax**

```fortran
CALL SYSTEM_CLOCK ([count] [, count_rate] [, count_max])
```

- **count** (Output; optional) Must be scalar and of type integer. It is set to a value based on the current value of the processor clock. The value is increased by one for each clock count until the value count_max is reached, and is reset to zero at the next count. (count lies in the range 0 to count_max.)

- **count_rate** (Output; optional) Must be scalar and of type integer or real. It is set to the number of processor clock counts per second.
If the type is INTEGER(2), *count_rate* is 1000. If the type is INTEGER(4), *count_rate* is 10000. If the type is INTEGER(8), *count_rate* is 1000000.

*count_max*  
(Output; optional) Must be scalar and of type integer. It is set to the maximum value that *count* can have, HUGE(0).

All integer arguments used must have the same integer kind parameter. If the type is INTEGER(1), *count*, *count_rate*, and *count_max* are all zero, indicating that there is no clock available to Intel® Fortran with an 8-bit range.

**Example**

Consider the following:

```fortran
integer(2) :: ic2, crate2, cmax2
integer(4) :: ic4, crate4, cmax4

call system_clock(count=ic2, count_rate=crate2, count_max=cmax2)
call system_clock(count=ic4, count_rate=crate4, count_max=cmax4)
print *, ic2, crate2, cmax2
print *, ic4, crate4, cmax4
end
```

This program was run on Thursday Dec 11, 1997 at 14:23:55 EST and produced the following output:

```
13880   1000  32767
1129498807       10000  2147483647
```

**SYSTEMQQ**

*Portability Function:* Executes a system command by passing a command string to the operating system’s command interpreter.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SYSTEMQQ (commandline)
```

*commandline*  
(Input) Character*(*. Command to be passed to the operating system.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.
If the function fails, call `GETLASTERRORQQ` to determine the reason. One of the following errors can be returned:

- ERR$2BIG - The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
- ERR$NOINT - The command interpreter cannot be found.
- ERR$NOEXEC - The command interpreter file has an invalid format and is not executable.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

The command line character limit for the `SYSTEMQQ` function is the same limit that your operating system command interpreter accepts.

Example

```plaintext
USE IFPORT
LOGICAL(4) result
result = SYSTEMQQ('copy c:\bin\fmath.dat &
                     c:\dat\fmath2.dat')
```

SYSTEM

**T to Z**

**TAN**

_Elément Intrinsèque Fonction (Général):_ Produit la tangente d’un argument.

**Syntax**

```plaintext
result = TAN (x)
```

\(x\) (Input) Must be of type real or complex. If \(x\) is of type real, it must be in radians and is treated as modulo.

**Results**

The result type and kind are the same as \(x\).

If \(x\) is of type real, the result is a value in radians.

If \(x\) is of type complex, the real part of the result is a value in radians.

<table>

</tbody>
</table>
Specific Name | Argument Type | Result Type
--- | --- | ---
CQTAN | COMPLEX(16) | COMPLEX(16)

1. The setting of compiler options specifying real size can affect CTAN.
2. This function can also be specified as ZTAN.

Example
TAN (2.0) has the value -2.185040.
TAN (0.8) has the value 1.029639.

TAND
**Elemental Intrinsic Function (Generic): Produces the tangent of an argument.**

Syntax
\[
\text{result} = \text{TAND} (x)
\]

x  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

Results
The result type and kind are the same as x.

Specific Name | Argument Type | Result Type
--- | --- | ---
TAND | REAL(4) | REAL(4)
DTAND | REAL(8) | REAL(8)
QTAND | REAL(16) | REAL(16)

Example
TAND (2.0) has the value 3.4920771E-02.
TAND (0.8) has the value 1.3963542E-02.

TANH
**Elemental Intrinsic Function (Generic): Produces a hyperbolic tangent.**

Syntax
\[
\text{result} = \text{TANH} (x)
\]

x  
(Input) Must be of type real or complex.

Results
The result type and kind are the same as x.
If x is of type complex, the imaginary part of the result is in radians.
<table>

</tr>
</tbody>
</table>

**Example**

TANH (2.0) has the value 0.9640276.
TANH (0.8) has the value 0.6640368.

**TARGET DATA**

*OpenMP* Fortran Compiler Directive: Maps variables to a device data environment for the extent of the region. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```
!$OMP TARGET DATA [clause[[,] clause]... ]
  block
!$OMP END TARGET DATA
```

- **clause**
  - DEVICE (integer-expression)
  - IF ([TARGET DATA:] scalar-logical-expression)
  - MAP ([map-type-modifier[,] map-type: ] list)
  - USE_DEVICE_PTR (list)

  Tells the construct to use a device pointer currently in the device data environment.

  The list items are converted into device pointers to the corresponding list item in the device data environment.

  References in the construct to a list item that appears in this clause must be to the address of the list item.

- **block**

  Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding task region for a TARGET DATA construct is the encountering task. The target region binds to the enclosing parallel or task region.

When a TARGET DATA construct is encountered, a new device data environment is created, and the encountering task executes the target data region.

A program must not depend on any ordering of the evaluations of the clauses of the TARGET DATA directive, or on any side effects of the evaluations of the clauses.

The same variable can be used in both the MAP clause and the USE_DEVICE_PTR clause:

```
!$OMP TARGET DATA MAP(X) USE_DEVICE_PTR(X)
  block
!$OMP END TARGET DATA
```
TARGET Directive

OpenMP Fortran Compiler Directive: Creates a device data environment and executes the construct on that device. This directive only applies when targeting Intel® Xeon Phi™ products.

Syntax

```fortran
!$OMP TARGET [clause[, clause]... ]

block

!$OMP END TARGET
```

clause

- **DEFAULTMAP (TOFROM:SCALAR)**
  
  Causes a scalar variable to be treated as if it appeared in a MAP clause with a map-type of TOFROM.
  
  If this clause is not specified, a scalar variable is not mapped; instead it has an implicit attribute of FIRSTPRIVATE. At most one DEFAULTMAP clause can appear in the directive.
  
- **DEPEND (dependence-type : list)**

- **DEVICE (integer-expression)**

- **IF ([TARGET:] scalar-logical-expression)**

- **IS_DEVICE_PTR (list)**

  Indicates that a list item is a device pointer currently in the device data environment and that it should be used directly.

  The list is one or more dummy arguments.

  If a list item in a MAP clause is an array section, and the array section is derived from a variable with a POINTER or ALLOCATABLE attribute, then the behavior is unspecified if the corresponding list item’s variable is modified in the region.

- **MAP ([[map-type-modifier[,] map-type: ] list)**

- **NOWAIT**

block

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding task for a TARGET construct is the encountering task. The target region binds to the enclosing parallel or task region.

This construct provides a superset of the functionality provided by the TARGET DATA construct, except for the clause USE_DEVICE_PTR.

The TARGET construct also specifies that the region is executed by a device. The encountering task waits for the device to complete the target region at the end of the construct.
If a TARGET, TARGET DATA, or TARGET UPDATE construct appears within an OMP TARGET region, the construct is ignored.

If a variable appears in a REDUCTION or LASTPRIVATE clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a map-type of TOFROM for REDUCTION and a map-type of FROM for LASTPRIVATE:

```plaintext
! SUM is treated as MAP (TOFROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO REDUCTION(+:SUM)

! X is treated as MAP (FROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO LASTPRIVATE(X)
```

A non-scalar variable referenced in a TARGET region and not explicitly mapped is implicitly treated as MAP (TOFROM):

```plaintext
INTEGER A(10)
!$OMP TARGET
  A(5) = 5          ! A is treated as MAP (TOFROM)
!$OMP END TARGET
```

If only a subsection of a non-scalar variable has been mapped in an outer target region, and that variable is then mapped implicitly inside a nested target region, that variable should not access memory outside of the mapped subsection of the variable.

**TARGET Statement**

**Statement and Attribute:** Specifies that an object can become the target of a pointer (it can be pointed to).

**Syntax**

The TARGET attribute can be specified in a type declaration statement or a TARGET statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls] TARGET [, att-ls] :: object [(a-spec)] [[coarray-spec]] [, object[(a-spec)] [[coarray-spec]]]...
```

**Statement:**

```
TARGET [::] object [(a-spec)] [[coarray-spec]] [, object[(a-spec)] [[coarray-spec]]]...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `object` Is the name of the object. The object must not be declared with the PARAMETER attribute.
- `a-spec` (Optional) Is an array specification or a coarray specification.
coarray-spec  (Optional) Is a deferred-coshape specification. The left bracket and right bracket are required.

Description
A pointer is associated with a target by pointer assignment or by an ALLOCATE statement. If an object does not have the TARGET attribute or has not been allocated (using an ALLOCATE statement), no part of it can be accessed by a pointer.

Example
The following example shows type declaration statements specifying the TARGET attribute:

```
TYPE(SYSTEM), TARGET :: FIRST
REAL, DIMENSION(20, 20), TARGET :: C, D
```

The following is an example of a TARGET statement:

```
TARGET :: C(50, 50), D
```

The following fragment is from the program POINTER2.F90 in the `<install-dir>/samples` subdirectory:

```
! An example of pointer assignment.
REAL, POINTER :: arrow1 (:)
REAL, POINTER :: arrow2 (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:)
ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye
arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1
...
```

TARGET ENTER DATA

OpenMP* Fortran Compiler Directive: Specifies that variables are mapped to a device data environment. This directive only applies when targeting Intel® Xeon Phi™ products.

Syntax

```
!$OMP TARGET ENTER DATA [clause[, clause]...] 
```

clause  Is one or more of the following:
- DEPEND (dependence-type : list)
The binding task for the TARGET ENTER DATA construct is the encountering task. TARGET ENTER DATA is a stand-alone directive.

When a TARGET ENTER DATA construct is encountered, the list items in the MAP clauses are mapped to the device data environment according to map-type. A map-type must be specified in all MAP clauses and must be either TO or ALLOC.

The TARGET ENTER DATA construct executes as if it was enclosed in a TASK construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit TASK construct that encloses the TARGET ENTER DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause scalar-logical-expression evaluates to .FALSE., the device is the host.

**See Also**

Syntax Rules for Compiler Directives
TARGET EXIT DATA
Parallel Processing Model for information about Binding Sets

**TARGET EXIT DATA**

*OpenMP* Fortran Compiler Directive: Specifies that variables are unmapped from a device data environment. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```
!$OMP TARGET EXIT DATA [clause[, clause]... ]
```

clause Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF ([TARGET EXIT DATA:] scalar-logical-expression)
- MAP ([map-type: ] list)
- NOWAIT

The binding task for the TARGET EXIT DATA construct is the encountering task. TARGET EXIT DATA is a stand-alone directive.

When a TARGET EXIT DATA construct is encountered, the list items in the MAP clauses are unmapped from the device data environment according to map-type. A map-type must be specified in all MAP clauses and must be FROM, RELEASE, or DELETE.

The TARGET EXIT DATA construct executes as if it was enclosed in a task construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit task construct that encloses the TARGET EXIT DATA construct.
If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause scalar-logical-expression evaluates to .FALSE., the device is the host.

**TARGET PARALLEL**

*OpenMP* Fortran Compiler Directive: Creates a device data environment in a parallel region and executes the construct on that device. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```
!$OMP TARGET PARALLEL [clause[, clause] ... ]

block
```

```
[!$OMP END TARGET PARALLEL]
```

clause  Can be any of the clauses accepted by the TARGET or PARALLEL directives with identical meanings and restrictions.

block    Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a PARALLEL construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately. The only exceptions are the following:

- If any IF clause in the directive includes a directive-name-modifier then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no directive-name-modifier can appear on the directive.
- At most one IF clause with the PARALLEL directive-name-modifier can appear on the directive.
- At most one IF clause with the TARGET directive-name-modifier can appear on the directive.

**See Also**
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
IF Clause
TARGET Directive
PARALLEL Directive

**TARGET PARALLEL DO**

*OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.
Syntax

```fortran
!$OMP TARGET PARALLEL DO [clause[, clause] ... ]
  do-loop
[ !$OMP END TARGET PARALLEL DO ]
clause
  Can be any of the clauses accepted by the TARGET or PARALLEL DO directives, except for the COPYIN clause.
do-loop
  Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
        You cannot branch out of a DO loop associated with a DO directive.
```

If the END TARGET PARALLEL DO directive is not specified, the TARGET PARALLEL DO is assumed at the end of do-loop. If used, the END TARGET PARALLEL DO directive must appear immediately after the end of do-loop.

The semantics are identical to explicitly specifying a TARGET directive immediately followed by a PARALLEL DO directive.

The restrictions for the TARGET and PARALLEL DO constructs apply to this directive except for the following:

- If any IF clause in the directive includes a **directive-name-modifier** then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no **directive-name-modifier** can appear on the directive.
- At most one IF clause with the PARALLEL **directive-name-modifier** can appear on the directive.
- At most one IF clause with the TARGET **directive-name-modifier** can appear on the directive.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
IF Clause
TARGET Directive
PARALLEL DO

**TARGET PARALLEL DO SIMD**

*OpenMP Fortran Compiler Directive:* Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

Syntax

```fortran
!$OMP TARGET PARALLEL DO SIMD [clause[, clause] ... ]
  do-loop
[ !$OMP END TARGET PARALLEL DO SIMD ]
clause
  Can be any of the clauses accepted by the TARGET or PARALLEL DO SIMD directives, except for the COPYIN clause.
do-loop
  Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
```
All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET PARALLEL DO SIMD directive is not specified, an END TARGET PARALLEL DO SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and PARALLEL DO SIMD constructs apply to this directive except for the following:

• If any IF clause in the directive includes a directive-name-modifier then all IF clauses in the directive must include a directive-name-modifier.
• At most one IF clause with no directive-name-modifier can appear on the directive.
• At most one IF clause with the PARALLEL directive-name-modifier can appear on the directive.
• At most one IF clause with the TARGET directive-name-modifier can appear on the directive.

TARGET SIMD

OpenMP* Fortran Compiler Directive: Specifies a TARGET construct that contains a SIMD construct and no other statement.

Syntax

```fortran
!$OMP TARGET SIMD [clause[, clause] ... ]
  do-loop
$$OMP END TARGET SIMD]
```

clause

do-loop

Can be any of the clauses accepted by the TARGET or SIMD directive, with identical meanings and restrictions

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.
You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET SIMD directive is not specified, an END TARGET SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and SIMD constructs apply to this directive.

TARGET TEAMS

*OpenMP* Fortran Compiler Directive:* Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```
!$OMP TARGET TEAMS [clause[, clause]... ]
```

```
block
```

```
!$OMP END TARGET TEAMS
```

*clause* Can be any of the clauses accepted by the TARGET or TEAMS directives with identical meanings and restrictions.

*block* Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a TEAMS construct.

TEAMS

TARGET TEAMS DISTRIBUTE

*OpenMP* Fortran Compiler Directive:* Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```
!$OMP TARGET TEAMS DISTRIBUTE [clause[, clause]... ]
```
do-loop

[$OMP END TARGET TEAMS DISTRIBUTE]

clause

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE construct.

If the END TARGET TEAMS DISTRIBUTE directive is not specified, an END TARGET TEAMS DISTRIBUTE directive is assumed at the end of do-loop.

**TARGET TEAMS DISTRIBUTED PARALLEL DO SIMD**

*OpenMP* Fortran Compiler Directive: Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```fortran
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD [clause[,,] clause]... ]
   do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD]
```

clause

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE PARALLEL DO SIMD directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTED PARALLEL DO SIMD construct.

If the END TARGET TEAMS DISTRIBUTED PARALLEL DO SIMD directive is not specified, an END TARGET TEAMS DISTRIBUTED PARALLEL DO SIMD directive is assumed at the end of do-loop.
TARGET TEAMS DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Xeon Phi™ products.

Syntax

```fortran
!$OMP TARGET TEAMS DISTRIBUTE SIMD [clause[,,] clause]... ]
   do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE SIMD]
```

| clause | Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE SIMD directives with identical meanings and restrictions. |
| do-loop | Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. |

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct containing a TEAMS DISTRIBUTE SIMD construct.

If the END TARGET TEAMS DISTRIBUTE SIMD directive is not specified, an END TARGET TEAMS DISTRIBUTE SIMD directive is assumed at the end of do-loop.
**TARGET UPDATE**

*OpenMP* Fortran Compiler Directive: Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

```fortran
!$OMP TARGET UPDATE motion-clause [, clause[, clause]... ]
```

- **motion-clause**
  - Is one of the following:
    - `FROM(list)`
    - `TO(list)`

  The *list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /).

  For each *list* item in a TO or FROM clause, there is a corresponding list item and an original list item; for more information, see the MAP clause. Note that if the corresponding list item is not present in the device data environment, the behavior is unspecified.

  For each *list* item in a TO clause, the value of the original list item is assigned to the corresponding list item.

  For each *list* item in a FROM clause, the value of the corresponding list item is assigned to the original list item.

  A *list* item may only appear in a TO or FROM clause, but not both.

- **clause**
  - Is one of the following:
    - `DEPEND(dependence-type : list)`
    - `DEVICE(integer-expression)`
    - `IF([TARGET UPDATE:] scalar-logical-expression)`
    - `NOWAIT`

The binding task for a TARGET UPDATE construct is the encountering task. The TARGET UPDATE directive is a stand-alone directive.

A TARGET UPDATE construct must not appear inside of a target region.

**See Also**

- OpenMP Fortran Compiler Directives
- Syntax Rules for Compiler Directives
- TARGET Directive
- TARGET DATA
- Parallel Processing Model for information about Binding Sets

**TASK**

*OpenMP* Fortran Compiler Directive: Defines a task region.
Syntax

!$OMP TASK [clause[,] clause] ... ]

  block

!$OMP END TASK

clause

Is one of the following:

- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- DEPEND (dependence-type : list)
- FINAL (scalar-logical-expression)
- FIRSTPRIVATE (list)
- IF ([TASK:] scalar-logical-expression)
- IN_REDUCTION (operator | intrinsic: list)
- MERGEABLE
- PRIORITY (priority-value)
- PRIVATE (list)
- SHARED (list)
- UNTIED

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The binding thread set of a TASK construct is the current team. A task region binds to the innermost enclosing parallel region.

The TASK and END TASK directive pair must appear in the same routine in the executable section of the code.

The END TASK directive denotes the end of the task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The encountering thread may immediately execute the task, or defer its execution. In the latter case, any thread in the team may be assigned the task.

A thread that encounters a task scheduling point within the task region may temporarily suspend the task region. By default, a task is then tied and its suspended task region can only be resumed by the thread that started its execution. However, if the untied clause is specified in a TASK construct, any thread in the team can resume the task region after a suspension. The untied clause is ignored in these cases:

- If a final clause has been specified in the same TASK construct and the final clause expression evaluates to .TRUE..
- If a task is an included task.

A TASK construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

The TASK construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion. An implementation may add task scheduling points anywhere in untied task regions.

Note that when storage is shared by an explicit task region, you must add proper synchronization to ensure that the storage does not reach the end of its lifetime before the explicit task region completes its execution.

A program must not depend on any ordering of the evaluations of the clauses of the TASK directive and it must not depend on any side effects of the evaluations of the clauses. A program that branches into or out of a task region is non-conforming.

Unsynchronized use of Fortran I/O statements by multiple tasks on the same unit has unspecified behavior.
Example

The following example calculates a Fibonacci number. The Fibonacci sequence is 1,1,2,3,5,8,13, etc., where the current number is the sum of the previous two numbers. If a call to function fib is encountered by a single thread in a parallel region, a nested task region will be spawned to carry out the computation in parallel.

```fortran
RECURSIVE INTEGER FUNCTION fib(n)
INTEGER n, i, j
IF (n .LT. 2) THEN
  fib = n
ELSE
  !$OMP TASK SHARED(i)
  i = fib(n-1)
  !$OMP END TASK
  !$OMP TASK SHARED(j)
  j = fib(n-2)
  !$OMP END TASK
  !$OMP TASKWAIT ! wait for the sub-tasks to complete before summing
  fib = i+j
END IF
END FUNCTION
```

The following example generates a large number of tasks in one thread and executes them with the threads in the parallel team. While generating these tasks, if the implementation reaches the limit generating unassigned tasks, the generating loop may be suspended and the thread used to execute unassigned tasks. When the number of unassigned tasks is sufficiently low, the thread resumes execution of the task generating loop.

```fortran
real*8 item(10000000)
integer i
!$omp parallel
!$omp single ! loop iteration variable i is private
  do i=1,10000000
    !$omp task ! i is firstprivate, item is shared
      call process(item(i))
    !$omp end task
  end do
!$omp end single
!$omp end parallel
end
```

The following example modifies the previous one to use an untied task to generate the unassigned tasks. If the implementation reaches the limit generating unassigned tasks and the generating loop is suspended, any other thread that becomes available can resume the task generation loop.

```fortran
real*8 item(10000000)
!$omp parallel
!$omp single!
$omp task untied
! loop iteration variable i is private
  do i=1,10000000
    !$omp task ! i is firstprivate, item is shared
      call process(item(i))
    !$omp end task
  end do
```

Language Reference
The following example demonstrates four tasks with dependences:

```fortran
integer :: a

!$omp task depend(out:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(out:a)
!$omp end task
```

In the above example, the first task does not depend on any previous one. The second and third tasks depend on the first task but not on each other. The last task depends on the second and third tasks. The following shows the dependency graph:
The following example shows a set of sibling tasks that have dependences between them:

```fortran
INTEGER :: A(0:N*B-1)
DO I=0,N-1
  !$OMP TASK DEPEND(OUT:A(I*B:(I+1)*B-1))
  CALL FILL(A(I*B:(I+1)*B-1))
  !$OMP END TASK
END DO
DO I=1,N-1
  IB = (I-1)*B+1
  BB = I*B+1
  !$OMP TASK DEPEND(INOUT:A(I*B:(I+1)*B-1)) DEPEND(IN:A((I+1)*B:(I+2)*B-1))
  CALL PROCESS(A(I*B:(I+1)*B-1), A((I+1)*B:(I+2)*B-1))
  !$OMP END TASK
END DO
DO I=1,N
  IB = (I-1)*B+1
  !$OMP TASK DEPEND(IN:A(I*B:(I+1)*B-1))
  CALL OUTPUT(A(I*B:(I+1)*B-1))
  !$OMP END TASK
END DO
```

In the above example, the tasks of the first loop will be independent of any other tasks since there is no previous task that expresses a dependence on the same list items. Tasks of the second loop will depend on two tasks from the first loop. Also, because dependences are constructed in a sequential order, the IN dependences force the tasks of the second loop to be dependent on the task from the previous iteration to be processed. Finally, tasks of the third loop can be executed when the corresponding Process task from the second loop has been executed. For example, if N was 4, the following shows the dependency graph:

**TASK_REDUCTION**

Specifies a reduction among tasks. The
**TASK_REDUCTION** clause is a reduction scoping clause.
Syntax

TASK_REDUCTION (reduction-identifier : list)

Arguments reduction-identifier and list are defined in REDUCTION clause. All the common restrictions for the REDUCTION clause apply to this clause.

See Also

IN_REDUCTION
DECLARE REDUCTION
REDUCTION
TASKGROUP

TASKGROUP

OpenMP* Fortran Compiler Directive: Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

Syntax

!$OMP TASKGROUP [clause[,] clause] ... ]

block

!$OMP END TASKGROUP

clause Is the following:

- TASK_REDUCTION (reduction-identifier : list)

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

A TASKGROUP construct binds to the current task region. The binding thread set of the taskgroup region is the current team.

When a thread encounters a TASKGROUP construct, it starts executing the region. There is an implicit task scheduling point at the end of the TASKGROUP region. The current task is suspended at the task scheduling point until all child tasks that it generated in the TASKGROUP region and all of their descendant tasks complete execution.

Any number of reduction clauses can be specified in the TASKGROUP directive, but a list item can appear only once in reduction clauses for that directive.

Parallel Processing Model for information about Binding Sets

TASKLOOP

OpenMP* Fortran Compiler Directive: Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks.
The iterations are distributed across tasks that are created by the construct and scheduled to be executed.

**Syntax**

```
!$OMP TASKLOOP [clause[, clause]... ]

   do-loop
   ![OMP END TASKLOOP]
```

clause

Is one of the following:

- **COLLAPSE (n)**
- **DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)**
- **FINAL (scalar-logical-expression)**
- **FIRSTPRIVATE (list)**
- **GRAINSIZE (grain-size)**

Specifies that the number of logical loop iterations assigned to each created task is greater than or equal to the minimum of the value of the grain-size positive integer expression and the number of logical loop iterations, but less than two times the value of the grain-size expression.

At most one GRAINSIZE clause can appear in a TASKLOOP directive.

- **IF ([TASKLOOP:] scalar-logical-expression)**

  If the scalar-logical-expression evaluates to false, undeferred tasks are generated. If a variable appears in the IF clause expression, it causes an implicit reference to the variable in all enclosing constructs.

  At most one IF clause can appear in a TASKLOOP directive.

- **IN_REDUCTION (reduction-identifier : list)**
- **LASTPRIVATE (CONDITIONAL : list)**
- **MERGEABLE**
- **NOGROUP**

  Specifies that no implicit taskgroup region is created.

- **NUM_TASKS (num-tasks)**

  Causes the TASKLOOP construct to create as many tasks as the minimum of the num-tasks positive scalar integer expression and the number of logical loop iterations. Each task must have at least one logical loop iteration.

- **PRIORITY (priority-value)**
- **PRIVATE (list)**
- **REDUCTION (reduction-identifier : list)**

  If you specify this clause, you cannot specify the NOGROUP clause.

- **SHARED (list)**
- **UNTIED**

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
If an END TASKLOOP directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The TASKLOOP construct inherits the restrictions of the loop construct. If any of the loop iteration variables would otherwise be shared, they are implicitly made private for the loop-iteration tasks created by the TASKLOOP construct. Unless the loop iteration variables are specified in a LASTPRIVATE clause on the TASKLOOP construct, their values after the loop are unspecified.

You cannot branch out of a DO loop associated with a TASKLOOP directive.

If you do not specify GRAINSIZE or NUM_TASKS, the number of loop tasks created and the number of logical loop iterations assigned to these tasks is implementation defined. The GRAINSIZE clause and NUM_TASKS clauses are mutually exclusive; they cannot appear in the same TASKLOOP directive.

The binding thread set of the TASKLOOP region is the current team. A TASKLOOP region binds to the innermost enclosing parallel region.

When a thread encounters a TASKLOOP construct, the construct partitions the associated loops into tasks for parallel execution of the loop iterations. The data environment of the created tasks is created according to the clauses specified in the TASKLOOP construct, any data environment ICVs, and any defaults that apply. The order of the creation of the loop tasks is unspecified. Programs that rely on any execution order of the logical loop iterations are non-conforming.

If used, the END TASKLOOP directive must appear immediately after the end of the loop. If you do not specify an END TASKLOOP directive, an END TASKLOOP directive is assumed at the end of the do-loop.

By default, the TASKLOOP construct executes as if it was enclosed in a TASKGROUP construct with no statements or directives outside of the TASKLOOP construct. Therefore, the TASKLOOP construct creates an implicit TASKGROUP region.

When a REDUCTION clause appears in a TASKLOOP construct, it behaves as if a TASK_REDUCTION clause was applied to the implicit TASKGROUP construct enclosing the TASKLOOP construct. For each task that is generated by the TASKLOOP construct, an IN_REDUCTION clause with the same reduction operator and the same list items that appear in the REDUCTION clause is applied to the task.

When an IN_REDUCTION clause appears in a TASKLOOP construct, an IN_REDUCTION clause with the same reduction operation and the same list items of the IN_REDUCTION clause is applied to the generated tasks.

The following restrictions also apply:

- A program that branches into or out of a TASKLOOP region is non-conforming.
- All loops associated with the TASKLOOP construct must be perfectly nested. There must be no intervening code nor any other OpenMP* directive between any two loops.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
TASK_REDUCTION

TASKLOOP SIMD

OpenMP* Fortran Compiler Directive: Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.
Syntax

```fortran
!$OMP TASKLOOP SIMD [clause[, clause]...] 
   do-loop 
[!$OMP END TASKLOOP SIMD] 
```

Can be almost all of the clauses accepted by the TASKLOOP or SIMD directives with identical meanings and restrictions. The only exception is that you cannot specify a REDUCTION clause.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team. You cannot branch out of a DO loop associated with a TASKLOOP directive.

If the END TASKLOOP SIMD directive is not specified, an END TASKLOOP SIMD directive is assumed at the end of do-loop.

The binding thread set of the TASKLOOP SIMD region is the current team. A TASKLOOP SIMD region binds to the innermost enclosing parallel region.

The TASKLOOP SIMD construct first distributes the iterations of the associated loops across tasks in a manner consistent with any clauses that apply to the TASKLOOP construct. The resulting tasks are then converted to SIMD loops in a manner consistent with any clauses that apply to the SIMD construct.

The effect of any clause that applies to both constructs is as if it were applied to both constructs separately, except for the COLLAPSE clause, which is applied once to the TASKLOOP construct.

This directive specifies a composite construct.

- OpenMP Fortran Compiler Directives
- Syntax Rules for Compiler Directives

TASKWAIT

OpenMP* Fortran Compiler Directive: Specifies a wait on the completion of child tasks generated since the beginning of the current task.

Syntax

```fortran
!$OMP TASKWAIT 
```

A TASKWAIT construct binds to the current task region. The binding thread set of the taskwait region is the current team.

The TASKWAIT region includes an implicit task scheduling point in the current task region. The current task region is suspended at the task scheduling point until execution of all its child tasks generated before the TASKWAIT region are completed.
TASKYIELD

OpenMP* Fortran Compiler Directive: Specifies that the current task can be suspended at this point in favor of execution of a different task.

Syntax

!$OMP TASKYIELD

A taskyield region binds to the current task region. The binding thread set of the taskyield region is the current team.

Because the TASKYIELD construct is a stand-alone directive, there are some restrictions on its placement within a program:

- The TASKYIELD directive can only be placed at a point where a Fortran executable statement is allowed.
- The TASKYIELD directive cannot be used as the action statement in an IF statement or as the executable statement following a label if the label is referenced in the program.

The TASKYIELD construct includes an explicit task scheduling point in the current task region.

Example

The following example shows use of the TASKYIELD directive. It is non-conforming, because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are stand-alone directives and cannot be the action statement of an IF statement or a labeled branch target.

```fortran
SUBROUTINE NONCONFORMING_STANDALONE()
    INTEGER A
    A = 1
    ! the FLUSH directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP FLUSH(A)
    ! the BARRIER directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP BARRIER
    ! the TASKWAIT directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP TASKWAIT
    ! the TASKYIELD directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP TASKYIELD
    GOTO 100
    ! the FLUSH directive must not be a labeled branch target statement
    !
100  !$OMP FLUSH(A)
    GOTO 200
```
The following version of the above example is conforming because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are enclosed in a compound statement.

```
SUBROUTINE CONFORMING_STANDALONE ()
   INTEGER N
   N = 1
   IF (N .NE. 0) THEN
      !$OMP FLUSH(N)
   ENDIF
   IF (N .NE. 0) THEN
      !$OMP BARRIER
   ENDIF
   IF (N .NE. 0) THEN
      !$OMP TASKWAIT
   ENDIF
   IF (N .NE. 0) THEN
      !$OMP TASKYIELD
   ENDIF
   GOTO 100
100 CONTINUE
   !$OMP FLUSH(N)
   GOTO 200
200 CONTINUE
   !$OMP BARRIER
   GOTO 300
300 CONTINUE
   !$OMP TASKWAIT
   GOTO 400
400 CONTINUE
   !$OMP TASKYIELD
END SUBROUTINE
```

**TEAMS**

**OpenMP* Fortran Compiler Directive:** Creates a league of thread teams inside a target region to execute a structured block in the master thread of each team.

**Syntax**

```
!$OMP TEAMS [clause[,] clause]... ]
  block
!$OMP END TEAMS
```

*clause* is one of the following:

- **DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)**
- **FIRSTPRIVATE (list)**
- **NUM_TEAMS (scalar-integer-expression)**
  Specifies the number of teams to be used in a parallel region. The *scalar-integer-expression* must evaluate to a positive scalar integer value.
  Only a single NUM_TEAMS clause can appear in the directive.
- **PRIVATE (list)**
- **REDUCTION (reduction-identifier : list)**
- **SHARED (list)**
- **THREAD_LIMIT (scalar-integer-expression)**
  Specifies the maximum number of threads participating in the contention group that each team initiates. The *scalar-integer-expression* must evaluate to a positive scalar integer value.
  At most one THREAD_LIMIT clause can appear in the directive.

*block* is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding thread set for a TEAMS construct is the encountering thread.

The TEAMS construct must appear within a TARGET construct. The enclosing TARGET construct must contain no other statements or directives outside of the TEAMS construct. The following are the only OpenMP* constructs that can be nested in the team’s region:

- **DISTRIBUTE**
- **PARALLEL**
- **PARALLEL SECTIONS**
- **PARALLEL WORKSHARE**
- **PARALLEL DO**
- **PARALLEL DO SIMD**

The thread that encounters this directive constructs a league of thread teams that execute the *block* in the master thread of each team. After the teams are created, the number of teams remains constant for the duration of the team’s parallel region.

The region following the TEAMS construct is executed by the master thread of each team. Other threads do not begin execution until the master thread encounters a parallel region. After the teams complete execution of the TEAMS construct region, the encountering thread resumes execution of the enclosing target region.
If NUM_TEAMS is not specified, the default number of teams is one. If THREAD_LIMIT is not specified, the default number of threads is \(\text{the-number-of-available-hardware-threads} / \text{NUM_TEAMS}\).

A program must not depend on any side effects or any ordering of the evaluation of clauses in the TEAMS directive.

Each team has a unique team number. You can use the OpenMP* run-time library routine OMP_GET_TEAM_NUM to get the team number of the calling thread.

Each thread within the team has a unique thread identifier returned by the OpenMP run-time library routine OMP_GET_THREAD_NUM. As in any thread team, the thread identifier starts at zero for the master thread up to THREAD_LIMIT - 1 for the remaining threads.

Immediately after this directive, only the master threads in each team are executing, the other team members will only start to execute at the next (nested) parallel region. Therefore, there are only NUM_TEAMS threads executing, and each of them has OMP_GET_THREAD_NUM() == 0.

TEAMS DISTRIBUTE

*OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a TEAMS construct.

Syntax

\[
!$\text{OMP TEAMS DISTRIBUTE } [\text{clause}[[,] \text{ clause}]... ] \\
\text{do-loop} \\
[!$\text{OMP END TEAMS DISTRIBUTE}]
\]

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>do-loop</td>
<td>Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops. The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.</td>
</tr>
</tbody>
</table>

This directive provides a shortcut for specifying a TEAMS construct containing a DISTRIBUTE construct.

If the END TEAMS DISTRIBUTE directive is not specified, an END TEAMS DISTRIBUTE directive is assumed at the end of do-loop.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

TEAMS DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

Syntax

```fortran
!$OMP TEAMS DISTRIBUTE PARALLEL DO [clause[,,] clause]... ]

   do-loop

[!$OMP END TEAMS DISTRIBUTE PARALLEL DO]
```

clause

Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO construct. Some clauses are permitted on both constructs.

If the END TEAMS DISTRIBUTE PARALLEL DO directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO directive is assumed at the end of do-loop.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

TEAMS DISTRIBUTE PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.

Syntax

```fortran
!$OMP TEAMS DISTRIBUTE PARALLEL DO SIMD [clause[,,] clause]... ]

   do-loop

[!$OMP END TEAMS DISTRIBUTE PARALLEL DO SIMD]
```
clause
Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO SIMD directives with identical meanings and restrictions.

do-loop
Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO SIMD construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately.

If the END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of do-loop.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

TEAMS DISTRIBUTE SIMD

OpenMP Fortran Compiler Directive: Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.

Syntax

```fortran
!$OMP TEAMS DISTRIBUTE SIMD [clause[, clause]...]  
do-loop
[!$OMP END TEAMS DISTRIBUTE SIMD]
```

clause
Can be any of the clauses accepted by the TEAMS or DISTRIBUTE SIMD directives with identical meanings and restrictions.

do-loop
Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.
This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE SIMD construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately.

If the END TEAMS DISTRIBUTE SIMD directive is not specified, an END TEAMS DISTRIBUTE SIMD directive is assumed at the end of do-loop.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

THIS_IMAGE

Transformational Intrinsic Function (Generic):
Returns cosubscripts for the image.

Syntax

\[
\text{result} = \text{THIS\_IMAGE} ([\text{coarray} [, \text{dim}]])
\]

\text{coarray} \quad \text{(Input; optional) Must be a coarray; it can be of any type. If it is allocatable, it must be allocated.}

\text{dim} \quad \text{(Input; optional) Must be a default integer scalar. Its value must be in the range 1 \leq \text{dim} \leq \text{n}, where \text{n} is the corank of \text{coarray}. The corresponding actual argument must not be an optional dummy argument.}

Results

The result type is default integer. It is scalar if \text{coarray} does not appear or \text{dim} is present; otherwise, the result has rank one and its size is equal to the corank of \text{coarray}.

The result depends on which arguments are specified:

- If no argument is specified, as in THIS_IMAGE ( ), the result is a scalar with a value equal to the index of the invoking image.
- If only \text{coarray} is specified, the result is the sequence of cosubscript values for \text{coarray} that would specify the invoking image.
- If \text{coarray} and \text{dim} are specified, the result is the value of cosubscript \text{dim} in the sequence of cosubscript values for \text{coarray} that would specify the invoking image.

Example

Consider that coarray C is declared by the following statement:

\[
\text{REAL C(5, 10) [10, 0:9, 0:*]}
\]

On image 5, THIS_IMAGE ( ) has the value 5 and THIS IMAGE (C) has the value [5, 0, 0]. For the same coarray on image 213, THIS_IMAGE (C) has the value [3, 1, 2].

In the following example, image 1 is used to read data. The other images then copy the data:

\[
\begin{align*}
\text{IF (THIS\_IMAGE()} & \text{==1) READ (*,*) P} \\
& \text{SYNC ALL} \\
& \text{P = P[1]}
\end{align*}
\]
THREADPRIVATE

OpenMP* Fortran Compiler Directive: Specifies named common blocks and certain variables to be private (local) to each thread; they are global within the thread.

Syntax

!$OMP THREADPRIVATE (list)

list

Is a comma-separated list of named common blocks, module variables, or variables that have the SAVE attribute. These objects are made private to a thread.

Note that common blocks must appear between slashes (/).

A blank common block cannot appear in a THREADPRIVATE directive.

A variable that appears in a THREADPRIVATE directive must be declared in the scope of a module or have the SAVE attribute, either explicitly or implicitly.

Each thread gets its own copy of the common block or variable, so data written to this object by one thread is not directly visible to other threads.

During serial portions and MASTER sections of the program, accesses are to the master thread copy of the common block or variable. On entry to the first parallel region, data in the THREADPRIVATE common blocks or variables should be assumed to be undefined unless a COPYIN clause is specified in the PARALLEL directive.

The THREADPRIVATE directive must appear in the section of a scoping unit in which the common block or variable is declared. Although variables in common blocks can be accessed by use association or host association, common block names cannot. This means that a common block name specified in a THREADPRIVATE directive must be declared to be a common block in the same scoping unit in which the THREADPRIVATE directive appears.

When a common block (which is initialized using DATA statements) appears in a THREADPRIVATE directive, each thread copy is initialized once prior to its first use. For subsequent parallel regions, data in THREADPRIVATE common blocks are guaranteed to persist only if the dynamic threads mechanism has been disabled and if the number of threads are the same for all the parallel regions.

A THREADPRIVATE common block or its constituent variables can appear only in a COPYIN clause. They are not permitted in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, SHARED, or REDUCTION clause. They are not affected by the DEFAULT clause.

If a THREADPRIVATE directive specifying a common block name appears in one program unit, then the directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. It must appear after the last COMMON statement in the program unit.

If a THREADPRIVATE variable or a THREADPRIVATE common block is declared with the BIND attribute, the corresponding C entities must also be specified in a threadprivate directive in the C program.

The following are other restrictions for a THREADPRIVATE variable:

- The variable must not appear in any clause except the COPYIN, COPYPRIVATE, SCHEDULE, NUM_THREADS, THREAD_LIMIT, and IF clauses.
- It is affected by a COPYIN clause if the variable appears in the COPYIN clause or it is in a common block that appears in the COPYIN clause.
- It must not be an element of a common block or appear in an EQUIVALENCE statement.
• If it is part of another variable (as an array or structure element), it cannot appear in a THREADPRIVATE directive clause.

**NOTE**
On Windows* systems, if you specify option /Qopenmp-threadprivate:compat, the compiler does not generate threadsafe code for common blocks in an !$OMP THREADPRIVATE directive unless at least one element in the common block is explicitly initialized. For more information, see the article titled: /Qopenmp-threadprivate:compat doesn't work with uninitialized threadprivate common blocks, which is located in http://intel.ly/1aHhsjc

**Example**

In the following example, the common blocks BLK1 and FIELDS are specified as thread private:

```fortran
COMMON /BLK/ SCRATCH
COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
(!$OMP THREADPRIVATE(/BLK/,/FIELDS/) )
(!$OMP PARALLEL DEFAULT(PRIVATE) COPYIN(/BLK1/,ZFIELD)
```

**See Also**
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**TIME Intrinsic Procedure**

*Intrinsic Subroutine (Generic):* Returns the current time as set within the system. TIME can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL TIME (buf)
```

*buf* (Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least eight bytes of storage.

The date is returned as a 8-byte ASCII character string taking the form hh:mm:ss, where:

- *hh* is the 2-digit hour
- *mm* is the 2-digit minute
- *ss* is the 2-digit second

If *buf* is of numeric type and smaller than 8 bytes, data corruption can occur.

If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 8 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

**Example**

```fortran
CHARACTER*1 HOUR(8)
...
CALL TIME (HOUR)
```
The length of the first array element in CHARACTER array HOUR is passed to the TIME subroutine. The subroutine then truncates the time to fit into the 1-character element, producing an incorrect result.

**See Also**
DATE_AND_TIME

TIME portability routine

**TIME Portability Routine**

*Portability Function or Subroutine:* The function returns the system time, in seconds, since 00:00:00 Greenwich mean time, January 1, 1970. TIME can be used as a portability function or subroutine, or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

**Module**

USE IFPORT

**Syntax**

**Function Syntax:**

\[
\text{result} = \text{TIME}(\ )
\]

**Subroutine Syntax:**

\[
\text{CALL TIME}(\text{timestr})
\]

*timestr* *(Output) Character*(*). Is the current time, based on a 24-hour clock, in the form hh:mm:ss, where hh, mm, and ss are two-digit representations of the current hour, minutes past the hour, and seconds past the minute, respectively.

**Results**

The result type is INTEGER(4). The result value is the number of seconds that have elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

The subroutine fills a parameter with the current time as a string in the format hh:mm:ss.

The value returned by this routine can be used as input to other portability date and time functions.

**Example**

```fortran
USE IFPORT
  INTEGER(4) int_time
  character*8 char_time
  int_time = TIME( )
  call TIME(char_time)
  print *, 'Integer: ', int_time, 'time: ', char_time
END
```

**See Also**
DATE_AND_TIME

TIME intrinsic procedure
TIMEF

**Portability Function: Returns the number of seconds since the first time it is called, or zero.**

Module

USE IFPORT

Syntax

result = TIMEF( )

Results

The result type is REAL(8). The result value is the number of seconds that have elapsed since the first time TIMEF was called.

The first time it is called, TIMEF returns 0.

Example

USE IFPORT
INTEGER i, j
REAL(8) elapsed_time
elapsed_time = TIMEF( )
DO i = 1, 100000
   j = j + 1
END DO
elapsed_time = TIMEF( )
PRINT *, elapsed_time
END

See Also

Date and Time Procedures

TINY

**Inquiry Intrinsic Function (Generic): Returns the smallest number in the model representing the same type and kind parameters as the argument.**

Syntax

result = TINY (x)

\[x\]

(Input) Must be of type real; it can be scalar or array valued.

Results

The result is a scalar with the same type and kind parameters as \(x\). The result has the value \(b \cdot e_{\text{min}} - 1\). Parameters \(b\) and \(e_{\text{min}}\) are defined in Model for Real Data.

Example

If \(X\) is of type REAL(4), TINY (X) has the value \(2^{-126}\).

The following shows another example:

```
REAL(8) r, result
r = 487923.3D0
result = TINY(r) ! returns 2.225073858507201E-308
```
TRACEBACKQQ

**Run-Time Subroutine**: Provides traceback information. Uses the Intel® Fortran run-time library traceback facility to generate a stack trace showing the program call stack as it appeared at the time of the call to TRACEBACKQQ().

**Module**

USE IFCORE

**Syntax**

CALL TRACEBACKQQ ([string] [,user_exit_code] [,status] [,eptr])

- **string** (Input; optional) CHARACTER*(*). A message string to precede the traceback output. It is recommended that the string be no more than 80 characters (one line) since that length appears better on output. However, this limit is not a restriction and it is not enforced. The string is output exactly as specified; no formatting or interpretation is done. If this argument is omitted, no header message string is produced.

- **user_exit_code** (Input; optional) INTEGER(4). An exit code. Two values are predefined:
  - A value of -1 causes the run-time system to return execution to the caller after producing traceback.
  - A value of zero (the default) causes the application to abort execution.

  Any other specified value causes the application to abort execution and return the specified value to the operating system.

- **status** (Input; optional) INTEGER(4). A status value. If specified, the runtime system returns the status value to the caller indicating that the traceback process was successful. The default is not to return status.

  Note that a returned status value is only an indication that the "attempt" to trace the call stack was completed successfully, not that it produced a useful result.

  You can include the file iosdef.f90 in your program to obtain symbolic definitions for the possible return values. A return value of FOR$IOS_SUCCESS (0) indicates success.

- **eptr** (Input; optional) Integer pointer. It is required if calling from a user-specified exception filter. If omitted, the default in null.

  To trace the stack after an exception has occurred, the runtime support needs access to the exception information supplied to the filter by the operating system.

  The eptr argument is a pointer to a T_EXCEPTION_POINTERS structure, which is defined in ifcore.f90. This argument is optional and is usually omitted. On Windows* systems,
The TRACEBACKQQ routine provides a standard way for an application to initiate a stack trace. It can be used to report application detected errors, debugging, and so forth. It uses the stack trace support in the Intel Fortran run-time library, and produces the same output that the run-time library produces for unhandled errors and exceptions.

The error message string normally included by the run-time system is replaced with the user-supplied message text, or omitted if no string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the run-time system.

**Example**

In the most simple case, you can generate a stack trace by coding the call to TRACEBACKQQ with no arguments:

```fortran
CALL TRACEBACKQQ()
```

This call causes the run-time library to generate a traceback report with no leading header message, from wherever the call site is, and terminate execution.

The following example generates a traceback report with no leading header message, from wherever the call site is, and aborts execution:

```fortran
USE IFCORE
CALL TRACEBACKQQ()
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution:

```fortran
USE IFCORE
CALL TRACEBACKQQ("My application message string")
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution, returning a status code of 123 to the operating system:

```fortran
USE IFCORE
CALL TRACEBACKQQ(STRING="Bad value for TEMP",USER_EXIT_CODE=123)
```

Consider the following:

```fortran
... 
USE IFCORE 
INTEGER(4) RTN_STS 
INCLUDE 'IOSDEF.FOR' 
... 
CALL TRACEBACKQQ(USER_EXIT_CODE=-1,STATUS=RTN_STS) 
IF (RTN_STS .EQ. FOR$IOS_SUCCESS) THEN 
  PRINT *, 'TRACEBACK WAS SUCCESSFUL' 
END IF 
... 
```

This example generates a traceback report with no header string, and returns to the caller to continue execution of the application. If the traceback process succeeds, a status will be returned in variable RTN_STS.
You can specify arguments that generate a stack trace with the user-supplied string as the header and instead of terminating execution, return control to the caller to continue execution of the application. For example:

```
CALL TRACEDBACKQ(STRING="Done with pass 1",USER_EXIT_CODE=-1)
```

By specifying a user exit code of -1, control returns to the calling program. Specifying a user exit code with a positive value requests that specified value be returned to the operating system. The default value is 0, which causes the application to abort execution.

Windows* Example:
The following example demonstrates the use of the EPTR argument when calling from a user-defined exception filter function. The premise of the example is a Fortran DLL containing entry points protected by a C try/except construct, such as:

```c
__declspec(dllexport) void FPE_TEST_WRAPPER ()
{
    __try {
        /* call the Fortran code... */
        FPE_TEST() ;
    }
    __except ( CHECK_EXCEPTION_INFO ( GetExceptionInformation() ) )
    {
        /*
        ** noncontinuable exception handling here, if any.
        */
    }
}
```

The C function shown above is guarding against a floating-point divide-by-zero exception. This function calls the user-supplied FPE_TEST (not shown). The Fortran function CHECK_EXCEPTION_INFO shown below (called in the __except filter expression above) can use TRACEDBACKQ to get a stack trace as follows:

```fortran
INTEGER*4 FUNCTION CHECK_EXCEPTION_INFO ( ExceptionInfo )
!DIR$ ATTRIBUTES DLLEXPORT::CHECK_EXCEPTION_INFO
USE IFWINTY
!DIR$ ATTRIBUTES REFERENCE :: ExceptionInfo
TYPE(T_EXCEPTION_POINTERS) ExceptionInfo
TYPE(T_EXCEPTION_RECORD) erecptr
TYPE(T_CONTEXT) ctxptr
POINTER(eptr,erecptr)
POINTER(ctxp,ctxptr)
INTEGER(4) EXIT_CODE,STS
CHARACTER(LEN=70) MYSTR
! Init the arguments to TRACEDBACKQ appropriately for your needs...
EXIT_CODE=-1
eptr = ExceptionInfo.ExceptionRecord
ctxp = ExceptionInfo.ContextRecord
IF ( erecptr.ExceptionCode .EQ. STATUS_FLOAT_DIVIDE_BY_ZERO ) THEN
    PRINT *, 'Saw floating divide by zero.'
    PRINT '(1x,a,z8.8)', 'ContextRecord.FloatSave.StatusWord = ', &
          ctxptr.FloatSave.StatusWord
    MYSTR = "FLTDIV EXCEPTION IN MY APPLICATION"
    CALL TRACEDBACKQ(MYSTR,EXIT_CODE,STS, %LOC(ExceptionInfo))
END IF
```

2166
To return a pointer to C run-time exception information pointers within a user-defined handler that was established with SIGNALQQ (or directly with the C signal function), you can call the GETEXCEPTIONPTRSQQ routine.

**See Also**
GETEXCEPTIONPTRSQQ

### TRAILZ

**Elemental Intrinsic Function (Specific):** Returns the number of trailing zero bits in an integer.

**Syntax**

```plaintext
result = TRAILZ (i)
```

- `i` *(Input)* Must be of type integer or logical.

**Results**

The result type is default integer. The result value is the number of trailing zeros in the binary representation of the integer `i`.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

Consider the following:

```plaintext
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
   TYPE *, TRAILZ(TWO**J) ! Prints 64, then 0 up to
ENDDO                   !   40 (trailing zeros)
END
```

### TRANSFER

**Transformational Intrinsic Function (Generic):** Converts the bit pattern of the first argument according to the type and kind parameters of the second argument.

**Syntax**

```plaintext
result = TRANSFER (source,mold[,size])
```

- `source` *(Input)* Must be a scalar or array (of any data type).
- `mold` *(Input)* Must be a scalar or array (of any data type). It provides the type characteristics (not a value) for the result.
- `size` *(Input; optional)* Must be scalar and of type integer. It provides the number of elements for the output result.

**Results**

The result has the same type and type parameters as `mold`. 
If \( \text{mold} \) is a scalar and \( \text{size} \) is omitted, the result is a scalar.

If \( \text{mold} \) is an array and \( \text{size} \) is omitted, the result is a rank-one array. Its size is the smallest that is possible to hold all of \( \text{source} \).

If \( \text{size} \) is present, the result is a rank-one array of size \( \text{size} \).

When the size of \( \text{source} \) is greater than zero, \( \text{mold} \) must not be an array with elements of size zero.

If the physical representation of the result is larger than \( \text{source} \), the result contains \( \text{source} \)'s bit pattern in its right-most bits; the left-most bits of the result are undefined.

If the physical representation of the result is smaller than \( \text{source} \), the result contains the right-most bits of \( \text{source} \)'s bit pattern.

**Example**

TRANSFER (1082130432, 0.0) has the value 4.0 (on processors that represent the values 4.0 and 1082130432 as the string of binary digits 0100 0000 1000 0000 0000 0000 0000 0000).

TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0))) results in a scalar whose value is (2.2, 3.3).

TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0)/)) results in a complex rank-one array of length 2. Its first element is (2.2, 3.3) and its second element has a real part with the value 4.4 and an undefined imaginary part.

TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0)/), 1) results in a complex rank-one array having one element with the value (2.2, 3.3).

The following shows another example:

```fortran
COMPLEX CVECTOR(2), CX(1)
! The next statement sets CVECTOR to
! [ 1.1 + 2.2i, 3.3 + 0.0i ]
CVECTOR = TRANSFER((/1.1, 2.2, 3.3, 0.0/), &
                   /(0.0, 0.0)/))
! The next statement sets CX to [ 1.1 + 2.2i ]
CX = TRANSFER((/1.1, 2.2, 3.3/), /(0.0, 0.0)/), &
     SIZE= 1)
WRITE(*,*) CVECTOR
WRITE(*,*) CX
END
```

The following example shows an error because the \( \text{source} \) size is greater than zero but \( \text{mold} \) is an array whose elements have zero size:

```fortran
CHARACTER(0),PARAMETER :: nothing1(100) = ''
PRINT *,SIZE(TRANSFER(111014,nothing1)) ! error
...
```

**TRANSPOSE**

*Transformational Intrinsic Function (Generic):* Transposes an array of rank two.

**Syntax**

\[
\text{result} = \text{TRANSPOSE (matrix)}
\]

\( \text{matrix} \) (Input) Must be a rank-two array. It may be of any data type.

**Results**

The result is a rank-two array with the same type and kind parameters as \( \text{matrix} \). Its shape is \((n, m)\), where \((m, n)\) is the shape of \( \text{matrix} \). For example, if the shape of \( \text{matrix} \) is \((4,6)\), the shape of the result is \((6,4)\).
Element \((i, j)\) of the result has the value \(matrix(j, i)\), where \(i\) is in the range 1 to \(n\), and \(j\) is in the range 1 to \(m\).

**Example**

\(B\) is the array

\[
\begin{bmatrix}
2 & 3 & 4 \\
5 & 6 & 7 \\
8 & 9 & 1
\end{bmatrix}.
\]

\(\text{TRANSPOSE} (B)\) has the value

\[
\begin{bmatrix}
2 & 5 & 8 \\
3 & 6 & 9 \\
4 & 7 & 1
\end{bmatrix}.
\]

The following shows another example:

```
INTEGER array(2, 3), result(3, 2)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
array is  1  3  5
    2  4  6
result = TRANSPOSE(array)
result is 1  2
    3  4
    5  6
END```

**See Also**

RESHAPE
PRODUCT

**TRIM**

*Transformational Intrinsic Function (Generic):*

*Returns the argument with trailing blanks removed.*

**Syntax**

\[
\text{result} = \text{TRIM} (\text{string})
\]

\(\text{string}\)          (Input) Must be a scalar of type character.

**Results**

The result is of type character with the same kind parameter as \(\text{string}\). Its length is the length of \(\text{string}\) minus the number of trailing blanks in \(\text{string}\).

The value of the result is the same as \(\text{string}\), except any trailing blanks are removed. If \(\text{string}\) contains only blank characters, the result has zero length.

**Example**

\(\text{TRIM (' NAME '}\) has the value ' NAME'.

\(\text{TRIM (' C D '}\) has the value ' C D'.

**Language Reference**

2169
The following shows another example:

```fortran
! next line prints 30
WRITE(*, *) LEN("I have blanks behind me       ")
! the next line prints 23
WRITE(*, *) LEN(TRIM("I have blanks behind me       "))
END
```

See Also

LEN_TRIM

TTYNAM

**Portability Subroutine**: Specifies a terminal device name.

**Module**

USE IFPORT

**Syntax**

CALL TTYNAM (string, lunit)

- **string**: (Output) Character*(*). Name of the terminal device. If the Fortran logical unit is not connected to a terminal, it returns a string filled with blanks.

- **lunit**: (Input) INTEGER(4). A Fortran logical unit number.

**Type Declarations**

**Statement**: Explicitly specifies the properties of data objects or functions.

**Syntax**

A type declaration has the general form:

```
type-spec[ [, att] ... :: ] v[/c-list/][, v[/c-list/]] ...
```

- **type-spec**
  - Is one of the following:
    - **intrin-type**
    - TYPE (intrin-type)
    - TYPE (derived-type-name)
    - For information about parameterized derived types, see **Parameterized Derived-Type Declarations**.
    - TYPE (*)
    - This defines the entity as an assumed-type object.
    - CLASS (derived-type-name)
    - CLASS (*)

- **intrin-type**
  - Is one of the following data type specifiers:
    - BYTE
INTEGER[[[KIND=]k]]
REAL[[[KIND=]k]]
DOUBLE PRECISION
COMPLEX[[[KIND=]k]]
DOUBLE COMPLEX
CHARACTER[[[KIND=]k]]
LOGICAL[[[KIND=]k]]

In the optional kind selector "([[KIND=]k]", k is the kind parameter. It must be an acceptable kind parameter for that data type. If the kind selector is not present, entities declared are of default type.

When type-spec is intrin-type, kind parameters for intrinsic numeric and logical data types can also be specified using the *n format, where n is the length (in bytes) of the entity; for example, INTEGER*4. The *n format cannot be used when type-spec is TYPE (intrin-type).

See each data type for further information on that type.

att

<td></td>
</tr>
<tr>
<td>dimension</td>
<td>private</td>
<td>volatile</td>
<td></td>
</tr>
</tbody>
</table>

1These are access specifiers.

You can also declare any attribute separately as a statement.

v

Is the name of a data object or function. It can optionally be followed by:

- An array specification, if the object is an array.
  
  In a function declaration, an array must be a deferred-shape array if it has the POINTER or ALLOCATABLE attribute; otherwise, it must be an explicit-shape array.
- A coarray specification, if the object is a coarray
- A character length, if the object is of type character.
- A constant expression preceded by = or by one of the following for pointer objects:
  
  • => NULL( )
  • => target (pointer initialization)
  • A codimension
A function name must be the name of an intrinsic function, external function, function dummy procedure, or statement function.

\textit{c-list} is a list of constants, as in a DATA statement. If \( v \) has the \textsc{parameter} attribute, the \textit{c-list} cannot be present.

The \textit{c-list} cannot specify more than one value unless it initializes an array. When initializing an array, the \textit{c-list} must contain a value for every element in the array.

**Description**

Type declaration statements must precede all executable statements.

In most cases, a type declaration statement overrides (or confirms) the implicit type of an entity. However, a variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

The double colon separator (::) is required only if the declaration contains an attribute specifier or initialization; otherwise it is optional.

**If \textit{att} or a double colon (::) appears, \textit{c-list} cannot be specified; for example:**

<table>
<thead>
<tr>
<th>Statement</th>
<th>Example 1</th>
<th>Example 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I /2/</td>
<td>Valid</td>
<td>Invalid</td>
</tr>
<tr>
<td>INTEGER, SAVE :: I /2/</td>
<td>Invalid</td>
<td>Valid</td>
</tr>
<tr>
<td>INTEGER, SAVE :: I = 2</td>
<td>Valid</td>
<td></td>
</tr>
</tbody>
</table>

The same attribute must not appear more than once in a given type declaration statement, and an entity cannot be given the same attribute more than once in a scoping unit.

If \textsc{class} is specified, the entity must be a dummy argument or have the \textsc{allocatable} or \textsc{pointer} attribute.

If the \textsc{parameter} attribute is specified, the declaration must contain a constant expression. The \textsc{parameter} attribute must not be specified for a dummy argument, a pointer, an allocatable entity, a function, or an object in a common block.

If \( => \text{NULL( )} \) is specified for a pointer, its initial association status is disassociated.

If \( => \text{target} \) is specified for a pointer, the following rules apply:

- The pointer must be type compatible with the target.
- The pointer and target must have the same rank.
- All nondeferred type parameters of the pointer must have the same values as the corresponding type parameters of the target.
- If the pointer has the \textsc{contiguous} attribute, the target must be contiguous.

A variable (or variable subobject) can only be initialized once in an executable program. If the variable is an array, it must have its shape specified in either the type declaration statement or a previous attribute specification statement in the same scoping unit.

The \textsc{intent}, \textsc{value}, and \textsc{optional} attributes can be specified only for dummy arguments.

The \textsc{intent} attribute must not be specified for a dummy procedure without the \textsc{pointer} attribute.

If the \textsc{value} attribute is specified, the length type parameter values must be omitted or specified by constant expressions. The \textsc{value} attribute must not be specified for a dummy procedure.

An entity must not have both the \textsc{external} attribute and the \textsc{intrinsic} attribute. It can only have one of these attributes if it is a function.

The \textsc{bind} attribute and the \textsc{protected} attribute can appear only in the specification part of a module.

A function result can be declared to have the \textsc{pointer} or \textsc{allocatable} attribute.
An automatic object cannot appear in a SAVE or DATA statement and it cannot be declared with a SAVE attribute nor be initially defined by an initialization.

The SAVE attribute must not be specified for:

- An object that is in a common block
- A procedure
- A dummy argument
- An automatic data object
- A function result
- An object with the PARAMETER attribute

The PROTECTED attribute is only allowed for a procedure pointer or named variable that is not in a common block. A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as:

- A pointer object in a NULLIFY statement
- A data pointer object or procedure pointer object in a pointer assignment statement
- An allocate object in an ALLOCATE statement or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following objects cannot be initialized in a type declaration:

- A dummy argument
- A function result
- An object in a named common block (unless the type declaration is in a block data program unit)
- An object in blank common
- An allocatable variable
- An external name
- An intrinsic name
- An automatic object
- An object that has the AUTOMATIC attribute

If a declaration contains a constant expression, but no PARAMETER attribute is specified, the object is a variable whose value is initially defined. The object becomes defined with the value determined from the constant expression according to the rules of intrinsic assignment.

When type-spec is intrin-type, the interpretation is exactly the same as it would have been without the keyword type and the parentheses. The following declarations for integers K and L and complexes A and B have identical results:

\[
\begin{align*}
\text{TYPE (INTEGER)} &:: \ K, \ L \\
\text{INTEGER} &:: \ K, \ L \\
\text{TYPE (COMPLEX (KIND (0.0D0)))} &:: \ A, \ B \\
\text{COMPLEX (KIND (0.0D0))} &:: \ A, \ B
\end{align*}
\]

A derived-type-name cannot be the same as the name of any standard intrinsic type. The type names BYTE and DOUBLECOMPLEX are not standard type names; they are Intel Fortran extensions. If BYTE or DOUBLECOMPLEX is declared to be a derived-type-name, it overrides the intrinsic name BYTE or DOUBLECOMPLEX. For example:

\[
\begin{align*}
\text{TYPE (DOUBLECOMPLEX)} &:: \ X \\
\text{BYTE} &:: \ Y
\end{align*}
\]

The presence of initialization gives the object the SAVE attribute, except for objects in named common blocks or objects with the PARAMETER attribute.

When the entity is an assumed-type object, the following rules apply:
• The entity has no declared type and its dynamic type and type parameters are assumed from its effective argument. An assumed-type object is unlimited polymorphic.
• An assumed-type object must be a dummy variable that does not have the ALLOCATABLE, CODIMENSION, INTENT(OUT), POINTER, or VALUE attribute and is not an explicit-shape array.
• An assumed-type object that is not assumed-shape and not assumed-rank is intended to be passed as the C address of the object. A TYPE(*) explicit-shape array is not permitted because there is insufficient information passed for an assumed-type explicit-shape array that is an actual argument corresponding to an assumed-shape dummy argument to compute element offsets.
• An assumed-type variable name must not appear in a designator or expression except as an actual argument corresponding to a dummy argument that is assumed-type, or as the first argument to any of the following intrinsic or intrinsic module functions: IS_CONTIGUOUS, LBOUND, PRESENT, RANK, SHAPE, SIZE, UBOUND, and C_LOC.
• An assumed-type actual argument that corresponds to an assumed-rank dummy argument must be assumed-shape or assumed-rank.

An object can have more than one attribute. The following table lists the compatible attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Compatible with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATABLE</td>
<td>AUTOMATIC, ASYNCHRONOUS, CODIMENSION, DIMENSION 1, PRIVATE, PROTECTED, PUBLIC,</td>
</tr>
<tr>
<td></td>
<td>SAVE, STATIC, TARGET, VOLATILE</td>

1 With deferred shape

**Example**

The following show valid type declaration statements:

```fortran
DOUBLE PRECISION B(6)
INTEGER(KIND=2) I
REAL(KIND=4) X, Y
REAL(4) X, Y
LOGICAL, DIMENSION(10,10) :: ARRAY_A, ARRAY_B
INTEGER, PARAMETER :: SMALLEST = SELECTED_REAL_KIND(6, 70)
REAL(KIND (0.0)) M
COMPLEX(KIND=8) :: D
TYPE(EMPLOYEE) :: MANAGER
```
REAL, INTRINSIC :: COS
CHARACTER(15) PROMPT
CHARACTER*12, SAVE :: HELLO_MSG
INTEGER COUNT, MATRIX(4,4), SUM
LOGICAL*2 SWITCH
REAL :: X = 2.0
TYPE (NUM), POINTER :: FIRST => NULL()

The following shows more examples:

REAL a (10)
LOGICAL, DIMENSION (5, 5) :: mask1, mask2
TYPE (COMPLEX) :: cube_root = (-0.5, 0.867)
INTEGER, PARAMETER :: short = SELECTED_INT_KIND (4)
REAL (KIND (0.0D0)) a1
TYPE (REAL (KIND = 4)) b
COMPLEX (KIND = KIND (0.0D0)) :: c
INTEGER (short) k ! Range at least -9999 to 9999
TYPE (member) :: george

The following shows an example of pointer initialization:

integer, target :: v (5) = [1, 2, 3, 4, 5]

type entry
  integer, pointer :: p (5) => v       ! pointer component default initialization
end type entry

type (entry), target :: bottom
type (entry), pointer :: top => bottom   ! pointer initialization

TYPE Statement (Derived Types)
Statement: Declares a variable to be of derived type.
It specifies the name of the user-defined type and the
types of its components.

Syntax
TYPE [[, attr-list] :: ] name [[(type-param-name-list)]
  [type-param-def-stmts]
END TYPE [name]

attr-list

Is one of the following:

- **access-spec**
  
  Is the PUBLIC or PRIVATE attribute. The attribute can only be specified if the derived-type definition is in the specification part of a module.

- **BIND(C)**

- **EXTENDS** *(parent-type-name)*
  
  where *parent-type-name* is the name of a previously defined extensible type.

- **ABSTRACT**

  The same *attr* must not appear more than once in any given derived-type statement.

  If the type definition contains or inherits a deferred binding, ABSTRACT must appear.

  The EXTENDS and ABSTRACT attributes apply to type extension and extended types. If ABSTRACT is specified, the type is an abstract type and it must be extensible.

  A derived type that does not have the SEQUENCE or BIND(C) attribute is extensible. Conversely, a derived type that has the SEQUENCE or BIND(C) attribute is not extensible.

name

Is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.

type-param-name-list

Is a list of type parameter names separated by commas. For more information, see Parameterized Derived-Type Declarations.

type-param-def-stmts

Is one or more INTEGER declarations of the type parameters named in the *type-param-name-list*. For more information, see Parameterized Derived-Type Declarations.

component-definition

Is one or more type declaration statements or procedure pointer statements defining the component of derived type.

The first component definition can be preceded by an optional PRIVATE or SEQUENCE statement. (Only one PRIVATE and only one SEQUENCE statement can appear in a given derived-type definition.)

If SEQUENCE is present, all derived types specified in component definitions must be sequence types.

Procedure pointer component definitions are described in Procedure Pointers as Derived-Type Components.

The syntax for a type declaration component definition is described below.
A type declaration component definition takes the following form:

```fortran
type[ [, attr] :: ] component[[ ( a-spec) ]] [[ coarray-spec ]] [ *char-len ] [ init-ex]
```

- **type**
  - Is a type specifier. It can be an intrinsic type or a previously defined derived type.
  - If the POINTER or the ALLOCATABLE attribute follows this specifier, the type can also be the type being defined or any accessible derived type, whether previously defined or not.

- **attr**
  - Is at most one of the following:
    - An optional POINTER attribute for a pointer component
    - An optional ALLOCATABLE attribute for a scalar component
    - An optional DIMENSION or ALLOCATABLE attribute for an array component
      - You cannot specify both the ALLOCATABLE and POINTER attribute.
    - An optional access specifier, PUBLIC or PRIVATE
    - An optional CODIMENSION [coarray-spec] to specify a coarray
    - An optional CONTIGUOUS attribute if the object is contiguous
  - Each attribute can only appear once in a given component definition.
  - If neither the POINTER nor the ALLOCATABLE attribute is specified, `type` must specify an intrinsic type or a previously defined derived type.
  - If neither the POINTER nor the ALLOCATABLE attribute is specified, each `a-spec` must be an explicit-shape specification.
  - If the POINTER or ALLOCATABLE attribute is specified, each component array specification `a-spec` must be a deferred shape specification (d-spec).
  - If a `coarray-spec` appears, it must be a deferred specification list consisting of one or more colons (:), the component must have the ALLOCATABLE attribute, and the component must not be of type C_PTR or C_FUNPTR.
  - A data component whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar and must not be a coarray.
  - If the CONTIGUOUS attribute is specified, the component must be an array with the POINTER attribute.

- **component**
  - Is the name of the component being defined.

- **a-spec**
  - Is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression.
  - If `component` is an array and the array bounds are not specified here, they must be specified following the DIMENSION attribute.
**coarray-spec**

Is a deferred-coshape specification. The left bracket and right bracket are required.

**char-len**

Is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.

**init-ex**

Is one of the following:

- = constant expression for nonpointer components
- => NULL( ) for pointer components

If `init-ex` is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components.

The constant expression is evaluated in the scoping unit of the type definition.

**Description**

If a name is specified following the END TYPE statement, it must be the same name that follows TYPE in the derived type statement.

A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.

The default accessibility attribute for a module is PUBLIC unless it has been changed by a PRIVATE statement with no entity-list.

A PUBLIC or PRIVATE keyword can only appear on the TYPE statement of a derived-type definition, or on a component or type-bound procedure declaration of the type if the derived-type definition is in the specification part of a module.

The PRIVATE statement can only be specified in the component-definition or type-bound-procedure-part if the derived-type definition is in the specification part of a module. A PRIVATE statement inside a component-definition part specifies that the default accessibility of all components of the derived type are PRIVATE. Similarly, a PRIVATE statement inside a type-bound-procedure-part specifies that the default accessibility of the type bound procedures of the derived type are PRIVATE. If the default accessibility of components or type-bound procedures is PRIVATE, individual components or type-bound procedures can be declared PUBLIC, overriding the default accessibility attribute.

If a type definition is PRIVATE, the type name and the structure constructor for the type are accessible only within the module containing the definition and in the descendants of that module.

Two data entities have the same type if they are both declared to be of the same derived type; the derived-type definition can be accessed from a module or a host scoping unit.

If EXTENDS appears and the type being defined has a coarray ultimate component, its parent type must have a coarray ultimate component.

Data entities in different scoping units also have the same type if the following is true:

- They are declared with reference to different derived-type definitions that specify the same type name.
- All have the SEQUENCE property.
- All have the BIND attribute.
- They have no components with PRIVATE accessibility.
- They have type parameters and components that agree in order, name, and attributes.

Otherwise, they are of different derived types.
A data component is a coarray if the component declaration contains a coarray specification. If the component declaration contains a coarray specification, it specifies the corank.

If BIND (C) is specified, the following rules apply:

- The derived type cannot be a SEQUENCE type.
- The derived type must not have type parameters.
- The derived type must not have the EXTENDS attribute.
- The derived type must not have a type-bound-procedure-part.
- Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.

**Example**

```fortran
! DERIVED.F90
! Define a derived-type structure, type variables, and assign values

TYPE member
    INTEGER age
    CHARACTER (LEN = 20) name
END TYPE member

TYPE (member) :: george
TYPE (member) :: ernie

george = member( 33, 'George Brown' )
ernie%age = 56
ernie%name = 'Ernie Brown'

WRITE (*,*) george
WRITE (*,*) ernie
END
```

The following shows another example of a derived type:

```fortran
TYPE mem_name
    SEQUENCE
    CHARACTER (LEN = 20) lastn
    CHARACTER (LEN = 20) firstn
    CHARACTER (LEN = 3) cos   ! this works because COS is a component name
END TYPE mem_name

TYPE member
    SEQUENCE
    TYPE (mem_name) :: name
    INTEGER age
    CHARACTER (LEN = 20) specialty
END TYPE member
```

In the following example, a and b are both variable arrays of derived type pair:

```fortran
USE, INTRINSIC :: ISO_C_BINDING
TYPE, BIND(C) :: pair
    INTEGER(C_INT) :: i, j
END TYPE

TYPE (pair) :: a, b(3)
```
The following example shows how you can use derived-type objects as components of other derived-type objects:

```fortran
TYPE employee_name
  CHARACTER(25) last_name
  CHARACTER(15) first_name
END TYPE
TYPE employee_addr
  CHARACTER(20) street_name
  INTEGER(2) street_number
  INTEGER(2) apt_number
  CHARACTER(20) city
  CHARACTER(2) state
  INTEGER(4) zip
END TYPE
```

Objects of these derived types can then be used within a third derived-type specification, such as:

```fortran
TYPE employee_data
  TYPE (employee_name) :: name
  TYPE (employee_addr) :: addr
  INTEGER(4) telephone
  INTEGER(2) date_of_birth
  INTEGER(2) date_of_hire
  INTEGER(2) social_security(3)
  LOGICAL(2) married
  INTEGER(2) dependents
END TYPE
```

The following program shows how you initialize components of a derived-type object:

```fortran
TYPE list_node
  CHARACTER(20) :: street_name = " "
  INTEGER(2) :: street_number = 0
  INTEGER(2) :: apt_number = -1
  CHARACTER(20) :: city = " 
  CHARACTER(2) :: state = "NH"
  INTEGER(4) :: zip = 0
  TYPE (list_node), pointer :: next => NULL()
END TYPE

TYPE (list_node) :: x = list_node (zip = 03054)
PRINT *, x%state, x%zip
END
```

The above prints the following:

```
NH 3054
```

Coarrays are a Fortran 2008 feature. The following example shows a derived-type definition with a coarray component:

```fortran
TYPE NEW_TYPE
  REAL, ALLOCATABLE, CODIMENSION[:,:,:] :: NEW(:,:,,:)
END TYPE NEW_TYPE
```

An object of type NEW_TYPE must be a scalar and it cannot be a pointer, allocatable, or a coarray.
The following example shows a derived-type definition containing a \texttt{coarray-spec}:

```fortran
  type t
    integer :: k
    real, allocatable :: x (:,:)[,:,:]
  end type t
```

In the following example, when the assignment to \texttt{DEST} occurs, \texttt{DEST\%TA} is unallocated: it is first allocated with the size of \texttt{SOURCE\%TA} and then the value of \texttt{SOURCE\%TA} is assigned into \texttt{DEST\%TA}:

```fortran
  TYPE T
   INTEGER I
  END TYPE T
  TYPE T2
   TYPE (T), ALLOCATABLE :: TA
  END TYPE T2
  TYPE (T2) SOURCE, DEST
  ALLOCATE(SOURCE\%TA)
  DEST = SOURCE
```

The use of allocatable components of recursive type can involve direct recursion, in which the type has a component that is the same type as its parent. The following example creates a five-element linked list using allocatable components of recursive type:

```fortran
  TYPE T
   INTEGER I
   TYPE(T), ALLOCATABLE :: NEXT
  END TYPE
  TYPE (T), ALLOCATABLE, TARGET :: ORIG, COPY
  TYPE (T), POINTER :: TA
  ALLOCATE(ORIG)
  TA => ORIG
  DO I=1,5
    TA\%I = I
    ALLOCATE(TA\%NEXT)
    TA => TA\%NEXT
  END DO
```

By using allocatable components rather than pointer components, there is no need to explicitly nullify component \texttt{NEXT} - it is set to an unallocated state automatically by the compiler. Because the semantics of \texttt{ALLOCATE(SOURCE=)} require the allocation and copying of all allocated allocatable components from \texttt{ORIG} into \texttt{COPY}, we can create a complete, unique copy of the entire linked list in one easy statement:

```fortran
  ALLOCATE(COPY, SOURCE=ORIG)
```

In addition to direct recursion, indirect recursion or forward referencing can also be used. In the following example, component \texttt{A} of type \texttt{T} is of type \texttt{T2}, a forward reference to a type not yet defined, while component \texttt{B} of type \texttt{T2} is of type \texttt{T}:

```fortran
  TYPE T
  TYPE(T2), ALLOCATABLE :: A
  END TYPE
  TYPE T2
  TYPE(T), ALLOCATABLE :: B
```

UBOUND

_Inquiry Intrinsic Function (Generic):_ Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.

Syntax

\[
\text{result} = \text{UBOUND} \left( \text{array} \ [, \ dim] \ [, \ kind] \right)
\]

- **array**
  
  (Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer. It can be an assumed-size array if \( dim \) is present with a value less than the rank of \( array \).

- **dim**
  
  (Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( array \).

- **kind**
  
  (Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If \( kind \) is present, the kind parameter of the result is that specified by \( kind \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rule applies if \( array \) is not assumed-rank:

- If \( dim \) is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of \( array \). Each element in the result corresponds to a dimension of \( array \).

The following rules apply if \( array \) is assumed-rank:
• If *dim* is present and *array* is assumed-rank, the value of the result is as if *array* were a whole array, with the extent of the final dimension of *array* when *array* is associated with an assumed-size array being considered to be −1.

• If **BOUND is invoked for an assumed-rank object that is associated with a scalar and *dim* is absent, the result is a zero-sized array. **BOUND cannot be invoked for an assumed-rank object that is associated with a scalar if *dim* is present because the rank of a scalar is zero and *dim* must be ≥ 1.

If *array* is an array section or an array expression that is not a whole array or array structure component, **BOUND(*array*, *dim*) has a value equal to the number of elements in the given dimension.

If *array* is a whole array or array structure component, **BOUND(*array*, *dim*) has a value equal to the upper bound for subscript *dim* of *array* (if *dim* is nonzero). If *dim* has size zero, the corresponding element of the result has the value zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following:

```fortran
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

**BOUND (ARRAY_A) is (3, 8).** **BOUND (ARRAY_A, DIM=2) is 8.**

**BOUND (ARRAY_B) is (8, 20).** **BOUND (ARRAY_B (5:8, :)) is (4,24) because the number of elements is significant for array section arguments.**

The following shows another example:

```fortran
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = **BOUND (ar1) ! returns [3, 5, 14]
res2 = **BOUND (ar1, DIM= 3) ! returns 14
res3 = **BOUND (vec1) ! returns [35]
END
```

**See Also**

LBOUND

**UCBOUND**

*Inquiry Intrinsic Function (Generic): Returns the upper cobounds of a coarray.*

**Syntax**

```fortran
result = **BOUND (coarray [,dim [, kind]])
```

*coarray*  
*(Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.*

*dim*  
*(Input; optional) Must be an integer scalar with a value in the range 1 <= *dim* <= *n*, where *n* is the corank of *coarray*. The corresponding actual argument must not be an optional dummy argument.*

*kind*  
*(Input; optional) Must be a scalar integer constant expression.*

**Results**

The result type is integer. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of default integer type. The result is scalar if *dim* is present; otherwise, the result is an array of rank one and size *n*, where *n* is the corank of *coarray*. 
The result depends on whether \textit{dim} is specified:

- If \textit{dim} is specified, \texttt{UCOBOUND (COARRAY, DIM)} has a value equal to the upper cobound for cosubscript \texttt{dim} of \texttt{coarray}.
- If \textit{dim} is not specified, \texttt{UCOBOUND (COARRAY)} has a value whose \textit{i}th element is equal to \texttt{UCOBOUND (COARRAY, i)}, for \textit{i} = 1, 2, \ldots, \textit{n}, where \textit{n} is the corank of \texttt{coarray}.

\textbf{Example}

If \texttt{A} is allocated by the statement \texttt{ALLOCATE (A [2:3, 7:*])}, then \texttt{LCOBOUND (A)} is [2, 7] and \texttt{LCOBOUND (A, DIM=2)} is 7.

If \texttt{NUM_Images()} has the value 30, and \texttt{coarray B} is allocated by the statement \texttt{ALLOCATE (B[2:3, 0:7, *])}, then \texttt{UCOBOUND (B)} is [3, 7, 2] and \texttt{UCOBOUND (B, DIM=2)} is 7. Note that the cosubscripts [3, 7, 2] do not correspond to an actual image.

\textbf{UNDEFINE}

\textit{Statement:} Removes a defined symbol.

\textbf{See Also}

See \texttt{DEFINE} and \texttt{UNDEFINE}.

\textbf{UNION and END UNION}

\textit{Statements:} Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.

\textbf{Syntax}

Each unique field or group of fields is defined by a separate map declaration.

\begin{verbatim}
UNION
  map-declaration
  map-declaration
  [map-declaration]
  . .
  [map-declaration]
END UNION
map-declaration
\end{verbatim}

\textit{Takes the following form:}

\begin{verbatim}
MAP
  field-declaration
  [field-declaration]
  . .
  [field-declaration]
END MAP
\end{verbatim}
field-declaration

Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.

As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.

Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.

Example

In the following example, the structure WORDS_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER*2 variables (WORD_0, WORD_1, and WORD_2), and the second, an INTEGER*4 variable, LONG:

```
STRUCTURE /WORDS_LONG/
  UNION
    MAP
      INTEGER*2  WORD_0, WORD_1, WORD_2
    END MAP
    MAP
      INTEGER*4  LONG
    END MAP
  END UNION
END STRUCTURE
```
The length of any record with the structure WORDS_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS_LONG:

**Memory Map of Structure WORDS_LONG**

In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```
UNION
  MAP
    CHARACTER*20 string1, CHARACTER*10 string2(6)
  END MAP
  MAP
    INTEGER*2 number(10), INTEGER*4 var(10), INTEGER*2
    +
    datum(10)
  END MAP
END UNION
```

- STRUCTURE and END STRUCTURE
- Record Structures

**UNLINK**

*Portability Function*: Deletes the file given by path.

**Module**

USE IFPORT

**Syntax**

```
result = UNLINK (name)
```

*name* (Input) Character*(*). Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

- ENOENT: The specified file could not be found.
• **EACCES:** The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.

**Example**

```fortran
USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirname
READ *, dirname
ISTATUS = UNLINK (dirname)
IF (ISTATUS) then
    print *, 'Error ', ISTATUS
END IF
END
```

**See Also**

SYSTEM
DELDIRQQ

**UNPACK**

**Transformational Intrinsic Function (Generic):**

* Takes elements from a rank-one array and unpacks them into another (possibly larger) array under the control of a mask.

**Syntax**

```fortran
result = UNPACK (vector, mask, field)
```

- **vector**
  - (Input) Must be a rank-one array. It may be of any data type. Its size must be at least \( t \), where \( t \) is the number of true elements in \( mask \).

- **mask**
  - (Input) Must be a logical array. It determines where elements of \( vector \) are placed when they are unpacked.

- **field**
  - (Input) Must be of the same type and type parameters as \( vector \) and conformable with \( mask \). Elements in \( field \) are inserted into the result array when the corresponding \( mask \) element has the value false.

**Results**

The result is an array with the same shape as \( mask \), and the same type and type parameters as \( vector \).

Elements in the result array are filled in array element order. If element \( i \) of \( mask \) is true, the corresponding element of the result is filled by the next element in \( vector \). Otherwise, it is filled by \( field \) (if \( field \) is scalar) or the \( i \)th element of \( field \) (if \( field \) is an array).

**Example**

\( N \) is the array

```
[ 0  0  1 ]
[ 1  0  1 ]
[ 1  0  0 ],
```
P is the array (2, 3, 4, 5), and Q is the array

\[
\begin{bmatrix}
T & F & F \\
F & T & F \\
T & T & F
\end{bmatrix}
\]

UNPACK (P, MASK=Q, FIELD=N) produces the result

\[
\begin{bmatrix}
2 & 0 & 1 \\
1 & 4 & 1 \\
3 & 5 & 0
\end{bmatrix}
\]

UNPACK (P, MASK=Q, FIELD=1) produces the result

\[
\begin{bmatrix}
2 & 1 & 1 \\
1 & 4 & 1 \\
3 & 5 & 1
\end{bmatrix}
\]

The following shows another example:

```fortran
LOGICAL mask (2, 3)
INTEGER vector(3) /1, 2, 3/, AR1(2, 3)
mask = RESHAPE((/.TRUE.,.FALSE.,.FALSE.,.TRUE..FALSE.,.TRUE.,
 & .TRUE.,.FALSE.,/), (/2, 3/))
! vector = [1 2 3] and mask = T F T
!                              F T F
AR1 = UNPACK(vector, mask, 8)  ! returns  1 8 3
!          8 2 8
END
```

RESHAPE
SHAPE

**UNPACKTIMEQQ**

*Portability Subroutine:* Unpacks a packed time and date value into its component parts.

**Syntax**

```fortran
CALL UNPACKTIMEQQ (timedate,iyr,imon,iday,ihr,imin,isec)
```

- **timedate** (Input) INTEGER(4). Packed time and date information.
- **iyr** (Output) INTEGER(2). Year (xxxxAD).
- **imon** (Output) INTEGER(2). Month (1 - 12).
- **iday** (Output) INTEGER(2). Day (1 - 31).
- **ihr** (Output) INTEGER(2). Hour (0 - 23).
- **imin** (Output) INTEGER(2). Minute (0 - 59).
- **isec** (Output) INTEGER(2). Second (0 - 59).
GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values.

The output values reflect the time zone set on the local computer and the daylight savings rules for that time zone.

Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

**Example**

```fortran
USE IFPORT
CHARACTER(80)    file
TYPE (FILESINFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec

file = 'd:\f90ps\bin\t???.*'
handle = FILE$FIRST
result = GETFILEINFOQQ(file, info, handle)
CALL UNPACKTIMEQQ(info%lastwrite, iyr, imon,&
   iday, ihr, imin, isec)
WRITE(*,*) iyr, imon, iday
WRITE(*,*) ihr, imin, isec
END
```

**See Also**

---

**UNREGISTERMOUSEEVENT (W*S)**

*QuickWin Function:* Removes the callback routine registered for a specified window by an earlier call to REGISTERMOUSEEVENT.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = UNREGISTERMOUSEEVENT (unit, mouseevents)
```

<table>
<thead>
<tr>
<th><strong>unit</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Unit number of the window whose callback routine on mouse events is to be unregistered.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>mouseevents</strong></th>
</tr>
</thead>
</table>
| (Input) INTEGER(4). One or more mouse events handled by the callback routine to be unregistered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:
- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$BUTTONUP - Left mouse button up
- MOUSE$BUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE$MOVE - Mouse moved |
Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer can be one of the following:

- MOUSE$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE$BADEVENT - The event specified is not supported.

Once you call UNREGISTERMOUSEEVENT, QuickWin no longer calls the callback routine specified earlier for the window when mouse events occur. Calling UNREGISTERMOUSEEVENT when no callback routine is registered for the window has no effect.

WAITONMOUSEEVENT

UNROLL and NOUNROLL

General Compiler Directive: Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.

Syntax

!DIR$ UNROLL [(n)] -or- !DIR$ UNROLL [=n]

!DIR$ NOUNROLL

n Is an integer constant. The range of n is 0 through 255.

If n is specified, the optimizer unrolls the loop n times. If n is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or O3 must be set.

Example

!DIR$ UNROLL
  do i =1, m
    b(i) = a(i) + 1
    d(i) = c(i) + 1
  enddo

The following shows another example:

!DIR$ UNROLL=4
  do i =1, m
    b(i) = a(c(i)) + 1
  enddo

O compiler option
UNROLL_AND_JAM and NOUNROLL_AND_JAM

General Compiler Directive: Hints to the compiler to enable or disable loop unrolling and jamming. These directives can only be applied to iterative DO loops.

Syntax

!DIR$ UNROLL_AND_JAM [(n)] -or- !DIR$ UNROLL_AND_JAM [=n]

!DIR$ NOUNROLL_AND_JAM

n Is an integer constant. The range of n is 0 through 255.

The UNROLL_AND_JAM directive partially unrolls one or more loops higher in the nest than the innermost loop and fuses (jams) the resulting loops back together. This transformation allows more reuses in the loop. This directive is not effective on innermost loops. You must ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this directive is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler will enable this transformation whenever possible.

The UNROLL_AND_JAM directive must precede the DO statement for each DO loop it affects. If n is specified, the optimizer unrolls the loop n times. If n is omitted or if it is outside the allowed range, the optimizer chooses the number of times to unroll the loop. The compiler generates correct code by comparing n and the loop count.

This directive is supported only when compiler option O3 is set. The UNROLL_AND_JAM directive overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size, it may be necessary to prevent unrolling of a nested or imperfect nested loop. In such cases, use the NOUNROLL_AND_JAM directive, which hints to the compiler not to unroll a specified loop.

Example

```fortran
integer a(10,10), b(10,10), c(10,10), d(10,10)
integer i, j, k

!dir$ unroll_and_jam = 6

do i=1,10
   !dir$ unroll_and_jam (6)
do j=1,10
   do k=1,10
      a (j, i) = a (j, i) + b (k, i) *c (k, j)
   end do
   ! k
end do
   ! j
end do
   ! i
end
```

UNTIED Clause

Parallel Directive Clause: Specifies that the task is never tied to the thread that started its execution.

Syntax

UNTIED

Any thread in the team can resume the task region after a suspension. For example, during runtime, the execution of a given task can start on thread A, break execution, and later resume on thread B.

USE

Statement: Gives a program unit accessibility to public entities in a module.

Syntax

USE [[, mod-nature] ::] name [, rename-list]
USE [[, mod-nature] ::] name, ONLY : [ only-list]

mod-nature

Is INTRINSIC or NON_INTRINSIC. If INTRINSIC is used, name must be the name of an intrinsic module. If NON_INTRINSIC is used, name must be the name of a nonintrinsic module. If mod-nature is not specified, name must be the name of an intrinsic or nonintrinsic module. If both are provided, the nonintrinsic module is used. It is an error to specify a user module and an intrinsic module of the same name in the same program unit (see Examples).

name

Is the name of the module.

rename-list

Is one or more items, separated by commas, having the following form:

local-name => mod-name

local-name

Is the name of the entity in the program unit using the module or is "OPERATOR (op-name)", where op-name is the name of a defined operator in the program unit using the module.

mod-name

Is the name of a public entity in the module or is "OPERATOR (op-name)", where op-name is the name of a public entity in the module.

only-list

Is one or more items, separated by commas, where each item is the name of a public entity in the module or a generic identifier (a generic name, a defined operator specified as "OPERATOR (op-name)", or defined assignment).

An entity in the only-list can also take the form:

[local-name =>] mod-name
Description

If the USE statement is specified without the ONLY option, the program unit has access to all public entities in the named module.

If the USE statement is specified with the ONLY option, the program unit has access to only those entities following the option.

If more than one USE statement for a given module appears in a scoping unit, the following rules apply:

- If one USE statement does not have the ONLY option, all public entities in the module are accessible, and any rename-lists and only-lists are interpreted as a single, concatenated rename-list.
- If all the USE statements have ONLY options, all the only-lists are interpreted as a single, concatenated only-list. Only those entities named in one or more of the only-lists are accessible.

If two or more generic interfaces that are accessible in a scoping unit have the same name, the same operator, or are both assignments, they are interpreted as a single generic interface. Otherwise, multiple accessible entities can have the same name only if no reference to the name is made in the scoping unit.

The local names of entities made accessible by a USE statement must not be declared locally other than in a PUBLIC, PRIVATE, VOLATILE, or ASYNCHRONOUS statement. Within a module, if a use-associated entity is declared VOLATILE or ASYNCHRONOUS, it has the default accessibility of a locally declared identifier.

The local names of use-associated entities can appear in namelist group lists, but not in a COMMON or EQUIVALENCE statement.

If the name of every module from which a use-associated entity is accessed appears in an accessibility statement, the default accessibility of the entity is PRIVATE if every such accessibility statement is PRIVATE, and PUBLIC if any such accessibility statement is PUBLIC.

The accessibility of a use associated entity within a module can be determined by applying the following rules in the specified order:

1. It is PUBLIC if the entity is specified in the entity-list of a PUBLIC statement. It is PRIVATE if the entity is specified in the entity-list of a PRIVATE statement.
2. If the entity is declared locally in an ASYNCHRONOUS or VOLATILE statement, go to 5.
3. It is PUBLIC if any module through which the entity is accessible appears in a PUBLIC statement.
4. It is PRIVATE if every module thru which the entity is accessible appears in a PRIVATE statement.
5. It is PUBLIC if there is a PUBLIC statement with no entity-list specified in the module. It is PRIVATE if there is a PRIVATE statement with no entity-list specified in the module.
6. It is PUBLIC.

Examples

The following shows examples of the USE statement:

```fortran
MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5), D(100)
END MODULE MOD_A
...
SUBROUTINE SUB_Y
  USE MOD_A, DX => D, EX => E   ! Array D has been renamed DX and array E
                             ! has been renamed EX. Scalar variables B
                             ! and C are also available to this
                             ! subroutine (using their module names).
END SUBROUTINE SUB_Y
...
SUBROUTINE SUB_Z
  USE MOD_A, ONLY: B, C         ! Only scalar variables B and C are
                             ! available to this subroutine
END SUBROUTINE SUB_Z
...```
You must not specify a user module and an intrinsic module of the same name in the same program unit. For example, if you specify a user module named ISO_FORTRAN_ENV, then it is illegal to specify the following in the same program unit:

```fortran
USE :: ISO_FORTRAN_ENV
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

The following example shows a module containing common blocks:

```fortran
MODULE COLORS
   COMMON /BLOCKA/ C, D(15)
   COMMON /BLOCKB/ E, F
...
END MODULE COLORS
...
FUNCTION HUE(A, B)
   USE COLORS
   ...
END FUNCTION HUE
```

The USE statement makes all of the variables in the common blocks in module COLORS available to the function HUE.

To provide data abstraction, a user-defined data type and operations to be performed on values of this type can be packaged together in a module. The following example shows such a module:

```fortran
MODULE CALCULATION
   TYPE ITEM
      REAL :: X, Y
   END TYPE ITEM

   INTERFACE OPERATOR (+)
      MODULE PROCEDURE ITEM_CALC
   END INTERFACE

   CONTAINS
      FUNCTION ITEM_CALC (A1, A2)
         TYPE(ITEM) A1, A2, ITEM_CALC
         ...
      END FUNCTION ITEM_CALC
      ...
END MODULE CALCULATION

PROGRAM TOTALS
USE CALCULATION
TYPE(ITEM) X, Y, Z
...
X = Y + Z
...
END
```

The USE statement allows program TOTALS access to both the type ITEM and the extended intrinsic operator + to perform calculations.

The following shows another example:

```fortran
! Module containing original type declarations
MODULE geometry
type square
   real side
   integer border
end type
```
The following shows a defined operator in a USE statement:

```fortran
USE mymod, OPERATOR(.localop.) => OPERATOR(.moduleop.)
```

Entities in modules can be accessed either through their given name, or through aliases declared in the USE statement of the main program unit. For example:

```fortran
USE MODULE_LIB, XTABS => CROSSTABS
```

This statement accesses the routine called CROSSTABS in MODULE_LIB by the name XTABS. This way, if two modules have routines called CROSSTABS, one program can use them both simultaneously by assigning a local name in its USE statement.

When a program or subprogram renames a module entity, the local name (XTABS, in the preceding example) is accessible throughout the scope of the program unit that names it.

The ONLY option also allows public variables to be renamed. Consider the following:

```fortran
USE MODULE_A, ONLY: VARIABLE_A => VAR_A
```

In this case, the host program accesses only VAR_A from module A, and refers to it by the name VARIABLE_A.

Consider the following example:

```fortran
MODULE FOO
  integer foos_integer
  PRIVATE
  integer foos_my_integer
END MODULE FOO
```

PRIVATE, in this case, makes the PRIVATE attribute the default for the entire module FOO. To make foos_integer accessible to other program units, add the line:

```fortran
PUBLIC :: foos_integer
```

Alternatively, to make only foos_my_integer inaccessible outside the module, rewrite the module as follows:

```fortran
MODULE FOO
  integer foos_integer
  integer, private::foos_my_integer
END MODULE FOO
```

Given the following module declarations:

```fortran
MODULE mod1
  INTEGER x1
END MODULE
```
MODULE mod2
    USE mod1
    INTEGER x2
END MODULE

Then in module mod3 below, x1 has default accessibility of PRIVATE:

MODULE mod3
    USE mod2
    PUBLIC x2 ! x2 is PUBLIC
    PRIVATE ! x1 is PRIVATE
END MODULE

In mod4 below, even though x1 is declared in mod1, and mod1 is declared PRIVATE in mod4, x1 is PUBLIC since it is declared VOLATILE and it assumes the default accessibility of PUBLIC of a locally declared identifier in mod4:

MODULE mod4
    USE mod1
    PRIVATE mod1
    VOLATILE x1 ! x1 is PUBLIC
END MODULE

In mod5 below, x1 and x2 are both PRIVATE since all modules from which they are accessed appear in PRIVATE statements:

MODULE mod5
    USE mod1
    USE mod2
    PRIVATE mod1
    PRIVATE mod2 ! x1 and x2 are PRIVATE
END MODULE

However, in mod6 below, both x1 and x2 are PUBLIC since they are accessible thru the use of mod2 which is declared PUBLIC:

MODULE mod6
    USE mod1
    USE mod2
    PRIVATE mod1
    PUBLIC mod2 ! x1 and x2 are PUBLIC
END MODULE

%VAL

Built-in Function: Changes the form of an actual argument. Passes the argument as an immediate value.

Syntax

%VAL (a)

a

(Input) An expression, record name, procedure name, array, character array section, or array element.

Description

The argument is passed as follows:
On IA-32 architecture, as a 32-bit immediate value. If the argument is integer (or logical) and shorter than 32 bits, it is sign-extended to a 32-bit value. For complex data types, %VAL passes two 32-bit arguments.

On Intel® 64 architecture, as a 64-bit immediate value. If the argument is integer (or logical) and shorter than 64 bits, it is sign-extended to a 64-bit value. For complex data types, %VAL passes two 64-bit arguments.

You must specify %VAL in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following tables list the Intel® Fortran defaults for argument passing, and the allowed uses of %VAL:

### Expressions

</tbody>
</table>

¹ If a logical or integer value occupies less than 64 bits of storage on Intel® 64 architecture, or 32 bits of storage on IA-32 architecture, it is converted to the correct size by sign extension. Use the ZEXT intrinsic function if zero extension is desired.
A character argument is passed by address and hidden length.

In Intel® Fortran record structures, the %VAL and %REF functions override related !DIR$ ATTRIBUTE settings.

Example

```
CALL SUB(2, %VAL(2))
```

Constant 2 is passed by reference. The second constant 2 is passed by immediate value.

CALL
%REF
%LOC

VALUE

Statement and Attribute: Specifies a type of argument association for a dummy argument.

Syntax

The VALUE attribute can be specified in a type declaration statement or a VALUE statement, and takes one of the following forms:

Type Declaration Statement:

```
type, [att-ls, ] VALUE [, att-ls] :: arg [, arg] ...
```

Statement:

```
VALUE [:::] arg [, arg]...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `arg` Is the name of a dummy argument.

Description

The VALUE attribute can be used in INTERFACE body or in a procedure. It can only be specified for dummy arguments. It cannot be specified for a dummy procedure.

An entity with the VALUE attribute must be a dummy data object that is not an assumed-size array or a coarray, and does not have a coarray ultimate component.

When this attribute is specified for a present dummy argument, the dummy argument becomes associated with a temporary, definable data object whose initial value is that of the corresponding actual argument. The actual mechanism by which this happens is determined by the compiler. If the procedure also has the BIND(C) attribute, the dummy argument is interoperable with the corresponding formal parameter of the C language prototype, causing the argument to be passed or received by value if C would do so.

When the VALUE attribute is used in a type declaration statement, any length type parameter values must be omitted or they must be specified by initialization expressions.

If the VALUE attribute is specified, you cannot specify a PARAMETER, EXTERNAL, POINTER, ALLOCATABLE, VOLATILE, or INTENT (INOUT or OUT) attribute in the same scoping unit.

You can use option assume nostd_value to tell the compiler to use non-standard semantics for VALUE so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.
Example
The following example shows how the VALUE attribute can be applied in a type declaration statement.

```fortran
j = 3
call sub (j)
write (*,*) j ! Writes 3
contains
subroutine sub (i)
  integer, value :: i
  i = 4
  write (*,*) i ! Writes 4
end subroutine sub
end
```

**assume** compiler option

### VECREMAINDER Clause

**General Directive Clause:** Allows the compiler to vectorize (or not to vectorize) any peel or remainder loops when the original loop is vectorized.

**Syntax**

```
[NO]VECREMAINDER
```

If !DIR$ VECTOR ALWAYS is specified, the following occurs:

- If VECREMAINDER is specified, the compiler vectorizes peel and remainder loops when the original main loop is vectorized.
- If NOVECREMAINDER is specified, the compiler does not vectorize peel or remainder loops when the original main loop is vectorized.
- If neither the VECREMAINDER or NOVECREMAINDER clause is specified, the compiler overrides efficiency heuristics of the vectorizer and it determines whether the loop can be vectorized.

See Also
VECTOR and NOVECTOR
SIMD Loop Directive

### VECTOR and NOVECTOR

**General Compiler Directive:** Overrides default heuristics for vectorization of DO loops. It can also affect certain optimizations.

**Syntax**

```
!DIR$ VECTOR [clause[, clause]...]
!DIR$ NOVECTOR
```

`clause` Is an optional vectorization or optimizer clause. It can be one or more of the following:
• **ALIGNED | UNALIGNED**

  Specifies that all data is aligned or no data is aligned in a DO loop. These clauses override efficiency heuristics in the optimizer.

  The ALIGNED clause instructs the compiler to assume all array references are aligned. As a result, misalignment properties analyzed from the program context, if any, will be discarded. The UNALIGNED clause is a hint to the compiler to avoid alignment optimizations; the compiler can still use available alignment information. These clauses disable advanced alignment optimizations of the compiler, such as dynamic or static loop peeling to make references aligned.

  Be careful when using the ALIGNED clause. The compiler may choose to use aligned data movement instructions, instructions with memory operands that require alignment, and/or nontemporal stores. Such instructions will cause a runtime exception if some of the access patterns are actually unaligned.

• **ALWAYS [ASSERT]**

  Enables or disables vectorization of a DO loop.

  The ALWAYS clause overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized. You should use the IVDEP directive to ignore assumed dependences.

• **DYNAMIC_ALIGN [(var)] | NODYNAMIC_ALIGN**

  Enables or disables dynamic alignment optimization. Dynamic alignment is an optimization the compiler attempts to perform by default. It involves peeling iterations from the vector loop into a scalar loop before the vector loop so that the vector loop aligns with a particular memory reference.

  If you specify (var) for DYNAMIC_ALIGN, you can indicate a scalar or array variable name on which to align. Specifying DYNAMIC_ALIGN, with or without (var) does not guarantee the optimization is performed; the compiler still uses heuristics to determine feasibility of the optimization. The NODYNAMIC_ALIGN clause disables the optimization for the loop.

• **G2S or NOG2S**

  Enables or disables the use of gather/scatter instructions in the lexically next loop.

  The G2S clause tells the optimizer to disable the generation of gather/scatter and to transform gather/scatter into unit-strided loads/stores plus a set of shuffles wherever possible. The NOG2S clause tells the optimizer to enable the generation of gather/scatter instructions and not to transform gather/scatter into unit-strided loads/stores.

  These clauses do not affect loops nested in the specified loop.

• **MASK_READWRITE | NOMASK READWRITE**
Enables or disables the generation of masked load and store operations within conditional statements.

The MASK_READWRITE clause directs the compiler to disable memory speculation, causing the generation of masked load and store operations within conditional statements. The NOMASK_READWRITE clause directs the compiler to enable memory speculation, causing the generation of unmasked loads and stores within conditional statements.

- **TEMPORAL | NONTEMPORAL ([var1 [, var2]...])**
  
  *var* is an optional memory reference in the form of a variable name.

Controls how the "stores" of register contents to memory are performed (streaming versus non-streaming).

The TEMPORAL clause directs the compiler to use temporal (that is, non-streaming) stores. The NONTEMPORAL clause directs the compiler to use non-temporal (that is, streaming) stores.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

- **[NO]VECREMAINDER**
- **VECTORLENGTH (n1 [, n2]...)**

Tells the vectorizor which vector length/factor to use when generating the main vector loop. *n* is an integer power of 2; the value must be 2, 4, 8, 16, 32, or 64. If more than one value is specified, the vectorizor will choose one of the specified vector lengths based on a cost model decision.

The VECTOR and NOVECTOR directives control vectorization of the DO loop that directly follows the directive.

If the MASK_READWRITE clause is specified, the compiler generates masked loads and stores within all conditional branches in the loop. If the NOMASK_READWRITE clause is specified, the compiler generates unmasked loads and stores for increased performance.

**Caution**
The VECTOR directive should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

**Example**
The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).
In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```fortran
!DIR$ VECTOR ALWAYS
do i = 1, 100, 2
   ! two references with stride 2 follow
   a(i) = b(i)
enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the NOVECTOR directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```fortran
!DIR$ NOVECTOR
do i = 1, 100
   a(i) = b(i) + c(i)
enddo
```

Rules for Loop Directives that Affect Array Assignment Statements

**VERIFY**

*Elemental Intrinsic Function (Generic):* Verifies that a set of characters contains all the characters in a string by identifying the first character in the string that is not in the set.

**Syntax**

```fortran
result = VERIFY (string, set [, back] [, kind])
```

- **string** (Input) Must be of type character.
- **set** (Input) Must be of type character with the same kind parameter as `string`.
- **back** (Input; optional) Must be of type logical.
- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `back` is omitted (or is present with the value false) and `string` has at least one character that is not in `set`, the value of the result is the position of the leftmost character of `string` that is not in `set`.

If `back` is present with the value true and `string` has at least one character that is not in `set`, the value of the result is the position of the rightmost character of `string` that is not in `set`.

If each character of `string` is in `set` or the length of `string` is zero, the value of the result is zero.
The setting of compiler options specifying integer size can affect this function.

**Example**

VERIFY ('CDDDC', 'C') has the value 2.

VERIFY ('CDDDC', 'C', BACK=.TRUE.) has the value 4.

VERIFY ('CDDDC', 'CD') has the value zero.

The following shows another example:

```fortran
INTEGER(4) position

position = VERIFY ('banana', 'nbc')  ! returns 2
position = VERIFY ('banana', 'nbc', BACK=.TRUE.)  ! returns 6
position = VERIFY ('banana', 'nbca')  ! returns 0
```

**VIRTUAL**

*Statement: Has the same form and effect as the DIMENSION statement. It is included for compatibility with PDP-11 FORTRAN.*

**See Also**

DIMENSION

**VOLATILE**

*Statement and Attribute: Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. It prevents objects from being optimized during compilation.*

**Syntax**

The VOLATILE attribute can be specified in a type declaration statement or a VOLATILE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls, ] VOLATILE [, att-ls] :: object[, object] ...
```

**Statement:**

```
VOLATILE [:] object[, object] ...
```

- `type` is a data type specifier.
- `att-ls` is an optional list of attribute specifiers.
- `object` is the name of an object, or the name of a common block enclosed in slashes.

A variable or COMMON block must be declared VOLATILE if it can be read or written in a way that is not visible to the compiler. For example:

- If an operating system feature is used to place a variable in shared memory (so that it can be accessed by other programs), the variable must be declared VOLATILE.
• If a variable is accessed or modified by a routine called by the operating system when an asynchronous event occurs, the variable must be declared VOLATILE.

If an array is declared VOLATILE, each element in the array becomes volatile. If a common block is declared VOLATILE, each variable in the common block becomes volatile.

If an object of derived type is declared VOLATILE, its components become volatile.

If a pointer is declared VOLATILE, the pointer itself becomes volatile.

A VOLATILE statement cannot specify the following:

• A procedure
• A namelist group

The VOLATILE attribute must not be specified for a coarray that is accessed by use or host association. A noncoarray object that has the VOLATILE attribute can be associated with an object that does not have the VOLATILE attribute, including by use or host association.

Example

The following example shows a type declaration statement specifying the VOLATILE attribute:

\[
\text{INTEGER, VOLATILE :: D, E}
\]

The following example shows a VOLATILE statement:

\[
\text{PROGRAM TEST}
\]
\[
\text{LOGICAL(KIND=1) IPI(4)}
\]
\[
\text{INTEGER(KIND=4) A, B, C, D, E, ILOOK}
\]
\[
\text{INTEGER(KIND=4) P1, P2, P3, P4}
\]
\[
\text{COMMON /BLK1/A, B, C}
\]
\[
\text{VOLATILE /BLK1/, D, E}
\]
\[
\text{EQUIVALENCE(ILOOK, IPI)}
\]
\[
\text{EQUIVALENCE(A, P1)}
\]
\[
\text{EQUIVALENCE(P1, P4)}
\]

The named common block, BLK1, and the variables D and E are volatile. Variables P1 and P4 become volatile because of the direct equivalence of P1 and the indirect equivalence of P4.

WAIT

Statement: Performs a wait operation for a specified pending asynchronous data transfer operation. It takes one of the following forms:

Syntax

\[
\]

WAIT io-unit

io-unit

(Input) Is an external unit specifier.

label

(Input) Is the label of the branch target statement that receives control if an error occurs.
id-var

(Input) Is a scalar integer variable that is the identifier of a pending data transfer operation for the specified unit. If it is specified, a wait operation is performed for that pending operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

msg-var

(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var

(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

A wait operation completes the processing of a pending data transfer operation. Each wait operation completes only a single data transfer operation, although a single statement may perform multiple wait operations.

The WAIT statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The EOR= specifier only has effect if the pending data transfer operation is a nonadvancing read. The END= specifier only has effect if the pending data transfer operation is a READ.

Example

The following example shows how the WAIT statement can be applied.

```
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1, file='asynch.dat', asynchronous='YES', &
    form='unformatted')
  write (1) (i,i=1,100)
  rewind (1)
  read (1, asynchronous='YES') array
  wait(1)
  write (*,*) array(1:10)
end
```

WAITONMOUSEEVENT (W*S)

QuickWin Function: Waits for the specified mouse input from the user.

Module

USE IFQWIN

Syntax

```
result = WAITONMOUSEEVENT (mouseevents, keystate, x, y)
```

mouseevents

(Input) INTEGER(4). One or more mouse events that must occur before the function returns. Symbolic constants for the possible mouse events are:

- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$LBUTTONUP - Left mouse button up
- MOUSE$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
• MOUSE$MOVE - Mouse moved

keystate
(Output) INTEGER(4). Bitwise inclusive OR of the state of the mouse during the event. The value returned in keystate can be any or all of the following symbolic constants:
• MOUSE$KS_LBUTTON - Left mouse button down during event
• MOUSE$KS_RBUTTON - Right mouse button down during event
• MOUSE$KS_SHIFT - SHIFTkey held down during event
• MOUSE$KS_CONTROL - CTRLkey held down during event

x
(Output) INTEGER(4). X position of the mouse when the event occurred.

y
(Output) INTEGER(4). Y position of the mouse when the event occurred.

Results
The result type is INTEGER(4). The result is the symbolic constant associated with the mouse event that occurred if successful. If the function fails, it returns the constant MOUSE$BADEVENT, meaning the event specified is not supported.

WAITONMOUSEEVENT does not return until the specified mouse input is received from the user. While waiting for a mouse event to occur, the status bar changes to read "Mouse input pending in XXX", where XXX is the name of the window. When a mouse event occurs, the status bar returns to its previous value.

A mouse event must happen in the window that had focus when WAITONMOUSEEVENT was initially called. Mouse events in other windows will not end the wait. Mouse events in other windows cause callbacks to be called for the other windows, if callbacks were previously registered for those windows.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system's CONTROL PANEL/MOUSE.

Example

```fortran
USE IFQWIN
INTEGER(4) mouseevent, keystate, x, y, result
...
mouseevent = IOR(MOUSE$RBUTTONDOWN,MOUSE$LBUTTONDOWN)
result = WAITONMOUSEEVENT (mouseevent, keystate, x , y)
!
! Wait until right or left mouse button is clicked, then check the keystate
! with the following:
!
if (IAND(MOUSE$KS_SHIFT,keystate) == MOUSE$KS_SHIFT) &
 & write (*,*) 'Shift key was down'
if (IAND(MOUSE$KS_CONTROL,keystate) == MOUSE$KS_CONTROL) &
 & write (*,*) 'Ctrl key was down'
```

WHERE

**Statement and Construct:** Lets you use masked array assignment, which performs an array operation on selected elements. This kind of assignment applies a logical test to an array on an element-by-element basis.
Syntax
Statement:
WHERE (mask-expr1) assign-stmt

Construct:
[name:]WHERE (mask-expr1)
  [where-body-stmt] ...
[ELSE WHERE(mask-expr2) [name]
  [where-body-stmt] ...]
[ELSE WHERE[name]
  [where-body-stmt] ...
END WHERE (name)

mask-expr1, mask-expr2 Are logical array expressions (called mask expressions).
assign-stmt Is an assignment statement of the form: array variable = array expression.
name Is the name of the WHERE construct.
where-body-stmt Is one of the following:
  • An assign-stmt
    The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
  • A WHERE statement or construct

Description
If a construct name is specified in a WHERE statement, the same name must appear in the corresponding END WHERE statement. The same construct name can optionally appear in any ELSE WHERE statement in the construct. (ELSE WHERE cannot specify a different name.)

In each assignment statement, the mask expression, the variable being assigned to, and the expression on the right side, must all be conformable. Also, the assignment statement cannot be a defined assignment.

Only the WHERE statement (or the first line of the WHERE construct) can be labeled as a branch target statement.

The following shows an example using a WHERE statement:

```fortran
INTEGER A, B, C
DIMENSION A(5), B(5), C(5)
DATA A /0,1,1,1,0/
DATA B /10,11,12,13,14/
C = -1
WHERE(A .NE. 0) C = B / A
```

The resulting array C contains: -1,11,12,13, and -1.

The assignment statement is only executed for those elements where the mask is true. Think of the mask expression as being evaluated first into a logical array that has the value true for those elements where A is positive. This array of trues and falses is applied to the arrays A, B and C in the assignment statement. The right side is only evaluated for elements for which the mask is true; assignment on the left side is only performed for those elements for which the mask is true. The elements for which the mask is false do not get assigned a value.
In a WHERE construct, the mask expression is evaluated first and only once. Every assignment statement following the WHERE is executed as if it were a WHERE statement with "mask-expr1" and every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(.NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

You should be careful if the statements have side effects, or modify each other or the mask expression.

The following is an example of the WHERE construct:

```fortran
DIMENSION PRESSURE(1000), TEMP(1000), PRECIPITATION(1000)
WHERE(PRESSURE .GE. 1.0)
  PRESSURE = PRESSURE + 1.0
  TEMP = TEMP - 10.0
ELSEWHERE
  PRECIPITATION = .TRUE.
ENDWHERE
```

The mask is applied to the arguments of functions on the right side of the assignment if they are considered to be elemental functions. Only elemental intrinsics are considered elemental functions. Transformational intrinsics, inquiry intrinsics, and functions or operations defined in the subprogram are considered to be nonelemental functions.

Consider the following example using LOG, an elemental function:

```fortran
WHERE(A .GT. 0)  B = LOG(A)
```

The mask is applied to A, and LOG is executed only for the positive values of A. The result of the LOG is assigned to those elements of B where the mask is true.

Consider the following example using SUM, a nonelemental function:

```fortran
REAL A, B
DIMENSION A(10,10), B(10)
WHERE(B .GT. 0.0)  B = SUM(A, DIM=1)
```

Since SUM is nonelemental, it is evaluated fully for all of A. Then, the assignment only happens for those elements for which the mask evaluated to true.

Consider the following example:

```fortran
REAL A, B, C
DIMENSION A(10,10), B(10), C(10)
WHERE(C .GT. 0.0)  B = SUM(LOG(A), DIM=1)/C
```

Because SUM is nonelemental, all of its arguments are evaluated fully regardless of whether they are elemental or not. In this example, LOG(A) is fully evaluated for all elements in A even though LOG is elemental. Notice that the mask is applied to the result of the SUM and to C to determine the right side. One way of thinking about this is that everything inside the argument list of a nonelemental function does not use the mask, everything outside does.

**Example**

```fortran
REAL(4) a(20)
...
WHERE (a > 0.0)
  a = LOG (a)
!LOG is invoked only for positive elements
END WHERE
```

- Arrays
WORKSHARE

OpenMP* Fortran Compiler Directive: Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

Syntax

```fortran
!$OMP WORKSHARE
   block
!$OMP END WORKSHARE [NOWAIT]
```

`block` is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The block is executed so that each statement is completed before the next statement is started and the evaluation of the right hand side of an assignment is completed before the effects of assigning to the left hand side occur.

The following are additional rules for `block`:

- It may contain statements which bind to lexically enclosed PARALLEL constructs. Statements in these PARALLEL constructs are not restricted.
- It may contain ATOMIC directives and CRITICAL constructs.
- It must only contain array assignment statements, scalar assignment statements, FORALL statements, FORALL constructs, WHERE statements, or WHERE constructs.
- It must not contain any user defined function calls unless the function is ELEMENTAL.

The binding thread set for a WORKSHARE construct is the current team. A workshare region binds to the innermost enclosing parallel region.

If you do not specify the NOWAIT keyword, synchronization is implied following the code.

Multithreaded code is not always generated for the statements inside the block of an OMP WORKSHARE construct. Some statements parallelize; others do not parallelize and instead execute sequentially inside an OMP SINGLE construct to preserve the correct semantics of WORKSHARE. Some specific details follow:

- Simple array assignments such as `A = B + C` parallelize.
- Simple array assignments with overlap such as `A = A + B + C` parallelize.
- Array assignments with user-defined function calls parallelize such as `A = A + F (B)`. F must be ELEMENTAL.
- Array assignments with array slices on the right hand side of the assignment such as `A = A + B(1:4) + C(1:4)` parallelize. If the lower bound of the left hand side or the array slice lower bound or the array slice stride on the right hand side is not 1, then the statement does not parallelize.
- Assigning into array slices does not parallelize.
- Scalar assignments do not parallelize – there is no work that needs to be done in parallel.
- FORALL and WHERE constructs do not parallelize.

---

**WRAPON (W*S)**

*Graphics Function:* Controls whether text output is *wrapped.*

---

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{WRAPON}\left(\text{option}\right)
\]

*option* (Input) INTEGER(2). Wrap mode. One of the following symbolic constants:

- $\$GWRAPOFF$ - Truncates lines at right edge of window border.
- $\$GWRAPON$ - Wraps lines at window border, scrolling if necessary.

**Results**

The result type is INTEGER(2). The result is the previous value of *option.*

WRAPON controls whether text output with the OUTTEXT function wraps to a new line or is truncated when the text output reaches the edge of the defined text window.

WRAPON does not affect font routines such as OUTGTEXT.

**Example**

```fortran
USE IFQWIN
INTEGER(2) row, status2
INTEGER(4) status4
TYPE ( rccoord ) curpos
TYPE ( windowconfig ) wc
LOGICAL status

status = GETWINDOWCONFIG( wc )
w$c%numtextcols = 80
w$c%numxpixels = -1
w$c%numypixels = -1
w$c%numtextrows = -1
w$c%numcolors = -1
w$c%fontsize = -1
w$c%title = "This is a test"C
w$c%bitsperpixel = -1
status = SETWINDOWCONFIG( wc )
status4 = SETTEXTCOLORRGB(#FF0000)
CALL CLEARSCREEN( $GCLEARSCREEN  )

! Display wrapped and unwrapped text in text windows.
CALL SETTEXTWINDOW( INT2(1),INT2(1),INT2(5),INT2(25))
CALL SETTEXTPOSITION(INT2(1),INT2(1), curpos )
status2 = WRAPON( $GWRAPON )
status4 = SETTEXTCOLORRGB(#00FF00)
DO i = 1, 5
    CALL OUTTEXT( 'Here text does wrap. ')
END DO
CALL SETTEXTWINDOW(INT2(7),INT2(10),INT2(11),INT2(40))
```

---

Language Reference 2211
CALL SETTEXTPOSITION(INT2(1),INT2(1),curpos)
status2 = WRAPON( $GWRAPOFF )
status4 = SETTEXTCOLORRGB(#008080)
DO row = 1, 5
   CALL SETTEXTPOSITION(INT2(row), INT2(1), curpos )
   CALL OUTTEXT('Here text does not wrap. ')
   CALL OUTTEXT('Here text does not wrap.'
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

SETTEXTWINDOW

WRITE Statement
Statement: Transfers output data to external sequential, direct-access, or internal records.

Syntax
Sequential
Formatted:

Formatted - List-Directed:

Formatted - Namelist:

Unformatted:

Direct-Access
Formatted:

Unformatted:

Internal
WRITE (iunit, format [, nml-group] [, iostat] [, err] [, iomsg])[io-list]

Internal Namelist
WRITE (iunit, nml-group [, iostat] [, err] [, iomsg])[io-list]
**eunit**

Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if *eunit* is not the first specifier in the list.

**format**

Is a format specifier. It is optionally prefaced by FMT= if *format* is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

**advance**

Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

**asynchronous**

Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

**decimal**

Is a decimal mode specifier (DECIMAL=dmode) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.

**delim**

Is a delimiter specifier (DELIM=del). If the value of del is 'APOSTROPHE', apostrophes delimit character constants. If the value is 'QUOTE', quotes delimit character constants. If the value of del is 'NONE', character constants have no delimiters.

**id**

Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

**pos**

Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

**round**

Is a rounding specifier (ROUND=rmode) that determines the I/O rounding mode for this WRITE statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.

**sign**

Is a plus sign specifier (SIGN=sn). This controls whether optional plus characters appear in formatted numeric output.

**iostat**

Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

**err**

Are branch specifiers if an error (ERR=label) condition occurs.

**iomsg**

Is an I/O message specifier (IOMSG=msg-var).

**io-list**

Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

**form**

Is the nonkeyword form of a format specifier (no FMT=).

**+**

Is the format specifier indicating list-directed formatting. (It can also be specified as FMT= *.)
nml-group

Is the namelist group specification for namelist I/O. Optionally preaced by NML=. NML= is required if nml-group is not the second I/O specifier. For more information, see Namelist Specifier.

rec

Is the cell number of a record to be accessed directly. It must be preaced by REC=.

iunit

Is an internal unit speciﬁer, optionally preaced by UNIT=. UNIT= is required if iunit is not the ﬁrst speciﬁer in the list.

It must be a character variable. It must not be an array section with a vector subscript.

If an item in io-list is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as eunit.

If you specify DECIMAL=, ROUND=, or SIGN= you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Example

! write to ﬁle
open(1,FILE='test.dat')
write (1, '(A20)') namedef

! write with FORMAT statement
WRITE (*, 10) (n, SQRT(FLOAT(n)), FLOAT(n)**(1.0/3.0), n = 1, 100)
10 FORMAT (I5, F8.4, F8.5)

The following shows another example:

WRITE(6,'("Expected ",F12.6")') 2.0

XOR

Elemental Intrinsic Function (Generic): An alternative name for intrinsic function IEOR.

See Also
See IEOR.
**ZEXT**

*Elemental Intrinsic Function (Generic)*: Extends an argument with zeros. This function is used primarily for bit-oriented operations. It cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{ZEXT} \ (x \ [,\ kind])
\]

- \(x\) (Input) Must be of type logical or integer.
- \(kind\) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If \(kind\) is present, the kind parameter of the result is that specified by \(kind\); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is \(x\) extended with zeros and treated as an unsigned value.

The storage requirements for integer constants are never less than two bytes. Integer constants within the range of constants that can be represented by a single byte still require two bytes of storage.

The setting of compiler options specifying integer size can affect this function.

-----------------|-----------------|-----------------
INTEGRER(8)      |  INTEGRER(8)    

¹These specific functions cannot be passed as actual arguments.

Example
Consider the following example:

```
INTEGER(2) W_VAR  /*'FFFF'X/
INTEGER(4) L_VAR
L_VAR = ZEXT( W_VAR )
```

This example stores an INTEGER(2) quantity in the low-order 16 bits of an INTEGER(4) quantity, with the resulting value of L_VAR being '0000FFFF'X. If the ZEXT function had not been used, the resulting value would have been 'FFFFFFFF'X, because W_VAR would have been converted to the left-hand operand's data type by sign extension.

Glossary
This section contains abbreviated definitions of some commonly used terms in this manual.

Glossary A

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>absolute pathname</td>
<td>A directory path specified in fixed relationship to the root directory. On Windows* systems, the first character is a backslash (). On Linux* and macOS* systems, the first character is a slash (/).</td>
</tr>
<tr>
<td>abstract interface</td>
<td>A named set of procedure characteristics that can be referenced in PROCEDURE declarations.</td>
</tr>
<tr>
<td>abstract type</td>
<td>A derived type, declared with the ABSTRACT keyword, which can be extended to declare an object. An abstract type cannot be used directly to declare an object.</td>
</tr>
<tr>
<td>active screen buffer</td>
<td>The screen buffer that is currently displayed in a console's window.</td>
</tr>
<tr>
<td>active window</td>
<td>A top-level window of the application with which the user is working. The Windows system identifies the active window by highlighting its title bar and border.</td>
</tr>
<tr>
<td>actual argument</td>
<td>A value (a variable, expression, or procedure) passed from a calling program unit to a subprogram (function or subroutine). See also dummy argument.</td>
</tr>
<tr>
<td>adjustable array</td>
<td>An explicit-shape array that is a dummy argument to a subprogram. The term is from FORTRAN 77. See also explicit-shape array.</td>
</tr>
<tr>
<td>aggregate reference</td>
<td>A reference to a record structure field.</td>
</tr>
<tr>
<td>allocatable array</td>
<td>A named array that has the ALLOCATABLE attribute. The array's rank is specified at compile time, but its bounds are determined at run time. Once space has been allocated for this type of array, the array has a shape and can be defined (and redefined) or referenced. It is an error to allocate an allocatable array that is currently allocated.</td>

<tr>
<td></td>
<td>• An actual argument--A variable, expression, or procedure passed from a calling program unit to a subprogram. See also actual argument.</td>
</tr>
<tr>
<td></td>
<td>• A dummy argument--A variable whose name appears in the parenthesized list following the procedure name in a FUNCTION statement, a SUBROUTINE statement, an ENTRY statement, or a statement function statement. See also dummy argument.</td>
</tr>
<tr>
<td>argument association</td>
<td>The relationship (or &quot;matching up&quot;) between an actual argument and dummy argument during the execution of a procedure reference.</td>
</tr>
<tr>
<td>argument keyword</td>
<td>The name of a dummy (formal) argument. The name is used in a subprogram definition. Argument keywords can be used when the subprogram is invoked to associate dummy arguments with actual arguments, so that the subprogram arguments can appear in any order.</td>
</tr>
<tr>
<td>array</td>
<td>A set of scalar data that all have the same type and kind type parameters. An array can be referenced by element (using a subscript), by section (using a section subscript list), or as a whole. An array has a rank (up to 31), bounds, size, and a shape.</td>
</tr>
<tr>
<td></td>
<td>An individual array element is a scalar object. An array section, which is itself an array, is a subset of the entire array. Contrast with scalar. See also bounds, conformable, shape, size, whole array, and zero-sized array.</td>
</tr>
<tr>
<td>array constructor</td>
<td>A mechanism used to specify a sequence of scalar values that produce a rank-one array.</td>
</tr>
<tr>
<td></td>
<td>To construct an array of rank greater than one, you must apply the RESHAPE intrinsic function to the array constructor.</td>
</tr>
<tr>
<td>array element</td>
<td>A scalar (individual) item in an array. An array element is identified by the array name followed by one or more subscripts in parentheses, indicating the element's position in the array. For example, B(3) or A(2,5).</td>
</tr>
<tr>
<td>array pointer</td>
<td>A pointer to an array. See also array and pointer.</td>
</tr>
</tbody>
</table>
array section
A subobject (or portion) of an array. It consists of the set of array elements or substrings of this set. The set (or section subscript list) is specified by subscripts, subscript triplets, or vector subscripts. If the set does not contain at least one subscript triplet or vector subscript, the reference indicates an array element, not an array.

array specification
A program statement specifying an array name and the number of dimensions the array contains (its rank). An array specification can appear in a DIMENSION or COMMON statement, or in a type declaration statement.

ASCII
The American Standard Code for Information Interchange. A 7-bit character encoding scheme associating an integer from 0 through 127 with 128 characters.

assignment statement
Usually, a statement that assigns (stores) the value of an expression on the right of an equal sign to the storage location of the variable to the left of the equal sign. In the case of Fortran pointers, the storage location is assigned, not the pointer itself.

associate name
The name of a construct entity associated with a selector of an ASSOCIATE or SELECT TYPE construct.

association
The relationship that allows an entity to be referenced by different names in one scoping unit or by the same or different names in more than one scoping unit. The principal kinds of association are argument, host, pointer, storage, and use association. See also argument association, host association, pointer association, storage association, and use association.

association status
Indicates whether or not a pointer is associated with a target. An association status is one of: undefined, associated, or disassociated. An undefined association status means a pointer can no longer be referenced, defined, or deallocated. An undefined pointer can, however, be allocated, nullified, or pointer assigned to a new target. See also allocation status.

assumed-length character argument
A dummy argument that assumes the length attribute of the corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

assumed-shape array
A dummy argument array that assumes the shape of its associated actual argument array. The rank of the array is the number of colons (:) specified in parentheses.

assumed-size array
A dummy array whose size (only) is assumed from its associated actual argument. The upper bound of its last dimension is specified by an asterisk (*). All other extents (if any) must be specified.

atomic subroutine
An intrinsic subroutine that performs an action on a variable (its ATOM argument) indivisibly.

attribute
A property of a data object that can be specified in a type declaration statement. These properties determine how the data object can be used in a program.

Most attributes can be alternatively specified in statements. For example, the DIMENSION statement has the same meaning as the DIMENSION attribute appearing in a type declaration statement.
**automatic array**
An explicit-shape array that is a local variable in a subprogram. It is not a dummy argument, and has bounds that are nonconstant specification expressions. The bounds (and shape) are determined at entry to the procedure by evaluating the bounds expressions. See also automatic object.

**automatic object**
A local data object that is created upon entry to a subprogram and disappears when the execution of the subprogram is completed. There are two kinds of automatic objects: arrays (of any data type) and objects of type CHARACTER. Automatic objects cannot be saved or initialized.

An automatic object is not a dummy argument, but is declared with a specification expression that is not a constant expression. The specification expression can be the bounds of the array or the length of the character object.

---

**Glossary B**

**background process**
On Linux* systems, a process for which the command interpreter is not waiting. Its process group differs from that of its controlling terminal, so it is blocked from most terminal access. Contrast with foreground process.

**background window**
Any window created by a thread other than the foreground thread.

**big endian**
A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the highest addressed byte. Contrast with little endian.

**binary constant**
A constant that is a string of binary (base 2) digits (0 or 1) enclosed by apostrophes or quotation marks and preceded by the letter B.

**binary operator**
An operator that acts on a pair of operands. The exponentiation, multiplication, division, and concatenation operators are binary operators.

**bit constant**
A constant that is a binary, octal, or hexadecimal number.

**bit field**
A contiguous group of bits within a binary pattern; they are specified by a starting bit position and length. Some intrinsic functions (for example, IBSET and BTEST) and the intrinsic subroutine MVBITS operate on bit fields.

**bitmap**
An array of bits that contains data that describes the colors found in a rectangular region on the screen (or the rectangular region found on a page of printer paper).

**blank common**
A common block (one or more contiguous areas of storage) without a name. Common blocks are defined by a COMMON statement.

**block**
In general, a group of related items treated as a physical unit. For example, a block can be a group of constructs or statements that perform a task; the task can be executed once, repeatedly, or not at all.

**block data program unit**
A program unit, containing a BLOCK DATA statement and its associated specification statements, that establishes common blocks and assigns initial values to the variables in named common blocks. In FORTRAN 77, this was called a block data subprogram.

<tbody>
<tr>
<td>bounds</td>
<td>The range of subscript values for elements of an array. The lower bound is the smallest subscript value in a dimension, and the upper bound is the largest subscript value in that dimension. Array bounds can be positive, zero, or negative. These bounds are specified in an array specification. See also array specification.</td>
</tr>
<tr>
<td>breakpoint</td>
<td>A critical point in a program, at which execution is stopped so that you can see if the program variables contain the correct values. Breakpoints are often used to debug programs.</td>
</tr>
<tr>
<td>brush</td>
<td>A bitmap that is used to fill the interior of closed shapes, polygons, ellipses, and paths.</td>
</tr>
<tr>
<td>brush origin</td>
<td>A coordinate that specifies the location of one of the pixels in a brush’s bitmap. The Windows system maps this pixel to the upper left corner of the window that contains the object to be painted. See also bitmap.</td>

<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>carriage-control character</td>
<td>A character in the first position of a printed record that determines the vertical spacing of the output line.</td>
</tr>
<tr>
<td>character constant</td>
<td>A constant that is a string of printable ASCII characters enclosed by apostrophes (’) or quotation marks (“).</td>
</tr>
<tr>
<td>character expression</td>
<td>A character constant, variable, function value, or another constant expression, separated by a concatenation operator (/); for example, DAY// 'FIRST'.</td>
</tr>
<tr>
<td>character storage unit</td>
<td>The unit of storage for holding a scalar value of default character type (and character length one) that is not a pointer. One character storage unit corresponds to one byte of memory.</td>
</tr>
<tr>
<td>character string</td>
<td>A sequence of contiguous characters; a character data value. See also character constant.</td>
</tr>
<tr>
<td>character substring</td>
<td>One or more contiguous characters in a character string.</td>
</tr>
<tr>
<td>child process</td>
<td>A process initiated by another process (the parent). The child process can operate independently from the parent process. Also, the parent process can suspend or terminate without affecting the child process. See also parent process.</td>
</tr>
<tr>
<td>child window</td>
<td>A window that has the WS_CHILD style. A child window always appears within the client area of its parent window. See also parent window.</td>
</tr>
<tr>
<td>column-major order</td>
<td>See order of subscript progression.</td>
</tr>
</tbody>
</table>
### coarray
A data entity that has nonzero corank. A Fortran program containing coarrays is interpreted as if it were replicated a fixed number of times and all copies were executed asynchronously. Its corank, cobounds, and coextents are given by the data in square brackets in its declaration or allocation.

### cobound
A bound (limit) of a codimension. The values of each lower cobound and upper cobound determine the cobounds of the coarray along a particular codimension.

### codimension
A dimension of the pattern formed by a set of corresponding coarrays.

### comment
Text that documents or explains a program. In free source form, a comment begins with an exclamation point (!), unless it appears in a Hollerith or character constant.

In fixed and tab source form, a comment begins with a letter C or an asterisk (*) in column 1. A comment can also begin with an exclamation point anywhere in a source line (except in a Hollerith or character constant) or in column 6 of a fixed-format line. The comment extends from the exclamation point to the end of the line.

The compiler does not process comments, but shows them in program listings. See also compiler directive.

### common block
A physical storage area shared by one or more program units. This storage area is defined by a COMMON statement. If the common block is given a name, it is a named common block; if it is not given a name, it is a blank common. See also blank common and named common block.

### compilation unit
The source or files that are compiled together to form a single object file, possibly using interprocedural optimization across source files.

### compiler directive
A structured comment that tells the compiler to perform certain tasks when it compiles a source program unit. Compiler directives are usually compiler-specific. (Some Fortran compilers call these directives "metacommands".)

### compiler option
An option (or flag) that can be used on the compiler command line to override the default behavior of the Intel® Fortran compiler.

### complex constant
A constant that is a pair of real or integer constants representing a complex number; the pair is separated by a comma and enclosed in parentheses. The first constant represents the real part of the number; the second constant represents the imaginary part. The following types of complex constants are available on all systems: COMPLEX(KIND=4), COMPLEX(KIND=8), and COMPLEX(KIND=16).

### complex type
A data type that represents the values of complex numbers. The value is expressed as a complex constant. See also data type.

### component
Part of a derived-type definition. There must be at least one component (intrinsic or derived type) in every derived-type definition.

### component order
The ordering of the components of a derived type that is used for intrinsic formatted input/output and for structure constructors.

### concatenate
The combination of two items into one by placing one of the items after the other. In Standard Fortran, the concatenation operator (//) is used to combine character items. See also character expression.

### conformable
Pertains to dimensionality. Two arrays are conformable if they have the same shape. A scalar is conformable with any array.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>conformance</td>
<td>See shape conformance.</td>
</tr>
<tr>
<td>conservative automatic inlining</td>
<td>The inline expansion of small procedures, with conservative heuristics to limit extra code.</td>
</tr>
<tr>
<td>console</td>
<td>An interface that provides input and output to character-mode applications.</td>
</tr>
<tr>
<td>constant</td>
<td>A data object whose value does not change during the execution of a program; the value is defined at the time of compilation. A constant can be named (using the PARAMETER attribute or statement) or unnamed. An unnamed constant is called a literal constant. The value of a constant can be numeric or logical, or it can be a character string. Contrast with variable.</td>
</tr>
<tr>
<td>constant expression</td>
<td>An expression that you can use as a kind type parameter, a named constant, or to specify an initial value for an entity. It is evaluated when a program is compiled.</td>
</tr>
<tr>
<td>construct</td>
<td>A series of statements starting with a statement denoting the kind of construct, such as DO, SELECT CASE, IF, FORALL, or WHERE, and ending with the appropriate termination statement.</td>
</tr>
<tr>
<td>construct association</td>
<td>The association between a selector and an associate name in an ASSOCIATE or SELECT TYPE construct.</td>
</tr>
<tr>
<td>contiguous</td>
<td>Pertaining to entities that are adjacent (next to one another) without intervening blanks (spaces); for example, contiguous characters or contiguous areas of storage.</td>
</tr>
<tr>
<td>control edit descriptor</td>
<td>A format descriptor that directly displays text or affects the conversions performed by subsequent data edit descriptors. Except for the slash descriptor, control edit descriptors are nonrepeatable.</td>
</tr>
<tr>
<td>control statement</td>
<td>A statement that alters the normal order of execution by transferring control to another part of a program unit or a subprogram. A control statement can be conditional (such as the IF construct or computed GO TO statement) or unconditional (such as the STOP or GO TO statement).</td>
</tr>
<tr>
<td>corank</td>
<td>The number of codimensions of a coarray.</td>
</tr>
<tr>
<td>critical section</td>
<td>An object used to synchronize the threads of a single process. Only one thread at a time can own a critical-section object.</td>
</tr>
</tbody>
</table>

### Glossary D

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>data abstraction</td>
<td>A style of programming in which you define types to represent objects in your program, define a set of operations for objects of each type, and restrict the operations to only this set, making the types abstract. The Standard Fortran modules, derived types, and defined operators, support this programming paradigm.</td>
</tr>
<tr>
<td>data edit descriptor</td>
<td>A repeatable format descriptor that causes the transfer or conversion of data to or from its internal representation. In FORTRAN 77, this term was called a field descriptor.</td>
</tr>
<tr>
<td>data entity</td>
<td>A data object that has a data type. It is the result of the evaluation of an expression, or the result of the execution of a function reference (the function result).</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>data item</td>
<td>A unit of data (or value) to be processed. Includes constants, variables, arrays, character substrings, or records.</td>
</tr>
<tr>
<td>data object</td>
<td>A constant, variable, or subobject (part) of a constant or variable. Its type may be specified implicitly or explicitly.</td>
</tr>
<tr>
<td>data type</td>
<td>The properties and internal representation that characterize data and functions. Each intrinsic and user-defined data type has a name, a set of operators, a set of values, and a way to show these values in a program. The basic intrinsic data types are integer, real, complex, logical, and character. The data value of an intrinsic data type depends on the value of the type parameter. See also type parameter.</td>
</tr>
<tr>
<td>data type declaration</td>
<td>See type declaration statement.</td>
</tr>
<tr>
<td>data type length specifier</td>
<td>The form <em>n appended to Intel® Fortran-specific data type names. For example, in REAL</em>4, the *4 is the data type length specifier.</td>
</tr>
<tr>
<td>deadlock</td>
<td>A bug where the execution of thread A is blocked indefinitely waiting for thread B to perform some action, while thread B is blocked waiting for thread A. For example, two threads on opposite ends of a named pipe can become deadlocked if each thread waits to read data written by the other thread. A single thread can also deadlock itself. See also thread.</td>
</tr>
<tr>
<td>declaration</td>
<td>See specification statement.</td>
</tr>
<tr>
<td>declared type</td>
<td>The type that a data entity is declared to have. For polymorphic data entities, it may differ from the type during execution (the dynamic type).</td>
</tr>
<tr>
<td>decorated name</td>
<td>An internal representation of a procedure name or variable name that contains information about where it is declared; for procedures, the information includes how it is called. Decorated names are mainly of interest in mixed-language programming, when calling Fortran routines from other languages.</td>
</tr>
<tr>
<td>default character</td>
<td>The kind for character constants if no kind type parameter is specified. Currently, the only kind type parameter for character constants is CHARACTER(1), the default character kind.</td>
</tr>
<tr>
<td>default complex</td>
<td>The kind for complex constants if no kind type parameter is specified. The default complex kind is affected by compiler options specifying double size. If no compiler option is specified, default complex is COMPLEX(4) (COMPLEX*8). See also default real.</td>
</tr>
<tr>
<td>default integer</td>
<td>The kind for integer constants if no kind type parameter is specified. The default integer kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default integer is INTEGER(4) (INTEGER*4). If a command line option affecting integer size has been specified, the integer has the kind specified, unless it is outside the range of the kind specified by the option. In this case, the kind type of the integer is the smallest integer kind which can hold the integer.</td>
</tr>
<tr>
<td>default logical</td>
<td>The kind for logical constants if no kind type parameter is specified. The default logical kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default logical is LOGICAL(4) (LOGICAL*4). See also default integer.</td>
</tr>
</tbody>
</table>
The kind for real constants if no kind type parameter is specified. The default real kind is affected by compiler options specifying real size and by the REAL directive. If neither of these is specified, default real is REAL(4) (REAL*4).

If a real constant is encountered that is outside the range for the default, an error occurs.

defered-shape array

An array pointer (an array with the POINTER attribute) or an allocatable array (an array with the ALLOCATABLE attribute). The size in each dimension is determined by pointer assignment or when the array is allocated.

The array specification contains a colon (:) for each dimension of the array. No bounds are specified.

definable

A property of variables. A variable is definable if its value can be changed by the appearance of its name or designator on the left of an assignment statement. An example of a variable that is not definable is an allocatable array that has not been allocated.

defined

For a data object, the property of having or being given a valid value.

defined assignment

An assignment statement that is not intrinsic, but is defined by a subroutine and an ASSIGNMENT(=) interface block. See also derived type and interface block.

defined operation

An operation that is not intrinsic, but is defined by a function program containing a generic interface block with the specifier OPERATOR. See also derived type and interface block.

denormalized number

A computational floating-point result smaller than the lowest value in the normal range of a data type (the smallest representable normalized number). You cannot write a constant for a denormalized number.

derived type

A data type that is user-defined and not intrinsic. It requires a type definition to name the type and specify its components (which can be intrinsic or user-defined types). A structure constructor can be used to specify a value of derived type. A component of a structure is referenced using a percent sign (%).

Operations on objects of derived types (structures) must be defined by a function with an OPERATOR interface. Assignment for derived types can be defined intrinsically, or be redefined by a subroutine with an ASSIGNMENT(=) interface. Structures can be used as procedure arguments and function results, and can appear in input and output lists. Also called a user-defined type. See also record, the first definition.

designator

A name that references a subobject (part of a data object) that can be defined and referenced separately from other parts of the data object. A designator is the name of the object followed by a selector that selects the subobject. For example, B(3) is a designator for an array element. Also called a subobject designator. See also selector and subobject.

dimension

A range of values for one subscript or index of an array. An array can have from 1 to 7 dimensions. The number of dimensions is the rank of the array.

dimension bounds

See bounds.
direct access
A method for retrieving or storing data in which the data (record) is identified by the record number, or the position of the record in the file. The record is accessed directly (nonsequentially); therefore, all information is equally accessible. Also called random access. Contrast with sequential access.

DLL
See Dynamic Link Library.

double-byte character set (DBCS)
A mapping of characters to their identifying numeric values, in which each value is 2 bytes wide. Double-byte character sets are sometimes used for languages that have more than 256 characters.

double-precision constant
A processor approximation to the value of a real number that occupies 8 bytes of memory and can assume a positive, negative, or zero value. The precision is greater than a constant of real (single-precision) type. For the precise ranges of the double-precision constants, see Data Representation Overview in the Compiler Reference. See also denormalized number.

driver program
A program that is the user interface to the language compiler. It accepts command line options and file names and causes one or more language utilities or system programs to process each file.

dummy aliasing
The sharing of memory locations between dummy (formal) arguments and other dummy arguments or COMMON variables that are assigned.

dummy argument
A variable whose name appears in the parenthesized list following the procedure name in a FUNCTION statement, a SUBROUTINE statement, an ENTRY statement, or a statement function statement. A dummy argument takes the value of the corresponding actual argument in the calling program unit (through argument association). Also called a formal argument.

dummy array
A dummy argument that is an array.

dummy pointer
A dummy argument that is a pointer.

dummy procedure
A dummy argument that is specified as a procedure or appears in a procedure reference. The corresponding actual argument must be a procedure.

Dynamic Link Library (DLL)
a separate source module compiled and linked independently of the applications that use it. Applications access the DLL through procedure calls. The code for a DLL is not included in the user's executable image, but the compiler automatically modifies the executable image to point to DLL procedures at run time.

dynamic type
The type of a data entity during execution of a program. The dynamic type of a data entity that is not polymorphic is the same as its declared type.

Glossary E

edit descriptor
A descriptor in a format specification. It can be a data edit descriptor, control edit descriptor, or string edit descriptor. See also control edit descriptor, data edit descriptor, and string edit descriptor.

element
See array element.

elemental
Pertains to an intrinsic operation, intrinsic procedure, or assignment statement that is independently applied to either of the following:
The elements of an array
Corresponding elements of a set of conformable arrays and scalars

end-of-file
The condition that exists when all records in a file open for sequential access have been read.

entity
A general term referring to any Standard Fortran concept; for example, a constant, a variable, a program unit, a statement label, a common block, a construct, an I/O unit and so forth.

environment variable
A symbolic variable that represents some element of the operating system, such as a path, a filename, or other literal data.

error number
An integer value denoting an I/O error condition, obtained by using the IOSTAT keyword in an I/O statement.

error termination
When error termination is initiated on an image, all images terminate execution. If an error condition occurs, error termination is initiated unless the error occurs in one of the following ways:

- During the execution of a statement that specifies a STAT= specifier
- During the execution of an I/O statement that specifies a STAT= or ERR= specifier
- During the execution of an intrinsic procedure with a present STAT argument.

In these cases, the STAT argument of the intrinsic procedure, or the stat-variable of the STAT= specifier becomes defined with a positive integer value and the program execution continues. See also normal termination.

exceptional values
For floating-point numbers, values outside the range of normalized numbers, including denormal (subnormal) numbers, infinity, Not-a-Number (NaN) values, zero, and other architecture-defined numbers.

executable construct
A CASE, DO, IF, WHERE, or FORALL construct.

executable program
A set of program units that include only one main program.

executable statement
A statement that specifies an action to be performed or controls one or more computational instructions.

explicit interface
A procedure interface whose properties are known within the scope of the calling program, and do not have to be assumed. These properties are the names of the procedure and its dummy arguments, the attributes of a procedure (if it is a function), and the attributes and order of the dummy arguments.

The following have explicit interfaces:
- Internal and module procedures (explicit by definition)
- Intrinsic procedures
- External procedures that have an interface block
- External procedures that are defined by the scoping unit and are recursive
- Dummy procedures that have an interface block

explicit-shape array
An array whose rank and bounds are specified when the array is declared.

expression
A data reference or a computation formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.
extended type

An extensible type that is an extension of another type. A type that is declared with the EXTENDS attribute.

extensible type

A type from which new types may be derived using the EXTENDS attribute. A nonsequence type that does not have the BIND attribute.

extent

The size of (number of elements in) one dimension of an array.

external file

A sequence of records that exists in a medium external to the executing program.

external procedure

A procedure that is contained in an external subprogram. External procedures can be used to share information (such as source files, common blocks, and public data in modules) and can be used independently of other procedures and program units. Also called an external routine.

external subprogram

A subroutine or function that is not contained in a main program, module, or another subprogram. A module is not a subprogram.

Glossary F

field

Can be either of the following:

- A set of contiguous characters, considered as a single item, in a record or line.
- A substructure of a STRUCTURE declaration.

field descriptor

See data edit descriptor.

field separator

The comma (,.) or slash (/) that separates edit descriptors in a format specification.

field width

The total number of characters in the field. See also field, the first definition.

file

A collection of logically related records. If the file is in internal storage, it is an internal file; if the file is on an input/output device, it is an external file.

file access

The way records are accessed (and stored) in a file. The standard Fortran file access modes are sequential and direct.

file handle

A unique identifier that the system assigns to a file when the file is opened or created. A file handle is valid until the file is closed.

file organization

The way records in a file are physically arranged on a storage device. Standard Fortran files can have sequential or relative organization.

final subroutine

A subroutine whose name appears in a FINAL statement in a type definition. It can be automatically invoked by the processor when an object of that type is finalized.

final task

A task that forces all of its descendant tasks to become included tasks.

fixed-length record type

A file format in which all the records are the same length.

floating-point environment

A collection of registers that control the behavior of floating-point (FP) machine instructions and indicate the current FP status. The floating-point environment may include rounding mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.
focus window
The window to which keyboard input is directed.

foreground process
On Linux* systems, a process for which the command interpreter is waiting. Its process group is the same as that of its controlling terminal, so the process is allowed to read from or write to the terminal. Contrast with background process.

foreground window
The window the user is currently working with. The system assigns a slightly higher priority to the thread that created the foreground window than it does to other threads.

foreign file
An unformatted file that contains data from a foreign platform, such as data from a CRAY*, IBM*, or big endian IEEE* machine.

format
A specific arrangement of data. A FORMAT statement specifies how data is to be read or written.

format specification
The part of a FORMAT statement that specifies explicit data arrangement. It is a list within parentheses that can include edit descriptors and field separators. A character expression can also specify format; the expression must evaluate to a valid format specification.

formatted data
Data written to a file by using formatted I/O statements. Such data contains ASCII representations of binary values.

formatted I/O statement
An I/O statement specifying a format for data transfer. The format specified can be explicit (specified in a format specification) or implicit (specified using list-directed or namelist formatting). Contrast with unformatted I/O statement. See also list-directed I/O statement and namelist I/O statement.

frame window
The outermost parent window in QuickWin.

function
A series of statements that perform some operation and return a single value (through the function or result name) to the calling program unit. A function is invoked by a function reference in a main program unit or a subprogram unit.

In Standard Fortran, a function can be used to define a new operator or extend the meaning of an intrinsic operator symbol. The function is invoked by the appearance of the new or extended operator in the expression (along with the appropriate operands). For example, the symbol * can be defined for logical operands, extending its intrinsic definition for numeric operands. See also function subprogram, statement function, and subroutine.

function reference
Used in an expression to invoke a function, it consists of the function name and its actual arguments. A function reference returns a value (through the function or result name) that is used to evaluate the calling expression.

function result
The result value associated with a particular execution or call to a function. This result can be of any data type (including derived type) and can be array-valued. In a FUNCTION statement, the RESULT option can be used to give the result a name different from the function name. This option is required for a recursive function that directly calls itself.

function subprogram
A sequence of statements beginning with a FUNCTION (or optional OPTIONS) statement that is not in an interface block and ending with the corresponding END statement. See also function.
Glossary G

**generic identifier**
A generic name, operator, or assignment specified in an `INTERFACE` statement that is associated with all of the procedures within the interface block. Also called a generic specification.

**global entity**
An entity (a program unit, common block, or external procedure) that can be used with the same meaning throughout the executable program. A global entity has global scope; it is accessible throughout an executable program. See also local entity.

**global section**
A data structure (for example, global COMMON) or shareable image section potentially available to all processes in the system.

Glossary H

**handle**
A value (often, but not always, a 32-bit integer) that identifies some operating system resource, for example, a window or a process. The handle value is returned from an operating system call when the resource is created; your program then passes that value as an argument to subsequent operating system routines to identify which resource is being accessed.

Your program should consider the handle value a "private" type and not try to interpret it as having any specific meaning (for example, an address).

**hexadecimal constant**
A constant that is a string of hexadecimal (base 16) digits (range 0 to 9, or an uppercase or lowercase letter in the range A to F) enclosed by apostrophes or quotation marks and preceded by the letter Z.

**Hollerith constant**
A constant that is a string of printable ASCII characters preceded by `nH`, where n is the number of characters in the string (including blanks and tabs).

**host**
Either the main program or subprogram that contains an internal procedure, or the module that contains a module procedure. The data environment of the host is available to the (internal or module) procedure.

**host association**
The process by which a module procedure, internal procedure, or derived-type definition accesses the entities of its host.

Glossary I

**image**
An instance of a Fortran program.

**image index**
An integer value that identifies an image.

**image control statement**
A statement that affects the execution ordering between images.

**implicit interface**
A procedure interface whose properties (the collection of names, attributes, and arguments of the procedure) are not known within the scope of the calling program, and have to be assumed. The information is assumed by the calling program from the properties of the procedure name and actual arguments in the procedure call.
implicit typing  The mechanism by which the data type for a variable is determined by the beginning letter of the variable name.

import library  A .LIB file that contains information about one or more dynamic-link libraries (DLLs), but does not contain the DLL's executable code. To provide the information needed to resolve the external references to DLL functions, the linker uses an import library when building an executable module of a process.

included task  A task for which execution is sequentially included in the generating task region; that is, the task is undeferred and executed immediately by the encountering thread.

index  Can be either of the following:
- The variable used as a loop counter in a DO statement.
- An intrinsic function specifying the starting position of a substring inside a string.

inheritance association  The relationship between the inherited components and the parent component in an extended type.

initialize  The assignment of an initial value to a variable.

inlining  An optimization that replaces a subprogram reference (CALL statement or function invocation) with the replicated code of the subprogram.

input/output (I/O)  The data that a program reads or writes. Also, devices to read and write data.

inquiry function  An intrinsic function whose result depends on properties of the principal argument, not the value of the argument.

integer constant  A constant that is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.

intent  An attribute of a dummy argument that is not a procedure or a pointer. It indicates whether the argument is used to transfer data into the procedure, out of the procedure, or both.

interactive process  A process that must periodically get user input to do its work. Contrast with background process.

interface  See procedure interface.

interface block  The sequence of statements starting with an INTERFACE statement and ending with the corresponding END INTERFACE statement.

interface body  The sequence of statements in an interface block starting with a FUNCTION or SUBROUTINE statement and ending with the corresponding END statement. Also called a procedure interface body.

internal file  The designated internal storage space (or variable buffer) that is manipulated during input and output. An internal file can be a character variable, character array, character array element, or character substring. In general, an internal file contains one record. However, an internal file that is a character array has one record for each array element.

internal procedure  A procedure (other than a statement function) that is contained within an internal subprogram. The program unit containing an internal procedure is called the host of the internal procedure. The internal
procedure (which appears between a CONTAINS and END statement) is local to its host and inherits the host's environment through host association.

**internal subprogram**
A subprogram contained in a main program or another subprogram.

**intrinsic**
Describes entities defined by the Fortran 2003 language (such as data types and procedures). Intrinsic entities can be used freely in any scoping unit.

**intrinsic procedure**
A subprogram supplied as part of the Fortran library that performs array, mathematical, numeric, character, bit manipulation, and other miscellaneous functions. Intrinsic procedures are automatically available to any Fortran program unit (unless specifically overridden by an EXTERNAL statement or a procedure interface block). Also called a built-in or library procedure.

**invoke**
To call upon; used especially with reference to subprograms. For example, to invoke a function is to execute the function.

**iteration count**
The number of executions of the DO range, which is determined as follows:

\[ \left( \frac{\text{terminal value} - \text{initial value} + \text{increment value}}{\text{increment value}} \right) \]

---

**Glossary K**

**keyword**
See argument keyword and statement keyword.

**kind type parameter**
Indicates the range of an intrinsic data type; for example: INTEGER(KIND=2). For real and complex types, it also indicates precision. If a specific kind parameter is not specified, the kind is the default for that type (for example, default integer). See also default character, default complex, default integer, default logical, and default real.

---

**Glossary L**

**label**
An integer, from 1 to 5 digits long, that precedes a statement and identifies it. For example, labels can be used to refer to a FORMAT statement or branch target statement.

**language extension**
An Intel® Fortran language element or interpretation that is not part of the Fortran 2003 standard.

**lexical token**
A sequence of one or more characters that have an indivisible interpretation. A lexical token is the smallest meaningful unit (a basic language element) of a Fortran statement; for example, constants, and statement keywords.

**library routines**
Files that contain functions, subroutines, and data that can be used by Fortran programs.

For example: one library contains routines that handle the various differences between Fortran and C in argument passing and data types; another contains run-time functions and subroutines for Windows* graphics and QuickWin* applications.
Some library routines are intrinsic (automatically available) to Fortran; others may require a specific **USE statement** to access the module defining the routines. See also **intrinsic procedure**.

**line**

A source form record consisting of 0 or more characters. A standard Fortran line is limited to a maximum of 132 characters.

**linker**

A system program that creates an executable program from one or more object files produced by a language compiler or assembler. The linker resolves external references, acquires referenced library routines, and performs other processing required to create Linux* and Windows* executable files.

**list-directed I/O statement**

An implicit, formatted I/O statement that uses an asterisk (*) specifier rather than an explicit format specification. See also **formatted I/O statement** and **namelist I/O statement**.

**listing**

A printed copy of a program.

**literal constant**

A constant without a name; its value is directly specified in a program. See also **named constant**.

**little endian**

A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the lowest addressed byte. This is the method used on Intel® systems. Contrast with **big endian**.

**local entity**

An entity that can be used only within the context of a subprogram (its scoping unit); for example, a statement label. A local entity has local scope. See also **global entity**.

**local optimization**

A level of optimization enabling optimizations within the source program unit and recognition of common expressions. See also **optimization**.

**local symbol**

A name defined in a program unit that is not accessible outside of that program unit.

**logical constant**

A constant that specifies the value .TRUE. or .FALSE..

**logical expression**

An integer or logical constant, variable, function value, or another constant expression, joined by a relational or logical operator. The logical expression is evaluated to a value of either true or false. For example, .NOT. 6.5 + (B .GT. D).

**logical operator**

A symbol that represents an operation on logical expressions. The logical operators are .AND., .OR., .NEQV., .XOR., .EQV., and .NOT..

**logical unit**

A channel in memory through which data transfer occurs between the program and the device or file. See also **unit identifier**.

**longword**

Four contiguous bytes (32 bits) starting on any addressable byte boundary. Bits are numbered 0 to 31. The address of the longword is the address of the byte containing bit 0. When the longword is interpreted as a signed integer, bit 31 is the sign bit. The value of signed integers is in the range -2**31 to 2**31-1. The value of unsigned integers is in the range 0 to 2**32-1.

**loop**

A group of statements that are executed repeatedly until an ending condition is reached.

**lower bounds**

See **bounds**.
## Glossary M

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>main program</td>
<td>The first program unit to receive control when a program is run; it exercises control over subprograms. The main program usually contains a <code>PROGRAM</code> statement (or does not contain a <code>SUBROUTINE</code>, <code>FUNCTION</code>, or <code>BLOCK DATA</code> statement). Contrast with subprogram.</td>
</tr>
<tr>
<td>makefile</td>
<td>On Linux* and macOS* systems, an argument to the make command containing a sequence of entries that specify dependencies. On Windows* systems, a file passed to the NMAKE utility containing a sequence of entries that specify dependencies. The contents of a makefile override the system built-in rules for maintaining, updating, and regenerating groups of programs. For more information on makefiles on Linux* and macOS* systems, see make(1). For more information on using makefiles, see Using Makefiles to Compile Your Application in Compiler Setup.</td>
</tr>
<tr>
<td>many-one array section</td>
<td>An array section with a vector subscript having two or more elements with the same value.</td>
</tr>
<tr>
<td>master thread</td>
<td>In an OpenMP* Fortran program, the thread that creates a team of threads when a parallel region (PARALLEL directive construct) is encountered. The statements in the parallel region are then executed in parallel by each thread in the team. At the end of the parallel region, the team threads synchronize and only the master thread continues execution. See also thread.</td>
</tr>
<tr>
<td>merged task</td>
<td>A task whose data environment, inclusive of internal control variables, is the same as that of its generating task region. Internal control variables (ICVs) are discussed in the latest OpenMP* specifications.</td>
</tr>
<tr>
<td>message file</td>
<td>A Linux* and macOS* catalog that contains the diagnostic message text of errors that can occur during program execution (run time).</td>
</tr>
<tr>
<td>metacommand</td>
<td>See compiler directive.</td>
</tr>
<tr>
<td>misaligned data</td>
<td>Data not aligned on a natural boundary. See also natural boundary.</td>
</tr>
<tr>
<td>module</td>
<td>A program unit that contains specifications and definitions that other program units can access (unless the module entities are declared PRIVATE). Modules are referenced in USE statements.</td>
</tr>
<tr>
<td>module procedure</td>
<td>A subroutine or function that is not an internal procedure and is contained in a module. The module procedure appears between a CONTAINS and END statement in its host module, and inherits the host module’s environment through host association. A module procedure can be declared PRIVATE to the module; it is public by default.</td>
</tr>
<tr>
<td>multibyte character set</td>
<td>A character set in which each character is identified by using more than one byte. Although Unicode characters are 2 bytes wide, the Unicode character set is not referred to by this term.</td>
</tr>
<tr>
<td>multitasking</td>
<td>The ability of an operating system to execute several programs (tasks) at once.</td>
</tr>
<tr>
<td>multithreading</td>
<td>The ability of an operating system to execute different parts of a program, called threads, simultaneously. If the system supports parallel processing, multiple processors may be used to execute the threads.</td>
</tr>
</tbody>
</table>
### Glossary N

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies an entity within a Fortran program unit (such as a variable, function result, common block, named constant, procedure, program unit, namelist group, or dummy argument). A name can contain letters, digits, underscores ( _ ), and the dollar sign ($) special character. The first character must be a letter or a dollar sign. In earlier versions of Fortran, this term was called a symbolic name.</td>
</tr>
<tr>
<td>name association</td>
<td>Pertains to argument, host, or use association. See also argument association, host association, and use association.</td>
</tr>
<tr>
<td>named common block</td>
<td>A common block (one or more contiguous areas of storage) with a name. Common blocks are defined by a COMMON statement.</td>
</tr>
<tr>
<td>named constant</td>
<td>A constant that has a name. In earlier versions of Fortran, this term was called a symbolic constant.</td>
</tr>
<tr>
<td>namelist I/O statement</td>
<td>An implicit, formatted I/O statement that uses a namelist group specifier rather than an explicit format specifier. See also formatted I/O statement and list-directed I/O statement.</td>
</tr>
<tr>
<td>NaN</td>
<td>Not-a-Number. The condition that results from a floating-point operation that has no mathematical meaning; for example, zero divided by zero.</td>
</tr>
<tr>
<td>natural boundary</td>
<td>The virtual address of a data item that is the multiple of the size of its data type. For example, a REAL(8) (REAL*8) data item aligned on natural boundaries has an address that is a multiple of eight.</td>
</tr>
<tr>
<td>naturally aligned record</td>
<td>A record that is aligned on a hardware-specific natural boundary; each field is naturally aligned. Contrast with packed record.</td>
</tr>
<tr>
<td>nesting</td>
<td>The placing of one entity (such as a construct, subprogram, format specification, or loop) inside another entity of the same kind. For example, nesting a loop within another loop (a nested loop), or nesting a subroutine within another subroutine.</td>
</tr>
<tr>
<td>nonexecutable statement</td>
<td>A Fortran statement that describes program attributes, but does not cause any action to be taken when the program is executed.</td>
</tr>
<tr>
<td>nonsignaled</td>
<td>The state of an object used for synchronization in one of the wait functions is either signaled or nonsignaled. A nonsignaled state can prevent the wait function from returning. See also wait function.</td>
</tr>
<tr>
<td>normal termination</td>
<td>Normal termination of an image is initiated when the image executes a STOP statement or an END [PROGRAM] statement. The image becomes a stopped image. Its coarrays remain accessible to other active images and may be defined or referenced by them. When the last active image initiates normal termination, all images terminate execution. See also error termination.</td>
</tr>
<tr>
<td>numeric expression</td>
<td>A numeric constant, variable, or function value, or combination of these, joined by numeric operators and parentheses, so that the entire expression can be evaluated to produce a single numeric value. For example, -L or X+(Y-4.5*Z).</td>
</tr>
<tr>
<td>numeric operator</td>
<td>A symbol designating an arithmetic operation. In Standard Fortran, the symbols +, -, *, /, and ** are used to designate addition, subtraction, multiplication, division, and exponentiation, respectively.</td>
</tr>
<tr>
<td><strong>numeric storage unit</strong></td>
<td>The unit of storage for holding a non-pointer scalar value of type default real, default integer, or default logical. One numeric storage unit corresponds to 4 bytes of memory.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>numeric type</strong></td>
<td>Integer, real, or complex type.</td>
</tr>
</tbody>
</table>

### Glossary O

<table>
<thead>
<tr>
<th><strong>object</strong></th>
<th>See data object.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>object file</strong></td>
<td>The binary output of a language processor (such as an assembler or compiler), which can either be executed or used as input to the linker.</td>
</tr>
<tr>
<td><strong>obsolescent feature</strong></td>
<td>A feature of earlier versions of Fortran that is considered to be redundant in Fortran 2003. These features are still in frequent use.</td>
</tr>
<tr>
<td><strong>octal constant</strong></td>
<td>A constant that is a string of octal (base 8) digits (range of 0 to 7) enclosed by apostrophes or quotation marks and preceded by the letter O.</td>
</tr>
<tr>
<td><strong>operand</strong></td>
<td>The passive element in an expression on which an operation is performed. Every expression must have at least one operand. For example, in I .NE. J, I and J are operands. Contrast with operator.</td>
</tr>
<tr>
<td><strong>operation</strong></td>
<td>A computation involving one or two operands.</td>
</tr>
<tr>
<td><strong>operator</strong></td>
<td>The active element in an expression that performs an operation. An expression can have zero or more operators. Intrinsic operators are arithmetic (+, -, *, /, and **) or logical (.AND., .NOT., and so on). For example, in I .NE. J, .NE. is the operator. Executable programs can define operators which are not intrinsic.</td>
</tr>
<tr>
<td><strong>optimization</strong></td>
<td>The process of producing efficient object or executing code that takes advantage of the hardware architecture to produce more efficient execution.</td>
</tr>
<tr>
<td><strong>optional argument</strong></td>
<td>A dummy argument that has the OPTIONAL attribute (or is included in an OPTIONAL statement in the procedure definition). This kind of argument does not have to be associated with an actual argument when its procedure is invoked.</td>
</tr>
<tr>
<td><strong>order of subscript progression</strong></td>
<td>A characteristic of a multidimensional array in which the leftmost subscripts vary most rapidly. Also called column-major order.</td>
</tr>
<tr>
<td><strong>overflow</strong></td>
<td>An error condition occurring when an arithmetic operation yields a result that is larger than the maximum value in the range of a data type.</td>
</tr>
</tbody>
</table>

### Glossary P

<table>
<thead>
<tr>
<th><strong>packed record</strong></th>
<th>A record that starts on an arbitrary byte boundary; each field starts in the next unused byte. Contrast with naturally aligned record.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pad</strong></td>
<td>The filling of unused positions in a field or character string with dummy data (such as zeros or blanks).</td>
</tr>
<tr>
<td><strong>parallel processing</strong></td>
<td>The simultaneous use of more than one processor (CPU) to execute a program.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>parameter</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>• In general, any quantity of interest in a given situation; often used in place of the term &quot;argument&quot;.</td>
</tr>
<tr>
<td></td>
<td>• A Fortran named constant.</td>
</tr>
<tr>
<td>parent component</td>
<td>The component of an entity of extended type that corresponds to its inherited portion.</td>
</tr>
<tr>
<td>parent process</td>
<td>A process that initiates and controls another process (child). The parent process defines the environment for the child process. Also, the parent process can suspend or terminate without affecting the child process. See also child process.</td>
</tr>
<tr>
<td>parent window</td>
<td>A window that has one or more child windows. See also child window.</td>
</tr>
<tr>
<td>parent type</td>
<td>The extensible type from which an extended type is derived.</td>
</tr>
<tr>
<td>passed-object dummy argument</td>
<td>The dummy argument of a type-bound procedure or procedure pointer component that becomes associated with the object through which the procedure was invoked.</td>
</tr>
<tr>
<td>pathname</td>
<td>The path from the root directory to a subdirectory or file. See also root.</td>
</tr>
<tr>
<td>pipe</td>
<td>A connection that allows one program to get its input directly from the output of another program.</td>
</tr>
<tr>
<td>platform</td>
<td>A combination of operating system and hardware that provides a distinct environment in which to use a software product (for example, Microsoft* Windows* on processors using IA-32 architecture).</td>
</tr>
<tr>
<td>pointer</td>
<td>A pointer is either a data pointer or a procedure pointer. A data pointer is a data entity that has the POINTER attribute. A procedure pointer is a procedure entity that has the POINTER attribute. A pointer is associated with a target by pointer assignment. A data pointer can also be associated with a target by allocation. A pointer that is not associated must not be referenced or defined. A disassociated pointer is not associated with a target. A pointer is disassociated following one of these events: Execution of a NULLIFY statement Pointer assignment with a disassociated pointer Default initialization Explicit initialization A data pointer can also be disassociated by execution of a DEALLOCATE statement. If a data pointer is an array, the rank is declared, but the extents are determined when the pointer is associated with a target. A data pointer is one of the following: A Fortran pointer An integer pointer</td>
</tr>
<tr>
<td></td>
<td>A data object that has the POINTER attribute. To be referenced or defined, it must be &quot;pointer-associated&quot; with a target (have storage space associated with it). If the pointer is an array, it must be pointer-associated to have a shape. See also pointer association.</td>
</tr>
<tr>
<td></td>
<td>A data object that contains the address of its paired variable. This is also called a Cray* pointer.</td>
</tr>
</tbody>
</table>
pointer assignment

The association of a pointer with a target by the execution of a pointer assignment statement or the execution of an assignment statement for a data object of derived type having the pointer as a subobject.

pointer association

The association of storage space to a Fortran pointer by means of a target. A pointer is associated with a target after pointer assignment or the valid execution of an ALLOCATE statement.

polymorphic object

An object that can have different types during program execution. An object declared with the CLASS keyword is polymorphic.

potential subobject component

For a derived type or a structure, a nonpointer component or a potential subobject component of a nonpointer component.

precision

The number of significant digits in a real number. See also double-precision constant, kind type parameter, and single-precision constant.

primary

The simplest form of an expression. A primary can be any of the following data objects:

- A constant
- A constant subobject (parent is a constant)
- A variable (scalar, structure, array, or pointer; an array cannot be assumed size)
- An array constructor
- A structure constructor
- A function reference
- An expression in parentheses

primary thread

The initial thread of a process. Also called the main thread or thread 1. See also thread.

procedure

A computation that can be invoked during program execution. It can be a subroutine or function, an internal, external, dummy or module procedure, or a statement function. A subprogram can define more than one procedure if it contains an ENTRY statement. See also subprogram.

procedure interface

The statements that specify the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.

If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration).

process object

A virtual address space, security profile, a set of threads that execute in the address space of the process, and a set of resources visible to all threads executing in the process. Several thread objects can be associated with a single process.

program

A set of instructions that can be compiled and executed by itself. Program blocks contain a declaration and an executable section.

program section

A particular common block or local data area for a particular routine containing equivalence groups.

program unit

The fundamental component of an executable program. A sequence of statements and comment lines. It can be a main program, a module, an external subprogram, or a block data program unit.
Glossary Q

quadword

Four contiguous words (64 bits) starting on any addressable byte boundary. Bits are numbered 0 to 63. (Bit 63 is used as the sign bit.) A quadword is identified by the address of the word containing the low-order bit (bit 0). The value of a signed quadword integer is in the range -2**63 to 2**63-1.

Glossary R

random access

See direct access.

rank

The number of dimensions of an array. A scalar has a rank of zero.

rank-one object

A data structure comprising scalar elements with the same data type and organized as a simple linear sequence. See also scalar.

real constant

A constant that is a number written with a decimal point, exponent, or both. It can have single precision (REAL(KIND=4)), double precision (REAL(KIND=8)), or quad precision (REAL(KIND=16)).

record

Can be either of the following:
- A set of logically related data items (in a file) that is treated as a unit; such a record contains one or more fields. This definition applies to I/O records and items that are declared in a record structure.
- One or more data items that are grouped in a structure declaration and specified in a RECORD statement.

record access

The method used to store and retrieve records in a file.

record structure declaration

A block of statements that define the fields in a record. The block begins with a STRUCTURE statement and ends with END STRUCTURE. The name of the structure must be specified in a RECORD statement.

record type

The property that determines whether records in a file are all the same length, of varying length, or use other conventions to define where one record ends and another begins.

recursion

Pertains to a subroutine or function that directly or indirectly references itself.

reference

Can be any of the following:
- For a data object, the appearance of its name, designator, or associated pointer where the value of the object is required. When an object is referenced, it must be defined.
- For a procedure, the appearance of its name, operator symbol, or assignment symbol that causes the procedure to be executed. Procedure reference is also called "calling" or "invoking" a procedure.
- For a module, the appearance of its name in a USE statement.

relational expression

An expression containing one relational operator and two operands of numeric or character type. The result is a value that is true or false. For example, A-C .GE. B+2 or DAY .EQ. 'MONDAY'.

relational operator

The symbols used to express a relational condition or expression. The relational operators are (.EQ., .NE., .LT., .LE., .GT., and .GE.).
relative file organization
A file organization that consists of a series of component positions, called cells, numbered consecutively from 1 to n. Intel Fortran uses these numbered, fixed-length cells to calculate the component's physical position in the file.

relative pathname
A directory path expressed in relation to any directory other than the root directory. Contrast with absolute pathname.

root
On Windows* systems, the top-level directory on a disk drive; it is represented by a backslash (\). For example, C:\ is the root directory for drive C.

On Linux* systems, the top-level directory in the file system; it is represented by a slash (/).

routine
A subprogram; a function or procedure. See also function, subroutine, and procedure.

run time
The time during which a computer executes the statements of a program.

Glossary S

saved object
A variable that retains its association status, allocation status, definition status, and value after execution of a RETURN or END statement in the scoping unit containing the declaration.

scalar
Pertaining to data items with a rank of zero. A single data object of any intrinsic or derived data type. Contrast with array. See also rank-one object.

scalar memory reference
A reference to a scalar variable, scalar record field, or array element that resolves into a single data item (having a data type) and can be assigned a value with an assignment statement. It is similar to a scalar reference, but it excludes constants, character substrings, and expressions.

scalar reference
A reference to a scalar variable, scalar record field, derived-type component, array element, constant, character substring, or expression that resolves into a single data item having a data type.

scalar variable
A variable name specifying one storage location.

scale factor
A number indicating the location of the decimal point in a real number and, if there is no exponent, the size of the number on input.

scope
The portion of a program in which a declaration or a particular name has meaning. Scope can be global (throughout an executable program), scoping unit (local to the scoping unit), or statement (within a statement, or part of a statement).

scoping unit
The part of the program in which a name has meaning. It is one of the following:

- A program unit or subprogram
- A derived-type definition
- A procedure interface body

Scoping units cannot overlap, though one scoping unit can contain another scoping unit. The outer scoping unit is called the host scoping unit.
section subscript

A subscript list (enclosed in parentheses and appended to the array name) indicating a portion (section) of an array. At least one of the subscripts in the list must be a subscript triplet or vector subscript. The number of section subscripts is the rank of the array. See also array section, subscript, subscript triplet, and vector subscript.

seed

A value (which can be assigned to a variable) that is required in order to properly determine the result of a calculation; for example, the argument k in the random number generator (RAN) function syntax:

\[ y = \text{RAN}(k) \]

selector

A mechanism for designating the following:

- Part of a data object (an array element or section, a substring, a derived type, or a structure component)
- The set of values for which a CASE block is executed

sequence

A set ordered by a one-to-one correspondence with the numbers 1 through n, where n is the total number of elements in the sequence. A sequence can be empty (contain no elements).

sequential access

A method for retrieving or storing data in which the data (record) is read from, written to, or removed from a file based on the logical order (sequence) of the record in the file. (The record cannot be accessed directly.) Contrast with direct access.

sequential file organization

A file organization in which records are stored one after the other, in the order in which they were written to the file.

shape

The rank and extents of an array. Shape can be represented by a rank-one array (vector) whose elements are the extents in each dimension.

shape conformance

Pertains to the rule concerning operands of binary intrinsic operations in expressions: to be in shape conformance, the two operands must both be arrays of the same shape, or one or both of the operands must be scalars.

short field termination

The use of a comma (,) to terminate the field of a numeric data edit descriptor. This technique overrides the field width (w) specification in the data edit descriptor and therefore avoids padding of the input field. The comma can only terminate fields less than w characters long. See also data edit descriptor.

signal

The software mechanism used to indicate that an exception condition (abnormal event) has been detected. For example, a signal can be generated by a program or hardware error, or by request of another program.

single-precision constant

A processor approximation of the value of a real number that occupies 4 bytes of memory and can assume a positive, negative, or zero value. The precision is less than a constant of double-precision type. For the precise ranges of the single-precision constants, see Data Representation Overview in the Compiler Reference. See also denormalized number.

size

The total number of elements in an array (the product of the extents).

source file

A program or portion of a program library, such as an object file, or image file.
specification expression  A restricted expression that is of type integer and has a scalar value. This type of expression appears only in the declaration of array bounds and character lengths.

specification statement  A nonexecutable statement that provides information about the data used in the source program. Such a statement can be used to allocate and initialize variables, arrays, records, and structures, and define other characteristics of names used in a program.

statement  An instruction in a programming language that represents a step in a sequence of actions or a set of declarations. In Standard Fortran, an ampersand can be used to continue a statement from one line to another, and a semicolon can be used to separate several statements on one line.

There are two main classes of statements: executable and nonexecutable.

statement function  A computing procedure defined by a single statement in the same program unit in which the procedure is referenced.

statement function definition  A statement that defines a statement function. Its form is the statement function name (followed by its optional dummy arguments in parentheses), followed by an equal sign (=), followed by a numeric, logical, or character expression.

A statement function definition must precede all executable statements and follow all specification statements.

statement keyword  A word that begins the syntax of a statement. All program statements (except assignment statements and statement function definitions) begin with a statement keyword. Examples are INTEGER, DO, IF, and WRITE.

statement label  See label.

static variable  A variable whose storage is allocated for the entire execution of a program.

storage association  The relationship between two storage sequences when the storage unit of one is the same as the storage unit of the other. Storage association is provided by the COMMON and EQUIVALENCE statements. For modules, pointers, allocatable arrays, and automatic data objects, the SEQUENCE statement defines a storage order for structures.

storage location  An addressable unit of main memory.

storage sequence  A sequence of any number of consecutive storage units. The size of a storage sequence is the number of storage units in the storage sequence. A sequence of storage sequences forms a composite storage sequence. See also storage association and storage unit.

storage unit  In a storage sequence, the number of storage units needed to represent one real, integer, logical, or character value. See also character storage unit, numeric storage unit, and storage sequence.

stride  The increment between subscript values that can optionally be specified in a subscript triplet. If it is omitted, it is assumed to be one.

string edit descriptor  A format descriptor that transfers characters to an output record.

structure  Can be either of the following:
- A scalar data object of derived (user-defined) type.
• An aggregate entity containing one or more fields or components.

structure component
Can be either of the following:
• One of the components of a structure.
• An array whose elements are components of the elements of an
  array of derived type.

structure constructor
A mechanism that is used to specify a scalar value of a derived type.
A structure constructor is the name of the type followed by a
parenthesized list of values for the components of the type.

subobject
Part of a data object (parent object) that can be referenced and
defined separately from other parts of the data object. A subobject
can be an array element, an array section, a substring, a derived
type, or a structure component. Subobjects are referenced by
designators and can be considered to be data objects themselves. See
also designator.

subobject designator
See designator.

subprogram
A function or subroutine subprogram that can be invoked from
another program unit to perform a specific task. A subprogram can
define more than one procedure if it contains an ENTRY statement.
Contrast with main program. See also procedure.

subroutine
A procedure that can return many values, a single value, or no value
to the calling program unit (through arguments). A subroutine is
invoked by a CALL statement in another program unit.

In recent versions of Fortran, a subroutine can also be used to specify
a defined assignment. Such assignments are invoked with an
ASSIGNMENT(=) interface block rather than the CALL statement. See
also function, statement function, and subroutine subprogram.

subroutine subprogram
A sequence of statements starting with a SUBROUTINE (or optional
OPTIONS) statement and ending with the corresponding END
statement. See also subroutine.

subscript
A scalar integer expression (enclosed in parentheses and appended to
the array name) indicating the position of an array element. The
number of subscripts is the rank of the array. See also array element.

subscript triplet
An item in a section subscript list specifying a range of values for the
array section. A subscript triplet contains at least one colon and has
three optional parts: a lower bound, an upper bound, and a stride.
Contrast with vector subscript. See also array section and section
subscript.

substring
A contiguous portion of a scalar character string. Do not confuse this
with the substring selector in an array section, where the result is
another array section, not a substring.

symbolic name
See name.

syntax
The formal structure of a statement or command string.
## Glossary T

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>The named data object associated with a pointer (in the form pointer-object =&gt; target). A target is declared in a type declaration statement that contains the TARGET attribute. See also pointer and pointer association.</td>
</tr>
<tr>
<td>thread</td>
<td>Part of a program that can run at the same time as other parts, usually with some form of communication and/or synchronization among the threads. See also multithreading.</td>
</tr>
<tr>
<td>transformational function</td>
<td>An intrinsic function that is not an elemental or inquiry function. A transformational function usually changes an array actual argument into a scalar result or another array, rather than applying the argument element by element.</td>
</tr>
<tr>
<td>truncation</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>• A technique that approximates a numeric value by dropping its fractional value and using only the integer portion.</td>
</tr>
<tr>
<td></td>
<td>• The process of removing one or more characters from the left or right of a number or string.</td>
</tr>
<tr>
<td>type declaration statement</td>
<td>A nonexecutable statement specifying the data type of one or more variables: an INTEGER, REAL, DOUBLE PRECISION, COMPLEX, DOUBLE COMPLEX, CHARACTER, LOGICAL, or TYPE statement. A type declaration statement may also specify attributes for the variables. Also called a type declaration or type specification.</td>
</tr>
<tr>
<td>type parameter</td>
<td>Defines an intrinsic data type. The type parameters are kind and length. The kind type parameter (KIND=) specifies the range for the integer data type, the precision and range for real and complex data types, and the machine representation method for the character and logical data types. The length type parameter (LEN=) specifies the length of a character string. See also kind type parameter.</td>
</tr>
<tr>
<td>type-bound procedure</td>
<td>A procedure that is bound to a derived type and referenced by means of an object of that type.</td>
</tr>
</tbody>
</table>

## Glossary U

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ultimate component</td>
<td>For a derived type or a structure, a component that is of intrinsic type or has the ALLOCATABLE or POINTER attribute, or an ultimate component of a component that is a derived type and does not have the ALLOCATABLE or POINTER attribute.</td>
</tr>
<tr>
<td>unary operator</td>
<td>An operator that operates on one operand. For example, the minus sign in -A and the .NOT. operator in .NOT. (J .GT. K).</td>
</tr>
<tr>
<td>undeferred task</td>
<td>A task for which execution is not deferred with respect to its generating task region; that is, its generating task region is suspended until execution of the undeferred task has finished.</td>
</tr>
<tr>
<td>undefined</td>
<td>For a data object, the property of not having a determinate value.</td>
</tr>
<tr>
<td>underflow</td>
<td>An error condition occurring when the result of an arithmetic operation yields a result that is smaller than the minimum value in the range of a data type. For example, in unsigned arithmetic, underflow occurs when a result is negative. See also denormalized number.</td>
</tr>
</tbody>
</table>
unformatted data
Data written to a file by using unformatted I/O statements; for example, binary numbers.

unformatted I/O statement
An I/O statement that does not contain format specifiers and therefore does not translate the data being transferred. Contrast with formatted I/O statement.

unformatted record
A record that is transmitted in internal format between internal and external storage.

unit identifier
The identifier that specifies an external unit or internal file. The identifier can be any one of the following:
- An integer expression whose value must be zero or positive
- An asterisk (*) that corresponds to the default (or implicit) I/O unit
- The name of a character scalar memory reference or character array name reference for an internal file
Also called a device code, or logical unit number.

unspecified storage unit
A unit of storage for holding a pointer or a scalar that is not a pointer and is of type other than default integer, default character, or default real.

upper bounds
See bounds.

use association
The process by which the entities in a module are made accessible to other scoping units (through a USE statement in the scoping unit).

user-defined assignment
See defined assignment.

user-defined operator
See defined operation.

user-defined type
See derived type.

**Glossary V**

variable
A data object (stored in a memory location) whose value can change during program execution. A variable can be a named data object, an array element, an array section, a structure component, or a substring. In FORTRAN 77, a variable was always scalar and named. Contrast with constant.

variable format expression
A numeric expression enclosed in angle brackets (<> ) that can be used in a FORMAT statement. If necessary, it is converted to integer type before use.

variable-length record type
A file format in which records may be of different lengths.

vector subscript
A rank-one array of integer values used as a section subscript to select elements from a parent array. Unlike a subscript triplet, a vector subscript specifies values (within the declared bounds for the dimension) in an arbitrary order. Contrast with subscript triplet. See also array section and section subscript.
### Glossary W

<table>
<thead>
<tr>
<th>term</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait function</td>
<td>A function that blocks the execution of a calling thread until a specified set of conditions has been satisfied.</td>
</tr>
<tr>
<td>whole array</td>
<td>An array reference (for example, in a type declaration statement) that consists of the array name alone, without subscript notation. Whole array operations affect every element in the array. See also array.</td>
</tr>
</tbody>
</table>

### Glossary Z

<table>
<thead>
<tr>
<th>term</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>zero-sized array</td>
<td>An array with at least one dimension that has at least one extent of zero. A zero-sized array has a size of zero and contains no elements. See also array.</td>
</tr>
</tbody>
</table>
**Supported Environment Variables**

You can customize your system environment by specifying paths where the compiler searches for certain files such as libraries, include files, configuration files, and certain settings.

### Compiler Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the compiler:

<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFORTCFG</td>
<td>Specifies a configuration file that the compiler should use instead of the default configuration file. By default, the compiler uses the default configuration file (ifort.cfg) from the same directory where the compiler executable resides.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong>&lt;br&gt;On Windows* operating systems, this environment variable cannot be set from Visual Studio.</td>
</tr>
<tr>
<td>INTEL_LICENSE_FILE</td>
<td>Specifies the location for the Intel license file.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong>&lt;br&gt;On Windows* operating systems, this environment variable cannot be set from Visual Studio.</td>
</tr>
<tr>
<td>__INTEL_PRE_FFLAGS</td>
<td>Specifies a set of compiler options to add to the compile line. This is an extension to the facility already provided in the compiler configuration file ifort.cfg.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong>&lt;br&gt;By default, a configuration file named (Windows*), icc.cfg (Linux*, macOS*), or icpc.cfg (Linux*, macOS*) ifort.cfg is used. This file is in the same directory as the compiler executable. To use another configuration file in another location, you can use the IFORTCFG environment variable to assign the directory and file name for the configuration file.</td>
</tr>
<tr>
<td>Compile-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>__INTEL_PRE_FFLAGS</strong></td>
<td>You can insert command line options in the prefix position using <strong>__INTEL_PRE_FFLAGS</strong>, or in the suffix position using <strong>__INTEL_POST_FFLAGS</strong>. The command line is built as follows:</td>
</tr>
<tr>
<td><strong>Syntax:</strong></td>
<td>\texttt{ifort &lt;PRE flags&gt; &lt;flags from configuration file&gt; &lt;flags from the compiler invocation&gt; &lt;POST flags&gt;}</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>The driver issues a warning that the compiler is overriding an option because of an environment variable, but only when you include the option /W5 (Windows*) or -w3 (Linux* and macOS*).</td>
</tr>
<tr>
<td><strong>INTEL_TARGET_ARCH_IA32</strong> (Linux* and Windows*)</td>
<td>Set this environment variable to target 32-bit compilations for all associated tools (this includes the compiler and Intel-specific linker tools). Without this environment variable, you will be required to use the explicit command line options, /Qm32 on Windows* and -m32 on Linux*, for each compiler invocation.</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>IA-32 architecture is no longer supported on macOS*.</td>
</tr>
<tr>
<td><strong>PATH</strong></td>
<td>Specifies the directories the system searches for binary executable files.</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>On Windows* this also affects the search for Dynamic Link Libraries (DLLs).</td>
</tr>
<tr>
<td><strong>TMP</strong></td>
<td>Specifies the location for temporary files. If none of these are specified, or writeable, or found, the compiler stores temporary files in /tmp (Linux, macOS*) or the current directory (Windows).</td>
</tr>
<tr>
<td><strong>TMPDIR</strong></td>
<td>The compiler searches for these variables in the following order: \texttt{TMP, TMPDIR, and TEMP}.</td>
</tr>
<tr>
<td><strong>TEMP</strong></td>
<td><strong>NOTE</strong> On Windows* operating systems, these environment variables cannot be set from Visual Studio.</td>
</tr>
<tr>
<td><strong>LD_LIBRARY_PATH</strong> (Linux*)</td>
<td>Specifies the location for shared objects (.so files).</td>
</tr>
<tr>
<td><strong>DYLD_LIBRARY_PATH</strong> (macOS*)</td>
<td>Specifies the path for dynamic libraries.</td>
</tr>
<tr>
<td><strong>INCLUDE</strong> (Windows*)</td>
<td>Specifies the directory path for the include files (files included by INCLUDE statements, #include files, RC INCLUDE files(^1), and module files referenced by USE statements).</td>
</tr>
</tbody>
</table>
### Compile-Time Environment Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lib</strong> (Windows*)</td>
<td>Specifies the directories for all libraries used by the compiler and linker.</td>
</tr>
<tr>
<td><strong>CPATH</strong> (Linux* and macOS*)</td>
<td>Specifies the path for include and module files.</td>
</tr>
<tr>
<td><strong>GCCROOT</strong> (Linux*)</td>
<td>Specifies the location of the gcc* binaries.</td>
</tr>
<tr>
<td><strong>GXX_INCLUDE</strong> (Linux*)</td>
<td>Specifies the location of the gcc headers.</td>
</tr>
<tr>
<td><strong>GXX_ROOT</strong> (Linux*)</td>
<td>Specifies the location of the gcc binaries.</td>
</tr>
<tr>
<td><strong>LIBRARY_PATH</strong> (Linux* and macOS*)</td>
<td>Specifies the path for libraries to be used during the link phase.</td>
</tr>
</tbody>
</table>

**NOTE**: INTEL_ROOT is an environment variable that is reserved for the Intel compiler. It’s use is not supported.

### Compiler Run-Time Environment Variables

The Intel® Fortran Compiler run-time system recognizes a number of environment variables. These variables can be used to customize run-time diagnostic error reporting, allow program continuation under certain conditions, disable the display of certain dialog boxes under certain conditions, and allow just-in-time debugging.

Environment variables relating to file I/O are interpreted when the file is opened. Other variables are read when the program starts.

The order of precedence for run-time environment variables is:

1. **OPEN keyword**
2. Environment variable(s)
3. Command line option

For Fortran runtime environment variables that are boolean (either enabled or disabled), the following tables describe values you can use to enable or disable them. These rules do not apply to environment variables for OpenMP* (OMP_) and their extensions (KMP_), PGO, or Intel® MIC Architecture.
### Setting a Run-Time Environment Variable to ON or OFF

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>An integer composed entirely of digits other than 0 enables the environment variable.</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>4938493848</td>
</tr>
<tr>
<td>A string starting with t or T, y or Y, enables the environment variable.</td>
</tr>
<tr>
<td>T</td>
</tr>
<tr>
<td>t</td>
</tr>
<tr>
<td>TRUE</td>
</tr>
<tr>
<td>TFALSE</td>
</tr>
<tr>
<td>Y</td>
</tr>
<tr>
<td>y</td>
</tr>
<tr>
<td>yes</td>
</tr>
<tr>
<td>yet</td>
</tr>
<tr>
<td>Anything that doesn't enable the environment variable disables it.</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>-1</td>
</tr>
<tr>
<td>+1</td>
</tr>
<tr>
<td>&lt;no value set&gt;</td>
</tr>
</tbody>
</table>

The following table summarizes compiler environment variables that are recognized at run time.

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_UFMTENDIAN</td>
<td>This variable specifies the numbers of the units to be used for little-endian-to-big-endian conversion purposes. See Environment Variable F_UFMTENDIAN Method. The variable is retrieved once when the first unit is opened, and then checked for every open.</td>
</tr>
<tr>
<td>FOR_COARRAY_CONFIG_FILE (Windows* and Linux*)</td>
<td>This variable specifies the coarray configuration file and path to be used at execution time. The variable overrides the value specified by the [Q]coarray-config-file=value qualifier at runtime.</td>
</tr>
<tr>
<td>FOR_COARRAY_DEBUG_STARTUP (Windows* and Linux*)</td>
<td>Boolean. When set to TRUE, this variable tells the Fortran run-time library to display the Message Passing Interface (MPI) launcher command that begins the underlying parallel support for coarrays.</td>
</tr>
<tr>
<td>FOR_COARRAY_MPI_VERBOSE (Windows* and Linux*)</td>
<td>Boolean. When set to TRUE, this variable tells the Fortran run-time library to pass the '-verbose' qualifier to the MPI support underlying the coarray implementation so that MPI will issue status and activity messages.</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>FOR_COARRAY_NUM_IMAGES</strong> (Windows* and Linux*)</td>
<td>This variable specifies the number of images created for coarrays. The value overrides the value specified by the [Q]coarray-num-images=value qualifier at runtime. If neither is specified, the number of logical processors is used.</td>
</tr>
</tbody>
</table>
| **FOR_DUMP_CORE_FILE** | Boolean. This variable must be lowercase for Linux. When set to TRUE, a core dump will be taken when any severe Intel® Fortran run-time error occurs. **Default:** FALSE  
\n\ndecfort_dump_flag is an alternate spelling for FOR_DUMP_CORE_FILE |
<p>| <strong>FOR_FASTMEM_NORETRY</strong> | Boolean. When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable or HBW memory is not available on the node then the run-time will report the failure to the user via STAT= or ERRMSG= or aborting the program with the appropriate error message. The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation. <strong>Default:</strong> TRUE |
| <strong>FOR_FASTMEM_RETRY</strong> | Boolean. When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable or HBW memory is not available on the node then memory will be allocated from the default memory allocator for that platform. The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation. <strong>Default:</strong> FALSE |
| <strong>FOR_FASTMEM_RETRY_WARN</strong> | Boolean. When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable or HBW memory is not available on the node then a warning message will be issued to stdout and memory will be allocated from the default memory allocator for that platform. |</p>
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation.</td>
</tr>
<tr>
<td><strong>Default:</strong> FALSE</td>
<td></td>
</tr>
<tr>
<td>FOR_FMT_TERMINATOR</td>
<td>This variable specifies the numbers of the units to have a specific record terminator. See Record Types.</td>
</tr>
<tr>
<td></td>
<td>The variable is retrieved once when the first unit is opened, and then checked for every open.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> FALSE</td>
</tr>
<tr>
<td>FORT_FMT_NO_WRAP_MARGIN</td>
<td>Boolean.</td>
</tr>
<tr>
<td></td>
<td>When set to TRUE, disables column wrapping in Fortran list-directed output when the record being written is longer than 80 characters.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>There is no environment variable to set a value for the right margin, this only disables wrapping. The RECL= open specifier can be used to set the right margin when the unit is opened.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> FALSE (Wrap margin)</td>
</tr>
<tr>
<td>FOR_ACCEPT</td>
<td>The ACCEPT statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_ACCEPT environment variable. If FOR_ACCEPT is not defined, the code ACCEPT f,iolist reads from standard input. If FOR_ACCEPT is defined (as a file name optionally containing a path), the specified file would be read.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> FALSE</td>
</tr>
<tr>
<td>FOR_DEBUGGER_IS_PRESENT</td>
<td>Boolean.</td>
</tr>
<tr>
<td></td>
<td>When set to TRUE, this variable tells the Fortran run-time library that your program is executing under a debugger, and generates debug exceptions whenever severe or continuable errors are detected.</td>
</tr>
<tr>
<td></td>
<td>Under normal conditions, this variable can be extracted from the operating system for Windows*.</td>
</tr>
<tr>
<td></td>
<td>On Linux* and macOS*, this variable must be set for debug exceptions. Setting this variable to TRUE when a program is not executing under a debugger causes unpredictable behavior.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> FALSE</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>FOR_DEFAULT_PRINT_DEVICE (Windows*)</td>
<td>This variable lets you specify the print device other than the default print device PRN (LPT1) for files closed (CLOSE statement) with the DISPOSE='PRINT' specifier. To specify a different print device for the file associated with the CLOSE statement DISPOSE='PRINT' specifier, set FOR_DEFAULT_PRINT_DEVICE to any legal spooled print device before executing the program.</td>
</tr>
<tr>
<td>FOR_DIAGNOSTIC_LOG_FILE</td>
<td>If this variable is set to the name of a file, diagnostic output is written to the specified file. The Fortran run-time system attempts to open that file (append output) and write the error information (ASCII text) to the file. Because the setting of FOR_DIAGNOSTIC_LOG_FILE is independent of FOR_DISABLE_DIAGNOSTIC_DISPLAY, you can disable the screen display of information but still capture the error information in a file. Because the text string you assign for the file name is used literally, you must specify the full name. If the file open fails, no error is reported and the run-time system continues diagnostic processing. See also Locating Run-Time Errors and Traceback.</td>
</tr>
<tr>
<td>FOR_DISABLE_DIAGNOSTIC_DISPLAY</td>
<td>Boolean. When set to TRUE, this variable disables the display of all error information. This variable is helpful if you just want to test the error status of your program and do not want the Fortran run-time system to display any information about an abnormal program termination. See also Traceback.</td>
</tr>
<tr>
<td>FOR_DISABLE_KMP_MALLOC</td>
<td>Boolean. When set to TRUE, this variable forces Fortran allocate statements to resolve to glibc malloc. <strong>Default</strong>: FALSE</td>
</tr>
<tr>
<td>FOR_FORCE_STACK_TRACE</td>
<td>Boolean. When set to TRUE, this variable forces a traceback to follow any run-time diagnostic message. <strong>If FOR_DISABLE_STACK_TRACE is also set, FOR_FORCE_STACK_TRACE takes precedence over FOR_DISABLE_STACK_TRACE</strong>. <strong>Default</strong>: FALSE</td>
</tr>
<tr>
<td>FOR_DISABLE_STACK_TRACE</td>
<td>Boolean.</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>When set to TRUE, this variable disables the call stack trace information that typically follows the displayed severe error message text. The Fortran run-time error message is displayed regardless of whether FOR_DISABLE_STACK_TRACE is set to TRUE. If the program is executing under a debugger, the automatic output of the stack trace information by the Fortran library will be disabled to reduce noise. Use the debugger’s stack trace facility to view the stack trace.</td>
</tr>
<tr>
<td>Default: FALSE</td>
<td>See also Locating Run-Time Errors and Traceback.</td>
</tr>
<tr>
<td>FOR_IGNORE_EXCEPTIONS</td>
<td>Boolean.</td>
</tr>
<tr>
<td></td>
<td>When set to TRUE, this variable disables default run-time exception handling to allow, for example, just-in-time debugging. The run-time system exception handler returns EXCEPTION_CONTINUE_SEARCH to the operating system, which looks for other handlers to service the exception.</td>
</tr>
<tr>
<td>Default: FALSE</td>
<td></td>
</tr>
<tr>
<td>FOR_NOERROR_DIALOGS</td>
<td>Boolean.</td>
</tr>
<tr>
<td></td>
<td>When set to TRUE, this variable disables the display of dialog boxes when certain exceptions or errors occur. This is useful when running many test programs in batch mode to prevent a failure from stopping execution of the entire test stream.</td>
</tr>
<tr>
<td>Default: FALSE</td>
<td></td>
</tr>
<tr>
<td>FOR_PRINT</td>
<td>Neither the PRINT statement nor a WRITE statement with an asterisk (<em>) in place of a unit number includes an explicit logical unit number. Instead, both use an implicit internal logical unit number and the FOR_PRINT environment variable. If FOR_PRINT is not defined, the code PRINT f,iolist or WRITE (</em>,f) iolist writes to standard output. If FOR_PRINT is defined (as a file name optionally containing a path), the specified file would be written to.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>FOR_READ</td>
<td>A READ statement that uses an asterisk (<em>) in place of a unit number does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_READ environment variable. If FOR_READ is not defined, the code READ (</em>,f) iolist or READ f,iolist reads from</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>FOR_TYPE</td>
<td>The <code>TYPE</code> statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the <code>FOR_TYPE</code> environment variable. If <code>FOR_TYPE</code> is not defined, the code <code>TYPE f,iolist</code> writes to standard output. If <code>FOR_TYPE</code> is defined (as a file name optionally containing a path), the specified file would be written to.</td>
</tr>
<tr>
<td>FORT блоксайз</td>
<td>Specifies the default BLOCKSIZE value to be used when <code>BLOCKSIZE=</code> is omitted on the <code>OPEN</code> statement. Valid values are 0 to 2147467264. Sizes are rounded up to the next 512-byte boundary. This variable applies to all Fortran I/O units except stderr, which is never buffered. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_БУФЕРЧУНТО</td>
<td>Specifies the default BUFFERCOUNT value to be used when <code>BUFFERCOUNT=</code> is omitted on the <code>OPEN</code> statement. Valid values are 0 to 127. If set to 0, the default value of 1 is used. This variable applies to all Fortran I/O units except stdout (units <code>*</code> and <code>6</code>) and stderr. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_БУФЕРЫД</td>
<td>Boolean. When set to TRUE, this variable specifies that buffered I/O should be used at run time for input and output on all Fortran I/O units, except stdout (units <code>*</code> and <code>6</code>). Output to stderr is never buffered. <strong>Default:</strong> FALSE</td>
</tr>
</tbody>
</table>
| FORT_БУФЕРЧУНТО=Т              | Specifies dynamic buffering for unformatted sequential `READ` operations:  
  - I/O list items with a size $\leq n$ are buffered and are moved one at a time from the buffer to the I/O list item.  
  - I/O list items with a size $> n$ are not buffered and are moved one at a time from the file to the I/O list item.
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORT_CONV_ERT_n</td>
<td>Specifies the data format for an unformatted file associated with a particular unit number ( n ), as described in Methods of Specifying the Data Format.</td>
</tr>
<tr>
<td>FORT_CONV_ERT_ext and FORT_CONV_ERT_ext</td>
<td>Specifies the data format for unformatted files with a particular file extension suffix (.ext), as described in Methods of Specifying the Data Format.</td>
</tr>
<tr>
<td>FORT_FMT_RECL</td>
<td>Specifies the default record length (normally 132 bytes) for formatted files. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_UFMT_RECL</td>
<td>Specifies the default record length (normally 2040 bytes) for unformatted files. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_n</td>
<td>Specifies the file name for a particular unit number ( n ), when a file name is not specified in the OPEN statement or an implicit OPEN is used, and the compiler option fpscomp with option keyword filesfromcmd was not specified. Preconnected files attached to units 0, 5, and 6 are associated with system standard I/O files by default.</td>
</tr>
<tr>
<td>INTEL_CHKP_REPORT_MODE (Linux*)</td>
<td>Changes the pointer checker reporting mode at runtime.</td>
</tr>
<tr>
<td>NLS_PATH (Linux* and macOS*)</td>
<td>Specifies the path for the Intel® Fortran run-time error message catalog.</td>
</tr>
<tr>
<td>TBK_ENABLE_VERBOSE_STACK_TRACE</td>
<td>Boolean. When set to TRUE, traceback output displays more detailed call stack information in the event of an error. The default brief output is usually sufficient to determine where an error occurred. Brief output includes up to twenty stack frames, reported one line per stack frame. For each frame, the image name containing the PC, routine name, line number, and source file are given. The verbose output, if selected, will provide the exception context record (in addition to the information in brief output) if the error was a machine exception (machine register dump), and for each frame, the return address, frame pointer and stack pointer and possible parameters to the routine. This output can be quite long (limited to 16K bytes) and use of the environment variable</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>FOR_DIAGNOSTIC_LOG_FILE</strong></td>
<td><strong>FOR_DIAGNOSTIC_LOG_FILE</strong> is recommended if you want to capture the output accurately. Most situations should not require the use of verbose output.</td>
</tr>
<tr>
<td><strong>Default:</strong> FALSE</td>

### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td>Internal barrier code will work differently depending on whether the cancellation is enabled. Barrier code should repeatedly check the global flag to figure out if the cancellation had been triggered. If a thread observes the cancellation it should leave the barrier prematurely with the return value 1 (may wake up other threads). Otherwise, it should leave the barrier with the return value 0.</td>
<td></td>
</tr>
</tbody>
</table>

| **OMP_CANCELLATION** |
| Enables (TRUE) or disables (FALSE) cancellation of the innermost enclosing region of the type specified. |
| **Default**: FALSE |
| **Example**: OMP_CANCELLATION=TRUE |

| **OMP_DISPLAY_ENV** |
| Enables (TRUE) or disables (FALSE) the printing to stderr of the OpenMP version number and the values associated with the OpenMP environment variable. |
| Possible values are: TRUE, FALSE, or VERBOSE. |
| **Default**: FALSE |
| **Example**: OMP_DISPLAY_ENV=TRUE |

| **OMP_DEFAULT_DEVICE** |
| Sets the device that will be used in a target region. The OpenMP routine `omp_set_default_device` or a device clause in a parallel directive can override this variable. |
| If no device with the specified device number exists, the code is executed on the host. If this environment variable is not set, device number 0 is used. |

| **OMP_DYNAMIC** |
| Enables (TRUE) or disables (FALSE) the dynamic adjustment of the number of threads. |
| **Default**: FALSE |
| **Example**: OMP_DYNAMIC=TRUE |

| **OMP_MAX_ACTIVE_LEVELS** |
| The maximum number of levels of parallel nesting for the program. |
| **Default**: 1 |
| **Syntax**: OMP_MAX_ACTIVE_LEVELS=TRUE |

<p>| <strong>OMP_NESTED</strong> |
| Enables (TRUE) or disables (FALSE) nested parallelism. |</p>
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_NUM_THREADS</td>
<td>Sets the maximum number of threads to use for OpenMP* parallel regions if no other value is specified in the application. The value can be a single integer, in which case it specifies the number of threads for all parallel regions. The value can also be a comma-separated list of integers, in which case each integer specifies the number of threads for a parallel region at a nesting level. The first position in the list represents the outer-most parallel nesting level, the second position represents the next-inner parallel nesting level, and so on. At any level, the integer can be left out of the list. If the first integer in a list is left out, it implies the normal default value for threads is used at the outer-most level. If the integer is left out of any other level, the number of threads for that level is inherited from the previous level. This environment variable applies to the options Qopenmp (Windows) or qopenmp (Linux and macOS*), or Qparallel (Windows) or parallel (Linux and macOS*). Default: The number of processors visible to the operating system Syntax: OMP_NUM_THREADS=value[,value]</td>
</tr>
<tr>
<td>OMP_PLACES</td>
<td>Specifies an explicit ordered list of places, either as an abstract name describing a set of places or as an explicit list of places described by nonnegative numbers. An exclusion operator &quot;!&quot; can also be used to exclude the number or place immediately following the operator. For explicit lists, the meaning of the numbers and how the numbering is done for a list of nonnegative numbers are implementation defined. Generally, the numbers represent the smallest unit of execution exposed by the execution environment, typically a hardware thread. Intervals can be specified using the &lt;lower-bound&gt;:&lt;length&gt;:[&lt;stride&gt;] notation to represent the following list of numbers: &quot;&lt;lower-bound&gt;, &lt;lower-bound&gt; + &lt;stride&gt;, ..., &lt;lower-bound&gt; +(&lt;length&gt;-1)*&lt;stride&gt;.&quot;</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>OMP_PROC_BIND (Windows, Linux)</td>
<td>Sets the thread affinity policy to be used for parallel regions at the corresponding nested level. Enables (TRUE) or disables (FALSE) the binding of threads to processor contexts. If enabled, this is the same as specifying KMP_AFFINITY=scatter. If disabled, this is the same as specifying KMP_AFFINITY=none.</td>
</tr>
</tbody>
</table>

When `<stride>` is omitted, a unit stride is assumed. Intervals can specify numbers within a place as well as sequences of places.

```
# EXPLICIT LIST EXAMPLE
setenv OMP_PLACES "{0,1,2,3},{4,5,6,7},{8,9,10,11},{12,13,14,15}"
setenv OMP_PLACES "{0:4},{4:4},{8:4},{12:4}"
setenv OMP_PLACES "{0:4}:4:4"
```

The abstract names listed below should be understood by the execution and runtime environment:

- **threads**: Each place corresponds to a single hardware thread on the target machine.
- **cores**: Each place corresponds to a single core (having one or more hardware threads) on the target machine.
- **sockets**: Each place corresponds to a single socket (consisting of one or more cores) on the target machine.

When requesting fewer places or more resources than available on the system, the determination of which resources of type `abstract_name` are to be included in the place list is implementation-defined. The precise definitions of the abstract names are implementation defined. An implementation may also add abstract names as appropriate for the target platform. The abstract name may be appended by a positive number in parentheses to denote the length of the place list to be created, that is `abstract_name(num-places)`.

```
# ABSTRACT NAMES EXAMPLE
setenv OMP_PLACES threads
setenv OMP_PLACES threads(4)
```

**NOTE**
If any numerical values cannot be mapped to a processor on the target platform the behavior is implementation-defined. The behavior is also implementation-defined when the OMP_PLACES environment variable is defined using an abstract name.

</tbody>
</table>
Run-Time Environment Variable | Description
---|---

**Use the optional suffixes to specify byte units:** $B$ (bytes), $K$ (Kilobytes), $M$ (Megabytes), $G$ (Gigabytes), or $T$ (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be $K$ (Kilobytes).

This variable does not affect the native operating system threads created by the user program, or the thread executing the sequential part of an OpenMP* program or parallel programs created using the option $Qparallel$ (Windows) or parallel (Linux and macOS*).

The kmp_{set, get}_stacksize_s() routines set/retrieve the value. The kmp_set_stacksize_s() routine must be called from sequential part, before first parallel region is created. Otherwise, calling kmp_set_stacksize_s() has no effect.

**Default (IA-32 architecture):** 2M

**Default (Intel® 64 architecture):** 4M

**Default (Intel® MIC architecture):** 4M (on supported OSes)

**NOTE** IA-32 architecture is no longer supported on macOS*.

**Related environment variables:** KMP_STACKSIZE (overrides OMP_STACKSIZE).

**Syntax:** OMP_STACKSIZE=value

Limits the number of simultaneously-executing threads in an OpenMP* program.

If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP* parallel region begins, a one-time warning message might be generated indicating that the number of threads in the team was reduced, but the program will continue.

This environment variable is only used for programs compiled with the following options: $Qopenmp$ (Windows) or qopenmp (Linux and macOS*), or $Qparallel$ (Windows) or parallel (Linux and macOS*).

The omp_get_thread_limit() routine returns the value of the limit.

**Default:** No enforced limit
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **OMP_WAIT_POLICY**           | Decides whether threads spin (active) or yield (passive) while they are waiting.  
OMP_WAIT_POLICY=ACTIVE is an alias for KMP_LIBRARY=turnaround, and  
OMP_WAIT_POLICY=PASSIVE is an alias for KMP_LIBRARY=throughput.  
**Default:** Passive  
**Syntax:** OMP_WAIT_POLICY=value |
| **KMP_AFFINITY (Windows, Linux)** | Enables run-time library to bind threads to physical processing units.  
You must set this environment variable before the first parallel region, or certain API calls including omp_get_max_threads(), omp_get_num_procs() and any affinity API calls. For detailed information on this environment variable, see Thread Affinity Interface.  
**Default:** noverbose,warnings,respect,granularity=core,none  
**Default (Intel® Xeon Phi™ product family):**  
noverbose,warnings,respect,granularity=fine,scatter,r,0,0  
Default (Windows* with multiple processor groups):  
noverbose,warnings,norespect,granularity=group,compact,0,0  
**NOTE** On Windows* with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows*). Otherwise, the respect affinity modifier is used. |
| **KMP_ALL_THREADS**           | Limits the number of simultaneously-executing threads in an OpenMP* program. If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, then the program may abort with an error message. If this limit is reached at the time an OpenMP* parallel region begins, a one-time  
**Related environment variable:** KMP_ALL_THREADS (overrides OMP_THREAD_LIMIT).  
**Example syntax:** OMP_THREAD_LIMIT=value |

### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <code>load_balance</code>: tries to avoid using more threads than available execution units on the machine;</td>
<td></td>
</tr>
<tr>
<td>• <code>thread_limit</code>: tries to avoid using more threads than total execution units on the machine.</td>
<td></td>
</tr>
</tbody>
</table>

**Default (IA-32 architecture):** `load_balance` (on all supported OSes)

**Default (Intel® 64 architecture):** `load_balance` (on all supported OSes)

**Default (Intel® MIC architecture):**
`thread_limit` (on supported OSes)

---

**NOTE** IA-32 architecture is no longer supported on macOS*.

---

**KMP_HOT_TEAMS_MAX_LEVEL**

Sets the maximum nested level to which teams of threads will be hot.

**NOTE**

A hot team is a team of threads optimized for faster reuse by subsequent parallel regions. In a hot team, threads are kept ready for execution of the next parallel region, in contrast to the cold team, which is freed after each parallel region, with its threads going into a common pool of threads.

For values of 2 and above, nested parallelism should be enabled.

**Default:** 1

**KMP_HOT_TEAMS_MODE**

Specifies the run-time behavior when the number of threads in a hot team is reduced.

Possible values:

- 0: Extra threads are freed and put into a common pool of threads.
- 1: Extra threads are kept in the team in reserve, for faster reuse in subsequent parallel regions.

**Default:** 0

**KMP_HW_SUBSET**

Specifies the number of sockets, cores per socket, and the number of threads per core, to use with an OpenMP® application, as an alternative to writing explicit affinity settings or a process affinity mask. You can also specify an offset value to set which resources to use.
### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>An extended syntax is available when KMP_TOPOLOGY_METHOD=hwloc. Depending on what resources are detected, you may be able to specify additional resources, such as NUMA nodes and groups of hardware resources that share certain cache levels. For example, tiles are sets of cores that share an L2 cache on some processors in the Intel® Xeon Phi™ family.</td>
</tr>
</tbody>
</table>

#### Basic syntax:

```plaintext
socketsS[@offset], coresC[@offset], threadsT
```

- **S**, **C** and **T** are not case-sensitive.
- **sockets** The number of sockets to use.
- **cores** The number of cores to use per socket.
- **threads** The number of threads to use per core.
- **offset** (Optional) The number of sockets or cores to skip.

#### Extended syntax when KMP_TOPOLOGY_METHOD=hwloc:

```plaintext
socketsS[@offset], numasN[@offset], tilesL2[@offset], coresC[@offset], threadsT
```

- **S**, **N**, **L2**, **C** and **T** are not case-sensitive. Some designators are aliases on some machines. Specifying duplicate or multiple alias designators for the same resource type is not allowed.
- **sockets** The number of sockets to use.
- **numas** If detectable, the number of NUMA nodes to use per socket, where available.
- **tiles** If detectable, the number of tiles to use per NUMA node, where available, otherwise per socket.
- **cores** The number of cores to use per socket, where available, otherwise per NUMA node, or per socket.
- **threads** The number of threads to use per core.
- **offset** (Optional) The number of sockets or cores to skip.
<table>

<tr>
<td></td>
<td>• cpuinfo</td>
</tr>
</tbody>
</table>
### Run-Time Environment Variable Description

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| KMP_CPUINFO_FILE | If `KMP_CPUINFO_FILE` is not specified, forces OpenMP* to parse `/proc/cpuinfo` to determine the topology (Linux* only). If `KMP_CPUINFO_FILE` is specified as described above, uses it (Windows* or Linux*). **
- group  
  Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows* 64-bit only) .
- flat  
  Models the machine as a flat (linear) list of processors.
- hwloc  
  Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows* processor groups. |

| KMP_VERSION | Enables (TRUE) or disables (FALSE) the printing of OpenMP* run-time library version information during program execution. **

**Default:** FALSE |

| KMP_WARNINGS | Enables (TRUE) or disables (FALSE) displaying warnings from the OpenMP* run-time library during program execution. **

**Default:** TRUE |

### Intel® Many Integrated Core (Intel® MIC) Environment Variables

<p>| MIC_ENV_PREFIX | Controls environment variables passed to the target. By default, all environment variables set on the host are passed to the target. Setting <code>MIC_ENV_PREFIX</code> passes only environment variables that have a prefix of the value of this variable. For example, setting <code>MIC_ENV_PREFIX=ABC</code> passes only environment variables that have a prefix of ABC. |</p>
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| MIC_PROXY_IO | Enables (1) or disables (0) the proxy of stderr and stdout, and specifies whether the process wants I/O proxy support between the host and target.  

**Default:** 1  

**Example:** MIC_PROXY_IO=0 |
| MIC_SEP_MONITOR | Enables (1) or disables (0) SEP at offload regions.  

**Default:** 0  

**Example:** MIC_SEP_MONITOR=1 |
| MIC_STACKSIZE | Specifies the stack size of the main thread for the offload. This value is typically much larger than the stack size for individual threads. It corresponds to what you would set with ulimit-s (BASH shell) or limit stacksize (C shell) if you were running natively on either the target or the host.  

Set this variable to `integerB|K|M|G|T`, where:  

- B = bytes  
- K = kilobytes  
- M = megabytes  
- G = gigabytes  
- T = terabytes |
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| MIC_USE_2MB_BUFFERS          | Use 2M pages for (size > MIC_USE_2MB_BUFFERS). Variables with the ALLOCATABLE or POINTER attribute whose runtime length exceeds the value of this environment variable are allocated in large pages. Set this variable to integerB|K|M|G|T, where:  
  - B = Bytes  
  - K = Kilobytes  
  - M = Megabytes  
  - G = Gigabytes  
  - T = Terabytes  
  **Example:** MIC_USE_2MB_BUFFERS=64K |
| OFFLOAD_DEVICES              | This variable is only available on Linux* systems. Restrictions the offload process to use only the coprocessors specified as the value of the variable. Set this variable to a comma-separated list of target device numbers in the range 0 to (number_of_devices_in_the_system -1), where 0 is the first coprocessor in the system, and (number_of_devices_in_the_system -1) is the last coprocessor in the system. Coprocessors available for offloading are numbered logically. The function OFFLOAD_NUMBER_OF_DEVICES returns the number of available coprocessors. Coprocessor indices that you use in the target specifier of the offload directives are mapped to coprocessors specified in OFFLOAD_DEVICES. **Default:** The offload process uses all devices. **Example:** OFFLOAD_DEVICES = 1,2  
  On a system with more than two coprocessors installed, this setting enables the application to use only coprocessors 1 and 2. Offloads to coprocessors 0 or 1 are performed on the second and third physical coprocessors. Offloads to target numbers higher than 1 wrap around, and all offloads remain within coprocessors 0 and 1. The function OFFLOAD_NUMBER_OF_DEVICES, executed on a coprocessor, returns 0 or 1 when the offload is running on coprocessor 1 or 2 as specified in OFFLOAD_DEVICES. |
Run-Time Environment Variable | Description
--- | ---
OFFLOAD_DEVICES | Setting this variable to an empty value (`export OFFLOAD_DEVICES=`) has no effect. Setting this variable to value `none` (`set OFFLOAD_DEVICES=none`) impacts the execution of offloaded code within your program as follows:
- When you use optional offloading, the code executes on the host CPU.
- When you use mandatory offloading, the program terminates with an offload error, reporting that a device is not available, when it reaches a point in the execution where the coprocessor requires initialization for offloading.

OFFLOAD_NODES

Defines a subset of a cluster (group of servers or nodes) that is available for offloading from the host system. When offloading within a cluster, this environment variable must be set to specify the available offload-able nodes.

The value of the environment variable is a comma-separated list of machine specifiers. A machine specifier is either a machine name or an IP address. The machine specifier may be optionally followed by a specification of the node type and fabric type in square brackets. The default node type is currently x200 and the default fabric type is OFI. More node and fabric types may be supported in the future.

The offloadable machines in OFFLOAD_NODES are assigned device numbers 0, 1, 2 and so on, in the order specified. These device numbers are available for offloading through `#pragma offload target(mic:<number>)`. The OFFLOAD_DEVICES environment variable may be used to restrict offloading to a subset of the available cluster machines.

**Default**: There is no default. The environment variable must be set if doing offload within a cluster.

**Example**: `export OFFLOAD_NODES="machine1,machine2,10.2.100.50"

**Example**: `export OFFLOAD_NODES="machine3[x200,OFI]"`
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD_NODES</td>
<td>In the following, machine2 and 10.2.100.50 will be used as processor 0 and 1 in target specified in the offload pragma.</td>
</tr>
<tr>
<td>export OFFLOAD_NODES</td>
<td>export OFFLOAD_NODES=&quot;machine1,machine2,10.2.100.50&quot;</td>
</tr>
<tr>
<td>export OFFLOAD_DEVICES</td>
<td>export OFFLOAD_DEVICES=1,2</td>
</tr>
<tr>
<td>OFFLOAD_INIT</td>
<td>Specifies a hint to the offload runtime indicating when to initialize targets. Possible values:</td>
</tr>
<tr>
<td>on_start</td>
<td>All available coprocessors are initialized before entering the main program.</td>
</tr>
<tr>
<td>on_offload</td>
<td>The target is initialized immediately before the first offload to it. Initialization is done only on the target that handles the offload.</td>
</tr>
<tr>
<td>on_offload_all</td>
<td>All available targets are initialized immediately before the first offload in an application.</td>
</tr>
<tr>
<td>Default: on_offload_all</td>
<td>Example: OFFLOAD_INIT=on_start</td>
</tr>
<tr>
<td>OFFLOAD_REPORT</td>
<td>Controls printing offload execution time, in seconds, and the amount of data transferred, in bytes. This environment variable is equivalent to using the __Offload_report API. Possible values:</td>
</tr>
<tr>
<td>1</td>
<td>Prints the offload computation time, in seconds.</td>
</tr>
<tr>
<td>2</td>
<td>In addition to the information produced at value 1, adds the amount of data transferred between the CPU and the target, in bytes.</td>
</tr>
<tr>
<td>3</td>
<td>In addition to the information produced at value 2, gives additional details on offload activity, including device initialization, and individual variable transfers.</td>
</tr>
<tr>
<td>None</td>
<td>Default: None</td>
</tr>
<tr>
<td>Example: OFFLOAD_REPORT=1</td>
<td>Example: OFFLOAD_REPORT=1</td>

Profile Guided Optimization (PGO_) Environment Variables

<p>| INTEL_PROF_DUMP_CUMULATIVE    | When using interval profile dumping (initiated by INTEL_PROF_DUMP_INTERVAL or the function _PGOPTI_Set_Interval_Prof_Dump) during the execution of an instrumented user application, allows creation of a single .dyn file to contain profiling information instead of multiple .dyn files. |</p>
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEL_PROF_DUMP_INTERVAL</td>
<td>Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application.</td>
</tr>
<tr>
<td>INTEL_PROF_DYN_PREFIX</td>
<td>Specifies the prefix to be used for the .dyn filename to distinguish it from the other .dyn files dumped by other PGO runs. Executing the instrumented application generates a .dyn filename as follows: <code>&lt;prefix&gt;_&lt;timestamp&gt;_&lt;pid&gt;.dyn</code>, where <code>&lt;prefix&gt;</code> is the identifier that you have specified.</td>
</tr>
<tr>
<td>PROF_DIR</td>
<td>Specifies the directory where profiling files (files with extensions .dyn, .dpi, .spi and so on) are stored. The default is to store the .dyn files in the source directory of the file containing the first executed instrumented routine in the binary compiled with <code>[Q]prof-gen</code> option. This variable applies to all three phases of the profiling process:</td>
</tr>
<tr>
<td>PROF_DPI</td>
<td>Name for the .dpi file. <strong>Default:</strong> pgopti.dpi</td>
</tr>
<tr>
<td>PROF_DUMP_INTERVAL</td>
<td>Deprecated; use INTEL_PROF_DUMP_INTERVAL instead.</td>
</tr>
<tr>
<td>PROF_NO_CLOBBER</td>
<td>Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new pgopti.dpi file if the .dyn files are newer than an existing pgopti.dpi file.</td>
</tr>
</tbody>
</table>
Run-Time Environment Variable | Description
--- | ---
 | When this variable is set, the compiler does not overwrite the existing pgopti.dpi file. Instead, the compiler issues a warning. You must remove the pgopti.dpi file if you want to use additional dynamic information files.

Using Other Methods to Set Environment Variables

All Operating Systems
From within a program: Call the SETENVQQ routine to set environment variables. For example:

```fortran
USE IFPORT
LOGICAL success
success = SETENVQQ("FORT9=C:\mydir\test.dat")
```

Depending on your operating system, there are additional ways to set environment variables.

Linux* and macOS*
Within the Bourne*/Bourne* Again shell (sh/bash), or the Korn shell (ksh), use the export command and assignment command to set an environment variable:

```bash
export FORT9
FORT9=/usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the Bourne*, Korn shell, or bash shells, use the unset command:

```bash
unset FORT9
```

Within the C shell (csh), use the setenv command to set an environment variable:

```csh
setenv FORT9 /usr/users/smith/test.dat
```
To remove the association of an environment variable and its value within the C shell, use the `unsetenv` command.

```bash
unsetenv FORT9
```

**Windows**

Environment variables in a command prompt session can be set using the SET command. Changes here will affect programs run from that command prompt only. For example:

```bash
set FORT9=C:\mdir\test.dat
```

To remove an environment variable, omit the value. For example:

```bash
set FORT9=
```

To display the current value, use the ECHO command and enclose the environment variable name in the percent signs as shown below:

```bash
echo %FORT9%
```

To display the values of all variables whose names begin with a string, use SET and omit the equal sign as shown below:

```bash
set FORT
```

In Microsoft Visual Studio you can specify environment variables that will be set when a program is run. In the project properties, edit the Configuration Properties > Debugging > Environment property and set the field to a series of name=value pairs separated by semicolons. For example:

```text
FORT9=C:\mdir\test.dat;FOR_FORCE_STACK_TRACE=TRUE
```

A default set of environment variables is established per user and at the system level. These can be specified through Control Panel > System > Advanced System Settings > Environment Variables.

---

**NOTE**

Changing system-wide environment variables affects command line builds (those done without IDE involvement), but not builds done through the IDE. IDE builds are managed in the IDE using **Tools** > **Options**. An exception to this is an IDE build (devenv) done from the command line that specifies the `useenv` option. In this case, the IDE uses the `PATH`, `INCLUDE`, and `LIB` environment variables defined for that command line.

- [Understanding Solutions Projects and Configurations](#)
- [Working with Visual Studio* solutions and projects](#)
Compiling and Linking Multithreaded Programs

When building a multithreaded application, be sure to link against the thread-safe version of the Fortran run-time libraries and to enable thread safety. This is specified by the `threads` and `reentrancy:threaded` compiler options. The Visual Studio* integrated development environment (IDE), described later in this topic, can also be used on Windows*.

You must also link with the correct library files. Some libraries, such as those for OpenMP* or coarrays, are always linked dynamically.

Linux* and macOS*

To create statically-linked, multithreaded programs, link with the static library named `libifcoremt.a`.

To use shared libraries, link your application with `libifcoremt.so` (Linux*) or `libifcoremt.dylib` (macOS*).

To compile and link your multithreaded program from the command line:

1. Make sure the `IA32ROOT` environment variable points to the directory containing your library files.
2. Compile and link the program with the `-threads` option. For example:
   ```
   ifort -threads mythread.f90
   ```

   **NOTE**
   To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option `threads` should also be used for the link step and for the compilation of the main routine.

Windows*

To create statically linked multithreaded programs, link with the re-entrant support library `LIBIFCOREMT.LIB`.

To use shared libraries, use the shared `LIBIFCOREMD.DLL` library, which is also re-entrant, and is referenced by linking your application with the `LIBIFCOREMD.LIB` import library.

Programs built with `LIBIFCOREMT.LIB` do not share Fortran run-time library code or data with any dynamic-link libraries they call. You must link with `LIBIFCOREMD.LIB` if you plan to call a DLL.

Additional Notes:

- The `/threads` option is automatically set when a multithreaded application is specified in the IDE.
- Specify the compiler options `/libs=dll` and `/threads` if you are using both multithreaded code and DLLs.
- You can use the `/libs=dll` and `/threads` options only with Fortran Console projects, not QuickWin applications.

To compile and link your multithreaded program using Visual Studio*:

1. Create a new project by clicking File > New > Project.
2. Select the Intel® Visual Fortran project type from Intel® Visual Fortran Projects in the left pane.
3. Add the file containing the source code to the project.
   - From the Project menu, select Properties. The Property Pages dialog box appears.
4. Choose the Fortran folder, Libraries category, and set the Runtime Library to Multithreaded or Multithread DLL (or their debug equivalents).
5. Create the executable file by choosing Build Solution from the Build menu.

To compile and link your multithreaded program from the command line:

1. Make sure your LIB environment variable points to the directory containing your library files.
2. Compile and link the program with the /threads option. For example:

   ifort /threads mythread.f90

   **NOTE**
   To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option threads should also be used for the link step and for the compilation of the main routine.

### Linking Tools and Options

This topic describes how to use the Intel® linking tools, xild (Linux* and macOS*) and xilink (Windows*).

The Intel® linking tools behave differently on different platforms. The following sections summarize the primary differences between linking behavior.

<table>
<thead>
<tr>
<th>Linux* and macOS* Linking Behavior Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>The linking tool invokes the Intel® Fortran Compiler to perform IPO if objects containing IR (intermediate representation) are found. These are mock objects. The tool invokes GNU ld to link the application.</td>
</tr>
<tr>
<td>The command-line syntax for xild is the same as that of the GNU linker: where:</td>
</tr>
<tr>
<td>- [options]: One or more options supported only by xild (optional).</td>
</tr>
<tr>
<td>- &lt;normal command-line&gt;: Linker command line containing a set of valid arguments for ld.</td>
</tr>
<tr>
<td>To create the file app using IPO, use the option o/[filename] as shown in the following example:</td>
</tr>
<tr>
<td>The linking tool calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker then calls ld to link the object files that are specified in the new list and produce the application with the name specified by the o option. The linker supports the ipo[n] and ipo-separate options.</td>
</tr>
<tr>
<td>To display a list of the supported link options from xild, use the following command:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Windows* Linking Behavior Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>The linking tool invokes the Intel® Fortran Compiler to perform multi-file IPO if objects containing IR (intermediate representation) is found. These are mock objects. It invokes the Microsoft linker link.exe to link the application.</td>
</tr>
<tr>
<td>The command-line syntax for the Intel® linker is the same as that of the Microsoft linker: where:</td>
</tr>
<tr>
<td>- [options]: One or more options supported only by xilink (optional).</td>
</tr>
<tr>
<td>- &lt;normal command-line&gt;: Linker command line containing a set of valid arguments for the Microsoft linker.</td>
</tr>
</tbody>
</table>
Windows® Linking Behavior Summary

To place the multifile IPO executable in `ipo_file.exe`, use the linker option `out:[filename]`, for example:

The linker calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker calls Microsoft `link.exe` to link the object files that are specified in the new list and produce the application with the name specified by the `out:[filename]` linker option.

To display a list of support link options from `xilink`, use the following command:

`xilink.exe` accepts all the options of `link.exe` and will pass them on to `link.exe` at the final linking stage.

Using the Linking Tools

You must use the Intel® linking tools to link your application if the following conditions apply:

- Your source files were compiled with multi-file IPO enabled. Multi-file IPO is enabled by specifying compiler option `[Q]ipo`
- You would normally invoke the GNU linker (`ld`) to link your application.
- You would normally invoke the Microsoft linker (`link.exe`) to link your application.

Linker Options

The following table provides information on linking options.

<table>
<thead>
<tr>
<th>Linking Tools Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>qdiag-</code></td>
<td>Controls the display of diagnostic information. The <code>type</code> is an action to perform on diagnostics. Possible values are:</td>
</tr>
<tr>
<td><code>[type]=</code></td>
<td>- <strong>Enable</strong>: Enables a diagnostic message or a group of messages.</td>
</tr>
<tr>
<td><code>[diag-list]</code></td>
<td>- <strong>Disable</strong>: Disables a diagnostic message or a group of messages.</td>
</tr>
<tr>
<td><code>thread</code></td>
<td>The <code>diag-list</code> is a diagnostic group or ID value. Possible values are:</td>
</tr>
<tr>
<td><code>vec</code></td>
<td>- <strong>thread</strong>: Specifies diagnostic messages that help in thread-enabling a program.</td>
</tr>
<tr>
<td><code>par</code></td>
<td>- <strong>vec</strong>: Specifies diagnostic messages issued by the vectorizer.</td>
</tr>
<tr>
<td><code>openmp</code></td>
<td>- <strong>par</strong>: Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).</td>
</tr>
<tr>
<td><code>warn</code></td>
<td>- <strong>openmp</strong>: Specifies diagnostic messages issued by the OpenMP parallelizer.</td>
</tr>
<tr>
<td><code>error</code></td>
<td>- <strong>warn</strong>: Specifies diagnostic messages that have a &quot;warning&quot; severity level.</td>
</tr>
<tr>
<td><code>remark</code></td>
<td>- <strong>error</strong>: Specifies diagnostic messages that have an &quot;error&quot; severity level.</td>
</tr>
<tr>
<td><code>cpu-dispatch</code></td>
<td>- <strong>remark</strong>: Specifies diagnostic messages that are remarks or comments.</td>
</tr>
<tr>
<td><code>id[,id,...]</code></td>
<td>- <code>cpu-dispatch</code>: Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.</td>
</tr>
<tr>
<td><code>tag[,tag,...]</code></td>
<td>- <code>id[,id,...]</code>: Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each &quot;id&quot;.</td>
</tr>
</tbody>
</table>
| `tag[,tag,...]`       | - `tag[,tag,...]`: Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each "tag".
<table>
<thead>
<tr>
<th>Linking Tools</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>m32 (Linux* only), m64 (Linux* and macOS*)</td>
<td>(Linux*) Only, <code>m32</code> generates code for IA-32 architecture. Option <code>-m32</code> is only available on Linux systems.</td>
</tr>
<tr>
<td>Qm32, Qm64 (Windows*)</td>
<td>(Q)m32 generates code for IA-32 architecture. Option <code>-m32</code> is only available on Linux systems.</td>
</tr>
<tr>
<td>Qm64</td>
<td>(Linux* and MacOS*)-m generates code for Intel® 64 architecture.</td>
</tr>
<tr>
<td>Qm32</td>
<td>For example, when your compilation environment is configured for Intel® 64 architecture, and you use <code>(Q)m32</code> with the compiler, you also need to use <code>qm32</code> on the linker command line to make sure the proper compilation target is set up for any IPO compilations or the final link.</td>
</tr>
</tbody>
</table>

**NOTE**
Diagnostic messages generated by this option can be affected by other options, such as `/arch (Windows*), `m` (Linux* and macOS*), or `(Q)x.`

**See Also**
* Using IPO from the command line

## Using Configuration Files

You can decrease the time you spend entering command-line options by using the configuration file to automate command-line entries. Configuration files are automatically processed every time you run the Intel® Fortran Compiler. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the specified command-line options when the compiler is invoked.

**NOTE**
Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use Using Response Files.

### Sample Configuration Files

The default configuration file `ifort.cfg` is located in the same directory as the compiler executable file. If you want to use a different configuration file than the default, you can use the `IFORTCFG` environment variable to specify the location of another configuration file.

**NOTE**
Anytime you instruct the compiler to use a different configuration file, the default configuration file(s) are ignored.

The following examples illustrate basic configuration files. The pound (`#`) character indicates that the rest of the line is a comment.

In the Windows* examples, the compiler reads the configuration file and invokes the `I` option every time you run the compiler, along with any options specified on the command line.
Using Response Files

You can use response files to:

- Specify options used during particular compilations or projects.
- Save this information in individual files.

Response files are invoked as options on the command line. Options in response files are inserted in the command line at the point where the response file is invoked. Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file without specifying it on the command line, it will not be invoked.

Use response files to decrease the time spent entering command-line options and to ensure consistency by automating command-line entries. Use individual response files to maintain options for specific projects.

Any number of options or file names can be placed on a line in a response file. Several response files can be referenced in the same command line. The following example shows how to specify a response file on the command line:

```
ifort @ [@responsefile2 ... ]
```

**NOTE**
An "at" sign (@) must precede the name of the response file on the command line.
Creating Fortran Executables

The simplest way to build an application is to compile all of your Fortran source files, then link the resulting object files into a single executable. You can build single-file executables using the `ifort` command. You can also use the Visual Studio* IDE on Windows*.

The executable file you build with this method contains all of the code needed to execute the program, including the run-time library. Because the program resides in a single file, it is easy to copy or install. The project contains all of the source and object files for the routines used to build the application. To use these routines in other projects, all source and object files must be relinked.

Exceptions to this are as follows:
- If you are using shared libraries, all code will not be contained in the executable file.
- On macOS*, the object files contain debug information and would need to be copied along with the executable.

Linking Debug Information

**Windows**

Use option `Z7` at compile time or option `debug` at link time to tell the compiler to generate symbolic debugging information in the object file. Alternately, use option `Zi` at link time to generate executables with debug information in the `.pdb` file.

**Linux**

Use option `g` at compile time to tell the compiler to generate symbolic debugging information in the object file.

Use option `gsplit-dwarf` to create a separate object file containing DWARF debug information. Because the DWARF object file is not used by the linker, this reduces the amount of debug information the linker must process and it results in a smaller executable file. See `gsplit-dwarf` for detailed information.

**macOS**

You can link the DWARF debug information from the object files for an executable using `dsymutil`, a utility included with Xcode*. By linking the debug information in an executable, you eliminate the need to retain object files specifically for debugging purposes.

The utility runs automatically in the following cases:
- When you use the Intel® Fortran Compiler to compile directly from source to executable using the command line with option `g`. For example:

```
ifort -g myprogram.f90
```

- When you compile using Xcode*.
In other cases, you must explicitly run `dsymutil`, such as when you compile using a make file that builds `.o` files and subsequently links the program.

**Debugging**

Depending on your operating system and architecture platform, several debuggers may be available to you. You can use the debugger provided by your operating system:

- On Linux* and macOS*, this debugger is `gdb`.
- On Windows*, the debugger is the Microsoft Visual Studio* debugger.

On Windows* systems, you can use your local (host) system to debug an application running on a remote system. For more information, see Using Remote Debugging.

**See Also**

Using Remote Debugging

**Preparing Your Program for Debugging**

This section describes preparing your program for debugging.

**Preparing for Debugging using the Command Line**

To prepare your program for debugging when using the command line (ifort command):

1. Correct any compilation and linker errors.
2. In a command window, such as the Fortran command window available from the Intel® Fortran program folder, compile and link the program with full debug information and no optimization:

```
// (Linux* OS and macOS*)
ifort -g file.f90
```

```
// (Windows* OS)
ifort /debug:full file.f90
```

On Linux* OS and on macOS*, specify the `g` compiler option to create unoptimized code and provide the symbol table and traceback information needed for symbolic debugging. The `notraceback` option cancels the traceback information.

On Windows* OS, specify the `debug` compiler option with keyword `full` to produce full debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking.

**Preparing for Debugging using Visual Studio***

The following applies to Windows* operating systems only.

To prepare your program for debugging when using the integrated development environment (IDE):

1. Start the IDE (select the appropriate version of Visual Studio* in the program folder).
2. Open the appropriate solution (using the Solution menu, either Open Solution or Recent Projects).
3. Open the Solution Explorer View.
4. To view the source file to be debugged, double-click on the file name. The screen resembles the following:
5. In the Build menu, select Configuration Manager and select the Debug configuration.

6. To check your project settings for compiling and linking, select the project name in Solution Explorer. Now, in the Project menu, select Properties, then click the Fortran folder in the left pane. Similarly, to check the debug options set for your project (such as command arguments or working directory), click the Debugging folder in the Property Pages dialog box.

7. To build your application, select Build > Build Solution.

8. Eliminate any compiler diagnostic messages using the text editor to resolve problems detected in the source code and recompile if needed.

9. Set breakpoints in the source file and debug the program. For more information, see Debugging the Squares Example Program.

**NOTE** You must set a breakpoint before starting the program, otherwise the program will run to completion, and exit.
Using Breakpoints in the Debugger

This topic applies to Fortran applications for Windows* only.

This topic describes how to use the Microsoft Visual Studio* debugger to set file and data breakpoints. Information is organized as follows:

- Viewing All Current Breakpoints
- Working with File Breakpoints
- Adding Conditions to File Breakpoints
- Working with Data Breakpoints

In addition to file and data breakpoints, the Visual Studio* debugger supports the following:

- Address breakpoints
- Function breakpoints
- Tracepoints

For information on these additional features, see the Microsoft documentation for your version of Visual Studio*.

Viewing All Current Breakpoints

You can view all currently set breakpoints in the Breakpoints window. To view all set breakpoints using the Breakpoints window:

1. In the Debug menu, select Windows > Breakpoints.
2. Scroll up or down in the Breakpoints list to view the breakpoints. Enabled breakpoints have a check mark in the check box and disabled breakpoints have an empty check box. The window displays all types of breakpoints.

Working with File Breakpoints

Use a file breakpoint to interrupt program execution when the program reaches a specified location within a file. Several symbols are used to show the status of file breakpoints; these appear in the left margin of the Source window:

- **Enabled** file breakpoints are identified as a red circle.
- **Disabled** file breakpoints are identified as a hollow circle in the left margin.

During debugging, a **currently active** breakpoint appears as a red circle containing a yellow arrow in the left margin of the Source window.

For a walk-through of a sample debugging session using file breakpoints, see Debugging the Squares Example Program.

To set (enable) a file breakpoint:

1. Open the desired source file in the solution.
2. In the Source window, click the line at which you want to enable a file breakpoint.
3. Do one of the following:
   - Click in the left margin of the line or press the F9 key. When you set a breakpoint, it is enabled by default.
• Right click on the desired line and select Insert Breakpoint from the pop-up menu.

To disable a file breakpoint:
1. In the Source window, click the line containing the file breakpoint you want to disable.
2. Do one of the following:
   • Right click on that line, and select Disable Breakpoint from the pop-up menu.
   • In the Debug menu, select Windows > Breakpoints, which opens the Breakpoints window. Select the check box for that breakpoint so it is unchecked (disabled).

To remove a file breakpoint:
1. In the Source window, click the line containing the file breakpoint you want to remove.
2. Do one of the following:
   • Click in the left margin of the line or press the F9 key. If the breakpoint was originally disabled, press F9 again to remove it.
   • Right click on that line, and select Delete Breakpoint from the pop-up menu.
   • In the Debug menu, select Windows > Breakpoints. In the Breakpoints window, select the breakpoint in the Name column and click the Delete button (which looks like an “X”).

To view the source code where a file breakpoint is set:
1. In the Debug menu, select Windows > Breakpoints.
2. In the Breakpoints window, click a file breakpoint.
3. Click the Go To Source Code button.
   This action takes you to the source code for a breakpoint set at a line number or function (or subroutine) name. In the case of function (or subroutine) names, the debugger must be running for this to work.

To remove all breakpoints (including data breakpoints):
In the Debug menu, select Delete All Breakpoints.

Adding Conditions to File Breakpoints
When you associate a condition with a file breakpoint, the program executes until that location is reached and the specified condition is met, such as when the value of an array element is greater than 1.

To add a condition to a breakpoint:
1. Set a file breakpoint.
2. Right-click in the associated line and select Breakpoint > Condition....
   The Breakpoint Condition dialog box appears.
   The condition that you specify in the Breakpoint Condition dialog box must relate to a local variable within the breakpoint’s scoping unit, or to a global variable. You must apply proper Fortran syntax in the Condition field in order for the specified condition to be properly detected. Consider the following examples:

To break when the local variable RecNum reaches a value of 7520, enter the following condition:

   ```
   RecNum == 7520
   ```

You can also specify joint conditions. To break when RecNum reaches at least 7520 and the variable Var2 is equal to 90, enter the following condition:

   ```
   RecNum >= 7520 .and. Var2 == 90
   ```

You can also specify an or condition. For example:

   ```
   Var1 == 3.14 .or. Var2 < 500.0
   ```
If the condition that you specify occurs at the chosen location when the program is run, a message box appears. If the breakpoint is set in part of a loop, continuing execution proceeds until the debugger detects another specified condition. If no such condition is detected, the debugger continues to the next breakpoint or, if no more breakpoints are set, until the end of the loop.

To disable, enable, or remove a file breakpoint with a defined condition, follow the general procedures for a file breakpoint. Use the checkbox for the **Condition** field to enable or disable the condition setting.

### Working with Data Breakpoints

Use a data breakpoint to interrupt program execution when the value of a certain variable changes. A data breakpoint displays a message box when the value of a variable changes, or, if a condition has been defined, when a condition is met. Unlike a file breakpoint, data breakpoints are not associated with a specific source location.

### Using Visual C++ Data Breakpoint Support

The Visual Studio* IDE does not provide data breakpoint support specifically for Fortran, but you can still use data breakpoints in a Fortran program; they are handled using the existing mechanism provided by Microsoft Visual C++*. This means that you must use Visual C++* syntax; you cannot enter the variable name or condition using Fortran syntax. The following guidelines apply:

- For scalar variables, enter the variable name in upper case. This allows Visual C++* to find the variable in the debug information and apply the correct breakpoint.
- For arrays and types, use the Fortran LOC intrinsic function in a **Watch** window or the **Immediate** window to obtain the address of the variable. Use this address in the variable name edit box.

For example, to prepare to set a data breakpoint at an array element a(5), do the following:

1. Select **Debug > Windows > Immediate**.
2. Enter `loc(a(5))` in the immediate window and press Enter.

   The result displayed is the address of the array element. The address may be displayed as a decimal number or a hexadecimal number, depending upon your current display mode. For a decimal number, you will enter it in the **Address:** field. For a hexadecimal number, you will use the Visual C++* hexadecimal syntax (0xnnnnnnnn) rather than the Fortran syntax (#nnnnnnnn) in the fields.

The following procedure applies to debugging the current routine (current scope).

#### To set a data breakpoint:

1. Start debugging.
2. In the **Debug** menu, select **New Breakpoint > New Data Breakpoint...**
3. Enter the desired address. Also enter the Byte Count and Language (specify C++).

   If you want to associate a condition with this breakpoint, right-click on the breakpoint in the **Breakpoints** window and choose **Condition**...

#### To disable, enable, or remove a data breakpoint:

1. In the **Debug** menu, select **Windows > Breakpoints**.
2. To disable or enable the data breakpoint, use the check box to the left of the data breakpoint (check indicates enabled).
3. To remove a data breakpoint, select the data breakpoint and click the **Delete** button.

Under certain conditions, the debugger may disable a data breakpoint. In this case, you should either try to enable it or remove and set it again.

#### To remove all breakpoints (including file breakpoints):

In the **Debug** menu, select **Delete All Breakpoints**.
Debugging the Squares Example Program

This topic applies to Fortran applications for Windows* only.

The example below shows a program called SQUARES that requires debugging. The program was compiled and linked without diagnostic messages from either the compiler or the linker, however, this program contains a logic error in an arithmetic expression.

```fortran
PROGRAM SQUARES
    INTEGER INARR(10), OUTARR(10), I, K
    ! Read the input array from the data file.
    OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')
    READ(8,*,END=5) N, (INARR(I), I=1,N)
    5   CLOSE (UNIT=8)
    ! Square all nonzero elements and store in OUTARR.
    K  = 0
    DO I = 1, N
        IF (INARR(I) .NE. 0) THEN
            OUTARR(K) = INARR(I)**2
        ENDIF
    END DO
    ! Print the squared output values. Then stop.
    PRINT 20, N
    20  FORMAT (' Total number of elements read is',I4)
    PRINT 30, K
    30  FORMAT (' Number of nonzero elements is',I4)
    DO I=1,K
        PRINT 40, I, OUTARR(K)
        40    FORMAT(' Element', I4, 'Has value',I6)
    END DO
END PROGRAM SQUARES
```

The program SQUARES performs the following functions:

- Reads a sequence of integer numbers from a data file and saves these numbers in the array INARR. The file datafile.dat contains one record with the integer values 4, 3, 2, 5, and 2. The first number indicates the number of data items that follow.
- Enters a loop in which it copies the square of each nonzero integer into another array OUTARR.
- Prints the number of nonzero elements in the original sequence and the square of each such element.

In the program, the logic error occurs because variable K, which keeps track of the current index into OUTARR, is not incremented in the loop on lines 9 through 13. The statement K = K + 1 should be inserted just before line 11.

This example assumes that the program was executed without array bounds checking (set by specifying nobounds for the check command-line option). When executed with array bounds checking, a run-time error message appears.

**Debugging Example:** The following shows how to debug a Windows* OS based program using the Microsoft integrated debugger within the integrated development environment (see Preparing Your Program for Debugging and Using Breakpoints in the Debugger). This example assumes a solution already exists.

**To debug this program:**

1. Start Visual Studio*.
2. In the File menu, select Open Solution. Open the solution containing the file.
3. Edit the file `squares.f90`: double-click the file name in the Solution Explorer View. The screen appears as follows:

The following toolbars are shown: Build toolbar, Standard toolbar.

4. To change the displayed toolbars, select View > Toolbars. To display the debug toolbar, select Debug.

5. Click the first executable line to set the cursor position. In this case, click the beginning of the OPEN statement line:

```
OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')
```

6. Click in the left margin of the first executable line to set a breakpoint. The red circle in the left margin of the text editor/debugger window shows where a breakpoint is set:
7. This example assumes you have previously built your application (see Preparing Your Program for Debugging).

In the **Debug** menu, select **Start Debugging**.

The debugger is now active. The current position is marked by a yellow arrow at the first executable line (the initial breakpoint).

8. If needed, you can set another breakpoint. Position the cursor at the line where you want to add a breakpoint, right click, and select **Breakpoint > Insert Breakpoint**.

9. Step through the lines of source code. You can do this with **Debug > Step Over** or with the **Step Over** button on the **Debug** toolbar.

10. Repeat the **Step Over** action and follow program execution into the **DO** loop and unto the end of the program. Position the cursor over the variable $K$ to view its value in a **Data Tip** box:
The error seems related to the value of variable \( K \).

11. In the **Text Editor**, add the line \( K = K + 1 \) as follows:

```
! Square all nonzero elements and store in OUTARR.
K = 0
DO I = 1, N
  IF (INARR(I) .NE. 0) THEN
    K = K + 1  ! add this line
    OUTARR(K) = INARR(I)**2
  ENDIF
END DO
```

12. Since you have modified the source, you need to rebuild the application:
   - In the **Debug** menu, select **Stop Debugging**
   - In the **Build** menu, select **Build debugtest**.
   - In the **Debug** menu, select **Start Debugging**.

   The output screen appears as follows:

```
Total number of elements read is  4
Number of nonzero elements is  4
Element 1 has value  9
Element 2 has value  4
Element 3 has value  25
Element 4 has value  4
```

13. The program now generates better results. You can examine the values of both the input array \( \text{INARR} \) (read from the file) and the output array \( \text{OUTARR} \) that the program calculates. In the **Text Editor** window, the previously set breakpoint remains set.

   In the **Debug** menu, select **Start Debugging**.
14. To view the values of certain variables as the program executes, display the Locals window. In the Debug menu, select Windows > Locals.

15. You can view the values of the local variables in the Locals window. Click the plus sign to view array values.

```
I

OUTARR { . . . }

INARR { . . . }
```

The Locals window does not let you display module variables or other non-local variables. To display non-local variables, display one of the Watch windows.

16. Although this example does not use module variables or non-local variables, you can drag a variable name into the Watch window so the variable can be displayed. The Watch window allows you to display expressions.

In the Text Editor window, select the variable name INARR (without its subscript syntax), drag it, and drop it into the Watch window, Name column:

17. Also drag the OUTARR array name to the Watch window. Click the Plus sign (+) to the left of the OUTARR variable's name to display the values of its array elements.

18. Execute lines of the program by using the Step Over button on the Debug toolbar. As the program executes, you can view the values of scalar variables with the data tips feature and view the values of arrays (or other variables) in the Watch window.

If a Disassembly window (shows disassembled code with source-code symbols) unintentionally appears, click the Step Out button on the debugger toolbar (or select Step Out in the Debug menu) as needed to dismiss the Disassembly window.

Preparing Your Program for Debugging
Using Breakpoints in the Debugger

Viewing Fortran Data Types in the Microsoft Debugger

This topic applies to Fortran applications for Windows* only.

The following general suggestions apply to different types of Fortran data:

- For scalar (nonarray) data, use the data tips (leave pointer on a variable name) feature or use the Locals window or a Watch window. Intel® Fortran does not support the Autos window.
- For single-dimension array data, derived-type data, record structure data, and COMPLEX data, use the Locals window or a Watch window.
- For common blocks exported from a DLL, enter the name of the common block in a Watch window. You will be able to view the common block variables like any other structure.
- By default, values of named constants (parameters) are not visible in the debugger. To make these visible, add the /debug-parameters:used option or /debug-parameters:all option when compiling the sources.

For information on using Data Tips, the Locals window, or a Watch window, see Debugging the Squares Example Program.

The following sections apply to using a Watch window:

- Specifying Array Sections
- Specifying Module Variables
- Specifying Format Specifiers

To display a Watch window:

1. In the Debug menu, select Windows > Watch.
2. In the submenu, click Watch 1, 2, 3, or 4.
Specifying Array Sections
You can specify array sections in a Watch window. For example, consider an array declared as:

```fortran
integer foo(10)
```

You can specify the following statement in a Watch window to see the 2nd, 5th, and 8th elements:

```fortran
foo(2:10:3)
```

When working with character arrays, this syntax may be combined with a substring specification. Consider the following array declaration:

```fortran
character*8 chr_arr(10)
```

You can specify the following statement in a Watch window to display the substring made up of character 3 through 8 of array elements 2 through 5:

```fortran
chr_arr(2:5)(3:8)
```

This support is available for arrays of any type, including array pointers, assumed-shape, allocatable, and assumed-size arrays.

Any valid integer expression can be used when specifying lower bound, upper bound, or stride. If the lower bound is omitted, the array lower bound is used. If the upper bound is omitted, the array upper bound is used. For example, consider the following declaration:

```fortran
integer foo(10)
```

To display:

- Elements 1 through 8, specify `foo(:8)`
- Elements 5 through 10, specify `foo(5:)`
- All 10 elements, specify `foo(:)`

Specifying Module Variables
To view a module variable in a Watch window, specify the module name, followed by `::`, followed by the variable name.

For example, to watch variable "bar" of module "foo", specify the following expression:

```fortran
foo::bar
```

Specifying Format Specifiers
You can use format specifiers in Watch windows to display variables in different data formats.

For example, given a REAL variable 'foo' in a program, it is now possible to see 'foo' in different floating point notation (by typing "foo,f" "foo,g" or "foo,e" in a Watch window) or as an integer ("foo,i" or "foo,d"), a hexadecimal value ("foo,x"), an an octal value ("foo,o"), and so on.

You can change the display format of variables in a Watch window using the formatting symbols in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Format</th>
<th>Value</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>d,i</td>
<td>signed decimal integer</td>
<td>0xF000F065</td>
<td>-268373915</td>
</tr>
<tr>
<td>o</td>
<td>unsigned octal integer</td>
<td>0xF065</td>
<td>0170145</td>
</tr>
<tr>
<td>x,X</td>
<td>Hexadecimal integer</td>
<td>61541 (decimal)</td>
<td>#0000F065</td>
</tr>
<tr>
<td>f</td>
<td>signed floating-point</td>
<td>3./2.</td>
<td>1.50000000</td>
</tr>
</tbody>
</table>
To use a formatting symbol, type the variable name, followed by a comma and the appropriate symbol. For example, if `var` has a value of `0x0065`, and you want to see the value in character form, type `var,c` in the Name column on the tab of the Watch window. When you press ENTER, the character-format value appears:

```
var,c = 'e'
```

You can use the formatting symbols shown in the following table to format the contents of memory locations:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Format</th>
<th>Value</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td><code>signed</code> scientific notation</td>
<td>3./2.</td>
<td>0.1500000E+01</td>
</tr>
<tr>
<td>g</td>
<td><code>signed</code> floating-point or <code>signed</code> scientific notation, whichever is shorter</td>
<td>3./2.</td>
<td>1.500000</td>
</tr>
<tr>
<td>c</td>
<td>Single character</td>
<td>0x0065</td>
<td>'e'</td>
</tr>
<tr>
<td>s</td>
<td>String</td>
<td>0x0012fde8</td>
<td>&quot;Hello world&quot;</td>
</tr>
</tbody>
</table>

With the memory location formatting symbols, you can type any value or expression that evaluates to a location.

A formatting character can also follow an expression:

```
rep+1,x
xloc,g
count,d
```

**NOTE**

You can apply formatting symbols to structures, arrays, pointers, and objects as unexpanded variables only. If you expand the variable, the specified formatting affects all members. You cannot apply formatting symbols to individual members.

**See Also**

Debugging the Squares Example Program
Viewing the Call Stack in the Microsoft Debugger

In most cases, your program will automatically stop at the point where the exception occurs, allowing you to view the source code and values of variables. If the error is related to an I/O statement, you may want to view the call stack.

If you want to view where your program is currently executing in the hierarchy of routines, you can display the Call Stack window in the debugger. For example, you may want to display this window to determine where in your program an exception occurs.

To view the call stack:

1. Start the debugger and stop at a breakpoint.
2. Select Debug > Windows > Call Stack.

A severe unhandled I/O programming error (such as an End-of-File condition) can occur while the program is executing in the debugger. When this occurs, the Fortran run-time system will raise a debug event automatically to stop program execution, allowing display of the Call Stack.

When the severe unhandled I/O error occurs in the debugger:

- An information box is displayed that contains:
  - User breakpoint called from code at 0xnnnnnnn
  - A window appears with your cursor in NTDLL disassembly code

Click OK to dismiss the information box.

Scanning down the Call Stack display, there will be a few frames from NTDLL and the Fortran run-time system displayed, then the actual Fortran routine with the I/O statement that caused the error. In the call stack, select the Fortran routine to display the Fortran code and the variables using the Locals window. The green arrow points to the I/O statement that caused the error.

This action all occurs after the error message and traceback information has been displayed. The error message and traceback information is available in the program output window. To view the program output window, either iconize (minimize) the integrated development environment (IDE) or click the icon for the output window in the task bar. You should not need the stack dump because you have the Call Stack window in the IDE, but the error message with the file name might be useful to see.

Locating Run-Time Errors
Traceback

Locating Unaligned Data

Unaligned data can slow program execution. You should determine the cause of the unaligned data, fix the source code (if necessary), and recompile and relink the program.

If your program encounters unaligned data at run time, to make it easier to debug the program, you should recompile and relink with the -g (Linux* OS and macOS*) or /debug:full (Windows* OS) option to generate sufficient table information and debug unoptimized code.

Debugging a Program that Encounters a Signal or Exception

If your program encounters a signal (exception) at run time, you may want to recompile and relink with certain command-line options before debugging the cause. The following will make it easier to debug the program:

- Use the fpe[n] option to control the handling of floating point exceptions.
• To generate sufficient symbol table information and debug unoptimized code, as with other debugging tasks, use the \texttt{-g} (Linux* and macOS*) or \texttt{/debug:full} (Windows*) compiler option.

**Debugging an Exception in the Microsoft Debugger (Windows*)**

You can request that the program always stop when a certain type of exception occurs. Because certain exceptions are caught by default by the Intel® Fortran run-time library, your program stops in the run-time library code. In most cases, you want the program to stop in your program's source code instead.

**To change how an exception is handled in the Microsoft debugger:**

1. In the **Debug** menu, select **Exceptions**.
2. View the displayed exceptions.
3. Select **Windows Exceptions**. Select each type of exception to be changed and change its handling using the radio buttons.
4. Start program execution using **Start** in the **Debug** menu.
5. When the exception occurs, you can now view the source line being executed, examine current variable values, execute the next instruction, and so on, to help you better understand that part of your program.
6. After you locate the error and correct the program, consider whether you want to reset the appropriate type of exception to "**Use Parent Setting**" before you debug the program again.

For machine exceptions, you can use the just-in-time debugging feature to debug your programs as they run outside of the visual development environment. To do this, set the following items:

• In **Tools > Options**, select **Native** in the **Debugging Just-In Time** category.
• Set the **FOR_IGNORE_EXCEPTIONS**, as listed in **Supported Environment Variables**, to **TRUE**.

**See Also**

**Supported Environment Variables**

**Debugging and Optimizations**

This topic describes the relationship between various command-line options that control debugging and optimizing.

Whenever you enable debugging with the \texttt{-g} option (Linux* and macOS*) or \texttt{/debug:full} option (Windows*), you disable optimizations. You can override this behavior by explicitly specifying compiler options for optimizations on the command line.

The following summarizes commonly used options for debugging and for optimization.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{-O0} (Linux* and macOS*)</td>
<td>Disables optimizations so you can debug your program before any optimization is attempted. This is the default behavior when debugging.</td>
</tr>
<tr>
<td>\texttt{/Od} (Windows*)</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>On Linux* and macOS*, \texttt{-fno-omit-frame-pointer} is set if either option \texttt{-O0} or \texttt{-g} is specified.</td>
</tr>
</tbody>
</table>

For more information, see the following topics:

• \texttt{-O0} (Linux* and macOS*) compiler option
• \texttt{/Od} (Windows*) compiler option

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{01}, \texttt{02}, or \texttt{03} (Linux* and macOS*)</td>
<td>Specifies the code optimization level for applications. If you use any of these options, it is recommended that you use \texttt{-debug extended} when debugging.</td>
</tr>
</tbody>
</table>

For more information, see the following topics:
Combining Optimization and Debugging

The compiler lets you generate code to support symbolic debugging when O1, O2, or O3 optimization options are specified on the command line along with -g (Linux* and macOS*) or /debug:full (Windows*); this produces symbolic debug information in the object file.

**NOTE**

Note that if you specify an O1, O2, or O3 option with the -g (Linux* and macOS*) or /debug:full (Windows*) option, some of the debugging information returned may be inaccurate as a side-effect of optimization.

To counter this on Linux* OS and macOS*, you should also specify the -debug extended option.

It is best to make your optimization and/or debugging choices explicit:

- If you need to debug your program excluding any optimization effect, use the -O0 (Linux* and macOS*) or /Od (Windows*) option, which turns off all the optimizations.
- If you need to debug your program with optimizations enabled, then you can specify the O1, O2, or O3 option on the command line along with debug extended.
NOTE
When no optimization level is specified, the -g or /debug:full option slows program execution; this is because this option turns on -O0 or /Od, which causes the slowdown. However, if both O2 and -g (Linux* and macOS*) or /debug:full (Windows*) are specified, for example, the code should not experience much of a slowdown.

Refer to the table below for the summary of the effects of using the -g or /debug:full option with the optimization options.

<table>
<thead>
<tr>
<th>These options</th>
<th>Produce these results</th>
</tr>
</thead>
<tbody>
<tr>
<td>-g (Linux* and macOS*)</td>
<td>Debugging information produced, -O0 (Linux* and macOS*) or /Od (Windows*) enabled (meaning optimizations are disabled). For Linux* and macOS*, -fp is also enabled for compilations targeted for IA-32 architecture.</td>
</tr>
<tr>
<td>/debug:full (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-g-O1 (Linux* and macOS*)</td>
<td>Debugging information produced, O1 optimizations enabled.</td>
</tr>
<tr>
<td>/debug:full /O1 (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-g-O2 (Linux* and macOS*)</td>
<td>Debugging information produced, O2 optimizations enabled.</td>
</tr>
<tr>
<td>/debug:full /O2 (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-g-O2 (Linux* and macOS*)</td>
<td>Debugging information produced, O2 optimizations enabled. Windows* using IA-32 architecture, /Oy disabled.</td>
</tr>
<tr>
<td>/debug:full /O2 /Oy- (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-g -O3 -fp (Linux* and macOS*)</td>
<td>Debugging information produced, O3 optimizations enabled. For Linux*, -fp enabled for compilations targeted for IA-32 architecture.</td>
</tr>
<tr>
<td>/debug:full /O3 (Windows*)</td>
<td></td>
</tr>
</tbody>
</table>

NOTE
Even the use of option debug extended with optimized programs may not allow you to examine all variables or to set breaks at all lines, due to code movement or removal during the optimization process.

Debugging Mixed-Language Programs

The Visual Studio* debugger let you debug mixed-language programs. Program flow of control across subprograms written in different languages is transparent.

The debugger uses debug information associated with the program to automatically identify the language of the current subprogram or code segment.

For example, if program execution is suspended in a subprogram in Fortran, the current language is seen as Fortran. If the debugger stops the program in a C function, the current language becomes C.

Debugging Multithreaded Programs

The debugging of multithreaded programs discussed in this topic applies to both the OpenMP* Fortran API and the Intel® Fortran parallel compiler directives. When a program uses parallel decomposition directives, you must take into consideration that the bug might be caused either by an incorrect program statement or it might be caused by an incorrect parallel decomposition directive. In either case, the program to be debugged can be executed by multiple threads simultaneously.

To determine the correctness of and debug multithreaded programs, you can use the following:
• Linux* and macOS* systems: gdb.
• Windows* operating systems: Microsoft Visual Studio* Debugger.
• Intel® Fortran Compiler debugging options and methods; in particular, debug and traceback options.

## Using Remote Debugging

The following applies to Microsoft* Visual Studio* 2013 and 2015.

Remote debugging lets you use your local (host) system to debug an application running on a remote system.

### Remote Debugging using Microsoft* Visual Studio*

There are two remote connection types available: DCOM ("Remote with Windows authentication") and TCP/IP ("Remote with no authentication"). For more information on initial setup for remote debugging, refer to the Microsoft* Visual Studio* remote debugging setup topics in the Microsoft* MSDN documentation.

Remote debugging typically requires use of the debugging monitor (msvsmon.exe). Run the monitor in the correct mode for the remote system’s architecture. To do this, on the remote system, select the program group Microsoft Visual Studio 2013 (or applicable version year), then choose Visual Studio Tools and select the correct Remote Debugger Folder.

Remote debugging also requires proper set up of the IDE Debugging property page on the host machine.

To set up remote debugging using the IDE property pages:

1. On the host machine, choose Project > Properties > Configuration Properties > Debugging. Your screen should resemble this image:
2. Specify the following:
   
   **Connection**: Use the drop-down box to select the type of connection.
   
   **Remote Server Name**: Use the drop-down box to select the name of the remote system.
   
   **Remote Command**: Type the command you want to issue on the remote machine. Typically, this is a pathname to an executable file (.exe) on the remote machine; for example: d:\remote\myapp.exe

3. Optionally, set **Attach** to **Yes** to attach to an application that is already running on the remote machine.

To start remote debugging:

1. Make sure you have the necessary remote debugging permissions on the remote machine. For example, you need Administrator privileges if you want to debug a process running on a remote machine under another account name.
2. Run the Remote Debugging Monitor on the remote machine.
3. Launch Microsoft* Visual Studio* on the host machine and use it to attach to a program you want to debug on the remote machine, or launch a program you want to debug on the remote machine.

**Remote Debugging Scenario**

This topic applies to Fortran applications for Windows* only.

The remote debugging scenario described here includes the cross-platform and cross-compilation remote debugging features. The following parameters apply:
Host platform: IA-32
Remote platform: Intel® 64
Name of host machine: HOST_MACHINE (domain name of host machine)
Name of remote machine: REMOTE_SERVER (domain name of remote machine)
Host OS: Windows* 10 - 32 Bit
Remote OS: Windows* 10 - 64 Bit
Executable for debugging: Win64 (x64)
Type of executable: Console application
Visual Studio*: Microsoft Visual Studio* 2017
Connection types: Remote with/without Windows authentication
Sessions: Remote debugging, remote execution, attach to process on a remote machine

1. HOST_MACHINE
   Start Visual Studio* 2017 on the host machine (HOST_MACHINE).
2. Create a new console application; for this example, use remote_2017.
3. Add the following lines to the remote_2017.f90 file:

   REAL, DIMENSION(1) :: xxx = 0
   PRINT *, 'Type one number: '
   READ (*,'(F10.3)') xxx
4. Open **Project > Properties** and create a new platform configuration for x64 using the **Configuration Manager**.

![Configuration Manager](image-url)
5. Make sure, that current (target) configuration is Debug|x64 and build the solution (Build > Build Solution). This invokes the cross-compiler and causes the 64-bit executable file remote_2017.exe to be built.

6. Run the remote_2017.exe application to make sure that it is 64-bit code. An error should result, explaining that it is not a valid Win32 application.

7. Run the Remote Desktop Connection program (%SystemRoot%\System32\mstsc.exe) and connect to the remote machine (REMOTE_SERVER).

8. Create C:\remote_dir on REMOTE_SERVER and copy remote_2017.exe from HOST_MACHINE to REMOTE_SERVER.

10. Set a breakpoint at line 27.

```
    !::remote_2017.f90
    !
    !::FUNCTIONS:
    !::remote_2017 -- 'Entry point of console application.'
    !
    !
    !*****************************************************************************
    !
    !::PROGRAM: 'remote_2017'
    !

```

11. Open Project > Properties and select Debugging. In the Remote Settings section, set the following properties:

   **Connection**: Remote with Windows authentication

   **Remote Machine**: REMOTE_SERVER

   **Remote Command**: C:\remote_dir\remote_2017.exe

12. Press F5 to start debugging.

   If there is a firewall you will get an Unable to start debugging error message. In this case go to REMOTE_SERVER, locate, and run the Remote Debugger application (64-bit mode). Find msvsmon.exe in the location where it was installed, or open the Start menu and search for Remote Debugger. Go back to LOCAL_SERVER and press F5 to start debugging.

13. Go to REMOTE_SERVER and make sure that the remote_2017 application is started.

14. Type 5 and press Enter. Go back to HOST_MACHINE.

15. Verify that the Debugger reaches the breakpoint at the line 27.

16. Open the Locals window and make sure that value xxx is 64-bit.
17. Press Shift+F5 to stop debugging and terminate the application on the remote server.
18. Open the project properties again, select **Debugging**, and set **Attach** to **Yes**.
20. Press F5 for attaching to a process.
21. Repeat steps 12-17 to check that the attach to process works correctly.
22. Open **Project > Properties** and set **Attach** to **No**.
23. Open **Project > Properties** and set **Connection** to **Remote with no authentication (Native only)**.
24. Go to **REMOTE_SERVER** and switch debugging monitor to No Authentication mode using the **Tools > Options** menu.
25. Repeat steps 12-22 to check that Remote with no authentication (Native only) mode works correctly.

**Results of Remote Debugging Exercise**

The results of this remote debugging exercise for Visual Studio* 2017 are summarized in the table below.

<table>
<thead>
<tr>
<th>Connection Type</th>
<th>Session</th>
<th>Result</th>
<th>Debugging Monitor status</th>
</tr>
</thead>
<tbody>
<tr>

Using Module (.mod) Files

One way to reduce potential confusion when you use the same source code in several projects is to organize the routines into modules and submodules. A module is a type of program unit that contains specifications of such entities as data objects, parameters, structures, procedures, and operators. These precompiled specifications and definitions can be used by one or more program units. Partial or complete access to the module entities is provided by the program's USE statement. Typical applications of modules are the specification of global data or the specification of a derived type and its associated operations.

Modules are excellent ways to organize programs. You can set up separate modules for:

- Commonly used routines
- Data definitions specific to certain operating systems
- System-dependent language extensions.

Submodules let you separate the interface of procedures from their implementation, making it easier to build applications and perform maintenance.

To USE a module, its source must first be compiled into a .mod file. The name of the .mod file is the module name, not the source file name. Similarly, submodules are compiled into .smod files - their parent modules or submodules must be compiled first. Compiling a module or submodule also creates an object file (.o or .obj) that must be included when linking the application.

When compiling a source that has a USE statement containing a module, the compiler looks for the corresponding .mod file in the same place it looks for include files. Submodule .smod files are used only when a child submodule is compiled.

Some programs require modules located in multiple directories. You can use compiler option $I$ when you compile the program to specify the location of the .mod and .smod files that should be included in the program.

Intrinsic modules, defined by the Fortran standard, are supplied in a system directory alongside the compiler binaries and libraries. These have a .modintr file type that is searched only when the Fortran source has USE, INTRINSIC.

You can use compiler option modulepath to specify the directory in which to create the module files. If you do not use this option, module files are created in the current directory.

Directories are searched for .mod and .smod files in this order:

1. In the directory of the source file that contains the USE statement
2. In the directories specified by compiler option modulepath
3. In the current working directory
4. In the directories specified by compiler options -I dir (Linux* and macOS*) or /include (Windows*)
5. In the directories specified with environment variables CPATH or INCLUDE
In the standard system directories

If building as part of a Microsoft Visual Studio* project that has dependent projects, the Fortran build system automatically searches the dependent projects for compiled .mod files.

You need to make sure that the module files are created before they are referenced by another program or subprogram. If the module and its USE statement are in the same source file, the module must appear first. The gen-dep compiler option creates a list of compiled module files that a source file depends upon. This list can be used with build utilities such as make to specify dependencies and to ensure that files that use a module are recompiled when the module is modified and recompiled.

Compiling Programs with Modules

If a file being compiled has one or more modules defined in it, the compiler generates one or more .mod or .smod files, along with object files.

For example, consider that file a.f90 contains modules defined as follows:

```
module test
  integer:: a
  contains
    subroutine f()
    end subroutine
  end module test

module payroll
  ...
end module payroll
```

The following compiler command:

```
ifort -c a.f90
```

generates the following files:

- test.mod
- payroll.mod
- a.o (Linux* and macOS*)
- a.obj (Windows*)

The .mod files contain the necessary information regarding the modules that have been defined in the program a.f90.

The following example uses the program mod_def.f90 which contains a module defined as follows:

```
module definedmod
  ...
end module
```

Compile the program as follows:

```
ifort -c mod_def.f90
```

This produces the object files mod_def.o (Linux* and macOS*) or mod_def.obj (Windows*) and also the .mod file definedmod.mod, all in the current directory.
Using Include Files

Include files are brought into a program with the #include preprocessor directive or a Fortran INCLUDE statement.

Directories are searched for include files in this order:

1. In the directory of the source file that contains the include
2. In the current working directory
3. In the directories specified by compiler option I.
4. In the directory specified by compiler option -isystem (Linux* and macOS* only)
5. In the directories specified with environment variables CPATH (Linux* and macOS*) or INCLUDE (Windows*)
6. In the standard system directories

The locations of directories to be searched are known as the include file path. More than one directory can be specified in the include file path.

Specifying and Removing an Include File Path

You can use compiler option I to indicate the location of include files (and also module files).

To prevent the compiler from searching the default path specified by the CPATH or the INCLUDE environment variable, use compiler option -X or /noinclude.

You can specify these options in the configuration file, ifort.cfg, or on the command line.

For example, to direct the compiler to search a specified path instead of the default path, use the following command line:

Example

// Linux* and macOS*
  ifort -X -I/alt/include newmain.f

// Windows*
  ifort /noinclude /IC:\Project2\include newmain.f
Advantages of Internal Procedures

Functions or subroutines that are used in only one program can be organized as internal procedures, following the CONTAINS statement of a program or module.

Internal procedures have the advantage of host association, that is, variables declared and used in the main program are also available to any internal procedure it may contain. For more information on procedures and host association, see Program Units and Procedures.

Internal procedures, like modules, provide a means of encapsulation. Modules can be used to store routines commonly used by many programs; internal procedures separate functions and subroutines whose use is limited or temporary.

Implications for Array Copies

Fortran language semantics sometimes require the compiler to make a temporary copy of an array or array slice. Situations where this can occur include:

- Passing a non-contiguous array to a procedure that does not declare it as assumed-shape
- Array expressions, especially those involving intrinsic functions RESHAPE, PACK, and MERGE
- Assignments of arrays where the array appears on both the left and right-hand sides of the assignment
- Assignments of POINTER arrays

By default, these temporary values are created on the stack and, if large, may result in a stack overflow error at runtime. The size of the stack can be increased, but with limitations dependent on the operating system. If you use compiler option heap-arrays, it tells the compiler to use heap allocation, rather than the stack, for such temporary copies. Heap allocation adds a small amount of overhead when creating and removing the temporary values, but this is usually inconsequential in comparison to the rest of the code.

Performance can be further improved by entirely eliminating the need for a temporary copy. For the first case in the above list, passing a non-contiguous array to a procedure expecting a contiguous array, enabling compiler option check:arg_temp Created will produce a run-time informational message when the compiler determines that the argument being passed is not contiguous. A run-time test is performed and if the argument is contiguous, no copy is made. However, this option will not issue a diagnostic message for other uses of temporary copies.

One way to avoid temporary copies for array arguments is to change the called procedure to declare the array as assumed-shape, with the DIMENSION(:) attribute. Such procedures require an explicit interface to be visible to the caller. This is best provided by placing the called procedure in a module or a CONTAINS section. As an alternative, an INTERFACE block can be declared.

Use of POINTER arrays makes it difficult for the compiler to know if a temporary value can be avoided. Where possible, replace POINTER with ALLOCATABLE, especially as components of derived types. The language definition directs the compiler to assume that ALLOCATABLE arrays are contiguous and that they do not overlap other variables, unlike POINTERs.
Another situation where the temporary values can be created is for automatic arrays, where an array’s bounds are dependent on a routine argument, use or host associated variable, or COMMON variable, and the array is a local variable in the procedure. As above, these automatic arrays are created on the stack by default; compiler option heap-arrays creates them on the heap. Consider making such arrays ALLOCATABLE instead; local ALLOCATABLE variables that do not have the SAVE attribute are automatically deallocated when the routine exits. For example, replace:

```fortran
SUBROUTINE SUB (N)
INTEGER, INTENT(IN) :: N
REAL :: A(N)
```

with:

```fortran
SUBROUTINE SUB(N)
INTEGER, INTENT(IN) :: N
REAL, ALLOCATABLE :: A(:)
ALLOCATE (A(N))
```

**See Also**

- ALLOCATABLE statement
- check compiler option
- DIMENSION statement
- heap-arrays compiler option
- MERGE intrinsic function
- PACK Function
- POINTER - Fortran statement
- RESHAPE intrinsic function
- SAVE statement
OpenMP* Support

The Intel® compiler supports most of OpenMP* Version Technical Report 4: Version 5.0 Preview 1. For the complete OpenMP specification, see the OpenMP* Application Program Interface Version TR4: Version 5.0 specification, which is available from the OpenMP* web site (http://www.openmp.org; see OpenMP Specifications on that site). The descriptions of OpenMP* language characteristics in this documentation often use terms defined in that specification.

The OpenMP* API provides symmetric multiprocessing (SMP) with the following major features:

- Relieves you from implementing the low-level details of iteration space partitioning, data sharing, thread creation, scheduling, or synchronization.
- Provides the benefit of performance available from shared memory multiprocessor and multi-core processor systems on all supported Intel architectures, including those processors with Intel® Hyper-Threading Technology (Intel® HT Technology).
- Provides support for the Intel® Xeon Phi™ coprocessor.

The compiler performs transformations to generate multithreaded code based on your placement of OpenMP* directives in the source program, making it simple to add threading to existing software. The Intel compiler compiles parallel programs and supports the industry-standard OpenMP* directives.

The compiler provides Intel-specific extensions to the OpenMP* specification including run-time library routines and environment variables. A summary of the compiler options appear in the OpenMP* Options Quick Reference.

Parallel Processing with OpenMP*

To compile with the OpenMP* API, add the directives in the form of the Fortran program comments to your code. The compiler processes the code and internally produces a multithreaded version which is then compiled into an executable with the parallelism implemented by threads that execute parallel regions or constructs.

Using Other Compilers

The OpenMP* specification does not define interoperability of multiple implementations, so the OpenMP* implementation supported by other compilers and OpenMP* support in the Intel compiler might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP* source compatibility that enable you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

The Intel compiler includes two sets of OpenMP* libraries, as described in OpenMP* Source Compatibility and Interoperability with Other Compilers.
OpenMP® Source Compatibility and Interoperability with Other Compilers

The Intel® Fortran Compiler includes OpenMP® libraries that are object-level compatible with OpenMP® support provided by certain versions of the following compilers:

- Microsoft® Visual C++® compiler on Windows®
- Intel® Fortran Compiler version 10.x (and later)

The term object-level interoperability refers to the ability to link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, such that the resulting executable runs successfully. In contrast, source compatibility means that the entire application is compiled and linked by one compiler, and you do not need to modify the sources to get the resulting executable to run successfully.

Different compilers support different versions of the OpenMP® specification. Based on the OpenMP® features your application uses, determine what version of the OpenMP® specification your application requires. If your application uses an OpenMP® specification level equal or less than the OpenMP® specification level supported by all the compilers, your application should have source compatibility with all compilers, but you need to link all object files and libraries with the same compiler's OpenMP® libraries.

The Intel OpenMP® run-time libraries provide source compatibility and object-level interoperability with the OpenMP® support provided by:

- Certain versions of Microsoft® Visual C++® libraries that support OpenMP®, starting with Visual C++ 2013.
- The Intel® Fortran Compiler versions 10.0 and later and their supplied OpenMP® compatibility libraries.

For Fortran applications on Linux® systems, it is not possible to link objects compiled by the Intel® Fortran Compiler (ifort) with objects compiled by the GNU® Fortran compiler (gfortran). Thus, for mixed-language C++ and Fortran applications, you can do one of the following:

- Combine objects created by gfortran and Intel® C++ objects.
- Combine objects created by the Intel® C++ Compiler and the Intel® Fortran Compiler.

Guidelines for Using Different Intel® Compiler Versions

To avoid possible linking or run-time problems, follow these guidelines:

- Object modules produced by current Intel compilers are not compatible with object modules compiled by the Intel® Fortran Compiler prior to version 10.0.
- Object modules produced by current versions of the Intel® Fortran Compiler are compatible with object modules produced by the compatibility libraries, for the Intel® Fortran Compiler versions 10.0 and later.
- Use dynamic instead of static OpenMP® libraries to avoid linking multiple copies of the libraries into a single program.

Guidelines for Using the Intel® Fortran Compiler with non-Intel Compilers

To avoid possible linking or run-time problems, follow these guidelines:

- Always link using the Intel® Fortran Compiler OpenMP® libraries. This avoids linking multiple copies of the OpenMP® runtime libraries from different compilers. It is easiest if you use the Intel compiler command (driver) to link the application, but it is possible to link with the Intel® Fortran Compiler OpenMP® libraries when linking the application using GCC or the Visual C++® compiler (or linker) commands.
- If possible, compile all the OpenMP® sources with the same compiler. If you compile (not link) using multiple compilers such as the Microsoft® Visual C++® or GNU® compilers that provide object-level interoperability with the libraries, see the instructions in Using the OpenMP® Libraries.
- Use dynamic instead of static OpenMP® libraries to avoid linking multiple copies of the libraries into a single program.

Limitations When Using OpenMP® Libraries with Other Compilers

Limitations of threadprivate objects on object-level interoperability:
• On Windows* systems, the Intel® Fortran Compiler by default (/Qopenmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than does the Microsoft* Visual C++* compiler. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® Fortran Compiler and the Visual C++* Compiler, the code compiled by the Intel® Fortran Compiler and the code compiled by the Visual C++* compiler reference different locations for the variable even when referenced by the same thread. Use the /Qopenmp-threadprivate:compat compiler option when compiling with the Intel® Fortran Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by Microsoft* Visual C++*.

• On Linux* systems, the Intel® Fortran Compiler by default (-qopenmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than GCC*. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® Fortran Compiler and GCC* compiler, the code compiled by the Intel® Fortran Compiler and the code compiled by the gcc reference different locations for the variable even when referenced by the same thread. Use the --openmp-threadprivate:compat compiler option when compiling with the Intel® Fortran Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by GCC.

Using the OpenMP* Libraries

Adding OpenMP* Support to your Application

To add OpenMP* support to your application, do the following:

1. Add the appropriate OpenMP* directives to your source code.
2. Compile the application with the Qopenmp (Windows) or qopenmp (Linux* and macOS*) option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at run-time. In addition, you may need to increase the stack allocated to individual threads by using the OMP_STACKSIZE environment variable or by setting the corresponding library routines.

You can set other environment variables to control multi-threaded code execution.

OpenMP Directive Syntax

To add OpenMP* support to your application, first add appropriate OpenMP* directives to your source code.

OpenMP* directives use a specific format and syntax. Intel Extension Routines to OpenMP* describes the OpenMP* extensions to the specification that have been added to the Intel® Fortran Compiler.

The following syntax illustrates using the directives in your source.

```
Example

<prefix> <directive> [<clause>[[,]<clause>...]]
```

where:

• <prefix> - Required for all OpenMP* directives. For free form source input, the prefix is !$OMP only; for fixed form source input, the prefix is !$OMP or C$OMP.
• <directive> - A valid OpenMP* directive. Must immediately follow the prefix; for example: !$OMP PARALLEL.
• [<clause>] - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
• [<newline>] - A required component of directive syntax. It precedes the structured block which is enclosed by this directive.
• [,]: Optional. Commas between more than one <clause> are optional.

The directives are interpreted as comments if you omit the Qopenmp (Windows) or qopenmp (Linux* and macOS*) option.

The OpenMP* constructs defining a parallel region have one of the following syntax forms:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| !$OMP <directive>  
  <structured block of code>  
  !$OMP END <directive>  
  † OR  
  !$OMP <directive>  
  <structured block of code>  
  # OR  
  !$OMP <directive> |

The following example demonstrates one way of using an OpenMP* directive to parallelize a loop.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| subroutine simple_omp(a, N)  
  use omp_lib  
  integer :: N, a(N)  
  !$OMP PARALLEL DO  
  do i = 1, N  
    a(i) = i*2  
  end do  
  end subroutine simple_omp |

**Compile the Application**

The Qopenmp (Windows) or qopenmp (Linux* and macOS*) option enables the parallelizer to generate multi-threaded code based on the OpenMP* directives in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

The Qopenmp (Windows) or qopenmp (Linux* and macOS*) option works with both -O0 (Linux* and macOS*) and /Od (Windows*) and with any optimization level of O1, O2 and O3.

Specifying -O0 (Linux* and macOS*) or /Od (Windows*) with the Qopenmp (Windows) or qopenmp (Linux* and macOS*) option helps to debug OpenMP* applications.

Compile your application using commands similar to those shown below:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -qopenmp source_file</td>
</tr>
<tr>
<td>macOS*</td>
<td>ifort -qopenmp source_file</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort /Qopenmp source_file</td>
</tr>
</tbody>
</table>

Assume that you compile the sample above, using commands similar to the following, where the c option instructs the compiler to compile the code without generating an executable:
**Operating System** | **Extended Syntax Example**
--- | ---
Linux* | ifort -qopenmp -c parallel.f90
macOS* | ifort -qopenmp -c parallel.f90
Windows* | ifort /Qopenmp /c parallel.f90

The compiler might return a message similar to the following:

**Example**

parallel.f90(20) : (col. 6) remark: OpenMP DEFINED LOOP WAS PARALLELIZED.

**Configure the OpenMP* Environment**

Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP* environment variable, `OMP_NUM_THREADS`.

**See Also**

- O compiler option
- OpenMP* Examples
- qopenmp, Qopenmp compiler option

**Parallel Processing Model**

A program containing OpenMP* API compiler directives begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

In the OpenMP* API, the PARALLEL and END PARALLEL directives define the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the master of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the master thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP* constructs. The comments in the code explain the structure of each construct or section.

**Example**

```
PROGRAM MAIN                     ! Begin serial execution.
...                              ! Only the initial thread executes.
 !$OMP PARALLEL                  ! Begin a Parallel construct, form a team.
  ...                          ! This code is executed by each team member.
 !$OMP SECTIONS                 ! Begin a worksharing construct.
    !$OMP SECTION               ! One unit of work.
      ...                      !
```
Using Orphaned Directives

In routines called from within parallel constructs, you can also use directives. Directives that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned directives. Orphaned directives allow you to execute portions of your program in parallel with only minimal changes to the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:

```
Example

subroutine F
  ...
  !$OMP PARALLEL...
      call G
  ...
subroutine G
  !$OMP DO... ! This is an orphaned directive.
  ...
```

This is an orphaned DO directive since the parallel region is not lexically present in subroutine G.

Data Environment Controls

You can control the data environment within parallel and worksharing constructs. Using directives and data environment clauses on directives, you can privatize named global-lifetime objects by using THREADPRIVATE directive, or control data scope attributes by using the data environment clauses for directives that support them.

The data scope attribute clauses are:

- DEFAULT
- FIRSTPRIVATE
- IN_REDUCTION
The data copying clauses are:

- COPYIN
- COPYPRIVATE

The data motion clause is:

- MAP

The miscellaneous clauses are:

- ALIGNED
- COLLAPSE
- DEPEND
- DEVICE
- FINAL
- IF
- MERGEABLE
- NOWAIT
- PRIORITY
- UNTIED

You can use several directive clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a directive, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP® API specification, for the variables affected by the directive.

**Determining How Many Threads to Use**

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/video size and resolution, depth/breadth/bushiness of tree-based structures, and size of list based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer the number of threads to employ until application run-time when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex threads on the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has higher-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the NUM_THREADS clause on parallel regions to control the number of threads employed and use the IF clause on parallel regions to decide whether to employ multiple threads at all. The OMP_SET_NUM_THREADS routine can also be used, but it also affects parallel regions created by the calling thread. The NUM_THREADS clause is local in its effect, so it does not impact other parallel regions. The disadvantages of explicitly setting a number of threads are:
1. In a system with a large number of processors, your application will use some but not all of the processors.
2. In a system with a small number of processors, your application may force over subscription that results in poor performance.

The Intel OpenMP runtime will create the same number of threads as the available number of logical processors unless you use the OMP_SET_NUM_THREADS routine. To determine the actual limits, use OMP_GET_THREAD_LIMIT() and OMP_GET_MAX_ACTIVE_LEVELS(). Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The OMP_THREAD_LIMIT environment variable limits the number of OpenMP* threads to use for the whole OpenMP* program. The OMP_MAX.getActive_levels environment variable limits the number of active nested parallel regions.

**Binding Sets**

The various binding sets describe which OpenMP constructs can be nested in which other OpenMP constructs and what effect that nesting has.

The binding region for an OpenMP construct is the enclosing region that determines the execution context and the scope of the effects of the directive:
- The binding region for an ORDERED construct is the innermost enclosing DO loop region.
- The binding region for a TASKWAIT construct is the innermost enclosing TASK region.
- For all other constructs for which the binding thread set is the current team or the binding task set is the current team tasks, the binding region is the innermost enclosing PARALLEL region.
- For constructs for which the binding task set is the generating task, the binding region is the region of the generating task.
- A PARALLEL construct need not be active nor explicit to be a binding region.
- A TASK construct need not be explicit to be a binding region.
- A region never binds to any region outside of the innermost enclosing parallel region.

The binding task set for an OpenMP construct is the set of tasks that are affected by, or provide the context for, the execution of a region. The binding task set for a given construct can be all tasks, the current team tasks, or the generating task.

The binding thread set for an OpenMP construct is the set of threads that are affected by, or provide the context for, the execution of a region. The binding thread set for a given construct can be all threads on a device, all threads in a contention group, the current team, or the encountering thread.

**Controlling Thread Allocation**

The KMP_HW_SUBSET and KMP_AFFINITY environment variables allow you to control how the OpenMP* runtime uses the hardware threads on the processors. These environment variables allow you to try different thread distributions on the cores of the processors and determine how these threads are bound to the cores. You can use the environment variables to work out what is optimal for your application.

The KMP_HW_SUBSET variable controls the allocation of hardware resources and the KMP_AFFINITY variable controls how the OpenMP* threads are bound to those resources.

**Controlling Thread Distribution**

The KMP_HW_SUBSET variable controls the hardware resource that will be used by the program. This variable specifies the number of sockets to use, how many cores to use per socket and how many threads to assign per core. For example, on Intel® Xeon Phi™ coprocessors, while each coprocessor can take up to four threads, specifying fewer than four threads per core may result in a better performance. While specifying two threads per core often yields better performance than one thread per core, specifying three or four threads per core may or may not improve the performance. This variable enables you to conveniently measure the performance of up to four threads per core.
For example, you can determine the effects of assigning 24, 48, 72, or the maximum 96 OpenMP* threads in a system with 24 cores by specifying the following variable settings:

<table>
<thead>
<tr>
<th>To Assign This Number of Threads ...</th>
<th>... Use This Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>KMP_HW_SUBSET=24c,1t</td>
</tr>
<tr>
<td>48</td>
<td>KMP_HW_SUBSET=24c,2t</td>
</tr>
<tr>
<td>72</td>
<td>KMP_HW_SUBSET=24c,3t</td>
</tr>
<tr>
<td>96</td>
<td>KMP_HW_SUBSET=24c,4t</td>
</tr>
</tbody>
</table>

NOTE
Take care when using the OMP_NUM_THREADS variable along with this variable. Using the OMP_NUM_THREADS variable can result in over or under subscription.

Controlling Thread Bindings
The KMP_AFFINITY variable controls how the OpenMP* threads are bound to the hardware resources allocated by the KMP_HW_SUBSET variable. While this variable can be set to several binding or affinity types, the following are the recommended affinity types to use to run your OpenMP* threads on the processor:

- **compact**: sequentially distribute the threads among the cores that share the same cache.
- **scatter**: distribute the threads among the cores without regard to the cache.

The following table shows how the threads are bound to the cores when you want to use three threads per core on two cores by specifying KMP_HW_SUBSET=2c,3t:

<table>
<thead>
<tr>
<th>Affinity</th>
<th>OpenMP* Threads on Core 0</th>
<th>OpenMP* Threads on Core 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_AFFINITY=compact</td>
<td>0, 1, 2</td>
<td>3, 4, 5</td>
</tr>
<tr>
<td>KMP_AFFINITY=scatter</td>
<td>0, 2, 4</td>
<td>1, 3, 5</td>
</tr>
</tbody>
</table>

Determining the Best Setting
To determine the best thread distribution and bindings using these variables, use the following:

1. Ensure that your OpenMP* code is working properly before using these environment variables.
2. Establish a baseline with your current OpenMP* code to compare to the performance when you allocate the threads to a processor.
3. Measure the performance of distributing one, two, three, or four threads per core by use the KMP_HW_SUBSET variable.
4. Measure the performance of binding the threads to the cores by using the KMP_AFFINITY variable.

Supported Environment Variables
**OpenMP* Directives Summary**

This is a summary of the OpenMP* directives supported in the Intel® Fortran Compiler. For detailed information about the OpenMP* API, see the *OpenMP Application Program Interface Version TR4: Version 5.0* specification, which is available from the OpenMP* web site.

In the directive lists below, an OpenMP directive is qualified with the word **Directive** when the name of the directive is also used for one or more elements besides the directive. For example: FLUSH refers to a directive, a statement, and a subroutine.

**PARALLEL Directive**

Use this directive to form a team of threads and execute those threads in parallel.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARALLEL Directive (OpenMP*)</td>
<td>Defines a parallel region.</td>
</tr>
</tbody>
</table>

**TASKING Directives**

Use this directive for deferring execution.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TASK</td>
<td>Defines a task region.</td>
</tr>
<tr>
<td>TASKLOOP</td>
<td>Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.</td>
</tr>
</tbody>
</table>

**WORKSHARING Directives**

Use these directives to share work among a team of threads.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO Directive</td>
<td>Identifies an iterative worksharing construct in which the iterations of the associated loop should be divided among threads in a team.</td>
</tr>
<tr>
<td>SECTIONS</td>
<td>Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>Specifies that a block of code is to be executed by only one thread in the team at a time.</td>
</tr>
<tr>
<td>WORKSHARE</td>
<td>Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.</td>
</tr>
</tbody>
</table>

**SYNCHRONIZATION Directives**

Use these directives to synchronize between threads.
### Directive Description

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC</td>
<td>Ensures that a specific memory location is updated atomically; this prevents the possibility of multiple, simultaneous reading and writing of threads.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.</td>
</tr>
<tr>
<td>CRITICAL Directive</td>
<td>Restricts access to a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>FLUSH Directive</td>
<td>Identifies synchronization points at which the threads in a team must provide a consistent view of memory.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.</td>
</tr>
<tr>
<td>TASKGROUP</td>
<td>Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.</td>
</tr>
<tr>
<td>TASKWAIT</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>TASKYIELD</td>
<td>Specifies that the current task can be suspended at this point in favor of execution of a different task.</td>
</tr>
</tbody>
</table>

### Data Environment Directive

Use this directive to give threads global private data.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THREADPRIVATE</td>
<td>Specifies named common blocks to be private (local) to each thread; they are global within the thread.</td>
</tr>
</tbody>
</table>

### Offload Target Control Directives

Use these directives to control execution on one or more offload targets.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECLARE TARGET</td>
<td>Specifies named routines and variables that are created or mapped to a device. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>DISTRIBUTED</td>
<td>Specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a teams construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET Directive</td>
<td>Creates a device data environment and executes the construct on that device. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET DATA</td>
<td>Maps variables to a device data environment for the extent of the region. This directive only applies to Intel® MIC Architecture.</td>
</tr>
</tbody>
</table>
### Directive | Description
---|---
**TARGET ENTER DATA** | Specifies that variables are mapped to a device data environment. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**TARGET EXIT DATA** | Specifies that variables are unmapped from a device data environment. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**TARGET UPDATE** | Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies to Intel® MIC Architecture.

**TEAMS** | Creates a league of thread teams inside a target region to execute a structured block in the master thread of each team. This directive only applies to Intel® MIC Architecture.

### Vectorization Directives
Use these directives to control execution on vector hardware.

| Directive | Description |
---|---|
**SIMD Directive (OpenMP*)** | Transforms the loop into a loop that will be executed concurrently using SIMD instructions. The *EARLY_EXIT* clause is an Intel-specific extension of the OpenMP* specification. *EARLY_EXIT*

- Allows vectorization of multiple exit loops. When this clause is specified:
  - Each operation before last lexical early exit of the loop may be executed as if early exit were not triggered within the SIMD chunk.
  - After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
  - Each list item specified in the *LINEAR* clause is computed based on the last iteration number upon exiting the loop.
  - The last value for *LINEARS* and conditional *LASTPRIVATE*s are preserved with respect to scalar execution.
  - The last value for *REDUCTION*s are computed as if the last iteration in the last SIMD chunk was executed up on exiting the loop.
  - The shared memory state may not be preserved with regard to scalar execution.
  - Exceptions are not allowed.

**DECLARE SIMD** | Generates a SIMD procedure.
Cancellation Constructs

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CANCEL</td>
<td>Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering task to proceed to the end of the cancelled construct.</td>
</tr>
<tr>
<td>CANCELLATION POINT</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.</td>
</tr>
</tbody>
</table>

Combined Directives

Use these directives as shortcuts for multiple directives in sequence. A combined construct is a shortcut for specifying one construct immediately nested inside another construct. A combined construct is semantically identical to that of explicitly specifying the first construct containing one instance of the second construct and no other statements.

A composite construct is composed of two constructs but does not have identical semantics to specifying one of the constructs immediately nested inside the other. A composite construct either adds semantics not included in the constructs from which it is composed or the nesting of the one construct inside the other is not conforming.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISTRIBUTE PARALLEL DO</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO SIMD</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DISTRIBUTE SIMD</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Provides an abbreviated way to specify a parallel region containing a single DO directive.</td>
</tr>
<tr>
<td>PARALLEL DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.</td>
</tr>
<tr>
<td>PARALLEL SECTIONS</td>
<td>Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.</td>
</tr>
<tr>
<td>PARALLEL WORKSHARE</td>
<td>Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.</td>
</tr>
<tr>
<td>Directive</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TARGET PARALLEL</td>
<td>Creates a device data environment in a parallel region and executes the construct on that device. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TARGET PARALLEL DO</td>
<td>Provides an abbreviated way to specify a TARGET construct that contains a PARALLEL DO construct and no other statement between them.</td>
</tr>
<tr>
<td>TARGET PARALLEL DO SIMD</td>
<td>Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement between them.</td>
</tr>
<tr>
<td>TARGET SIMD</td>
<td>Specifies a TARGET construct that contains a SIMD construct and no other statement between them.</td>
</tr>
<tr>
<td>TARGET TEAMS</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).</td>
</tr>
<tr>
<td>TASKLOOP SIMD ¹</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP® tasks.</td>
</tr>
<tr>
<td>Directive</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies that loop iterations will be distributed among the master threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE SIMD</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams.</td>
</tr>
</tbody>
</table>

Footnotes:

1 This directive specifies a composite construct.

**OpenMP** Library Support

**OpenMP** Run-time Library Routines

OpenMP provides run-time library routines to help you manage your program in parallel mode. Many of these run-time library routines have corresponding environment variables that can be set as defaults. The run-time library routines let you dynamically change these factors to assist in controlling your program. In all cases, a call to a run-time library routine overrides any corresponding environment variable. These routines are all external procedures.

**Caution**

Running OpenMP runtime library routines may initialize the OpenMP runtime environment, which might cause a situation where subsequent programmatic setting of OpenMP environment variables has no effect. To avoid this situation, you can use the Intel extension routine `kmp_set_defaults()` to set OpenMP environment variables.

The compiler supports all the OpenMP run-time library routines. Refer to the OpenMP API specification for detailed information about using these routines.

Include the appropriate declarations of the routines in the program unit containing the routine by adding a statement similar to the following:

```
use omp_lib
```

The compiler provides module files in the ..\include (Linux* and macOS*) or ..\include (Windows*) directory of your compiler installation.
The integer parameter openmp_version in omp_lib.mod (and omp_lib.h, an INCLUDE version of omp_lib.mod) has the decimal value yyyymm where yyyy and mm are the year and month of the version of the OpenMP API supported by the current version of the compiler and libraries. See the predefined preprocessor symbol _OPENMP for more information.

**NOTE**

Some of the routines interfaces have offload equivalents. The offload equivalent takes two additional arguments to specify the target type and target number. For more information, see [Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment](#).

The following table lists the keys that specify the data types of the dummy arguments for each of the listed routines:

<table>
<thead>
<tr>
<th>Key</th>
<th>OMP_LIB Kind</th>
<th>BIND(C) Kind</th>
<th>KIND=</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER ( int )</td>
<td>OMP_INTEGER_KIND_D</td>
<td>C_INT</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL ( log )</td>
<td>OMP_LOGICAL_KIND_D</td>
<td></td>
<td>4</td>
</tr>
<tr>
<td>REAL ( dp )</td>
<td>DOUBLE PRECISION</td>
<td>C_DOUBLE</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER(OMP_LOCK_KIND)</td>
<td>C_INTPTR_T</td>
<td>intptr_t &lt;&lt;1&gt;&gt;</td>
<td></td>
</tr>
<tr>
<td>INTEGER(OMP_NEST_LOCK_KIND)</td>
<td>C_INTPTR_T</td>
<td>intptr_t &lt;&lt;1&gt;&gt;</td>
<td></td>
</tr>
<tr>
<td>INTEGER (OMP_SCHED_KIND)</td>
<td>OMP_INTEGER_KIND_D</td>
<td>C_INT</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(OMP_PROC_BIND_KIND)</td>
<td>OMP_INTEGER_KIND_D</td>
<td>C_INT</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(OMP_LOCK_HINT_KIND)</td>
<td>C_INTPTR_T</td>
<td>intptr_t &lt;&lt;1&gt;&gt;</td>
<td></td>
</tr>
</tbody>
</table>

intptr_t is an integer that is large enough to hold a pointer (address). With the Intel® Fortran Compiler, this is INTEGER(4) when building a 32-bit application and INTEGER(8) when building a 64-bit application. It is the value returned by the Intel Fortran intrinsic INT_PTR_KIND().

### Execution Environment Routines

Use these routines to monitor and influence threads and the parallel environment.

<table>
<thead>
<tr>
<th>Routine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBROUTINE OMP_SET_NUM_THREADS(num_threads)</td>
<td>Sets the number of threads to use for subsequent parallel regions created by the calling thread.</td>
</tr>
<tr>
<td>INTEGER(int) num_threads</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_DYNAMIC(dynamic_threads)</td>
<td>Enables or disables dynamic adjustment of the number of threads used to execute a parallel region. If dynamic_threads is .TRUE., dynamic threads are enabled. If dynamic_threads is .FALSE., dynamic threads are disabled by default.</td>
</tr>
<tr>
<td>LOGICAL dynamic_threads</td>
<td></td>
</tr>
<tr>
<td>Routine</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_NESTED(nested) LOGICAL(log) nested</td>
<td>Enables or disables nested parallelism. If \textit{nested} is \texttt{.TRUE.}, nested parallelism is enabled. If \textit{nested} is \texttt{.FALSE.}, nested parallelism is disabled. Nested parallelism is disabled by default.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_NUM_THREADS()</td>
<td>Returns the number of threads that are being used in the current parallel region. This function does not necessarily return the value inherited by the calling thread from the \texttt{OMP_SET_NUM_THREADS()} function.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_MAX_THREADS()</td>
<td>Returns the number of threads available to subsequent parallel regions created by the calling thread.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_THREAD_NUM()</td>
<td>Returns the thread number of the calling thread, within the context of the current parallel region.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_NUM_PROCS()</td>
<td>Returns the number of processors available to the program.</td>
</tr>
<tr>
<td>LOGICAL(log) FUNCTION OMP_IN_PARALLEL()</td>
<td>Returns \texttt{.TRUE.} if called within the dynamic extent of a parallel region executing in parallel; otherwise returns \texttt{.FALSE.}.</td>
</tr>
<tr>
<td>LOGICAL(log) FUNCTION OMP_IN_FINAL()</td>
<td>Returns \texttt{.TRUE.} if called within a final task region; otherwise returns \texttt{.FALSE.}.</td>
</tr>
<tr>
<td>LOGICAL(log) FUNCTION OMP_GET_DYNAMIC()</td>
<td>Returns \texttt{.TRUE.} if dynamic thread adjustment is enabled, otherwise returns \texttt{.FALSE.}.</td>
</tr>
<tr>
<td>LOGICAL FUNCTION OMP_GET_NESTED()</td>
<td>Returns \texttt{.TRUE.} if nested parallelism is enabled, otherwise returns \texttt{.FALSE.}.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_THREAD_LIMIT()</td>
<td>Returns the maximum number of simultaneously executing threads in an OpenMP* program.</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_MAX_ACTIVE_LEVELS(max_active_levels) INTEGER max_active_levels</td>
<td>Limits the number of nested active parallel regions. The call is ignored if negative \texttt{max_active_levels} specified.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_MAX_ACTIVE_LEVELS()</td>
<td>Returns the maximum number of nested active parallel regions.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_LEVEL()</td>
<td>Returns the number of nested parallel regions (whether active or inactive) enclosing the task that contains the call, not including the implicit parallel region.</td>
</tr>
<tr>
<td>Routine</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_ACTIVE_LEVEL()</td>
<td>Returns the number of nested, active parallel regions enclosing the task that contains the call.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_ANCESTOR_THREAD_NUM(level) INTEGER level</td>
<td>Returns the thread number of the ancestor at a given nest level of the current thread.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_TEAM_SIZE(level) INTEGER level</td>
<td>Returns the size of the thread team to which the ancestor or the current thread belongs for the specified nested level of the current thread.</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_SCHEDULE(kind,chunk_size) INTEGER(KIND=omp_sched_kind) kind INTEGER(int) chunk_size</td>
<td>Determines the schedule of a worksharing loop that is applied when 'runtime' is used as the schedule kind.</td>
</tr>
<tr>
<td>SUBROUTINE OMP_GET_SCHEDULE(kind,chunk_size) INTEGER(KIND=omp_sched_chunk_size) kind INTEGER(int) chunk_size</td>
<td>Returns the schedule of a worksharing loop that is applied when the 'runtime' schedule is used.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_PROC_BIND_KIND) OMP_GET_PROC_BIND()</td>
<td>Returns the currently active thread affinity policy, which is set by environment variable OMP_PROC_BIND. This policy is used for subsequent nested parallel regions.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_NUM_PLACES()</td>
<td>Returns the number of places available to the execution environment in the place list of the initial task, usually threads, cores, or sockets.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_PLACE_NUM_PROCS(place_num) INTEGER(int) place_num</td>
<td>Returns the number of processors associated with the place numbered place_num. The routine returns zero when place_num is negative or is greater than or equal to OMP_GET_NUM_PLACES().</td>
</tr>
<tr>
<td>SUBROUTINE OMP_GET_PLACE_PROC_IDS(place_num,ids) INTEGER(int) place_num INTEGER(int) ids(*)</td>
<td>Returns the numerical identifiers of each processor associated with the place numbered place_num. The numerical identifiers are non-negative and their meaning is implementation defined. The numerical identifiers are returned in the array ids and their order in the array is implementation defined. ids must have at least OMP_GET_PLACE_NUM_PROCS(place_num) elements. The routine has no effect when place_num is greater than or equal to OMP_GET_NUM_PLACES().</td>
</tr>
<tr>
<td>Routine</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_PLACE_NUM()</td>
<td>Returns the place number of the place to which the encountering thread is bound. The returned value is between 0 and OMP_GET_NUM_PLACES() - 1, inclusive. When the encountering thread is not bound to a place, the routine returns -1.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_DEFAULT_DEVICE()</td>
<td>Returns the default device number.</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_DEFAULT_DEVICE(device_number)</td>
<td>Sets the default device number.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_NUM_DEVICES()</td>
<td>Gets the number of target devices.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_NUM_TEAMS()</td>
<td>Gets the number of teams in the current teams region.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_TEAM_NUM()</td>
<td>Gets the team number of the calling thread.</td>
</tr>
<tr>
<td>LOGICAL(log) FUNCTION OMP_GET_CANCELLATION()</td>
<td>Returns .TRUE. if cancellation is enabled; otherwise, .FALSE.. This routine can be affected by the setting for environment variable OMP_CANCELLATION.</td>
</tr>
<tr>
<td>LOGICAL(log) FUNCTION OMP_IS_INITIAL_DEVICE()</td>
<td>Returns .TRUE. if the current task is running on the host device; otherwise, .FALSE..</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_INITIAL_DEVICE()</td>
<td>Returns the device number of the host device. The value of the device number is implementation defined. If it is between 0 and OMP_GET_NUM_DEVICES()-1, then it is valid in all device constructs and routines; if it is outside that range, then it is only valid in the device memory routines and not in the DEVICE clause.</td>
</tr>
<tr>
<td>INTEGER(int) FUNCTION OMP_GET_MAX_TASK_PRIORITY()</td>
<td>Returns the maximum value that can be specified in the PRIORITY clause.</td>
</tr>
</tbody>
</table>

**Lock Routines**

Use these routines to affect OpenMP* locks.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBROUTINE OMP_INIT_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND)svar</td>
<td>Initializes the lock associated with the simple lock variable svar for use in subsequent calls.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>SUBROUTINE OMP_INIT_LOCK_WITH_HINT(svar, hint)</td>
<td>Initializes the lock associated with svar to the unlocked state, optionally choosing a specific lock implementation based on hint.</td>
</tr>
<tr>
<td>INTEGER (KIND=OMP_LOCK_KIND) svar</td>
<td></td>
</tr>
<tr>
<td>INTEGER (KIND=OMP_LOCK_HINT_KIND) hint</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_DESTROY_LOCK(svar)</td>
<td>Causes the lock specified by svar to become undefined or uninitialized. The lock must be initialized and not locked.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_LOCK_KIND)svar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_LOCK(svar)</td>
<td>Forces the executing thread to wait until the lock associated with svar is available. The thread is granted ownership of the lock when it becomes available. The lock must be initialized.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_LOCK_KIND)svar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_UNSET_LOCK(svar)</td>
<td>Releases the executing thread from ownership of the lock associated with svar. The behavior is undefined if the executing thread does not own the lock associated with svar.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_LOCK_KIND)svar</td>
<td></td>
</tr>
<tr>
<td>LOGICAL(log) OMP_TEST_LOCK(svar)</td>
<td>Attempts to set the lock associated with svar. If successful, returns .TRUE., otherwise returns .FALSE.. The lock must be initialized.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_LOCK_KIND)svar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_INIT_NEST_LOCK(nvar)</td>
<td>Initializes the nested lock associated with the nested lock variable nvar for use in the subsequent calls.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_INIT_NEST_LOCK_WITH_HINT(nvar, hint)</td>
<td>Initializes the nested lock associated with nvar to the unlocked state, optionally choosing a specific lock implementation based on hint. The nesting count for nvar is set to zero.</td>
</tr>
<tr>
<td>INTEGER (KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
<tr>
<td>INTEGER (KIND=OMP_LOCK_HINT_KIND)hint</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_DESTROY_NEST_LOCK(nvar)</td>
<td>Causes the nested lock associated with nvar to become undefined or uninitialized. The lock must be initialized and not locked.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_NEST_LOCK(nvar)</td>
<td>Forces the executing thread to wait until the nested lock associated with nvar is available. If the thread already owns the lock, then the lock nesting count is incremented. The lock must be initialized.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE OMP_UNSET_NEST_LOCK(nvar)</td>
<td>Releases the executing thread from ownership of the nested lock associated with nvar if the nesting count is zero; otherwise, the nesting count is decremented. Behavior is undefined if the executing thread does not own the nested lock associated with nvar.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
<tr>
<td>INTEGER(int) OMP_TEST_NEST_LOCK(nvar)</td>
<td>Attempts to set the nested lock specified by nvar. If successful, returns the nesting count, otherwise returns zero.</td>
</tr>
<tr>
<td>INTEGER(KIND=OMP_NEST_LOCK_KIND)nvar</td>
<td></td>
</tr>
</tbody>
</table>
Timing Routines

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL (dp) FUNCTION OMP_GET_WTIME()</td>
<td>Returns a double precision value equal to the elapsed wall clock time (in seconds) relative to an arbitrary reference time. The reference time does not change during program execution.</td>
</tr>
<tr>
<td>REAL (dp) FUNCTION OMP_GET_WTICK()</td>
<td>Returns a double precision value equal to the number of seconds between successive clock ticks.</td>
</tr>
</tbody>
</table>

The following parameter constants are defined in OMP_LIB.MOD and can be set or returned in the KIND dummy argument in OMP_SET_SCHEDULE and OMP_GET_SCHEDULE:

- integer(omp_sched_kind), parameter :: omp_sched_static = 1
- integer(omp_sched_kind), parameter :: omp_sched_dynamic = 2
- integer(omp_sched_kind), parameter :: omp_sched_guided = 3
- integer(omp_sched_kind), parameter :: omp_sched_auto = 4

The following parameter constants are defined in OMP_LIB.MOD and represent values returned by OMP_GET_PROC_BIND:

- integer (omp_proc_bind_kind), parameter :: omp_proc_bind_false = 0
- integer (omp_proc_bind_kind), parameter :: omp_proc_bind_true = 1
- integer (omp_proc_bind_kind), parameter :: omp_proc_bind_master = 2
- integer (omp_proc_bind_kind), parameter :: omp_proc_bind_close = 3
- integer (omp_proc_bind_kind), parameter :: omp_proc_bind_spread = 4

The following parameter constants are defined in OMP_LIB.MOD and can be set in the HINT dummy argument in OMP_INIT_LOCK_WITH_HINT and OMP_INIT_NEST_LOCK_WITH_HINT:

- integer (omp_lock_hint_kind), parameter :: omp_lock_hint_none = 0
- integer (omp_lock_hint_kind), parameter :: omp_lock_hint_uncontended = 1
- integer (omp_lock_hint_kind), parameter :: omp_lock_hint_contended = 2
- integer (omp_lock_hint_kind), parameter :: omp_lock_hint_nonspeculative = 4
- integer (omp_lock_hint_kind), parameter :: omp_lock_hint_speculative = 8

The hints can be combined by using the + operator in Fortran. The effect of the combined hint is implementation defined. Combining omp_lock_hint_none with any other hint is equivalent to specifying the other hint. The following restrictions apply to combined hints:

- Hints omp_lock_hint_uncontended and omp_lock_hint_contended cannot be combined.
- Hints omp_lock_hint_nonspeculative and omp_lock_hint_nonspeculative cannot be combined.

Intel® Compiler Extension Routines to OpenMP*

The Intel compiler implements the following group of routines as extensions to the OpenMP* run-time library:

- Get and set the execution environment
- Get and set the stack size for parallel threads
- Memory allocation
- Get and set the thread sleep time for the throughput execution mode
The Intel extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in the other compiler. To execute these OpenMP* routines, use the `openmp-stubs` option.

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the `OMP_STACKSIZE` environment variable rather than the `KMP_SET_STACKSIZE_S()` library routine.

**NOTE**  
A run-time call to an Intel extension routine takes precedence over the corresponding environment variable setting.

### Execution Environment

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBROUTINE KMP_SET_DEFAULTS(STRING) CHARACTER*(*) STRING</td>
<td>Sets OpenMP* environment variables defined as a list of variables separated by &quot;</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_THROUGHPUT()</td>
<td>Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_TURNAROUND()</td>
<td>Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_SERIAL()</td>
<td>Sets execution mode to serial.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY(LIBNUM) INTEGER (KIND=OMP_INTEGER_KIND) LIBNUM</td>
<td>Sets execution mode indicated by the value passed to the function. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• 1 - serial mode</td>
</tr>
<tr>
<td></td>
<td>• 2 - turnaround mode</td>
</tr>
<tr>
<td></td>
<td>• 3 - throughput mode</td>
</tr>
<tr>
<td>Call this routine before the first parallel region is executed.</td>
<td></td>
</tr>
<tr>
<td>FUNCTION KMP_GET_LIBRARY() INTEGER (KIND=OMP_INTEGER_KIND) KMP_GET_LIBRARY</td>
<td>Returns a value corresponding to the current execution mode:</td>
</tr>
<tr>
<td></td>
<td>• 1 - serial</td>
</tr>
<tr>
<td></td>
<td>• 2 - turnaround</td>
</tr>
<tr>
<td></td>
<td>• 3 - throughput</td>
</tr>
</tbody>
</table>

### Stack Size

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION KMP_GET_STACKSIZE_S() INTEGER(KIND=KMP_SIZE_T_KIND) &amp; KMP_GET_STACKSIZE_S</td>
<td>Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with</td>
</tr>
</tbody>
</table>
FUNCTION KMP_GET_STACKSIZE()
INTEGER KMP_GET_STACKSIZE

SUBROUTINE KMP_SET_STACKSIZE_S(size)
INTEGER (KIND=KMP_SIZE_T_KIND)size

SUBROUTINE KMP_SET_STACKSIZE_S(size)
INTEGER size

Memory Allocation

The Intel compiler implements a group of memory allocation routines as an extension to the OpenMP* runtime library to enable threads to allocate memory from a heap local to each thread. These routines are: KMP_MALLOC(), KMP_CALLOC(), and KMP_REALLOC().

The memory allocated by these routines must also be freed by the KMP_FREE() routine. While you can allocate memory in one thread and then free that memory in a different thread, this mode of operation incurs a slight performance penalty.

Working with the local heap might lead to improved application performance because synchronization is not required.

SUBROUTINE KMP_FREE(ptr)
INTEGER (KIND=KMP_POINTER_KIND)ptr

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION KMP_MALLOC(size)</td>
<td>Allocate memory block of size bytes from thread-local heap.</td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_POINTER_KIND)KMP_MALLOC</td>
<td></td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_SIZE_T_KIND)size</td>
<td></td>
</tr>
<tr>
<td>FUNCTION KMP_CALLOC(nelem,elsize)</td>
<td>Allocate array of nelem elements of size elsize from thread-local heap.</td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_POINTER_KIND)KMP_CALLOC</td>
<td></td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_SIZE_T_KIND)nelem</td>
<td></td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_SIZE_T_KIND)elsize</td>
<td></td>
</tr>
<tr>
<td>FUNCTION KMP_REALLOC(ptr, size)</td>
<td>Reallocate memory block at address ptr and size bytes from thread-local heap.</td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_POINTER_KIND)KMP_REALLOC</td>
<td></td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_POINTER_KIND)ptr</td>
<td></td>
</tr>
<tr>
<td>INTEGER(KIND=KMP_SIZE_T_KIND)size</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE KMP_FREE(ptr)</td>
<td>Free memory block at address ptr from thread-local heap.</td>
</tr>
<tr>
<td>INTEGER (KIND=KMP_POINTER_KIND)ptr</td>
<td></td>
</tr>
</tbody>
</table>
Memory must have been previously allocated with KMP_MALLOC(), KMP_CALLOC(), or KMP_REALLOC().

Thread Sleep Time
In the throughput OpenMP* Support Libraries, threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the KMP_BLOCKTIME environment variable or by the KMP_SET_BLOCKTIME() function.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function KMP_GET_BLOCKTIME(\n  INTEGER KMP_GET_BLOCKTIME)</td>
<td>Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the KMP_BLOCKTIME environment variable or by KMP_SET_BLOCKTIME().</td>
</tr>
<tr>
<td>FUNCTION KMP_SET_BLOCKTIME(msec)\n  INTEGER msec</td>
<td>Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP* team threads formed by the calling thread. The routine does not affect the block time for any other threads.</td>
</tr>
</tbody>
</table>

OpenMP* Run-time Library Routines
OpenMP* Support Libraries

OpenMP* Support Libraries
The Intel® Compiler provides support libraries for OpenMP*. There are several kinds of libraries:

- **Performance**: supports parallel OpenMP* execution.
- **Stubs**: supports serial execution of OpenMP* applications.

Each kind of library is available for both dynamic and static linking on Linux* and macOS* operating systems. Only dynamic linking is supported on Windows* operating systems.

Performance Libraries
To use these libraries, specify the [Q]openmp compiler option.

Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.
Many routines in the OpenMP* support libraries are more optimized for Intel® microprocessors than for non-Intel microprocessors.

**Stubs Libraries**

To use these libraries, specify -[Q]openmp-stubs compiler option. These allow you to compile OpenMP* applications in serial mode and provide stubs for OpenMP* routines and extended Intel-specific routines.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Dynamic Link</th>
<th>Static Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>libiompstubs5.so</td>
<td>libiompstubs5.a</td>
</tr>
<tr>
<td>macOS*</td>
<td>libiompstubs5.dylib</td>
<td>libiompstubs5.a</td>
</tr>
<tr>
<td>Windows*</td>
<td>libiompstubs5md.lib</td>
<td>libiompstubs5md.dll</td>
</tr>
</tbody>
</table>

**Execution modes**

The Intel® Compiler enables you to run an application under different execution modes specified at run time; the libraries support the turnaround, throughput, and serial modes. Use the KMP_LIBRARY environment variable to select the modes at run time.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>throughput (default)</td>
<td>The throughput mode allows the program to yield to other running programs and adjust resource usage to produce efficient execution in a dynamic environment.</td>
</tr>
<tr>
<td></td>
<td>In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work.</td>
</tr>
<tr>
<td></td>
<td>After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications.</td>
</tr>
<tr>
<td></td>
<td>The amount of time to wait before sleeping is set either by the KMP_BLOCKTIME environment variable or by the KMP_SET_BLOCKTIME() function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP* execution, but may penalize other concurrently-running OpenMP* or threaded applications.</td>
</tr>
</tbody>
</table>
### Mode Description

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>turnaround</strong></td>
<td>The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads (although they are still subject to KMP_BLOCKTIME control). In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time.</td>
</tr>
<tr>
<td><strong>serial</strong></td>
<td>The serial mode forces parallel applications to run as a single thread.</td>
</tr>
</tbody>
</table>

**NOTE**
Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at run time. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.

**Supported Environment Variables**

**Using the OpenMP* Libraries**

This section describes the steps needed to set up and use the OpenMP* Libraries from the command line. On Windows* systems, you can also build applications compiled with the OpenMP libraries in the Microsoft Visual Studio* development environment.

For a summary of the support provided by the libraries provided with Intel compilers, see OpenMP* Source Compatibility and Interoperability with Other Compilers.

For a list of the options and libraries used by the OpenMP* libraries, see OpenMP* Support Libraries.

Set up your environment for access to the Intel® Fortran Compiler to ensure that the appropriate OpenMP* library is available during linking. On Windows* systems, you can either execute the appropriate batch (.bat) file or use the command-line window supplied in the compiler program folder that already has the environment set up. On Linux* and macOS* systems, you can source the appropriate script file (ifortvars file).

To use the gfortran compiler with the Intel OpenMP library along with the OpenMP* API functions, do the following:

1. Use the use omp_lib statement to compile the omp_lib.f90 source file, which is in the Intel® Fortran Compiler include directory.  
2. Add the -I option to the compile command line with appropriate path to the directory containing the resulting module file.

During compilation, ensure that the version of omp_lib.h or omp_lib.mod used when compiling is the version provided by that compiler.

**Caution**
Be aware that when using the gcc* or Microsoft* compiler, you may inadvertently use inappropriate header/module files. To avoid this, copy the header/module file(s) to a separate directory and put it in the appropriate include path using the -I option.
If a program uses data structures or classes that contain members with data types defined in `omp_lib.h` file, then source files that use those data structures should all be compiled with the same `omp_lib.h` file.

The command for the Intel® Fortran Compiler is `ifort`.

For information on the OpenMP* libraries and options used by the Intel® Fortran Compiler, see OpenMP* Support Libraries.

**Command-Line Examples, Windows***

To compile and link (build) the entire application with one command using the Compatibility libraries, specify the following Intel® Fortran Compiler command:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source, dynamic link</td>
<td><code>ifort /MD /Qopenmp hello.f90</code></td>
</tr>
</tbody>
</table>

When using the Microsoft* Visual C++* compiler, you should link with the Intel OpenMP compatibility library. You need to avoid linking the Microsoft* OpenMP run-time library (`vcomp`) and explicitly pass the name of the Intel OpenMP compatibility library as linker options (following `/link`):

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source, dynamic link</td>
<td><code>cl /MD /openmp hello.c /link /nodefaultlib:vcomp libiomp5md.lib</code></td>
</tr>
</tbody>
</table>

You can also use the Intel® Fortran Compiler with the Visual C++* compiler to compile parts of the application and create object files (object-level interoperability). In this example, the Intel® Fortran Compiler compiles and links the entire application:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources,</td>
<td><code>cl /MD /openmp /c f1.c f2.c</code></td>
</tr>
<tr>
<td>dynamic link</td>
<td><code>ifort /MD /Qopenmp /c f3.f f4.f</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort /MD /Qopenmp f1.obj f2.obj f3.obj f4.obj /Feapp /link /nodefaultlib:vcomp</code></td>
</tr>
</tbody>
</table>

The first command produces two object files compiled by Visual C++* compiler, and the second command produces two more object files compiled by the Intel® Fortran Compiler. The final command links all four object files into an application.

Alternatively, the third line below uses the Visual C++* linker to link the application and specifies the Compatibility library `libiomp5md.lib` at the end of the third command:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources,</td>
<td><code>cl /MD /openmp /c f1.c f2.c</code></td>
</tr>
<tr>
<td>dynamic link</td>
<td><code>ifort /MD /Qopenmp /c f3.f f4.f</code></td>
</tr>
<tr>
<td></td>
<td><code>link f1.obj f2.obj f3.obj f4.obj /out:app.exe /nodefaultlib:vcomp libiomp5md.lib</code></td>
</tr>
</tbody>
</table>

The following example shows the use of interprocedural optimization by the Intel® Fortran Compiler on several files, the Visual C++* compiler compiles several files, and the Visual C++* linker links the object files to create the executable:
<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources, dynamic link</td>
<td><code>ifort /MD /Qopenmp /O3 /Qipo /Qipo-c f1.f f2.f f3.f</code>&lt;br&gt;<code>cl /MD /openmp /O2 /c f4.c f5.c</code>&lt;br&gt;<code>cl /MD /openmp /O2 ipo_out.obj f4.obj f5.obj /Feapp /link /nodefaultlib:vcomp libiomp5md.lib</code></td>
</tr>
</tbody>
</table>

The first command uses the Intel® Fortran Compiler to produce an optimized multi-file object file named `ipo_out.obj` by default (the `/Fe` option is not required). The second command uses the Visual C++* compiler to produce two more object files. The third command uses the Visual C++* `cl` command to link all three object files using the Intel® Fortran Compiler OpenMP library.

### Command-Line Examples, Linux*

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® Fortran Compiler command on Linux* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source</td>
<td><code>ifort -qopenmp hello.f90</code></td>
</tr>
</tbody>
</table>

By default, the Intel® Fortran Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The Intel® Fortran Compiler option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and macOS* systems (default is `-qopenmp-link=dynamic`).

You can also use the Intel® C++ Compiler `icc/icpc` with `gcc/g++` compilers to compile parts of the application and create object files (object-level interoperability).

In this example, `gcc` compiles the C file `foo.c` (the `gcc` option `-fopenmp` enables OpenMP* support), and the Intel® Fortran Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c</code>&lt;br&gt;<code>ifort -qopenmp foo.o</code></td>
</tr>
</tbody>
</table>

When using `gcc` or `g++` compiler to link the application with the Intel® Fortran Compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP library name using the `-l` option, the Linux* `pthread` library using the `-l` option, and path to the Intel® libraries where the Intel® C++ compiler is installed using the `-L` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c bar.c</code>&lt;br&gt;<code>gcc foo.o bar.o -liomp5 -lpthread -L&lt;icc_dir&gt;/lib</code></td>
</tr>
</tbody>
</table>

You can mix object files, but it is easier to use the Intel® Fortran Compiler to link the application so you do not need to specify the `gcc-l` option, `-L` option, and the `-lpthread` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c</code>&lt;br&gt;<code>icc -qopenmp -c bar.c (Linux* and macOS*)</code></td>
</tr>
</tbody>
</table>
You can mix OpenMP* object files compiled with gcc, the Intel® C++ Compiler, and the Intel® Fortran Compiler.

**NOTE**
You cannot mix object files compiled by the Intel® Fortran compiler and the gfortran compiler.

The table illustrates examples of using the Intel® Fortran compiler to link all the objects:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
</table>
| Mixed C and Fortran sources| `icc -qopenmp -c ibar.c`  
                             | `gcc -fopenmp -c gbar.c`  
                             | `ifort -qopenmp -c foo.f`  
                             | `ifort -qopenmp foo.o ibar.o gbar.o` |
|                            |                                                                          |

When using the Intel® Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel® Fortran Compiler `ifort`, specify the `-nofor-main` option on the `ifort` command line during linking.

**NOTE**
Do not mix objects created by the Intel® Fortran Compiler (`ifort`) with the GNU Fortran Compiler (`gfortran`); instead, recompile all Fortran sources with the same Fortran compiler. The GNU Fortran Compiler is only available on Linux operating systems.

Similarly, you can mix object files compiled with the Intel® C++ Compiler, the GNU C/C++ compiler, and the GNU Fortran Compiler (`gfortran`), if you link with the GNU Fortran Compiler (`gfortran`). When using GNU `gfortran` compiler to link the application with the Intel® Fortran Compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP compatibility library name and the Intel irc libraries using the `-l` options, the Linux* pthread library using the `-l` option, and path to the Intel® libraries where the Intel® C++ Compiler is installed using the `-L` option. You do not need to specify the `-fopenmp` option on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
</table>
| Mixed C and GNU Fortran sources| `icc -qopenmp -c ibar.c`  
                             | `gcc -fopenmp -c gbar.c`  
                             | `gfortran -fopenmp -c foo.f`  
                             | `gfortran foo.o ibar.o gbar.o -lirc -liomp5 -lpthread -lc -L<icc_dir>/lib` |
|                            |                                                                          |

Alternatively, you could use the Intel® Fortran Compiler to link the application, but need to pass multiple `gfortran` libraries using the `-l` options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td><code>gfortran -fopenmp -c foo.f</code></td>
</tr>
</tbody>
</table>
### Command-Line Examples, macOS*

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® Fortran Compiler command on macOS* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source</td>
<td><code>ifort -qopenmp hello.f90</code></td>
</tr>
</tbody>
</table>

By default, the Intel® Fortran Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The Intel® Fortran Compiler option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and macOS* systems (default is `-qopenmp-link=dynamic`).

You can also use the Intel® C++ Compiler `icc/icc/icc` with gcc/g++ compilers to compile parts of the application and create object files (object-level interoperability).

**NOTE**

Mixed compiling using Intel® C++ Compiler with GCC compilers is possible only on older macOS* platforms. The latest macOS* v10.x platforms do not include the GCC compiler, and the Clang compiler included in the latest macOS* 10.x does not support OpenMP* implementation. Future versions of Clang compiler may support OpenMP* implementation.

In this example, `icl` or `icc` compiles the C file `foo.c`, `icpc` compiles the file `ifoo.cpp`, the option `Qopenmp` (Windows*) or `qopenmp` (Linux* or macOS*) enables OpenMP* support, and the Intel® Fortran Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>icc -qopenmp -c foo.c</code></td>
</tr>
<tr>
<td>C++ source</td>
<td><code>icpc -qopenmp -c ifoo.cpp</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -qopenmp foo.o ifoo.o</code></td>
</tr>
</tbody>
</table>

**NOTE**

GCC is absent on macOS* v10.9 and later (that is, Xcode 5.x and later). However, you may install GCC along with the Intel® C++ Compiler.

You can mix object files, but it is easier to use the Intel compiler to link the application so you do not need to specify the `gcc-l` option, `-L` option, and the `-lpthread` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>icc -qopenmp -c bar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -qopenmp -c foo.f90</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -qopenmp foo.o bar.o</code></td>
</tr>
</tbody>
</table>
When using the Intel® Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel® Fortran Compiler ifort, specify the -nofor-main option on the ifort command line during linking.

Alternatively, you could use the Intel® Fortran Compiler to link the application, but need to pass multiple gfortran libraries using the -l options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
</table>
| Mixed C and Fortran sources | gfortran -fopenmp -c foo.f  
|                       | icc -qopenmp -c ibar.c

Thread Affinity Interface (Linux* and Windows*)

The Intel® runtime library has the ability to bind OpenMP* threads to physical processing units. The interface is controlled using the KMP_AFFINITY environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

Thread affinity restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows* systems and versions of Linux* systems that have kernel support for thread affinity, but is not supported by macOS*.

The Intel OpenMP runtime library has the ability to bind OpenMP* threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP* threads to the processors based upon their physical location in the machine. This interface is controlled entirely by the KMP_AFFINITY environment variable.
- The mid-level affinity interface uses an environment variable to explicitly specify which processors (labeled with integer IDs) are bound to OpenMP* threads. This interface provides compatibility with the gcc* GOMP_AFFINITY environment variable, but you can also invoke it by using the KMP_AFFINITY environment variable. The GOMP_AFFINITY environment variable is supported on Linux* systems only, but users on Windows* or Linux* systems can use the similar functionality provided by the KMP_AFFINITY environment variable.
- The low-level affinity interface uses APIs to enable OpenMP* threads to make calls into the OpenMP* runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to sched_setaffinity and related functions on Linux* systems or to SetThreadAffinityMask and related functions on Windows* systems. In addition, you can specify certain options of the KMP_AFFINITY environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type KMP_AFFINITY to disabled, which disables the low-level affinity interface, or you could use the KMP_AFFINITY or GOMP_AFFINITY environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section:

- The total number of processing elements on the machine is referred to as the number of OS thread contexts.
• Each processing element is referred to as an Operating System processor, or OS proc.
• Each OS processor has a unique integer identifier associated with it, called an OS proc ID.
• The term package refers to a single or multi-core processor chip.
• The term OpenMP* Global Thread ID (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then \( n\text{-threads-var} - 1 \) new threads are created with GTIDs ranging from 1 to \( n\text{threads-var} - 1 \), and each thread's GTID is equal to the OpenMP* thread number returned by function `omp_get_thread_num()`. The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID, and can be used by programs containing arbitrarily many levels of parallelism.

Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

### The KMP_AFFINITY Environment Variable

**NOTE**
You must set the KMP_AFFINITY environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

The KMP_AFFINITY environment variable uses the following general syntax:

**Syntax**

```
KMP_AFFINITY= [<modifier>,...]<type>[,<permute>][,<offset>]
```

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a modifier of verbose and a type of none.

The following table describes the supported specific arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>modifier</td>
<td>noverbose</td>
<td>Optional. String consisting of keyword and specifier.</td>
</tr>
<tr>
<td></td>
<td>respect</td>
<td>• granularity=&lt;specifier&gt; takes the following specifiers: fine, thread, core, and tile</td>
</tr>
<tr>
<td></td>
<td>granularity=core</td>
<td>• norespect</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• noverbose</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• nowarnings</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• proclist={&lt;proc-list&gt;}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• respect</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• verbose</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• warnings</td>
</tr>
</tbody>
</table>

The syntax for `<proc-list>` is explained in mid-level affinity interface.

**NOTE**
<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>none</td>
<td>On Windows* with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows*). Otherwise, the respect affinity modifier is used. Required string. Indicates the thread affinity to use.</td>
</tr>
<tr>
<td>permute</td>
<td>0</td>
<td>Optional. Positive integer value. Not valid with type values of explicit, none, or disabled.</td>
</tr>
<tr>
<td>offset</td>
<td>0</td>
<td>Optional. Positive integer value. Not valid with type values of explicit, none, or disabled.</td>
</tr>
</tbody>
</table>

**Affinity Types**

Type is the only required argument.

**type = none (default)**

Does not bind OpenMP* threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP* thread affinity interface to determine machine topology. Specify KMP_AFFINITY=verbose,none to list a machine topology map.

**type = balanced**
Places threads on separate cores until all cores have at least one thread, similar to the scatter type. However, when the runtime must use multiple hardware thread contexts on the same core, the balanced type ensures that the OpenMP* thread numbers are close to each other, which scatter does not do. This affinity type is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.

**NOTE**
The OpenMP* environment variable OMP_PROC_BIND=spread is similar to KMP_AFFINITY=balanced and is available on all platforms, including multi-socket CPU systems.

**type = compact**
Specifying compact assigns the OpenMP* thread \(<n>+1\) to a free thread context as close as possible to the thread context where the \(<n>\) OpenMP* thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

**type = disabled**
Specifying disabled completely disables the thread affinity interfaces. This forces the OpenMP* run-time library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as kmp_set_affinity and kmp_get_affinity, which have no effect and will return a nonzero error code.

**type = explicit**
Specifying explicit assigns OpenMP* threads to a list of OS proc IDs that have been explicitly specified by using the proclist= modifier, which is required for this affinity type. See Explicitly Specifying OS Proc IDs (GOMP_CPU_AFFINITY).

**type = scatter**
Specifying scatter distributes the threads as evenly as possible across the entire system. scatter is the opposite of compact; so the leaves of the node are most significant when sorting through the machine topology map.

**Deprecated Types: logical and physical**
Types logical and physical are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

For logical and physical affinity types, a single trailing integer is interpreted as an offset specifier instead of a permute specifier. In contrast, with compact and scatter types, a single trailing integer is interpreted as a permute specifier.

- Specifying logical assigns OpenMP* threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to compact, except that the permute specifier is not allowed. Thus, KMP_AFFINITY=logical,\(n\) is equivalent to KMP_AFFINITY=compact,0,\(n\) (this equivalence is true regardless of the whether or not a granularity=fine modifier is present).
- Specifying physical assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to logical. For systems where multiple thread contexts exist per core, physical is equivalent to compact with a permute specifier of 1; that is, KMP_AFFINITY=physical,\(n\) is equivalent to KMP_AFFINITY=compact,1,\(n\) (regardless of the whether or not a granularity=fine modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the permute specifier.

**Examples of Types** compact and scatter
The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Intel® Hyper-Threading Technology (Intel® HT Technology) enabled.

The following figure also illustrates the binding of OpenMP* thread to hardware thread contexts when specifying `KMP_AFFINITY=granularity=fine,compact`.

Specifying `scatter` on the same system as shown in the figure above, the OpenMP* threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying `KMP_AFFINITY=granularity=fine,scatter`.

**permute and offset combinations**

For both `compact` and `scatter`, `permute` and `offset` are allowed; however, if you specify only one integer, the compiler interprets the value as a permute specifier. Both `permute` and `offset` default to 0.
The *permute* specifier controls which levels are most significant when sorting the machine topology map. A value for permute forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The *offset* specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying `KMP_AFFINITY=granularity=fine,compact,0,3`.

Consider the hardware configuration from the previous example, running an OpenMP* application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP* threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using `KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.
The OpenMP\* thread \(n+1\) is bound to a thread context as close as possible to OpenMP\* thread \(n\), but on a different core. Once each core has been assigned one OpenMP\* thread, the subsequent OpenMP\* threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.

**Modifier Values for Affinity Types**

Modifiers are optional arguments that precede type. If you do not specify a modifier, the `noverbose`, `respect`, and `granularity=core` modifiers are used automatically.

Modifiers are interpreted in order from left to right, and can negate each other. For example, specifying `KMP_AFFINITY=verbose,noverbose,scatter` is therefore equivalent to setting `KMP_AFFINITY=noverbose,scatter`, or just `KMP_AFFINITY=scatter`.

**modifier = noverbose (default)**

Does not print verbose messages.

**modifier = verbose**

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP\* thread bindings to physical thread contexts.

Information about binding OpenMP\* threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP\* thread is printed as a set of OS processor IDs.

For example, specifying `KMP_AFFINITY=verbose,scatter` on a dual core system with two processors, with Intel\® Hyper-Threading Technology (Intel\® HT Technology) disabled, results in a message listing similar to the following when then program is executed:

---

**Verbose, scatter message**

... 
`KMP_AFFINITY: Affinity capable, using global cpuid info`  
`KMP_AFFINITY: Initial OS proc set respected:  
\(\{0,1,2,3\}\)`  
`KMP_AFFINITY: 4 available OS procs - Uniform topology of  
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)  
...
verbose, scatter message

KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 1 maps to package 1 core 0 [thread 0]
KMP_AFFINITY: OS proc 2 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 3 maps to package 0 core 1 [thread 0]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {1}

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

<table>
<thead>
<tr>
<th>Message String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;affinity capable&quot;</td>
<td>Indicates that all components (compiler, operating system, and hardware) support affinity, so thread binding is possible.</td>
</tr>
<tr>
<td>&quot;using global cpuid info&quot;</td>
<td>Indicates that the machine topology was discovered by binding a thread to each operating system processor and decoding the output of the cpuid instruction.</td>
</tr>
<tr>
<td>&quot;using local cpuid info&quot;</td>
<td>Indicates that the compiler is decoding the output of the cpuid instruction, issued by only the initial thread, and is assuming a machine topology using the number of operating system processors.</td>
</tr>
<tr>
<td>&quot;using /proc/cpuinfo&quot;</td>
<td>Linux* only. Indicates that cpuinfo is being used to determine machine topology.</td>
</tr>
<tr>
<td>&quot;using flat&quot;</td>
<td>Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.</td>
</tr>
<tr>
<td>&quot;uniform topology of&quot;</td>
<td>The machine topology map is a full tree with no missing leaves at any level.</td>
</tr>
</tbody>
</table>

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP* thread context ID is printed next unless the affinity type is none. The thread level is contained in brackets (in the listing shown above). This implies that there is no representation of the thread context level in the machine topology map. For more information, see Determining Machine Topology.

modiﬁer = granularity

Binding OpenMP* threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled; however, it is usually not beneﬁcial to bind each OpenMP* thread to a particular thread context on a speciﬁc core. Granularity describes the lowest levels that OpenMP* threads are allowed to ﬂoat within a topology map.

This modiﬁer supports the following additional speciﬁers.

<table>
<thead>
<tr>
<th>Speciﬁer</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>core</td>
<td>Default. Allows all the OpenMP* threads bound to a core to ﬂoat between the different thread contexts.</td>
</tr>
<tr>
<td>Specifier</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fine or thread</td>
<td>The finest granularity level. Causes each OpenMP* thread to be bound to a single thread context. The two specifiers are functionally equivalent.</td>
</tr>
<tr>
<td>tile</td>
<td>Allows all the OpenMP* threads bound to a tile to float between the different thread contexts of cores the tile consists of.</td>
</tr>
</tbody>
</table>

Specifying `KMP_AFFINITY=verbose,granularity=core,compact` on the same dual core system with two processors as in the previous section, but with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, results in a message listing similar to the following when the program is executed:

```
Verbose, granularity=core,compact message
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected: {0,1,2,3,4,5,6,7}
KMP_AFFINITY: 8 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {1,5}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {1,5}
KMP_AFFINITY: Internal thread 6 bound to OS proc set {3,7}
KMP_AFFINITY: Internal thread 7 bound to OS proc set {3,7}
```

The affinity mask for each OpenMP* thread is shown in the listing (above) as the set of operating system processor to which the OpenMP* thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP* thread bindings.
In contrast, specifying `KMP_AFFINITY=verbose,granularity=fine,compact` or `KMP_AFFINITY=verbose,granularity=thread,compact` binds each OpenMP* thread to a single hardware thread context when the program is executed:

<table>
<thead>
<tr>
<th>Verbose, granularity=fine,compact message</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_AFFINITY: Affinity capable, using global cpuid info</td>
</tr>
<tr>
<td>KMP_AFFINITY: Initial OS proc set respected:</td>
</tr>
<tr>
<td>{0,1,2,3,4,5,6,7}</td>
</tr>
<tr>
<td>KMP_AFFINITY: 8 available OS procs - Uniform topology of</td>
</tr>
<tr>
<td>KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc to physical thread map ([ ] =&gt; level not in map):</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0</td>
</tr>
<tr>
<td>KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 1 bound to OS proc set {4}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 3 bound to OS proc set {6}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 4 bound to OS proc set {1}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 5 bound to OS proc set {5}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 6 bound to OS proc set {3}</td>
</tr>
<tr>
<td>KMP_AFFINITY: Internal thread 7 bound to OS proc set {7}</td>
</tr>
</tbody>
</table>

The OpenMP* to hardware context binding for this example was illustrated in the first example.

Specifying `granularity=fine` will always cause each OpenMP* thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

**modifier = respect (default)**

Respect the process' original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP* run-time library. The behavior differs between Linux* and Windows*:
• On Windows*: Respect original affinity mask for the process.
• On Linux*: Respect the affinity mask for the thread that initializes the OpenMP* run-time library.

Specifying KMP_AFFINITY=verbose,compact for the same system used in the previous example, with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, and invoking the library with an initial affinity mask of \{4,5,6,7\} (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with Intel® HT Technology disabled.

**Verbose,compact message**

</tbody>
</table>

Because there are eight thread contexts on the machine, by default the compiler created eight threads for an OpenMP* parallel construct.

The brackets around thread 1 indicate that the thread context level is ignored, and is not present in the topology map. The following figure illustrates the corresponding machine topology map.

![Machine topology map](image)

When using the local cpuid information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Intel® Hyper-Threading Technology (Intel® HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.
modifier = norespect
Do not respect original affinity mask for the process. Binds OpenMP* threads to all operating system processors.

In early versions of the OpenMP* run-time library that supported only the physical and logical affinity types, norespect was the default and was not recognized as a modifier.

The default was changed to respect when types compact and scatter were added; therefore, thread bindings for the logical and physical affinity types may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

modifier = nowarnings
Do not print warning messages from the affinity interface.

modifier = warnings (default)
Print warning messages from the affinity interface (default).

Determining Machine Topology
On IA-32 and Intel® 64 architecture systems, if the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the cpuid instruction to obtain the package id, core id, and thread context id. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the cpuid instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the package ID, core ID, and thread context ID.

There are two ways to specify the APIC ID in the cpuid instruction - the legacy method in leaf 4, and the more modern method in leaf 11. Only 256 unique APIC IDs are available in leaf 4. Leaf 11 has no such limitation.

Normally, all core ids on a package and all thread context ids on a core are contiguous; however, numbering assignment gaps are common for package ids, as shown in the figure above.

If the compiler cannot determine the machine topology using any other method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be flat. For example, a flat topology assumes the operating system process N maps to package N, and there exists only one thread context per core and only one core for each package.

If the machine topology cannot be accurately determined as described above, the user can manually copy /proc/cpuinfo to a temporary file, correct any errors, and specify the machine topology to the OpenMP* runtime library via the environment variable KMP_CPUINFO_FILE=<temp_filename>, as described in the section KMP_CPUINFO_FILE and /proc/cpuinfo.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.
**KMP_CPUINFO_FILE and /proc/cpuinfo**

One of the methods the Intel® C++ Compiler OpenMP runtime library can use to detect the machine topology on Linux® systems is to parse the contents of /proc/cpuinfo. If the contents of this file (or a device mapped into the Linux® file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file <temp_file>, correct it or extend it with the necessary information, and set KMP_CPUINFO_FILE=<temp_file>.

If you do this, the OpenMP® runtime library will read the <temp_file> location pointed to by KMP_CPUINFO_FILE instead of the information contained in /proc/cpuinfo or attempting to detect the machine topology by decoding the APIC IDs. That is, the information contained in the <temp_file> overrides these other methods. You can use the KMP_CPUINFO_FILE interface on Windows® systems, where /proc/cpuinfo does not exist.

The content of /proc/cpuinfo or <temp_file> should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in <temp_file> or /proc/cpuinfo:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processor</td>
<td>Specifies the OS ID for the processing element. The OS ID must be unique. The processor and physical id fields are the only ones that are required to use the interface.</td>
</tr>
<tr>
<td>physical id</td>
<td>Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the Intel compiler OpenMP run-time library’s model of the machine topology.</td>
</tr>
<tr>
<td>core id</td>
<td>Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core level will not exist in the machine topology map (even if some of the core ID fields are non-zero).</td>
</tr>
<tr>
<td>thread id</td>
<td>Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).</td>
</tr>
<tr>
<td>node_0 id</td>
<td>This is a extension to the normal contents of /proc/cpuinfo that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels n are supported. The node_0 level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on.</td>
</tr>
</tbody>
</table>

Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.
NOTE
It is common for the thread id field to be missing from /proc/cpuinfo on many Linux* variants, and for a field labeled siblings to specify the number of threads per node or number of nodes per package. However, the Intel OpenMP runtime library ignores fields labeled siblings so it can distinguish between the thread id and siblings fields. When this situation arises, the warning message Physical node/pkg/core/thread ids not unique appears (unless the type specified is nowarnings).

Windows* Processor Groups
On a 64-bit Windows* operating system, it is possible for multiple processor groups to accommodate more than 64 processors. Each group is limited in size, up to a maximum value of sixty-four (64) processors.

If multiple processor groups are detected, the default is to model the machine as a 2-level tree, where level 0 are for the processors in a group, and level 1 are for the different groups. Threads are assigned to a group until there are as many OpenMP* threads bound to the groups as there are processors in the group. Subsequent threads are assigned to the next group, and so on.

By default, threads are allowed to float among all processors in a group, that is to say, granularity equals the group [granularity=group]. You can override this binding and explicitly use another affinity type like compact, scatter, and so on. If you do so, the granularity must be sufficiently fine to prevent a thread from being bound to multiple processors in different groups.

Using a Specific Machine Topology Modeling Method (KMP_TOPOLOGY_METHOD)
You can set the KMP_TOPOLOGY_METHOD environment variable to force OpenMP* to use a particular machine topology modeling method.

<table>

Explicitly Specifying OS Processor IDs (GOMP_CPU_AFFINITY)

NOTE
You must set the GOMP_CPU_AFFINITY environment variable before the first parallel region, or certain API calls including omp_get_max_threads(), omp_get_num_procs() and any affinity API calls, as described in Low Level Affinity API, below.

Instead of allowing the library to detect the hardware topology and automatically assign OpenMP* threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

This list may either be specified by using the proclist modifier along with the explicit affinity type in the KMP_AFFINITY environment variable, or by using the GOMP_AFFINITY environment variable (for compatibility with gcc) when using the OpenMP* Source Compatibility and Interoperability with Other Compilers.

On Linux* systems, when using the Intel OpenMP compatibility libraries enabled by the compiler option -qopenmp-lib compat, you can use the GOMP_AFFINITY environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by libgomp (assume that <proc_list> produces the entire GOMP_AFFINITY environment string):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;proc_list&gt; :=</td>
<td>&lt;entry&gt;</td>
</tr>
<tr>
<td>&lt;elem&gt; :=</td>
<td>&lt;proc_spec&gt;</td>
</tr>
<tr>
<td>&lt;proc_spec&gt; :=</td>
<td>&lt;proc_id&gt;</td>
</tr>
<tr>
<td>&lt;range&gt; :=</td>
<td>&lt;proc_id&gt; - &lt;proc_id&gt;</td>
</tr>
<tr>
<td>&lt;proc_id&gt; :=</td>
<td>&lt;positive_int&gt;</td>
</tr>
</tbody>
</table>

OS processors specified in this list are then assigned to OpenMP* threads, in order of OpenMP* Global Thread IDs. If more OpenMP* threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP* Global Thread ID n is bound to list element n mod <list_size>.

Consider the machine previously mentioned: a dual core, dual-package machine without Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates six OpenMP* threads instead of 4 (the default), oversubscribing the machine. If GOMP_AFFINITY=3,0-2, then OpenMP* threads are bound as shown in the figure below, just as should happen when compiling with gcc and linking with libgomp:
The same syntax can be used to specify the OS proc ID list in the proclist=\[<proc_list>\] modifier in the KMP_AFFINITY environment variable string. There is a slight difference: in order to have strictly the same semantics as in the gcc OpenMP* runtime library libgomp: the GOMP_AFFINITY environment variable implies granularity=fine. If you specify the OS proc list in the KMP_AFFINITY environment variable without a granularity= specifier, then the default granularity is not changed. That is, OpenMP* threads are allowed to float between the different thread contexts on a single core. Thus GOMP_AFFINITY=<proc_list> is an alias for KMP_AFFINITY="granularity=fine,proclist=\[<proc_list>\],explicit".

In the KMP_AFFINITY environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP* thread may execute ("œfloat") enclosed in brackets:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;proc_list&gt;</td>
<td>:= &lt;proc_id&gt;</td>
</tr>
<tr>
<td>&lt;float_list&gt;</td>
<td>:= &lt;proc_id&gt;</td>
</tr>
</tbody>
</table>

This allows functionality similarity to the granularity= specifier, but it is more flexible. The OS processors on which an OpenMP* thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the previous example, we may allow OpenMP* threads 2 and 3 to "œfloat" between OS processor 1 and OS processor 2 by using KMP_AFFINITY="granularity=fine,proclist=[3,0,\{1,2\},\{1,2\}],explicit", as shown in the figure below:
If `verbose` were also specified, the output when the application is executed would include:

```
KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,(1,2),(1,2)],explicit"
```

**Low Level Affinity API**

Instead of relying on the user to specify the OpenMP* thread to OS proc binding by setting an environment variable before program execution starts (or by using the `kmp_settings` interface before the first parallel region is reached), each OpenMP* thread can determine the desired set of OS procs on which it is to execute and bind to them with the `kmp_set_affinity` API call.
Caution
When you use this affinity interface you take complete control of the hardware resources on which
your threads run. To do that sensibly you need to understand in detail how the logical CPUs, the
enumeration of hardware threads controlled by the OS, map to the physical hardware of the specific
machine on which you are running. That mapping can be, and likely is, different on different machines,
so you risk binding machine-specific information into your code, which can result in explicitly forcing
bad affinities when your code runs on a different machine. And if you are concerned with optimization
at this level of detail, your code is probably valuable, and therefore will probably move to another
machine.

This interface may also allow you to ignore the resource limitations that were set by the program
startup mechanism, such as MPI, specifically to prevent multiple OpenMP processes on the same node
from using the same hardware threads. Again, this can result in explicitly forcing affinities that cause
bad performance, and the OpenMP runtime will neither prevent this from happening, nor warn you
when it does. These are expert interfaces and you must use them with caution.

It is recommended, therefore, to use the higher level affinity settings if you possibly can, because they
are more portable and do not require this low level knowledge.

The Fortran API interfaces follow, where the type name `kmp_affinity_mask_t` is defined in `omp_lib.h` or
`omp_lib.mod`:

**NOTE**
Some of these interfaces have offload equivalents. The offload equivalent takes two additional
arguments to specify the target type and target number. For more information, see Calling Functions
on the CPU to Modify the Coprocessor’s Execution Environment.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
</table>
| integer function kmp_set_affinity(mask)  
integer (kind=kmp_affinity_mask_kind) mask | Sets the affinity mask for the current OpenMP* thread to mask, where mask is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code. |
| integer kmp_get_affinity(mask)  
integer (kind=kmp_affinity_mask_kind) mask | Retrieves the affinity mask for the current OpenMP* thread, and stores it in mask, which must have previously been initialized with a call to kmp_create_affinity_mask(). Returns either a zero (0) upon success or a nonzero error code. |
| integer function kmp_get_affinity_max_proc() | Returns the maximum OS proc ID that is on the machine, plus 1. All OS proc IDs are guaranteed to be between 0 (inclusive) and kmp_get_affinity_max_proc() (exclusive). |
| subroutine kmp_create_affinity_mask(mask)  
integer (kind=kmp_affinity_mask_kind) mask | Allocates a new OpenMP* thread affinity mask, and initializes mask to the empty set of OS procs. The implementation is free to use an object of kmp_affinity_mask_kind either as the set itself, |
Once an OpenMP* thread has set its own affinity mask via a successful call to `kmp_set_affinity()`, then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to `kmp_set_affinity()`.

Between parallel regions, the affinity mask (and the corresponding OpenMP* thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP* Application Program Interface. For more information, see the OpenMP* API specification (http://www.openmp.org), some relevant parts of which are provided below:

In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions."

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, you can mimic the behavior of the KMP_AFFINITY environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP* specification.

The following example shows how these low-level interfaces can be used. This code binds the executing thread to the specified logical CPU:

```fortran
subroutine kmp_destroy_affinity_mask(mask)
integer (kind=kmp_affinity_mask_kind) mask

integer function kmp_set_affinity_mask_proc(proc, mask)
integer proc
integer (kind=kmp_affinity_mask_kind) mask

integer function kmp_unset_affinity_mask_proc(proc, mask)
integer proc
integer (kind=kmp_affinity_mask_kind) mask

integer function kmp_get_affinity_mask_proc(proc, mask)
integer proc
integer (kind=kmp_affinity_mask_kind) mask
```
Example

! Force the executing thread to execute on logical CPU i
! Returns .TRUE. on success, .FALSE. on failure

function forceAffinity (i)
    use omp_lib
    logical forceAffinity
    integer, intent(in) :: i

    integer(kmp_affinity_mask_kind) :: mask
    call kmp_create_affinity_mask(mask)
    forceAffinity = (kmp_set_affinity_mask_proc(i, mask) == 0)
    if (.not. forceAffinity) return
    forceAffinity = (kmp_set_affinity_mask(mask) == 0)
    return
end function forceAffinity

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP* thread to physical processing element bindings could differ and you might be explicitly force a bad distribution.

OpenMP* Advanced Issues

This topic discusses how to use the OpenMP* library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP*.

OpenMP* provides specific function calls, and environment variables. See the following topics to refresh your memory about the primary functions and environment variable used in this topic:
- OpenMP* Run-time Library Routines
- OpenMP* Environment Variables

To use the function calls, include the omp_lib.h header file or specify use omp_lib to use the Fortran90 module file. These files are installed in the INCLUDE directory during the compiler installation, and compile the application using the [-Q]openmp option.

The following example, which demonstrates how to use the OpenMP* functions to print the alphabet, also illustrates several important concepts:

1. When using functions instead of directives, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.
2. It becomes difficult to compile without OpenMP* support.
3. It is very easy to introduce simple bugs, as in the loop (below) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.
4. You lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.
Debugging threaded applications is a complex process because debuggers change the run-time performance, which can mask race conditions. Even print statements can mask issues, because they use synchronization and operating system functions. OpenMP* itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables, and inserts additional code. A debugger that supports OpenMP* can help you to examine variables and step through threaded code. You can use Intel® Inspector to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.

Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs.

The DEFAULT(NONE) clause, shown below, can be used to help find those hard-to-spot variables. If you specify DEFAULT(NONE), then every variable must be declared with a data-sharing attribute clause.

```
Example

#include "omp_lib.h"
integer i
integer LettersPerThread, ThisThreadNum, StartLetter, EndLetter

call omp_set_num_threads(4)
!
OMP PARALLEL PRIVATE(i)

    ! OMP_NUM_THREADS is not a multiple of 26,
    ! which can be considered a bug in this code.
LettersPerThread = 26 / omp_get_num_threads()
ThisThreadNum = omp_get_thread_num()
StartLetter = 'a'+ThisThreadNum*LettersPerThread
EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread

    DO i = StartLetter, EndLetter - 1
        write( *,FMT='(A)',ADVANCE='NO') char(i)
    END DO
!
OMP END PARALLEL
write('*','*
end
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the FIRSTPRIVATE and LASTPRIVATE clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can’t find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn’t work, try setting the entire program to run in serial by setting the compiler-specific environment variable KMP_LIBRARY=serial.

If the code is still not working, and you are not using any OpenMP* API function calls, compile it without the [Q]openmp option to make sure the serial version works. If you are using OpenMP* API function calls, use the [Q]openmp-stubs option.
Performance

OpenMP* threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.

Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on $n$ CPUs. With OpenMP*, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the [Q]openmp option to generate a single-threaded version, or build with the [Q]openmp-stubs option, and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code. If the overhead of a parallel region is large compared to the compute time, you may want to use an if clause to execute the section serially.

Interoperability with OpenMP* in C/C++

The Intel® Fortran Compiler does not support Fortran calling C/C++ or C/C++ calling Fortran when both caller and callee are using OpenMP* constructs.

Fortran code that uses OpenMP* constructs can call C/C++ as long as the C/C++ code does not use OpenMP* constructs.

</tr>
<tr>
<td>OMP_STACKSIZE environment variable</td>
<td>If the value does not conform to the specified format or the implementation cannot provide a stack of the specified size, then Intel's OpenMP* implementation sets the value of stacksize-var ICV to the default size, which is specified as being from 1MB to 4MB depending on the architecture.</td>
</tr>
<tr>
<td>OMP_MAX_ACTIVE_LEVELS environment variable</td>
<td>If the value is a negative integer or is greater than the number of parallel levels an implementation can support, then Intel's OpenMP* implementation sets the value of the max-active-levels-var ICV to the maximum number of parallel levels supported on a particular platform.</td>
</tr>
</tbody>
</table>
### OMP_THREAD_LIMIT environment variable

If the requested value is greater than the number of threads an implementation can support, or if the value is a negative integer, then Intel's OpenMP* implementation sets the value of the thread-limit-var ICV to the maximum number of threads supported on a particular platform. If the requested value is zero then the implementation sets the value of the thread-limit-var ICV to 1.

### Runtime library definitions

Intel's OpenMP* implementation provides both the include file `omp_lib.h` and the module `omp_lib`.

### OpenMP* Examples

The following examples show how to use several OpenMP* features.

#### A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The `END DO` has a `NOWAIT` because there is an implicit barrier at the end of the parallel region.

```fortran
Example

subroutine do_1(a,b,n)
    real a(n,n), b(n,n)
    !$OMP PARALLEL SHARED(A,B,N)
    !$OMP DO SCHEDULE(DYNAMIC,1) PRIVATE(I,J)
        do i = 2, n
            do j = 1, i
                b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
            end do
        end do
    !$OMP END DO NOWAIT
    !$OMP END PARALLEL
end
```

#### Two Difference Operators: DO Loop Version

The example uses two parallel loops fused to reduce fork/join overhead. The first `END DO` directive has a `NOWAIT` clause because all the data used in the second loop is different than all the data used in the first loop.

```fortran
Example

subroutine do_2(a,b,c,d,m,n)
    real a(n,n), b(n,n), c(m,m), d(m,m)
    !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
    !$OMP DO SCHEDULE(DYNAMIC,1)
        do i = 2, n
            do j = 1, i
                b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
            end do
        end do
    !$OMP END DO
    !$OMP END PARALLEL
end
```
**Example**

```
!$OMP END DO NOWAIT
!$OMP DO SCHEDULE(DYNAMIC,1)
   do i = 2, m
      do j = 1, i
         d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
      end do
   end do
!$OMP END DO NOWAIT
!$OMP END PARALLEL
end
```

**Two Difference Operators: SECTIONS Version**

The example demonstrates the use of the `SECTIONS` directive. The logic is identical to the preceding `DO` example, but uses `SECTIONS` instead of `DO`. Here the speedup is limited to two because there are only two units of work whereas in the example above there are \((n-1) + (m-1)\) units of work.

```
subroutine sections_1(a,b,c,d,m,n)
   real a(n,n), b(n,n), c(m,m), d(m,m)
   !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
   !$OMP SECTIONS
      !$OMP SECTION
      do i = 2, n
         do j = 1, i
            b(j,i)=( a(j,i) + a(j,i-1) ) / 2.0
         end do
      end do
      !$OMP SECTION
      do i = 2, m
         do j = 1, i
            d(j,i)=( c(j,i) + c(j,i-1) ) / 2.0
         end do
      end do
   !$OMP END SECTIONS NOWAIT
   !$OMP END PARALLEL
end
```

**Updating a Shared Scalar**

This example demonstrates how to use a `SINGLE` construct to update an element of the shared array `a`. The optional `nowait` clause after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the `SINGLE` construct.

```
subroutine sp_1a(a,b,n)
   real a(n), b(n)
   !$OMP PARALLEL SHARED(A,B,N) PRIVATE(I)
   !$OMP DO
      do i = 1, n
         a(i) = 1.0 / a(i)
      end do
   !$OMP END DO
end
```
Coarrays

Using Coarrays

Coarrays are not supported on macOS* systems.

Coarrays, a data sharing concept standardized in Fortran 2008 and extended in Fortran 2018, enable parallel processing using multiple copies of a single program. Each copy, called an image, has ordinary local variables and also shared variables called coarrays or covariables. A covariable, which can be either an array or a scalar, is a variable whose storage spans all the images in the program. In this Partitioned Global Address Space (PGAS) model, each image can access its own piece of a covariable as a local variable and can access those pieces that live on other images using coindices, which are enclosed in square brackets.

Intel® Fortran supports coarray programs that run using shared memory on a multicore or multiprocessor system. In some products (see the Feature Requirements section), coarray programs can also be built to run using distributed memory across a Linux* or Windows* cluster. They can also run on Linux* systems when targeting Intel® Xeon Phi™ products.

Please refer to the product system requirements in the Release Notes for further details.

For more information on how to write programs using coarrays, see books on the Fortran 2008 language or the ISO Fortran 2008 standard.

Using Coarray Program Syntax

The additional syntax required by Fortran 2008 coarrays includes:

- CODIMENSION attribute and "[cobounds]" to declare an object a coarray (covariable)
- [coindices] notation to reference covariables on other images
- SYNC ALL, SYNC IMAGES, and SYNC MEMORY statements to provide points where images must communicate to synchronize shared data
- CRITICAL and END CRITICAL statements to form a block of code executed by one image at a time
- LOCK and UNLOCK statements to control objects called locks, used to synchronize actions on specific images
- ERROR STOP statement to end all images
- ALLOCATE and DEALLOCATE statements may specify coarrays
- Intrinsic procedures IMAGE_INDEX, LCOBOUND, NUM_IMAGES, THIS_IMAGE, and UCOBOUND
- ATOMIC_DEFINE and ATOMIC_REF for defining and referencing an atomic variable

The following Fortran 2018 coarray extensions are also supported:

- EVENT POST and EVENT WAIT statements to synchronize execution between two images
- Intrinsic procedures COSHAPE and EVENT_QUERY

Using the Coarray Compiler Options
You must use the `-coarray` (Linux) or `/Qcoarray` (Windows) compiler option (hereafter referred to as `[Q]coarray`) to enable the compiler to recognize coarray syntax. If you do not use this compiler option, a program that uses coarray syntax or features produces a compile-time error.

In the list that follows, only one option is valid on the command line; if multiple coarray compiler options are specified, the last one specified is used. An exception to this rule is the `[Q]coarray` compiler option using keyword `single`; if specified, this option takes precedence regardless of where it appears on the command line.

- Using `[Q]coarray` with no keyword is equivalent to running on one node (shared memory).
- Using `[Q]coarray` with keyword `shared` causes the underlying Intel® Message Passing Interface (MPI) parallelization to run on one node with multiple cores or processors with shared memory.
- Using `[Q]coarray` with keyword `distributed` requires a special license to be installed (see the Feature Requirements section) and causes the underlying Intel® MPI Library parallelization to run in a multi-node environment (multiple CPUs with distributed memory).
- Using `-coarray=coprocessor` (Linux*) specifies a configuration where the first images runs on the host and other images run on the host or the target. A configuration file specifies your exact configuration and determines where the images will be run. Use the `-coarray-config-file=filename` compiler option to specify a configuration file.
- Using `[Q]coarray` with keyword `single` creates an executable that will not be replicated, resulting in a single running image. (This is in contrast to the self-replicating behavior that occurs when any other coarray keyword is specified.) This option is useful for debugging purposes.

No special procedure is necessary to run a program that uses coarrays; you simply run the executable file. The underlying parallelization implementation uses the Intel® MPI Library. Installation of the compiler automatically installs the necessary Intel® MPI run-time libraries to run on shared memory. Products supporting clusters will also install the necessary Intel® MPI Library run-time libraries to run on distributed memory. Use of coarray applications with any other MPI implementation, or with OpenMP*, is not supported.

By default, the number of images created is equal to the number of execution units on the current system. You can override this by specifying a number using the `[Q]coarray-num-images` compiler option on the `ifort` command line that compiles the main program. You can also specify the number of images at execution time in the environment variable `FOR_COARRAY_NUM_IMAGES`.

### Using a Configuration File

Use of the config-file option is appropriate only in a limited number of cases:

- As mentioned previously, you need to specify a configuration file when using the `-coarray=coprocessor` (Linux*) compiler option syntax.
- You can take advantage of Intel® MPI Library features in the coarray environment. To do so, specify the command line segments used by "mpiexec -config filename" in a file named `filename` and pass that file name to the Intel® MPI Library using the `/[Q]coarray-config-file` compiler option. If the `[Q]coarray-num-images` compiler option also appears on the command line, it will be overridden by what is in the configuration file. Rules for using an MPI configuration files are as follows:
  - The format of a configuration file is described in the Intel® MPI Library documentation; you will need to add the MPI option "-genv FOR_ICAF_STATUS launched" in the configuration file in order for coarrays to work on multi-node (distributed memory) systems.
  - You can also set the environment variable `FOR_COARRAY_CONFIG_FILE` to be the filename and path of the Intel® MPI Library configuration file you want to use at execution time.

### Examples on Windows*:

- `/Qcoarray:shared /Qcoarray-num-images:8` runs a coarray program on shared memory using 8 images.
- `/Qcoarray:shared /Qcoarray-config-file:filename` runs a coarray program on shared memory using the MPI configuration detailed in `filename`.
- `/Qcoarray:distributed /Qcoarray-config-file:filename` runs a coarray program on distributed memory using the Intel® MPI Library configuration detailed in `filename`.

### Examples on Linux*:

- `–coarray=shared –coarray-num-images=8` runs a coarray program on shared memory using 8 images.
-coarray=distributed -coarray-num-images=8 runs a coarray program on distributed memory across 8 images.

-coarray=coprocessor -coarray-config-file=filename runs a coarray program on a configuration where the first images runs on the host processor and other images run on some combination of host processors or coprocessors based on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture). This command line specifies use of the Intel® MPI Library configuration detailed in filename.

**Considerations When Running Coprocessors based on the Intel® MIC Architecture**

The compiler installation provides the necessary Intel® MPI run-time libraries and binaries on the coprocessor's file system, but these must be manually copied to the card's file system whenever the card is rebooted.

Move to the mpirt directory and copy the Intel® MPI files as shown:

```bash
sudo scp lib/mic/libmpi_mt.so mic0:/lib64/libmpi_mt.so
sudo scp bin/mic/mpiexec.hydra mic0:/bin/mpiexec.hydra
sudo scp bin/mic/pmi_proxy mic0:/bin/pmi_proxy
```

From that same directory, the Intel® Fortran run-time libraries for coarray support should also be copied to the card's file system:

```bash
sudo scp lib/mic/libmpi_mt.so mic0:/lib64/libmpi_mt.so
sudo scp bin/mic/mpiexec.hydra mic0:/bin/mpiexec.hydra
sudo scp bin/mic/pmi_proxy mic0:/bin/pmi_proxy
```

**Sample Coarray Configurations When Running on the Coprocessor**

Following are several sample configurations.

**Sample Configuration:** Image 1 on host; images 2-N on coprocessors based on Intel® MIC Architecture

In this configuration, the coarray program runs some of its images on the host and some of its images on coprocessors.

For this configuration, you would specify the following:

```bash
ifort -coarray=coprocessor -coarray-config-file=MixedPlatform.conf myProg.f90 -o myProg
```

This creates two executables; myProg and myProgMIC. Copy myProgMIC to the card's file system, and specify that location in the configuration file.

The MixedPlatform.conf file would contain the following:

```bash
-n 1 -host <hostid-of-CPU> -genv FOR_ICAF_STATUS=T ./myProg :
-n 4 -host <hostid-of-mic> genv FOR_ICAF_STATUS=T /home/mydir/myProgMIC:
```

**Sample Configuration:** Image 1 on host processor; images 2-N spread on host processor, coprocessor(s)

This is a variant of the previous configuration. Here, the configuration file specifies additional images on either the host processor or coprocessor. The `-n X` option is used to specify the number of images associated with each type of host. For example, to run 4 images on the CPU and 2 images each on four coprocessors, the configuration file would contain the following:

```bash
-n 4 -host MYCPU -genv FOR_ICAF_STATUS=true ./myProg :
-n 2 -host CARD1 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :
-n 2 -host CARD2 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :
-n 2 -host CARD3 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :
-n 2 -host CARD4 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :
```

Given the configuration file listed above, myProg should expect `num_images()` to be 12.

**Sample Configuration:** Images 1-N on host processor, with offloaded code on coprocessor
In this configuration, all coarray images run on the host processor, but each image has offloaded code that is running on the coprocessors.

For this configuration, you would specify the following:

```fortran
ifort -coarray -coarray-num-images=X myProg.f90 -o myProg
```

For this configuration, your code must contain offload regions, marked by directives, such as:

```fortran
!DIR$ OFFLOAD BEGIN
<user code>
!DIR$ END OFFLOAD
```

There are further restrictions on your code:

- A coindexed object may not be used within an offload region
- An image control statement may not be used within an offload region
- A coindexed object may not be used within an OpenMP* region
- An image control statement may not be used within an OpenMP region

**Optimization Notice**

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**Debugging a Coarray Application (Linux*)**

*Steps to perform to debug a coarray application.*

For the following, you need an application with shared variables or coarrays whose storage spans all the images in a program.

Follow these steps to debug your coarray application:

1. Add a stall loop to your application before the area of code you wish to debug.

```fortran
LOGICAL VOLATILE :: WAIT_FOR_DEBUGGER
LOGICAL, VOLATILE :: TICK
!
! Other code may be here
!
DO WHILE(WAIT_FOR_DEBUGGER)
  TICK = .NOT. TICK
```

---

2368
The use of VOLATILE is required to ensure that the loop will not be removed by the compiler. If the problem is only found on one image, you can wrap the loop in IF (THIS_IMAGE() .EQ. 4) THEN or the like.

2. Compile and link with debug enabled (-g).

3. Create at least N+1 terminal windows on the machine where the application will be running, where N is the number of images your application will have.

4. In a terminal window, start the application.

```
linuxprompt> ./my_app
```

5. In each of the other terminal windows, set your default directory to be the same as the location of the application executable. Use the `ps` command in one of the windows to find out which processes are running your application:

```
linuxprompt> ps -ef | grep 'whoami' | grep my_app
```

There will be several processes. The oldest is the one you started in step 4 – it has run the MPI launcher and is now waiting for the others to terminate. Do not debug it.

The others will look like this:

```
<your-user-name> 25653 25650 98 15:06 ? 00:00:49 my_app
<your-user-name> 25654 25651 97 15:06 ? 00:00:48 my_app
<your-user-name> 25655 25649 98 15:06 ? 00:00:49 my_app
```

The first number is the PID of the process (for example, 25653 in the first line). In the steps below, the PIDs of these N processes are referred to as P1, P2, and so on. When you type the commands, replace the text <P1> with the actual value of the PID for process 1, and so on.

6. In each window other than the first, start your debugger and set it to stop processes when attached:

```
linuxprompt> gdb
```

7. Attach to one of the processes. For example, attach to P1 in window 1, attach to P2 in window 2, and so on.

```
(gdb) attach <P1>
```

8. Get execution out of the stall loop:

```
(gdb) set WAIT_FOR_DEBUGGER = .false.
```

You are now ready to debug your coarray application by examining the data and code paths in the various images.

### Automatic Parallelization

The auto-parallelization feature of the Intel® Fortran Compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP* directives. The OpenMP* and auto-parallelization features provide the performance gains from shared memory on multiprocessor and dual core systems.

The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel.

This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.
The guided auto-parallelization feature of the Intel® Fortran Compiler helps you locate portions in your serial code that can be parallelized further. You can invoke guidance for parallelization, vectorization, or data transformation using specified compiler options of the [-guide](#) series.

Automatic parallelization frees developers from having to:

- Find loops that are good worksharing candidates.
- Perform the dataflow analysis to verify correct parallel execution.
- Partition the data for threaded code generation as is needed in programming with OpenMP* directives.

Although OpenMP* directives enable serial applications to transform into parallel applications quickly, you must explicitly identify specific portions of your application code that contain parallelism and add the appropriate compiler directives. Auto-parallelization, which is triggered by the [-parallel](#) option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort is needed.

**NOTE** In order to execute a program that uses auto-parallelization on Linux* or macOS* systems, you must include the `-parallel` compiler option when you compile and link your program.

**NOTE** Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and macOS*), or `-x`.

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.

### Example 1: Original Serial Code

```fortran
subroutine ser(a, b, c)
  integer, dimension(100) :: a, b, c
  do i=1,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine ser
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

### Example 2: Transformed Parallel Code

```fortran
subroutine par(a, b, c)
  integer, dimension(100) :: a, b, c
  ! Thread 1
  do i=1,50
    a(i) = a(i) + b(i) * c(i)
  enddo
  ! Thread 2
  do i=51,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine par
```
Auto-Vectorization and Parallelization

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts
the sequential program to process 2, 4, 8, or (up to) 16 elements in one operation, depending on the data
type. In some cases, auto-parallelization and vectorization can be combined for better performance results.
For example, in the code below, thread-level parallelism can be exploited in the outermost loop, while
instruction-level parallelism can be exploited in the innermost loop.

Example

```
DO I = 1, 100 ! Execute groups of iterations in different threads (TLP)
  DO J = 1, 32 ! Execute in SIMD style with multimedia extension (ILP)
    A(J,I) = A(J,I) + 1
  ENDDO
ENDDO
```

With the relatively small effort of adding OpenMP* directives to existing code you can transform a sequential
program into a parallel program. The [Q]openmp option must be specified to enable the OpenMP directives.
The following example shows OpenMP* directives within the code.

Example

```
!OMP$ PARALLEL PRIVATE(NUM), SHARED (X,A,B,C)
! Defines a parallel region
!OMP$ PARALLEL DO
! Specifies a parallel region that
! implicitly contains a single DO directive
DO I = 1, 1000
  NUM = FOO(B(i), C(I))
  X(I) = BAR(A(I), NUM)
! Assume FOO and BAR have no other effect
ENDDO
```

**NOTE**

Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these
options may perform additional optimizations on Intel® microprocessors than they perform on non-
Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may
perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks
(internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop
scheduling, reductions, memory allocation, and thread affinity and binding.

Using Parallelism Reports

To generate a parallelism report, use the -opt-report-phase=par (Linux* and macOS*) or
the /Qopt-report-phase:par option along with the -opt-report=n or /Qopt-report:n option. By default
the auto-parallelism report generates a medium level of detail, where n=2. You can use [Q]opt-report
option along with the [Q]opt-report-phase option if you want a greater or lesser level of detail. Specifying
a value of '5' generates the maximum diagnostic details.

Run the report by entering commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
<tr>
<td>macOS*</td>
<td>ifort -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
</tbody>
</table>
The output, by default, produces a file with the same name as the object file, with .optrpt extension, and is written into the same directory as the object file. Using the above command-line entries, you will obtain an output file called sample.optrpt. Use the [Q]opt-report-file option to specify any other name for the output file that captures the report results. Use the arguments stdout or stderr to send the optimization report to stdout or stderr.

For more information on options to generate reports see the Optimization Report Options topic.

Enabling Auto-parallelization

To enable the auto-parallelizer, use the [Q]parallel option. This option detects parallel loops capable of being executed safely in parallel, and automatically generates multi-threaded code for these loops.

NOTE
You may need to set the KMP_STACKSIZE environment variable to an appropriately large size to enable parallelization with this option.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

An example of the command using auto-parallelization is as follows:
Commanding auto-parallelization in Linux*

```shell
ifort -c -parallel myprog.f
```

Commanding auto-parallelization in Windows*

```shell
ifort -c /Qparallel myprog.f
```

Commanding auto-parallelization in macOS*

```shell
ifort -c -parallel myprog.f
```

Auto-parallelization uses two specific directives: `!DIR$ PARALLEL` and `!DIR$ NOPARALLEL`.

The format of an auto-parallelization compiler directive is below:

**Syntax**

```
!DIR$ <directive>
```

Because auto-parallelization directives begin with an exclamation point, the directives take the form of comments if you omit the `[/Q]parallel` option.

The `!DIR$ PARALLEL` directive instructs the compiler to ignore dependencies that it assumes may exist and that would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored. In addition, `PARALLEL [ALWAYS]` overrides the compiler heuristics that estimate the likelihood that parallelization of a loop increases performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the `ASSERT` keyword is added, as in `!DIR$ PARALLEL [ALWAYS [ASSERT]]`, the compiler generates an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

The `!DIR$ NOPARALLEL` directive disables auto-parallelization.

For example, in the following code, the `NOPARALLEL` directive disables auto-parallelization.

**Example**

```fortran
program main
 parameter (n=100)
 integer x(n),a(n)
 !DIR$ NOPARALLEL
 do i=1,n
   x(i) = i
 enddo
 !DIR$ PARALLEL
 do i=1,n
   a( x(i) ) = i
 enddo
end
```

**Programming with Auto-parallelization**

The auto-parallelization feature implements some concepts of OpenMP*, such as the worksharing construct (with the `PARALLEL DO` directive). This section provides details on auto-parallelization.
Guidelines for Effective Auto-parallelization Usage

A loop can be parallelized if it meets the following criteria:

- The loop is countable at compile time: This means that an expression representing how many times the loop will execute (loop trip count) can be generated just before entering the loop.
- There are no FLOW (READ after WRITE), OUTPUT (WRITE after WRITE) or ANTI (WRITE after READ) loop-carried data dependencies. A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler's discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by run-time dependency testing.

The compiler may generate a run-time test for the profitability of executing in parallel for loop, with loop parameters that are not compile-time constants.

Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:

- Expose the trip count of loops whenever possible; use constants where the trip count is known and save loop parameters in local variables.
- Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.
- Insert the ![DIR$ PARALLEL](139x485) directive to disambiguate assumed data dependencies.
- Insert the ![DIR$ NOPARALLEL](139x472) directive before loops known to have insufficient work to justify the overhead of sharing among threads.

Auto-parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:

1. **Data flow analysis**: Computing the flow of data through the program.
2. **Loop classification**: Determining loop candidates for parallelization based on correctness and efficiency, as shown by Enabling Auto-parallelization.
3. **Dependency analysis**: Computing the dependency analysis for references in each loop nest.
4. **High-level parallelization**: Analyzing the dependency graph to determine loops that can execute in parallel, and computing run-time dependency.
5. **Data partitioning**: Examining data reference and partition based on the following types of access: `SHARED`, `PRIVATE`, and `FIRSTPRIVATE`.
6. **Multithreaded code generation**: Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel run-time routines for thread creation and synchronization.

**NOTE**
Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Enabling Auto-parallelization
Enabling Further Loop Parallelization for Multicore Platforms

Parallelizing loops for multicore platforms is subject to certain conditions. Three requirements must be met for the compiler to parallelize a loop:

- The number of iterations must be known before entry into a loop to insure that the work can be divided in advance. A do while loop, for example, usually cannot be made parallel.
- There can be no jumps into or out of the loop.
- The loop iterations must be independent (no cross-iteration dependencies).

Correct results must not logically depend on the order in which the iterations are executed. There may be slight variations in the accumulated rounding error, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location, for example, if they depend on function arguments, run-time data, or the results of complex calculations.

If the compiler cannot prove that pointers or array references are safe, it will not parallelize the loop, except in limited cases when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at run-time.

If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the !DIR$ PARALLEL directive.

Parallelizing Loops with Cross-iteration Dependencies

Before the compiler can auto-parallelize a loop, it must prove that the loop does not have potential cross-iteration dependencies that prevent parallelization. A cross-iteration dependency exists if a memory location is written to in an iteration of a loop and accessed (read from or written to) in another iteration of the loop. Cross-iteration dependencies often occur in loops that access overlapping array ranges, such as a loop that reads from a(1:100) and writes to a(0:99).

Sometimes, even though a loop does not have cross-iteration dependencies, the compiler does not have enough information to prove it and does not parallelize the loop. In such cases, you can assist the compiler by providing additional information about the loop using the !DIR$ PARALLEL directive. Adding the !DIR$ PARALLEL directive before a DO loop informs the compiler that the loop does not have cross-iteration dependencies. Auto-parallelization analysis ignores potential dependencies that it assumes could exist; however, the compiler still may not parallelize the loop if heuristics estimate parallelization is unlikely to increase performance of the loop.

The Fortran DO CONCURRENT construct also specifies that there are no cross-iteration dependencies.

The !DIR$ PARALLEL ALWAYS directive has the same effect to ignore potential dependencies as the !DIR$ PARALLEL directive, but it also overrides the compiler heuristics that estimate the likelihood that parallelization of a loop would increase performance. It allows a loop to be parallelized even when the compiler estimates that parallelization might not improve performance.

The !DIR$ NOPARALLEL directive prevents auto-parallelization of the immediately following DO loop. Unlike !DIR$ PARALLEL, which is a hint, the NOPARALLEL directive is guaranteed to prevent parallelization of the following loop.

These directives take effect only if auto-parallelization is enabled by the option [Q]parallel.
Parallelizing Loops with Private Clauses

When you use the Guided Auto Parallelism feature, the compiler's auto-parallelizer gives you advice on where to alter your program to enhance parallelization. For instance, you may get advice to check if a condition (that the compiler could not prove) is true, and if true, to insert `!DIR$ PARALLEL` in your source code so that the associated loop is parallelized when you recompile.

To specify that it is legal for each thread to create a new, private copy (not visible by other threads) of a variable, and replace the original variable in the loop with the new private variable, use the `!DIR$ PARALLEL` directive with the `private` clause. The `private` clause allows you to list scalar and array type variables and specify the number of array elements to privatize.

Use the `firstprivate` clause to specify private variables that need to be initialized with the original value before entering the parallel loop.

Use the `lastprivate` clause to specify those variables with a value you want to reuse after it exits a parallelized loop. When you use the `lastprivate` clause to handle a particular privatized variable, the value is copied to the original variable when it exits from the parallelized loop.

**NOTE**

Do not use the same variable in both `private` and `lastprivate` clauses for the same loop. You will get an error message.

Parallelizing Loops with External Function Calls

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependencies. Fortran90 programmers can use the PURE attribute to assert that subroutines and functions contain no side effects. You can invoke interprocedural optimization with the `[Q]ipo` option. Using this option gives the compiler the opportunity to analyze the called function for side effects.

Parallelizing Loops with OpenMP*

When the compiler is unable to automatically parallelize loops you know to be parallel, use OpenMP*. OpenMP* is the preferred solution because you understand the code better than the compiler and can express parallelism at a coarser granularity. Alternatively, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

Threshold Parameter to Parallelize Loops

If a loop can be parallelized, it does not necessarily mean that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `[Q]par-threshold` compiler option adjusts this behavior. The threshold ranges from 0 to 100, where 0 instructs the compiler to always parallelize a safe loop and 100 instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `[Q]par-report` option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized and indicate probable reason(s) why. See OpenMP* and Parallel Processing Options for more information on the using these compiler options.

The following example illustrates using the options in combination.
Example code

```fortran
subroutine add(k, a, b)
    integer :: k
    real :: a(10000), b(10000)
    do i = 1, 10000
        a(i) = a(i+k) + b(i)
    end do
end subroutine add
```

Because the compiler does not know the value of \( k \), the compiler assumes the iterations depend on each other, for example if \( k \) equals -1, even if the actual case is otherwise. You can override the compiler by inserting the `!DIR$ PARALLEL` directive.

Example

```fortran
subroutine add(k, a, b)
    integer :: k
    real :: a(10000), b(10000)
    !DIR$ PARALLEL
    do i = 1, 10000
        a(i) = a(i+k) + b(i)
    end do
end subroutine add
```

Caution

Do not call this function with a value of \( k \) that is less than 10000; passing a value less than 10000 could lead to incorrect results.

Vectorization

Automatic Vectorization
Automatic Vectorization Overview

The automatic vectorizer (also called the auto-vectorizer) is a component of the Intel® compiler that automatically uses SIMD instructions in the Intel® Streaming SIMD Extensions (Intel® SSE, Intel® SSE2, Intel® SSE3 and Intel® SSE4), Supplemental Streaming SIMD Extensions (SSSE3) instruction sets, and the Intel® Advanced Vector Extensions (Intel® AVX, Intel® AVX2) instruction sets. The vectorizer detects operations in the program that can be done in parallel and converts the sequential operations to parallel; for example, the vectorizer converts the sequential SIMD instruction that processes up to 16 elements into a parallel operation, depending on the data type.

Automatic vectorization occurs when the Intel® Compiler generates packed SIMD instructions to unroll a loop. Because the packed instructions operate on more than one data element at a time, the loop executes more efficiently. This process is referred to as auto-vectorization only to emphasize that the compiler identifies and optimizes suitable loops on its own, without requiring any special action by you. However, it is useful to note that in some cases, certain keywords or directives may be applied in the code for auto-vectorization to occur.

The compiler supports a variety of auto-vectorizing hints that can help the compiler to generate effective vector instructions. Automatic vectorization is supported on IA-32 and Intel® 64 architectures. Intel® Advisor XE, a separate tool included in some editions of Intel® Parallel Studio XE, provides a Vectorization Advisor feature that can analyze the compiler's optimization reports and make recommendations for enhancing vectorization.

Programming Guidelines for Vectorization

The goal of including the vectorizer component in the Intel® Fortran Compiler is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help by supplying the compiler with additional information; for example, by using auto-vectorizer hints or directives.

Guidelines to Vectorize Innermost Loops

Follow these guidelines to vectorize innermost loop bodies.

Use:

• straight-line code (a single basic block).
• vector data only; that is, arrays and invariant expressions on the right hand side of assignments.

Array references can appear on the left hand side of assignments.
• only assignment statements.

Avoid:

• function calls (other than math library calls).
• non-vectorizable operations (either because the loop cannot be vectorized, or because an operation is emulated through a number of instructions).
• mixing vectorizable types in the same loop (leads to lower resource utilization).
• data-dependent loop exit conditions (leads to loss of vectorization).

To make your code vectorizable, you will often need to make some changes to your loops. You should only make changes needed to enable vectorization, and avoid these common changes:
• loop unrolling, which the compiler performs automatically.
• decomposing one loop with several statements in the body into several single-statement loops.

Restrictions
There are a number of restrictions that you should consider. Vectorization depends on two major factors: hardware and style of source code.

<table>
<thead>
<tr>
<th>Factor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware</td>
<td>The compiler is limited by restrictions imposed by the underlying hardware. In the case of Intel® Streaming SIMD Extensions (Intel® SSE), the vector memory operations are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.</td>
</tr>
<tr>
<td>Style of source code</td>
<td>The style in which you write source code can inhibit vectorization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.</td>
</tr>
</tbody>
</table>

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, pointer arithmetic, and memory operations within the loop bodies.

By understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization.

Guidelines for Writing Vectorizable Code
Follow these guidelines to write vectorizable code:
• Use simple DO loops. Avoid complex loop termination conditions – the upper iteration limit must be invariant within the loop. For the innermost loop in a nest of loops, you could set the upper limit iteration to be a function of the outer loop indices.
• Write straight-line code. Avoid branches such as DO, GOTO, or ASSIGN statements; most function calls; or IF constructs that can not be treated as masked assignments.
• Avoid dependencies between loop iterations or at the least, avoid read-after-write dependencies.
• Try to use array notations instead of the use of pointers. Without help, the compiler often cannot tell whether it is safe to vectorize code containing pointers.
• Wherever possible, use the loop index directly in array subscripts instead of incrementing a separate counter for use as an array address.
• Access memory efficiently:
  • Favor inner loops with unit stride.
  • Minimize indirect addressing.
  • Align your data to 16-byte boundaries (for Intel® SSE instructions).
• Choose a suitable data layout with care. Most multimedia extension instruction sets are rather sensitive to alignment. The data movement instructions of Intel® SSE, for example, operate much more efficiently on data that is aligned at a 16-byte boundary in memory. Therefore, the success of a vectorizing compiler also depends on its ability to select an appropriate data layout which, in combination with code restructuring (like loop peeling), results in aligned memory accesses throughout the program.
• Use aligned data structures: Data structure alignment is the adjustment of any data object in relation with other objects.

**Caution**
Use this hint with care. Incorrect usage of aligned data movements result in an exception when using Intel® SSE.

• Use structure of arrays (SoA) instead of array of structures (AoS): An array is the most common type of data structure that contains a contiguous collection of data items that can be accessed by an ordinal index. You can organize this data as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization is excellent for encapsulation it can be a hindrance for use of vector processing. To make vectorization of the resulting code more effective, you can also select appropriate data structures.

**Dynamic Alignment Optimizations**
Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

To enable or disable dynamic data alignment optimizations, specify the option `qopt-dynamic-align[-]` (Windows) or `[no-]qopt-dynamic-align[-]` (Linux).

**Using Aligned Data Structures**
Data structure alignment is the adjustment of any data object with relation to other objects. The Intel® Fortran Compiler may align individual variables to start at certain addresses to speed up memory access. Misaligned memory accesses can incur large performance losses on certain target processors that do not support them in hardware.

Alignment is a property of a memory address, expressed as the numeric address modulo of powers of two. In addition to its address, a single datum also has a size. A datum is called 'naturally aligned' if its address is aligned to its size, otherwise it is called 'misaligned'. For example, an 8-byte floating-point datum is naturally aligned if the address used to identify it is aligned to eight (8).

A data structure is a way of storing data in a computer so that it can be used efficiently. Often, a carefully chosen data structure allows a more efficient algorithm to be used. A well-designed data structure allows a variety of critical operations to be performed, using as little resources - both execution time and memory space - as possible.

In the example data structure above, if the type `short` is stored in two bytes of memory then each member of the data structure is aligned to a boundary of two bytes. `Data1` would be at offset 0, `Data2` at offset 2 and `Data3` at offset 4. The size of this structure is six bytes. The type of each member of the structure usually has a required alignment, meaning that it is aligned on a pre-determined boundary, unless you request otherwise. In cases where the compiler has taken sub-optimal alignment decisions, you can use the declaration `declspec(align(base,offset))`, where $0 \leq offset < base$ and base is a power of two, to allocate a data structure at offset from a certain base.

If the first element of both arrays is aligned at a 16-byte boundary, then either an unaligned load of elements from b or an unaligned store of elements into a must be used after vectorization.

**NOTE**
In this case, peeling off an iteration will not help.

However, you can enforce the alignment shown below, which results in two aligned access patterns after vectorization (assuming an 8-byte size for doubles):
Run-time optimization provides a generally effective way to obtain aligned access patterns at the expense of a slight increase in code size and testing. If incoming access patterns are guaranteed to be aligned at a 16-byte boundary, you can avoid this overhead with the hint `__assume_aligned(x, 16);` in the function to convey this information to the compiler.

For example, suppose you can introduce an optimization in the case where a block of memory with address \( n_2 \) is aligned on a 16-byte boundary. You could use `__assume(n2%16==0)`.

**Caution**
Use this hint with care. Incorrect use of aligned data movements result in an exception for Intel® SSE.

### Using Structure of Arrays versus Array of Structures

The most common and well-known data structure is the array that contains a contiguous collection of data items, which can be accessed by an ordinal index. This data can be organized as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization works excellently for encapsulation, for vector processing it works poorly.

You can select appropriate data structures to make vectorization of the resulting code more effective. To illustrate this point, compare the traditional array of structures (AoS) arrangement for storing the \( r, g, b \) components of a set of three-dimensional points with the alternative structure of arrays (SoA) arrangement for storing this set.

With the AoS arrangement, a loop that visits all components of an RGB point before moving to the next point exhibits a good locality of reference because all elements in the fetched cache lines are utilized. The disadvantage of the AoS arrangement is that each individual memory reference in such a loop exhibits a non-unit stride, which, in general, adversely affects vector performance. Furthermore, a loop that visits only one component of all points exhibits less satisfactory locality of reference because many of the elements in the fetched cache lines remain unused.

In contrast, with the SoA arrangement the unit-stride memory references are more amenable to effective vectorization and still exhibit good locality of reference within each of the three data streams. Consequently, an application that uses the SoA arrangement may ultimately outperform an application based on the AoS arrangement when compiled with a vectorizing compiler, even if this performance difference is not directly apparent during the early implementation phase.

Before you start vectorization, try out some simple rules:

- Make your data structures vector-friendly.
- Make sure that inner loop indices correspond to the outermost (last) array index in your data (row-major order).
- Use structure of arrays over array of structures.

For instance when dealing with three-dimensional coordinates, use three separate arrays for each component (SoA), instead of using one array of three-component structures (AoS). To avoid dependencies between loops that will eventually prevent vectorization, use three separate arrays for each component (SoA), instead of...
one array of three-component structures (AoS). When you use the AoS arrangement, each iteration produces
one result by computing XYZ, but it can at best use only 75% of the SSE unit because the forth component is
not used. Sometimes, the compiler may use only one component (25%). When you use the SoA
arrangement, each iteration produces four results by computing XXXX, YYYY and ZZZZ, using 100% of the
SSE unit. A drawback for the SoA arrangement is that your code will likely be three times as long. On the
other hand, the compiler might not be able to vectorize AoS arranged code at all.

If your original data layout is in AoS format, you may even want to consider a conversion to SoA on the fly,
before the critical loop. If it gets vectorized, it may be worth the effort!

To summarize:

• Use the smallest data types that gives the needed precision to maximize potential SIMD width. (If only
16-bits are needed, using a short rather than an int can make the difference between 8-way or four-
way SIMD parallelism, respectively.)
• Avoid mixing data types to minimize type conversions.
• Avoid operations not supported in SIMD hardware.
• Use all the instruction sets available for your processor. Use the appropriate command line option for your
processor type, or select the appropriate IDE option (Windows* only):
  • Project > Properties > Visual Fortran > Code Generation > Intel Processor-Specific
    Optimization, if your application runs only on Intel® processors.
  • Project > Properties > Visual Fortran > Code Generation > Enable Enhanced Instruction
    Set, if your application runs on compatible, non-Intel processors.
• Vectorizing compilers usually have some built-in efficiency heuristics to decide whether vectorization is
likely to improve performance. The Intel® Fortran Compiler disables vectorization of loops with many
unaligned or non-unit stride data access patterns. If experimentation reveals that vectorization improves
performance, you can override this behavior using the !DIR$ VECTOR ALWAYS hint before the loop; the
compiler vectorizes any loop regardless of the outcome of the efficiency analysis (provided, of course, that
vectorization is safe).

Using Automatic Vectorization

Automatic vectorization is supported on IA-32 and Intel® 64 architectures. The information below will guide
you in setting up the auto-vectorizer.

Vectorization Speed-up

Where does the vectorization speedup come from? Consider the following sample code fragment, where a, b
and c are integer arrays:

<table>
<thead>
<tr>
<th>Sample Code Fragment</th>
</tr>
</thead>
<tbody>
<tr>
<td>do I=1,MAX</td>
</tr>
<tr>
<td>C(I)=A(I)+B(I)</td>
</tr>
<tr>
<td>end do</td>
</tr>
</tbody>
</table>
If vectorization is not enabled (that is, you compile using \texttt{O1} or \texttt{[Q]vec-} options), for each iteration, the compiler processes the code such that there is a lot of unused space in the SIMD registers, even though each of the registers could hold three additional integers. If vectorization is enabled (compiled using \texttt{O2} or higher options), the compiler may use the additional registers to perform four additions in a single instruction. The compiler looks for vectorization opportunities whenever you compile at default optimization (\texttt{O2}) or higher.

\textbf{NOTE}

Using this option enables vectorization at default optimization levels for both Intel\textsuperscript{®} microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel\textsuperscript{®} microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as \texttt{/arch} (Windows\textsuperscript{*}), \texttt{--m} (Linux\textsuperscript{*} and macOS\textsuperscript{*}), or \texttt{[Q]x}.

\textbf{Tip}

To allow comparisons between vectorized and not-vectorized code, disable vectorization using the \texttt{/Qvec-} (Windows\textsuperscript{*}) or \texttt{--no-vec} (Linux\textsuperscript{*} or macOS\textsuperscript{*}) option; enable vectorization using the \texttt{O2} option.

To get information on whether a loop was vectorized or not, enable generation of the optimization report using the options \texttt{Qopt-report:1 Qopt-report-phase:vec} (Windows\textsuperscript{*}) or \texttt{qopt-report=1 qopt-report-phase=vec} (Linux\textsuperscript{*} and macOS\textsuperscript{*}) options. These options generate a separate report in an \texttt{.optrpt} file that includes optimization messages. In Visual Studio, the program source is annotated with the report's messages, or you can read the resulting \texttt{.optrpt} file using a text editor. A message appears for every loop that is vectorized, such as:

\begin{verbatim}
Example: Vectorization Report

> ifort /Qopt-report:1 matvec.f90
> type matvec.optrpt

... LOOP BEGIN at C:\Projects\vec_samples\matvec.f90(38,6)
   remark #15300: LOOP WAS VECTORIZED
   LOOP END

\end{verbatim}

The source line number (38 in the above example) refers to either the beginning or the end of the loop.

To get details about the type of loop transformations and optimizations that took place, use the \texttt{[Q]opt-report-phase} option by itself or along with the \texttt{[Q]opt-report} option.

How significant is the performance enhancement? To evaluate performance enhancement yourself, run \texttt{vec_samples}:

1. Open an Intel\textsuperscript{®} Compiler command line window.
   - \textbf{On Windows\textsuperscript{*}}: Under the Start menu item for your Intel product, select an icon under Compiler and Performance Libraries > Command Prompt with Intel Compiler
   - \textbf{On Linux\textsuperscript{*} and macOS\textsuperscript{*}}: Source an environment script such as \texttt{compilervars.sh} or the \texttt{compilervars.csh} in the \texttt{<installdir>/bin} directory and use the attribute appropriate for the architecture.
2. Navigate to the \texttt{<install-dir>/Samples/<locale>/Fortran\ directory. On Windows, unzip the sample project \texttt{vec_samples.zip} to a writable directory. This small application multiplies a vector by a matrix using the following loop:
Example: Vector Matrix Multiplication

\[
\text{do } i=1, \text{size1} \\
\quad c(i) = c(i) + a(i,j) \times b(j) \\
\text{end do}
\]

3. Build and run the application, first without enabling auto-vectorization. The default \texttt{O2} optimization enables vectorization, so you need to disable it with a separate option. Note the time taken for the application to run.

Example: Building and Running an Application without Auto-vectorization

// (Linux* and macOS*)
ifort -no-vec driver.f90 matvec.f90 -o NoVectMult
./NoVectMult

// (Windows*)
ifort /Qvec- driver.f90 matvec.f90 /exe:NoVectMult
NoVectMult

4. Now build and run the application, this time with auto-vectorization. Note the time taken for the application to run.

Example: Building and Running an Application with Auto-vectorization

// (Linux* and macOS*)
ifort driver.f90 matvec.f90 -o VectMult
./VectMult

// (Windows*)
ifort driver.f90 matvec.f90 /exe:VectMult
VectMult

When you compare the timing of the two runs, you may see that the vectorized version runs faster. The time for the non-vectorized version is only slightly faster than would be obtained by compiling with the \texttt{O1} option.

Obstacles to Vectorization

The following do not always prevent vectorization, but frequently either prevent it or cause the compiler to decide that vectorization would not be worthwhile.

- **Non-contiguous memory access:** Four consecutive integers or floating-point values, or two consecutive doubles, may be loaded directly from memory in a single SSE instruction. But if the four integers are not adjacent, they must be loaded separately using multiple instructions, which is considerably less efficient. The most common examples of non-contiguous memory access are loops with non-unit stride or with indirect addressing, as in the examples below. The compiler rarely vectorizes such loops, unless the amount of computational work is large compared to the overhead from non-contiguous memory access.

Example: Non-contiguous Memory Access

```
! arrays accessed with stride 2
do I=1,SIZE,2; B(I)=B(I)+(A(I)*X(I)); end do

! inner loop accesses a A with stride SIZE
do J=1,SIZE
  do I=1,SIZE
    B(I)=B(I)+(A(J,I)*X(J))
  end do
end do
```
The typical message from the vectorization report is: vectorization possible but seems inefficient, although indirect addressing may also result in the following report: Existence of vector dependence.

- **Data dependencies:** Vectorization entails changes in the order of operations within a loop, since each SIMD instruction operates on several data elements at once. Vectorization is only possible if this change of order does not change the results of the calculation.

  - The simplest case is when data elements that are written (stored to) do not appear in any other iteration of the individual loop. In this case, all the iterations of the original loop are independent of each other, and can be executed in any order, without changing the result. The loop may be safely executed using any parallel method, including vectorization. All the examples considered so far fall into this category.

  - When a variable is written in one iteration and read in a subsequent iteration, there is a “read-after-write” dependency, also known as a flow dependency, as in this example:

```
Example: Flow Dependency

DO J=2,5
   A(J)=A(J-1)+1
END DO
```

So the value of j gets propagated to all A(J). This cannot safely be vectorized: if the first two iterations are executed simultaneously by a SIMD instruction, the value of A(2) is used by the second iteration before it has been calculated by the first iteration.

  - When a variable is read in one iteration and written in a subsequent iteration, this is a write-after-read dependency, also known as an anti-dependency, as in the following example:

```
Example: Write-after-read Dependency

do J=2,MAX; A(J-1)=A(J)+1; end do
   ! this is equivalent to:
   A(1)=A(2)+1
   A(2)=A(3)+1
   A(3)=A(4)+1
   A(4)=A(5)+1
```

This write-after-read dependency is not safe for general parallel execution, since the iteration with the write may execute before the iteration with the read. However, for vectorization, no iteration with a higher value of j can complete before an iteration with a lower value of j, and so vectorization is safe (that is, it gives the same result as non-vectorized code) in this case. The following example, however, may not be safe, since vectorization might cause some elements of A to be overwritten by the first SIMD instruction before being used for the second SIMD instruction.

```
Example: Unsafe Vectorization

do J=1,MAX
   A(J-1)=A(J)+1
   B(J)=A(J)*2
end do
```
Example: Unsafe Vectorization

```fortran
! this is equivalent to:
A(1)=A(2)+1
A(2)=A(3)+1
A(3)=A(4)+1
A(4)=A(5)+1
```

- Read-after-read situations are not really dependencies, and do not prevent vectorization or parallel execution. If a variable is unwritten, it does not matter how often it is read.
- Write-after-write, or ‘output’, dependencies, where the same variable is written to in more than one iteration, are in general unsafe for parallel execution, including vectorization.
- One important exception, that apparently contains all of the above types of dependency:

Example: Dependency Exception

```fortran
MYSUM=0
do J=1,MAX; MYSUM = MYSUM + A(J)*B(J); end do
```

Although `MYSUM` is both read and written in every iteration, the compiler recognizes such reduction idioms, and is able to vectorize them safely. The loop in the first example was another example of a reduction, with a loop-invariant array element in place of a scalar.

These types of dependencies between loop iterations are sometimes known as loop-carried dependencies.

The above examples are of proven dependencies. The compiler cannot safely vectorize a loop if there is even a potential dependency. Consider the following example:

Example: Potential Dependency

```fortran
real, pointer :: A(:),B(:),C(:)
...
do I=1,SIZE; C(I)=A(I)*B(I); end do
```

In the above example, the compiler needs to determine whether, for some iteration `I`, `C(I)` might refer to the same memory location as `A(I)` or `B(I)` for a different iteration. Such memory locations are sometimes said to be aliased. For example, if `A(I)` pointed to the same memory location as `C(I-1)`, there would be a read-after-write dependency as in the earlier example. If the compiler cannot exclude this possibility, it will not vectorize the loop unless you provide the compiler with hints. You can also avoid this problem by making the arrays ALLOCATABLE instead of POINTER, as the compiler knows these cannot be aliased.

Vectorization and Loops

This topic provides more information on the interaction between the auto-vectorizer and loops.
Interactions with Loop Parallelization

Combine the [Q]parallel and [Q]x options to instruct the Intel® Fortran Compiler to attempt both Auto-Parallelization and automatic loop vectorization in the same compilation.

**NOTE**
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

**NOTE**
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

In some rare cases, a successful loop parallelization (either automatically or by means of OpenMP* directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where the /Qopt-report:2 /Qopt-report-phase:vec (Windows) or -qopt-report=2 -qopt-report-phase=vec (Linux and macOS*) options indicate that loops were not successfully vectorized.

Types of Vectorized Loops

For integer loops, the 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) and the Intel® Advanced Vector Extensions (Intel® AVX) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types, with limited support for the 64-bit integer data type.

Vectorization may proceed if the final precision of integer wrap-around arithmetic is preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the Intel® SSE and the Intel® AVX instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators:

- addition (+)
- subtraction (-)
- multiplication (*)
- division (/)

Additionally, Intel® SSE provide SIMD instructions for the binary MIN and MAX and unary SQRT operators. SIMD versions of several other mathematical operators (like the trigonometric functions SIN, COS, and TAN) are supported in software in a vector mathematical run-time library that is provided with the Intel® Fortran Compiler.

To be vectorizable, loops must be:
• **Countable:** The loop trip count must be known at entry to the loop at runtime, though it need not be known at compile time (that is, the trip count can be a variable but the variable must remain constant for the duration of the loop). This implies that exit from the loop must not be data-dependent.

• **Innermost loop of a nest:** The only exception is if an original outer loop is transformed into an inner loop as a result of some other prior optimization phase, such as unrolling, loop collapsing or interchange, or an original outermost loop is transformed to an innermost loop due to loop materialization.

• **Without function calls:** Even a `print` statement is sufficient to prevent a loop from getting vectorized. The vectorization report message is typically: non-standard loop is not a vectorization candidate. The two major exceptions are for intrinsic math functions and for functions that may be inlined.

Intrinsic math functions are allowed, because the compiler runtime library contains vectorized versions of these functions. See the table below for a list of these functions; most exist in both float and double versions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>acos</td>
<td>atanh</td>
<td>exp2</td>
<td>tan</td>
</tr>
<tr>
<td>acosh</td>
<td>ceiling</td>
<td>floor</td>
<td>tanh</td>
</tr>
<tr>
<td>anint</td>
<td>cos</td>
<td>log</td>
<td></td>
</tr>
<tr>
<td>asin</td>
<td>cosh</td>
<td>log10</td>
<td></td>
</tr>
<tr>
<td>asinh</td>
<td>erf</td>
<td>sin</td>
<td></td>
</tr>
<tr>
<td>atan</td>
<td>erfc</td>
<td>sinh</td>
<td></td>
</tr>
<tr>
<td>atan2</td>
<td>exp</td>
<td>sqrt</td>
<td></td>
</tr>
</tbody>
</table>

The loop in the following example may be vectorized because `sqrt()` is vectorizable and `func()` gets inlined. Inlining is enabled at default optimization for functions in the same source file. An inlining report may be obtained by setting the options `/Qopt-report:2 /Qopt-report-phase:ipo` (Windows) or `-qopt-report=2 -qopt-report-phase=ipo` (Linux).

**Statements in the Loop Body**

The vectorizable operations are different for floating-point and integer data.

**Integer Array Operations**

The statements within the loop body may be arithmetic or logical operations (again, typically for arrays). Arithmetic operations are limited to such operations as addition, subtraction, ABS, MIN, and MAX. Logical operations include bitwise AND, OR, and XOR operators. You can mix data types but this may potentially cost you in terms of lowering efficiency.

**Other Operations**

No statements other than the preceding floating-point and integer operations are valid. The loop body cannot contain any function calls other than the ones described above.

**Data Dependency**

Data dependency relations represent the required ordering constraints on the operations in serial loops. Because vectorization rearranges the order in which operations are executed, any auto-vectorizer must have at its disposal some form of data dependency analysis.

An example where data dependencies prohibit vectorization is shown below. In this example, the value of each element of an array is dependent on the value of its neighbor that was computed in the previous iteration.
Example 1: Data-dependent Loop

```fortran
subroutine dep(data, n)
  real :: data(n)
  integer :: i
  do i = 1, n-1
    data(i) = data(i-1)*0.25 + data(i)*0.5 + data(i+1)*0.25
  end do
end subroutine dep
```

The loop in the above example is not vectorizable because the WRITE to the current element `data(i)` is dependent on the use of the preceding element `data(i-1)`, which has already been written to and changed in the previous iteration. To see this, look at the access patterns of the array for the first two iterations as shown below.

Example 2: Data-dependency Vectorization Patterns

```
I=1: READ DATA(0)
    READ DATA(1)
    READ DATA(2)
    WRITE DATA(1)
I=2: READ DATA(1)
    READ DATA(2)
    READ DATA(3)
    WRITE DATA(2)
```

In the normal sequential version of this loop, the value of `DATA(1)` read from during the second iteration was written to in the first iteration. For vectorization, it must be possible to do the iterations in parallel, without changing the semantics of the original loop.

Example 3: Data Independent Loop

```fortran
do i=1,100
  a(i)=b(i)
end do
```

! which has the following access pattern
```
read b(1)
write a(1)
read b(2)
write b(2)
```

Data Dependency Analysis

Data dependency analysis involves finding the conditions under which two memory accesses may overlap. Given two references in a program, the conditions are defined by:

- whether the referenced variables may be aliases for the same (or overlapping) regions in memory.
- for array references, the relationship between the subscripts.

The data dependency analyzer for array references is organized as a series of tests, which progressively increase in power as well as in time and space costs.

First, a number of simple tests are performed in a dimension-by-dimension manner, since independency in any dimension will exclude any dependency relationship. Multidimensional arrays references that may cross their declared dimension boundaries can be converted to their linearized form before the tests are applied.
Some of the simple tests that can be used are the fast greatest common divisor (GCD) test and the extended bounds test. The GCD test proves independency if the GCD of the coefficients of loop indices cannot evenly divide the constant term. The extended bounds test checks for potential overlap of the extreme values in subscript expressions.

If all simple tests fail to prove independency, the compiler will eventually resort to a powerful hierarchical dependency solver that uses Fourier-Motzkin elimination to solve the data dependency problem in all dimensions.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**Loop Constructs**

Loops can be formed with the usual `DO-END DO` and `DO WHILE`, or by using an `IF/GOTO` and a label. Loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized.

**Example: Vectorizable structure**

```fortran
subroutine vec(a, b, c)
   dimension a(100), b(100), c(100)
   integer i
   i = 1
   do while (i .le. 100)
      a(i) = b(i) * c(i)
      if (a(i) .lt. 0.0) a(i) = 0.0
      i = i + 1
   enddo
end subroutine vec
```

The following example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.
**Example: Non-vectorizable structure**

```fortran
subroutine no_vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
  ! The next statement allows early exit from the loop and prevents vectorization of the loop.
  ! if (a(i) .lt. 0.0) go to 10
  i = i + 1
  enddo
  10 continue
end subroutine no_vec
END
```

**Loop Exit Conditions**

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable; in other words, the number of iterations must be expressed as one of the following:

- A constant.
- A loop invariant term.
- A linear function of outermost loop indices.

In the case where a loop's exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable.

**Example: Countable Loop**

```fortran
subroutine cnt1 (a, b, c, n, lb)
  dimension a(n), b(n), c(n)
  integer n, lb, i, count
  ! Number of iterations is "n - lb + 1"
  count = n
  do while (count .ge. lb)
    a(i) = b(i) * c(i)
    count = count - 1
    i = i + 1
  enddo ! lb is not defined within loop
end
```

The following example demonstrates a different countable loop construct.

**Example: Countable Loop**

```fortran
! Number of iterations is (n-m+2)/2
subroutine cnt2 (a, b, c, m, n)
  dimension a(n), b(n), c(n)
  integer i, l, m, n
  i = 1;
  do l = m,n,2
    a(i) = b(i) * c(i)
  enddo
end
```
The following examples demonstrate a loop construct that is non-countable due to dependency loop variant count value.

**Example: Countable Loop**

```fortran
i = i + 1
enddo
end
```

**Example: Non-Countable Loop**

```fortran
! Number of iterations is dependent on a(i)
subroutine foo (a, b, c)
  dimension a(100),b(100),c(100)
  integer i
  i = 1
  do while (a(i) .gt. 0.0)
    a(i) = b(i) * c(i)
    i = i + 1
  enddo
end
```

**Strip-mining and Cleanup**

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encodings of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- By increasing the temporal and spatial locality in the data cache if the data are reusable in different passes of an algorithm.
- By reducing the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. In the case of Intel® Streaming SIMD Extensions, this vector or strip-length is reduced by four times: four floating-point data items per single Intel® SSE single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the following loop:

**Example: Before Vectorization**

```fortran
i = 1
do while (i<=n)
  a(i) = b(i) + c(i) ! Original loop code
  i = i + 1
end do
```

The compiler might handle the strip mining and loop cleaning by restructuring the loop in the following manner:

**Example: After Vectorization**

```fortran
!The vectorizer generates the following two loops
i = 1
do while (i < (n - mod(n,4)))
```
Example: After Vectorization

![Vector strip-mined loop.  
\[ a(i:i+3) = b(i:i+3) + c(i:i+3) \]  
\[ i = i + 4 \]  
end do  
\[ \text{do while (i <= n)} \]  
\[ a(i) = b(i) + c(i) \]  
\[ i = i + 1 \]  
end do

Loop Blocking

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, thereby maximizing data reuse.

Consider the following example. The two-dimensional array \( A \) is referenced in the \( j \) (column) direction and then in the \( i \) (row) direction (column-major order); array \( B \) is referenced in the opposite manner (row-major order). Assume the memory layout is in column-major order; therefore, the access strides of array \( A \) and \( B \) for the code would be 1 and \( \text{MAX} \), respectively. \( BS = \text{block} \_\text{size}; \text{MAX} \) must be evenly divisible by \( BS \).

Consider the following loop example code:

Example: Original loop

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I =1, MAX
   DO J = 1, MAX
      A(I,J) = A(I,J) + B(J,I)
   ENDDO
ENDDO
```

The arrays could be blocked into smaller chunks so that the total combined size of the two blocked chunks is smaller than the cache size, which can improve data reuse. One possible way of doing this is demonstrated below:

Example: Transformed Loop after blocking

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I =1, MAX, BS
   DO J = 1, MAX, BS
      DO II = I, I+MAX, BS-1
         DO JJ = J, J+MAX, BS-1
            A(II,JJ) = A(II,JJ) + B(JJ,II)
         ENDDO
      ENDDO
   ENDDO
ENDDO
```

Loop Interchange and Subscripts: Matrix Multiply

Loop interchange is often used for improving memory access patterns. Matrix multiplication is commonly written as shown in the following example:
Example: Typical Matrix Multiplication

```fortran
subroutine matmul_slow(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do i = 1, n
    do j = 1, n
      do k = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      end do
    end do
  end do
end subroutine matmul_slow
```

The use of \( B(K,J) \) is not a stride-1 reference and therefore will not be vectorized efficiently.

If the loops are interchanged, however, all the references will become stride-1 as shown in the following example.

Example: Matrix Multiplication with Stride-1

```fortran
subroutine matmul_fast(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do j = 1, n
    do k = 1, n
      do i = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      enddo
    enddo
  enddo
end subroutine matmul_fast
```

Interchanging is not always possible because of dependencies, which can lead to different results.

**Explicit Vector Programming**

**User-Mandated or SIMD Vectorization**

User-mandated or SIMD vectorization supplements automatic vectorization just like OpenMP* parallelization supplements automatic parallelization. The following figure illustrates this relationship. User-mandated vectorization is implemented as a single-instruction-multiple-data (SIMD) feature and is referred to as SIMD vectorization.

**NOTE**

The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.
SIMD vectorization uses the !$OMP SIMD directive to effect loop vectorization. You must add this directive to a loop and recompile to vectorize the loop using the option -qopenmp-simd (Linux and macOS*) or Qopenmp-simd (Windows*).

Consider an example in Fortran where the compiler does not automatically vectorize the loop due to the unknown data dependence distance between \( i \) and \( 2 \times i \). If you know that \( X \) is large enough that data \( A(i) \) and \( A(2i) \) don’t overlap within a reasonable number of iterations, perhaps 64, you can enforce vectorization of the loop using !$OMP SIMD. If you know that they don’t overlap in at least 8 iterations you may additionally specify !$OMP SIMD SIMDLEN(8) to avoid vectorization that is too wide, which might lead to overlap.

**Example: without !$OMP SIMD**

```fortran
[D:/simd] cat example1.f
subroutine add(A, N, X)
integer N, X
real A(N)
DO I=X, N
   A(I) = A(I) + A(2*I)
ENDDO
End
```

```bash
```

```
Begin optimization report for: ADD

Report from: Vector optimizations [vec]

===========================================================================

Example: with !$OMP SIMD

```
subroutine add(A, N, X)
integer N, X
real    A(N)
!X may be 8 or more, so on overlap with 8 iterations at least
!$OMP SIMD SIMDLEN(8)
DO I=X, N
   A(I) = A(I) + A(2*I)
ENDDO
End
```

```
Begin optimization report for: ADD
   Report from: Vector optimizations [vec]

LOOP BEGIN at example1.f(6,9)
  <Peeled loop for vectorization>
LOOP END

LOOP BEGIN at example1.f(6,9)
   remark #15301: OpenMP SIMD LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at example1.f(6,9)
  <Remainder loop for vectorization>
LOOP END
===========================================================================
```

The one big difference between using !$OMP SIMD and auto-vectorization hints is that with !$OMP SIMD, the compiler generates a warning when it is unable to vectorize the loop. With auto-vectorization hints, actual vectorization is still under the discretion of the compiler, even when you use the !DIRS VECTOR ALWAYS hint.

$OMP SIMD has optional clauses to guide the compiler on how vectorization must proceed. Use these clauses appropriately so that the compiler obtains enough information to generate correct vector code. For more information on the clauses, see the !$OMP SIMD description.

## Additional Semantics

Note the following points when using the !$OMP SIMD directive.

- A variable may belong to zero or one of the following: private, linear, or reduction.
- Within the vector loop, an expression is evaluated as a vector value if it is private, linear, reduction, or it has a sub-expression that is evaluated to a vector value. Otherwise, it is evaluated as a scalar value (that is, broadcast the same value to all iterations). Scalar value does not necessarily mean loop invariant, although that is the most frequently seen usage pattern of scalar value.
• A vector value may not be assigned to a scalar L-value. It is an error.
• A scalar L-value may not be assigned under a vector condition. It is an error.
• The computed GOTO statement is not supported.

Using vector Declaration

Consider the following Intel® Visual Fortran example code for a program to compare serial and vector computations using a user-defined function, foo().

**NOTE** All code examples in this section are applicable for Fortran on Windows* only.

### Example: Where user-defined function is not vectorized

```fortran
!! file simdmain.f90
program simdtest
use IFPORT
! Test vector function in external file.
implicit none
interface
   integer function foo(a, b)
      integer a, b
   end function foo
end interface

integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1, a2, s_a3, v_a3
logical :: err_flag = .false.

! compute random numbers for arrays
do j = 1, N
   do i = 1, M
      a1(i,j) = rand() * M
      a2(i,j) = rand() * M
   end do
end do

! compute serial results
do j = 1, N
   !dir$ novector
   do i = 1, M
      s_a3(i,j) = foo(a1(i,j), a2(i,j))
   end do
end do

! compute vector results
do j = 1, N
   do i = 1, M
      v_a3(i,j) = foo(a1(i,j), a2(i,j))
   end do
end do
```
Example: Where user-defined function is not vectorized

```fortran
! compare serial and vector results
do j = 1, N
  do i = 1, M
    if (s_a3(i,j) .ne. v_a3(i,j)) then
      err_flag = .true.
      print *, s_a3(i, j), v_a3(i,j)
    end if
  end do
end do
if (err_flag .eq. .true.) then
  write(*,*) "FAILED"
else
  write(*,*) "PASSED"
end if
end program

!! file: vecfoo.f90
integer function foo(a, b)
implicit none
integer, intent(in) :: a, b
foo = a - b
end function
```

```bash
simdmain.f90 vecfoo.f90
```

Begin optimization report for: SIMDTEST

   Report from: Vector optimizations [vec]

   LOOP BEGIN at simdmain.f90(33,3)
   remark #15319: loop was not vectorized: novector directive used
   LOOP END

   LOOP BEGIN at simdmain.f90(54,2)
   remark #15541: outer loop was not auto-vectorized: consider using SIMD directive

   LOOP BEGIN at simdmain.f90(47,3)
   remark #15344: loop was not vectorized: vector dependence prevents vectorization. First
   dependence is shown below.
   Use level 5 report for details
   remark #15346: vector dependence: assumed OUTPUT dependence between at(50:5) and at (50:5)
   LOOP END

   LOOP END

   Non-optimizable loops:

   LOOP BEGIN at simdmain.f90(28,2)
   remark #15543: loop was not vectorized: loop with function call not considered an
   optimization candidate.
   LOOP BEGIN at simdmain.f90(27,3)
```
Example: Where user-defined function is not vectorized

remark #15543: loop was not vectorized: loop with function call not considered an optimization candidate.
LOOP END
LOOP END

LOOP BEGIN at simdmain.f90(36,2)
  remark #15543: loop was not vectorized: loop with function call not considered an optimization candidate.
  LOOP END

LOOP BEGIN at simdmain.f90(43,3)
  remark #15543: loop was not vectorized: loop with function call not considered an optimization candidate.

LOOP BEGIN at simdmain.f90(42,4)
  remark #15543: loop was not vectorized: loop with function call not considered an optimization candidate.
  LOOP END

LOOP END

When you compile the above code, the loop containing the foo() function is not auto-vectorized because the auto-vectorizer does not know what foo() does unless it is inlined to this call site.

In such cases where the function call is not inlined, you can use the !DIR$ attributes vector::function-name-list declaration to vectorize the loop and the function foo(). All you need to do is add the vector declaration to the function declaration, and recompile the code. The loop and function are vectorized.

Example: Where loop with user-defined function with vector declaration is auto-vectorized

!! file simdmain.f90
program simdtest
! Test vector function in external file.
use IFPORT
implicit none
interface
  integer function foo(a, b)
  !$omp declare simd
    integer a, b
  end function foo
end interface

integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1
integer, dimension(M,N) :: a2
integer, dimension(M,N) :: s_a3
integer, dimension(M,N) :: v_a3
logical :: err_flag = .false.

! compute random numbers for arrays
do j = 1, N
  do i = 1, M
Example: Where loop with user-defined function with vector declaration is auto-vectorized

```fortran
  a1(i,j) = rand() * M
  a2(i,j) = rand() * M
  end do
  end do

  ! compute serial results
  do j = 1, N
    !dir$ novector
    do i = 1, M
      s_a3(i,j) = foo(a1(i,j), a2(i,j))
    end do
    end do

  ! compute vector results
  do j = 1, N
    do i = 1, M
      v_a3(i,j) = foo(a1(i,j), a2(i,j))
    end do
  end do

  ! compare serial and vector results
  do j = 1, N
    do i = 1, M
      if (s_a3(i,j) .ne. v_a3(i,j)) then
        err_flag = .true.
        print *, s_a3(i,j), v_a3(i,j)
      end if
    end do
  end do

  if (err_flag .eq. .true.) then
    write(*,*) "FAILED"
  else
    write(*,*) "PASSED"
  end if
  end program
```

```fortran

remark #15347: FUNCTION WAS VECTORIZED with xmm, simdlen=4, unmasked, formal parameter types: (vector,vector)
===========================================================================
Begin optimization report for: FOO..xM4vv
Report from: Vector optimizations [vec]
remark #15347: FUNCTION WAS VECTORIZED with xmm, simdlen=4, masked, formal parameter types:
Restrictions on Using !$omp declare simd declaration

Vectorization depends on two major factors: hardware and the style of source code. When using the vector declaration, the following features are not allowed:

- Locks, barriers, atomic construct, critical sections (These are allowed inside !$OMP ORDERED SIMD blocks).
- Computed and assigned GOTO and SELECT CASE constructs (in some cases these may be supported and converted to IF statements).
- The GOTO statement, into or out of a function.
- An ENTRY statement.

Non-vector function calls are generally allowed within vector functions but calls to such functions are serialized lane-by-lane and so might perform poorly. Also for SIMD-enabled functions it is not allowed to have side effects except writes by their arguments. This rule can be violated by non-vector function calls, so be careful executing such calls in SIMD-enabled functions and subroutines.

Formal parameters must be of the following data types:

- (un)signed 8, 16, 32, or 64-bit integer
- 32- or 64-bit floating point
- 64- or 128-bit complex

Function Annotations and the SIMD Directive for Vectorization

Function Annotations and the SIMD Directive for Vectorization

This topic presents specific Fortran language features that better help to vectorize code.

NOTE
The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x.

The !DIR$ ATTRIBUTES ALIGN:N directive enables you to overcome hardware alignment constraints. The restrict qualifier and the auto-vectorization hints address the stylistic issues due to lexical scope, data dependency, and ambiguity resolution. The SIMD feature's directive allows you to enforce vectorization of loops.

You can use the !DIR$ ATTRIBUTES VECTOR[:clauses]:function-name-listdirective to vectorize user-defined functions and loops. For SIMD usage, a function with the VECTOR attribute is called from a loop that is being vectorized.

You can use the and declarations to provide a user-defined vector implementation for a function.

The usage model of the VECTOR attribute is that the code generated for the function actually takes a small section ( VECTORLENGTH ) of the array, by value, and exploits SIMD parallelism, whereas the implementation of task parallelism is done at the call site.
The following table summarizes the language features that help vectorize code.

<table>
<thead>
<tr>
<th>Language Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DIR$ ATTRIBUTES ALIGN : n :: var</td>
<td>Directs the compiler to align the variable to an n-byte boundary. Address of the variable is address mod n=0.</td>
</tr>
<tr>
<td>!DIR$ ATTRIBUTES VECTOR [: clauses] :: function-name-list</td>
<td>Provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. The clauses are: • PROCESSOR • VECTORLENGTH • LINEAR • UNIFORM • [NO]MASK</td>
</tr>
</tbody>
</table>

### Auto-Vectorization Hints

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DIR$ IVDEP</td>
<td>Instructs the compiler to ignore assumed vector dependencies.</td>
</tr>
<tr>
<td>!DIR$ VECTOR [ALWAYS]</td>
<td>Specifies how to vectorize the loop and indicates that efficiency heuristics should be ignored. Using the ASSERT keyword with the VECTOR [ALWAYS] directive generates an error-level assertion message if the compiler efficiency heuristics indicate that the loop cannot be vectorized. Use !DIR$ IVDEP to ignore the assumed dependencies.</td>
</tr>
<tr>
<td>!DIR$ NOVECTOR</td>
<td>Specifies that the loop should never be vectorized.</td>
</tr>
</tbody>

- VECTOR ALWAYS and NOVECTOR directive
- ATTRIBUTE directive
- User-mandated or SIMD Vectorization

---

**NOTE**

Some directives are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.
Guided Auto Parallelism

NOTE This feature has been deprecated.

The Guided Auto Parallelism (GAP) feature of the Intel® Fortran Compiler is a tool that offers selective advice to improve the performance of serially-coded applications by suggesting changes that take advantage of the compiler’s ability to automatically vectorize and parallelize code and improve the efficiency of data operations. Despite having the words “auto parallelism” in the name, this tool does not require a threaded code implementation to improve the execution performance of the code, or require that the code is already threaded or parallel.

Advanced optimization techniques, such as inter-procedural analysis or profile-guided feedback, are not needed to use this feature. Using the [Q]guide set of options in addition to the compiler options normally used is sufficient to enable the GAP feature, with the requirement that you must compile with O2 or higher optimization levels. The compiler does not generate any object files or executables during the GAP run.

In debug mode (/zi on Windows*, -g on Linux*), the compiler’s optimization level defaults to /Od (on Windows*) or -O0 (on Linux* and macOS*); thus O2 (or a higher level optimization) must be specified explicitly on the command-line.

NOTE Use the [Q]diag-disable option along with the [Q]guide option to direct the compiler to suppress specific diagnostic messages. For example, the options: // (Windows*) /Qguide, /Qdiag-disable:30534 and // (Linux* and macOS*) -guide, -diag-disable:30534 tell the compiler not to emit the 30534 diagnostic. The [Q]diag-disable mechanism works the same way as it does for compiler-warnings.

If you decide to follow the advice offered by the GAP tool by making the suggested code changes and/or using the suggested compiler options, you must then recompile the program without the [Q]guide option.

Any advice generated by the compiler when using the GAP tool is optional; it can be implemented or rejected. The advice typically falls under three broad categories:

- **Advice for source modifications**: The compiler advises you to make source changes that are localized to a loop-nest or a routine. For example, the tool may recommend that you use a local-variable for the upper-bound of a loop, or that you should initialize a local variable unconditionally at the top of the loop-body, .
- **Advice to apply directives**: The compiler advises you to apply a new directive on a certain loop-level if the directive semantics can be satisfied (you must verify this). In many cases, you may be able to apply the directive (thus implicitly asserting new program/loop properties) that the compiler can take advantage of to perform enhanced optimizations.
- **Advice to add compiler options**: The compiler advises you to add command-line options that assert new properties; .

NOTE These suggested compiler options apply to the entire file. It is your responsibility to check that the properties asserted by these options are valid for the entire file, and not just the loop in question.

If you use GAP options along with option [Q]parallel, the compiler may suggest options to further parallelize your application. The compiler may also offer advice on enabling other optimizations of your application, including vectorization.
If you use the GAP options without enabling auto parallelism (without using the \texttt{[Q]parallel} option), the compiler may only suggest enabling optimizations such as vectorization for your application. This approach is recommended when you wish to improve the performance of a single-threaded code without the use of parallelization or when you want to improve the performance of threaded applications that do not rely on the compiler for auto parallelism.

Using Guided Auto Parallelism

The Guided Auto Parallelism feature of the Intel\textsuperscript{®} Fortran Compiler is a tool offering selective advice to improve the performance of serially-coded applications. The tool suggests changes that take advantage of the compiler's ability to automatically vectorize and parallelize code as well as improve the efficiency of data operations. The tool does not require that you implement threaded code to improve the execution performance of your code, nor does it require that your code is already threaded or parallel code.

To invoke this tool, use the compiler option \texttt{[Q]guide[=n]} . Using this option causes the compiler to generate messages suggesting ways to optimize the performance of your application. You can also use more specific compiler options such as \texttt{[Q]guide-vec}, \texttt{[Q]guide-par}, and \texttt{[Q]guide-data-trans} , to perform individual guided optimizations for vectorizing, parallelizing, and data transformation of your application.

When any guided auto parallelism option is used, the compiler provides only diagnostic advice. Object files or executables are not created in this mode. See the table below for descriptions of the options.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{[Q]guide}</td>
<td>Allows you to set a level of guidance for auto-vectorization and data transformation analysis. To obtain guidance for auto parallelism, you must use the \texttt{[Q]parallel} option along with the \texttt{[Q]guide} option.</td>
</tr>
<tr>
<td>\texttt{[Q]guide-par}</td>
<td>Allows you to set a level of guidance only for auto parallelism analysis. \textbf{NOTE} You must use the \texttt{[Q]parallel} option along with the \texttt{[Q]guide-par} option to get this advice.</td>
</tr>
<tr>
<td>\texttt{[Q]guide-vec}</td>
<td>Allows you to set a level of guidance for auto-vectorization analysis only.</td>
</tr>
<tr>
<td>\texttt{[Q]guide-data-trans}</td>
<td>Allows you to set a level of guidance for data transformation analysis only.</td>
</tr>
</tbody>
</table>

For all of the above options, the optional argument \textit{n} specifies the level of guidance. The argument \textit{n} takes the values 1-4. When \textit{n} is not specified, the default is 4. If you specify \textit{n}=1 or 2, a standard level of guidance is provided.

When you use \textit{n}=3 or \textit{n}=4, you may get advanced messages. For example, you may get messages about how to optimize a particular loop-nest or get a message on how exception-handling inside a loop-nest affects optimizations for that loop-nest. Or you may get a message on how to provide extra information to the compiler on cost-modeling (expected values of trip-counts, and so on).
If you simultaneously specify a level of guidance for the general [Q]guide option and also for one or more of the other specific guide options, the level of guidance \( n \) for the specific guide option overrides the general [Q]guide option setting.

If you do not specify a level of guidance for the general [Q]guide option, but do set a level of guidance for one or more of the specific guide options, the [Q]guide option is set equal to the greatest value passed to the specific guide options.

Capturing Guidance Messages

The guided auto parallelism tool analyzes all of your serial code or individual parts of your code and generates advisory messages. By default, messages that are generated by the guided auto parallelism tool are output to stderr.

To capture messages in a file, use the options listed in the following table.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide-file</td>
<td>Gather all messages generated during a guided auto-parallelization run into the specified file.</td>
</tr>
<tr>
<td>[Q]guide-file-append</td>
<td>Allows you to specify the file into which all messages generated during a guided auto parallelism run should be appended.</td>
</tr>
</tbody>
</table>

For the above options, the file_name argument can also include a path. If a path is not specified, the file is created in the current working directory. If there is already a file named file_name, it is overwritten when you use the [Q]guide-file option. If you do not include an extension as part of the file_name, the extension .guide is appended.

Configuring Code Regions for GAP Messages

To limit guided auto parallelism analysis to specific regions (hotspots) in your application, use the options mentioned in the table below.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide-opts</td>
<td>Allows you to analyze specified code elements, identified by string.</td>
</tr>
<tr>
<td>[Q]guide-profile</td>
<td>Allows you to specify a loop profiler data file (or a set of files) when used with [Q]guide option.</td>
</tr>
</tbody>
</table>

Compiler option [Q]guide-profile is deprecated. There is no replacement option.

You must use the [Q]guide-opts option along with one of the guided auto parallelism options, such as [Q]guide, [Q]guide-vec, [Q]guide-par, and [Q]guide-data-trans. Use the string parameter to provide information about known areas of interest (hotspots). The string parameter takes one or more of the following variables: filename, routine, range. The compiler parses the string parameter and generates syntax errors if there are any.
Follow these guidelines when using the `string` parameter:

- Use only valid file names, routine names, and line numbers. The guided auto parallelism tool ignores invalid values and issues a diagnostic message stating what was ignored.
- Enclose routine names within single quotation marks. Specify original source names (demangled names) as routine names. A routine name alone may not always be sufficient to uniquely identify a routine. You may need to specify additional parameter information to uniquely identify the routine.

For any specified routine name, the GAP tool first tries to uniquely identify the routine using specified routine information. If that is not possible, then it selects all routines with the specified routine name. The GAP tool uses the parameter information, if specified, to narrow the selection.

- When inlining is involved, use the callee line numbers. The generated messages also use the callee line numbers.

Alternatively, you can automate and narrow down the targeted regions to specific hotspots in your application code by using the `Qguide-profile` option with the `Qguide` option.

**Windows* Syntax**

`/Qguide-opts:string`

**Linux* and macOS* Syntax**

`-guide-opts=string`

The region targeted by the `Qguide` option, when used along with the `Qguide-profile` option, is configured by processing the XML data file(s) produced from a loop-profiler-instrumented run. The loop profiler result files are specified as the actual loop profiler data file, or as the directory name where loop profile data files are stored.

**Guided Auto Parallelism Messages**

The Guided Auto Parallelism (GAP) messages provide advice that should improve optimizations. The messages provide suggestions for:

- Automatic parallelization of loop nests
- Automatic vectorization of inner loops
- Data transformation
You must decide whether to follow a particular suggestion. For example, if the advice is to apply a particular directive, you must understand the semantics of the directive and carefully consider whether it can be safely applied to the loop (or loop nest) in question.

If you apply the directive improperly, the compiler may generate incorrect code, causing the application to execute incorrectly.

If you do not fully understand the suggested advice, please refer to the relevant topics in the compiler documentation before applying that advice.

Once you apply the suggested advice, the compiler assumes that it is correct and it does not perform any checks or issue any warnings.

In general, messages that relate to loops tend to target vectorization and/or parallelization of loops. If you are not familiar with loop optimizations, please refer to the compiler documentation on this kind of optimization.

Optimizations can be helped or hindered when data is fetched from or stored to memory. Sometimes these fetch and store operations are referred to as reads and writes, but do not confuse these with READ and WRITE input/output statements. A READ statement (input) is only one of many ways to cause a store to memory, and a WRITE statement (output) is only one of many ways to cause a fetch from memory. Values in an expression must be fetched from (read from) memory before the expression can be evaluated. Variables on the left-hand side of an assignment will be the target of a store to (write to) memory. Actual arguments passed to called procedures can be fetched from and stored to memory.

Loop Constructs

**GAP Message (Diagnostic ID 30506)**

**Message**

If the following operation(s) can be safely performed unconditionally, the loop at line %d will be vectorized by adding a "%s ivdep" statement right before the loop: %s.

**Advice**

Add "!DIR$ IVDEP" before the specified loop.

This directive enables the vectorization of the loop at the specified line. Insure that any conditional divide, sqrt, and inverse sqrt operations will not alter the exception semantics expected by the program when they are performed unconditionally.

**Example**

Consider the following:

```fortran
subroutine foo(a, n)
    integer n
    real a(n)
    do i=1,n
        if (a(i) .gt. 0) then
            a(i) = 1 / a(i)
        endif
    enddo
end
```
In this case, the compiler is unable to vectorize the loop since the condition "a(i) .gt. 0" may be guarding floating-point exceptions for the divide.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, n)
    integer n
    real a(n)
!dir$ ivdep
    do i=1,n
        if (a(i) .gt. 0) then
            a(i) = 1 / a(i)
        endif
    enddo
end
```

**Verify**

Confirm that the program operands have safe values for all iterations.

**GAP Message (Diagnostic ID 30513)**

**Message**

Insert a ">%s ivdep" statement right before the loop at line %d to vectorize the loop.

**Advice**

Add "!DIR$ IVDEP" before the specified loop. This directive enables the vectorization of the loop at the specified line by ignoring some of the assumed cross-iteration data dependencies.

**Example**

Consider the following:

```fortran
subroutine foo(a, m, n)
    integer m, n
    real a(n)
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```

In this case, the compiler is unable to vectorize the loop because m could be -1, where each iteration is dependent on the previous iteration. If m is known to be positive, you can vectorize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, m, n)
    integer m, n
    real a(n)
!dir$ ivdep
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```
Verify

Confirm that any arrays in the loop do not have unsafe cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop. Make sure that there are no such dependencies, or that any cross-iteration dependencies can be safely ignored.

GAP Message (Diagnostic ID 30515)

Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be vectorized.

Advice

You should unconditionally initialize the scalar variables at the beginning of the specified loop. This allows the vectorizer to privatize those variables for each iteration and vectorize the loop. You must ensure that all the uses of those variables see the same values before and after the source code change.

Example

Consider the following:

```fortran
subroutine foo(a, n)
  integer n
  do i=1,n
    if (a(i) .gt. 0) then
      b = a(i)
      a(i) = 1 / a(i)
    endif
    if (a(i) .gt. 1) then
      a(i) = a(i) + b
    endif
  enddo
end
```

In this case, the compiler is unable to vectorize the loop because it failed to privatize the variable b. Vectorization is assisted when assignment to b occurs in each iteration where the value of b is used. One of the ways to do this is to assign the value in every iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```fortran
subroutine foo(a, n)
  integer n
  real a(n), b
  do i=1,n
    b = a(i)
    if (a(i) .gt. 0) then
      a(i) = 1 / a(i)
    endif
    if (a(i) .gt. 1) then
      a(i) = a(i) + b
    endif
  enddo
end
```
**Verify**
Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

**GAP Message (Diagnostic ID 30519)**

**Message**
Insert a "%%s parallel" statement right before the loop at line %d to parallelize the loop.

**Advice**
Add "!DIR$ PARALLEL" before the specified loop. This directive enables the parallelization of the loop at the specified line by ignoring assumed cross-iteration data dependencies.

**Example**
Consider the following:

```fortran
subroutine foo(a, m, n)
    real a(n)
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```

In this case, the compiler is unable to parallelize the loop without further information about \(m\). For example, if \(m\) is negative, then each iteration will be dependent on the previous iteration. However, if \(m\) is known to be greater than \(n\), you can parallelize the loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, m, n)
    real a(n)
    !dir$ parallel
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```

**Verify**
Confirm that any arrays in the loop do not have cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop.

**GAP Message (Diagnostic ID 30521)**

**Message**
Assign a value to the variable(s) "%%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.
Advice

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

Example

Consider the following:

```fortran
subroutine foo (A, B, cond1, cond2)
  integer, parameter :: N = 100000
  integer I
  real(8) A(N), B(N), T
  logical cond1, cond2
  do I = 1, N
    if (cond1) T = i + 1
    if (cond2) T = i - 1
    A(I) = T
  end do
end
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable \( t \) without further information. If you know that cond1 or cond2 is true, or both cond1 and cond2 are true, then you can assist the parallelizer by ensuring that any iteration that uses \( t \) also writes to \( t \) before its use in the same iteration. One of the ways to do this is to assign a value to \( t \) at the top of each iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```fortran
subroutine foo (A, B, cond1, cond2)
  integer, parameter :: N = 100000
  integer I
  real(8) A(N), B(N), T
  logical cond1, cond2
  do I = 1, N
    T = 0
    if (cond1) T = i + 1
    if (cond2) T = i - 1
    A(I) = T
  end do
end
```

Verify

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

See Also

GAP Message (Diagnostic ID 30523)

GAP Message (Diagnostic ID 30522)

Message

Insert a "%

% parallel private(%)" statement right before the loop at line %d to parallelize the loop.
Advice
Add "!DIR$ PARALLEL PRIVATE" before the specified loop. This directive enables the parallelization of the loop at the specified line.

Example
Consider the following:

```fortran
subroutine foo (A, B, C, n, m1, m2)
  real (4) A(10000, 10), B(10000, 10), C(10000, 10)
  integer n, m1, m2
  real W(1000)
  integer i, j
  do i=1,n
    do j=1,m1
      W(j) = A(j,i) * B(j,i)
    end do
    do j=1,m2
      C(j,i) = W(j) + 1.0
    end do
  end do
end
```

In this case, the compiler does not parallelize the loop since it cannot determine whether m1 >= m2.

If you know that this property is true, and that no element of W is fetched before it is written to after the loop, then you can use the recommended directive.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo (A, B, C, n, m1, m2)
  real (4) A(10000, 10), B(10000, 10), C(10000, 10)
  integer n, m1, m2
  real W(1000)
  integer i, j
  !DIR$ PARALLEL PRIVATE (W)
  do i=1,n
    do j=1,m1
      W(j) = A(j,i) * B(j,i)
    end do
    do j=1,m2
      C(j,i) = W(j) + 1.0
    end do
  end do
end
```

Verify
Before an element of an array can be fetched in the loop, there must have been a previous store to it during the same loop iteration. In addition, if an element is fetched after the loop, there must have been a previous write to it before the fetch after the loop.

GAP Message (Diagnostic ID 30523)

Message
Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.
**Advice**

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a PARALLEL directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

**Verify**

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration or have been privatized by means of the private clause of a PARALLEL directive.

**See Also**

GAP Message (Diagnostic ID 30521)

**GAP Message (Diagnostic ID 30525)**

**Message**

Insert a "%s loop count min(%d)" statement right before the loop at line %d to parallelize the loop.

**Advice**

Add "!DIR$ LOOP COUNT" before the specified loop. This directive indicates the minimum trip count (number of iterations) of the loop that enables the parallelization of the loop.

**Example**

Consider the following:

```fortran
subroutine foo (n)
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  integer :: i, n
  do i =1, n
    A(i) = B(i) * B(i)
  end do
end subroutine foo
```

In this case, if the trip count of the loop at line 5 is greater than 128, then use the LOOP COUNT directive to parallelize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo (n)
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  integer :: i, n
  !dir$ loop count min(128)
  do i =1, n
    A(i) = B(i) * B(i)
  end do
end subroutine foo
```

Make sure that the loop has a minimum of 128 iterations.

**Verify**

Confirm that the loop has the minimum number of iterations, as specified in the diagnostic message.
See Also
Guided Auto Parallelism Messages provides advice for improving optimizations

GAP Message (Diagnostic ID 30526)

Message
To parallelize the loop at line %d, annotate the routine %s with %s.

Advice
If the loop contains a call to a function, the compiler cannot parallelize the loop without more information about the function being called.

However, if the function being called in the loop is an elemental function or a function specified with ATTRIBUTES CONCURRENCY_SAFE, then the call does not inhibit parallelization of the loop.

Example
Consider the following:

```fortran
subroutine foo ()
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  interface
    function bar (k)
      integer :: bar, k
    end function bar
  end interface

  integer :: i
  do i =1, N2
    A(i) = B(i) * bar(N2)
  end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine bar as elemental.

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```fortran
subroutine foo ()
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  interface
    function bar (k)
      !dir$ attributes concurrency_safe : profitable :: bar
      integer :: bar, k
    end function bar
  end interface

  integer :: i
  do i =1, N2
    A(i) = B(i) * bar(N2)
  end do
end subroutine foo
```
Verify

Confirm the routine satisfies the semantics of this annotation. A weaker annotation able to achieve a similar effect is `ATTRIBUTES CONCURRENCY_SAFE(PROFITABLE)`.

See Also

GAP Message (Diagnostic ID 30528)

GAP Message (Diagnostic ID 30528)

Message

Add "%s" to the declaration of routine "%s" in order to parallelize the loop at line %d. Adding "%s" achieves a similar effect.

Advice

Confirm that the routine specified is indeed an elemental function or an `ATTRIBUTES CONCURRENCY_SAFE` function before following the advice to add the annotation.

If the routine is not one of these kinds of functions, try to inline it with a `FORCEINLINE RECURSIVE` directive. This action may or may not be beneficial.

Example

Consider the following:

```fortran
subroutine foo ()
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    interface
      function bar (k)
        integer :: bar, k
        end function bar
    end interface
    integer :: i
    do i = 1, N2
        A(i) = B(i) * bar(N2)
    end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine `bar` as elemental.

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```fortran
subroutine foo ()
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    interface
      function bar (k)
        !dir$ attributes concurrency_safe : profitable
        integer :: bar, k
        end function bar
    end interface
    integer :: i
    do i = 1, N2
        A(i) = B(i) * bar(N2)
    end do
end subroutine foo
```
Verify
Confirm that the routine satisfies the semantics of this declaration. Another way to help the loop being parallelized is to inline the routine with the FORCEINLINE RECURSIVE directive, but this method does not guarantee parallelization.

See Also
GAP Message (Diagnostic ID 30526)

GAP Message (Diagnostic ID 30531)

Message
Store the value of the upper-bound expression of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = upper-bound of loop" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

Advice
Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler cannot output the exact upper-bound variable to be replaced.

Verify
Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

See Also
GAP Message (Diagnostic ID 30532)

GAP Message (Diagnostic ID 30532)

Message
Store the value of the upper-bound expression (%s) of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = %s" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

Advice
Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which in turn enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler can output the exact upper-bound variable to be replaced.

Verify
Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

See Also
GAP Message (Diagnostic ID 30531)
GAP Message (Diagnostic ID 30533)

Message
Compile with the %s option to vectorize and/or parallelize the loop at line %d.

Advice
Use the \texttt{[q or Q]opt-subscript-in-range} option for the specified file during compilation. This option helps the compiler vectorize and parallelize the loop at the specified line. You must verify that the loops in the file do not contain very large integers and are not likely to generate very large integers in intermediate computations. A very large integer is loosely defined as follows: On an \(n\)-bit machine, a very large integer is typically \(\geq 2^{n-2}\). For example, on a 32-bit machine, a very large integer would be \(\geq 2^{30}\).

Verify
Confirm that no loop in the program contains or generates very large integers (typically very large integers are \(\geq 2^{30}\)).

GAP Message (Diagnostic ID 30538)

Message
Moving the block of code that consists of a function-call (line %d), if-condition (line %d), and an early return (line %d) to outside the loop may enable parallelization of the loop at line %d.

Advice
Move the function call and an associated return from inside the loop (perhaps by inserting them before the loop) to help parallelize the loop.

This kind of function-leading-to-return inside a loop usually handles some error-condition inside the loop. If this error check can be done before starting the execution of the loop without changing the program semantics, the compiler may be able to parallelize the loop thus improving performance.

Verify
Confirm that the function call does not rely on any computation inside the loop and that restructuring the code as suggested above, retains the original program semantics.

\textit{Intel® Many Integrated Core Architecture (Intel® MIC Architecture)}

This topic only applies when targeting \textit{Intel® Many Integrated Core Architecture (Intel® MIC Architecture)}. Offload is not supported on Windows* systems.

The \textit{Intel® Xeon Phi™} processors are based on the \textit{Intel® Many Integrated Core architecture (Intel® MIC architecture)}.

The \textit{Intel® Fortran Compiler} provides several elements to enable programming for and building binaries to run on the \textit{Intel® Many Integrated Core Architecture (Intel® MIC Architecture)}, including:
• language extensions
• compiler options
• environment variables
• OpenMP* considerations

Code that is defined for offloading runs on an Intel® Xeon® processor-based host, running Linux® or Windows®, and on targets supporting Intel® MIC Architecture.

**Programming for Intel® MIC Architecture**

You can write parallel programs that offload sections of code to run on the Intel® MIC Architecture, or alternatively, that run natively on Intel® MIC Architecture. Compiling a source file that contains extensions to facilitate programming for the Intel MIC Architecture creates what is called a fat binary which contains both the host binary and an offload binary. Fat binaries can be objects, archives, or executables depending on the options used at compilation. Refer to the documentation on the Offload Extract Tool (offload_extract) for information on how to extract the offload binary from the fat binary.

The compiler provides the following language extensions to facilitate programming for Intel® MIC Architecture:

<table>
<thead>
<tr>
<th>Name</th>

Programming for Intel® MIC Architecture

Overview: Heterogeneous Programming
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

About Heterogeneous Programming
The compiler includes language extensions that simplify writing parallel programs that can offload sections to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Execution begins on the host CPU and, based on user-defined code, some sections are offloaded to the coprocessor.

Heterogeneous programming must deal with two differences from traditional CPU programming:
- The instruction sets on the CPU and the coprocessor are similar, but not identical.
- The host CPU and the coprocessor do not share common system memory.

Programming Model
The compiler deals with the lack of shared system memory by using directives with the prefix OFFLOAD_.

This model is appropriate for dealing with flat data structures such as scalars, arrays and structs that are bit-wise copyable.

Data in this model is copied back and forth between the CPU and the coprocessor around regions of offloaded code. The data selected for transfer is a combination of variables implicitly transferred because they are lexically referenced within offload constructs, and variables explicitly listed in clauses in the directive.

Specifying that a construct should run on the coprocessor does not guarantee that it will. The presence of an Intel® MIC Architecture-based subsystem and its availability at the offload point determines if the offload succeeds. When an offload fails, the program exits with an error message.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Dealing with Multiple Coprocessors in a System

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Use the functions described in this section to determine:

- the number of coprocessors in a system
- the coprocessor on which a program is running

Use the header file `mic_lib.f90` to define the interfaces for these functions and their usage. Include it with `USE mic_lib`.

**NOTE**

In a system with multiple coprocessors, you need to specify the `target-number` argument when using the `offload` directive to reliably use data persistence. When you use `alloc_if` or `free_if` to implement data persistence on the coprocessor, but do not specify `target-number`, the compiler runtime randomly chooses a coprocessor, so the chosen coprocessor could be one on which the data is not available.

Determining the Number of Coprocessors in a System

To determine the number of coprocessors in the system, use the function `result = OFFLOAD_NUMBER_OF_DEVICES()`.

The function returns an integer equal to the number of coprocessors installed and working in the system. If none are installed and working, the return value is 0.

Determining the Coprocessor on Which a Program is Running

To determine the coprocessor that is executing the program, use the function `result = OFFLOAD_GET_DEVICE_NUMBER()`.

The function returns an integer equal to the number of the coprocessor executing the program, where 0 is the first card. If the program is executing on the CPU, the return value is -1.

Determining if Code has Completed Running on a Coprocessor

To determine if a section of offloaded code has completed running on a given coprocessor, you can use the API `OFFLOAD_SIGNALED()`.

The syntax for this API is:

```
OFFLOAD_SIGNALED(target_number, signal)
```

Offload Using a Directive

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This programming model is suitable when the data exchanged between the CPU and the coprocessor consists of scalars, arrays, and Fortran derived types that can be copied from one variable to another using a simple memcpy.

Data that flows between the CPU and the coprocessor must have a flat structure.

Data that is created and used entirely on the CPU, or used entirely within the offloaded regions, can be arbitrarily complex, including multi-dimensional arrays, and any composition of data structures using pointers, arrays and Fortran derived types.

You control the data transfer between the CPU and the coprocessor. The data transfer consists of densely packed data structures. You can select the data to be transferred at the point of offload, without needing to declare or allocate it in any special way.

ATTRIBUTES OFFLOAD
OFFLOAD_TRANSFER
OFFLOAD_WAIT
OFFLOAD BEGIN and END OFFLOAD
Rules for Placement of Directives

Initiating an Offload

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

You can place the OFFLOAD directive before a subroutine call statement, a function call statement of the form x = func() or an OpenMP* parallel directive.

For example:

```
!DIR$ OFFLOAD BEGIN target(mic : target_id) &
   inout(numEs) in(all_Vals) out(E_vals)
   do k = 1, MAXSZ
      if ( MODULO(all_Vals(k),2) == 0 ) then
         numEs = numEs + 1
         E_vals(numEs) = all_Vals(k)
      endif
   enddo
!DIR$ END OFFLOAD
```

This code excerpt finds the even numbers and then puts those numbers into an array. The code excerpt begins with !DIR$ OFFLOAD BEGIN, and ends with !DIR$ END OFFLOAD. The compiler builds the code block to run on both the host and target.

While the instruction sets for the host and targets are similar, they do not share the same system memory. This means that the variables used by the code block must exist on both the host and the target. To ensure that they do, the directives use specifiers to define the variables to copy between the host and target.

- The in specifier defines a variable as strictly an input to the target. The value is not copied back to the host.
- The out specifier defines a variable as strictly an output of the target. The host does not copy the variable to the target.
- The inout specifier defines a variable that is both copied from the host to the target and back from the target to the host.

The directive also has the target (mic:target_number) specifier to direct the code to a specific target in a system with multiple targets.
When the main program has offload constructs, by default the compiler builds an application that runs on both the host and target. However, you can also build the same source code to run on just the CPU, using the negative form of the [Q]offload compiler option.

Placing Variables and Functions on the Coprocessor
These attributes ensure that variables and functions are available on the coprocessor.

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

The statement following the offload directive is converted into an outlined function that runs on the coprocessor. This code is permitted to call other functions. To ensure that these called functions are also available on the coprocessor, you must specify one of the following special function attributes, using the ATTRIBUTES OFFLOAD directive:

```
!DIR$ ATTRIBUTES OFFLOAD: target-name :: routine-name[, routine-name] ...
!DIR$ ATTRIBUTES OFFLOAD: target-name :: variable-name[, variable-name] ...
```

All functions in the program are always compiled for the CPU and are available to be called on the CPU. However, only functions marked with the special attribute are available to be called by offloaded code, and only these functions can be called on the coprocessor.

Global variables are treated in a similar fashion. All global variables are always present in the CPU code. But only global variables with the target attribute are compiled into the binary offloaded to the coprocessor.

Compiling only functions and data explicitly marked with the target attribute into the Intel® MIC Architecture binary ensures that the code on the coprocessor is as small as possible.

The compiler issues warnings for functions and data referenced within offloaded code that do not have the target attribute.

Example

```fortran
module offload_test
    public
    !DIR$ ATTRIBUTES OFFLOAD:mic :: global_value
    integer :: global_value
    contains
        !DIR$ ATTRIBUTES OFFLOAD:mic :: incr_global
        integer function incr_global
        global_value = global_value + 1
        incr_global = global_value
        return
    end function incr_global
end module offload_test

program main
    use offload_test
    integer i
    i = incr_global()
    print *, "global = ", global_value, "i = ", i, " (should be the same)"
```

Intel® Fortran Compiler 19.0 Developer Guide and Reference
NOTE
The presence of a function call within an offloaded construct with a target attribute does not
automatically declare that function as available on that target. The function definition must include the
appropriate target attribute to ensure that the function is available on the target.

NOTE
The definition and all declarations of a variable or function with a target attribute must be consistent
with each other across all compilation units.

Managing Memory Allocation for Pointer and Allocatable Variables
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated
feature. This topic will be removed in a future release.
Creating Fortran pointer targets and allocatable variables is referred to here as dynamic memory variables.
Memory management on the CPU for dynamic memory variables used in offloaded programs is the same as
non-offload programs. That is, the offload directives do not affect memory allocation and freeing on the CPU.
As usual, you, the programmer, must do this.
Memory management on the coprocessor for dynamic memory variables named in in and out clauses of !
DIR$ OFFLOAD is done automatically by the compiler and runtime system.

Target Memory Management for Input Dynamic Memory Variables
For in variables of a !DIR$ OFFLOAD the default behavior is to do a fresh memory allocation for each
dynamic memory variable. On return from the construct the memory is de-allocated. In order to retain data
between offloads, you can use the alloc_if and free_if qualifiers to modify the memory allocation
defaults on the coprocessor.
The alloc_if qualifier specifies a logical condition that controls whether the dynamic memory variables in
the in clause are allocated a fresh block of memory on the target when the construct is executed on the
target. If the expression evaluates to .true., a fresh memory allocation is performed for each variable listed
in the clause. If the condition evaluates to .false., the existing pointer values on the target are reused. You
must ensure that a block of memory of sufficient size has been previously allocated for the variables on the
target by using a free_if(.false.) clause on an earlier offload.
The free_if qualifier specifies a logical condition which controls whether to free the memory allocated for
the dynamic memory variables in an in clause. If the expression evaluates to .true., the memory pointed
to by each variable listed in the clause is freed. If the condition evaluates to .false., no action is taken on
the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated
memory.
The alloc_if and free_if logical expressions are evaluated on the CPU at the point the construct is
offloaded to the target.
Target Memory Management for Output Dynamic Memory Variables

By default an `out` variable is allocated fresh memory on the target at the start of an offload and the memory is freed at the end of the offload. The `alloc_if` and `free_if` modifiers change the defaults. The expressions are evaluated on the host and used to control coprocessor memory allocation.

When the output value is received on the host, no memory allocation is done. The variables listed in `out` clauses must point to allocated memory of sufficient size to receive the results on the host.

Transferring Data into Pre-allocated Memory on the Target

As described in the previous section a dynamic memory variable in an `in`, `out`, `inout`, or `nocopy` clause can retain the target memory allocation when you set the `free_if` modifier to `false`. You can reuse that memory in subsequent offloads by using `in`, `out`, `inout`, or `nocopy` and specifying `alloc_if(.false.)`. When target memory is allocated it is associated with the value of the CPU dynamic memory variable used as the destination in the `in`, `out`, `inout`, or `nocopy` clause. When target memory is to be reused, it is located using the value of the CPU dynamic memory variable that is the destination of that transfer. The associations between the CPU address used when target memory is allocated and the target memory are automatically maintained by the offload runtime library. The associations are created or dropped along with target memory allocation or deallocation. Create the association at allocation time using `alloc_if(.true.)` `free_if(.false.)` and delete the association at de-allocation time using `free_if(.true.)`.

Pointers to static data on the CPU are special-cased. The `alloc_if` and `free_if` modifiers are ignored when the following are both true:

- The CPU address used during creation of a target memory association points to statically allocated data.
- The variable is also available in the target binary because it has `ATTRIBUTES OFFLOAD:mic`.

The target's statically allocated memory is used as the destination of the transfer. This target memory is not dynamically allocated and never freed.

There is only one block of target memory associated with a CPU address. It is an error to call `alloc_if(.true.)` to create a second association for a CPU address before freeing the existing one. The new association overwrites the earlier one, which has the potential for causing memory leaks on the target.

It is an error to call `free_if(.true.)` for transferred dynamic memory if a matching association is not found. The attempted removal of an association is silently ignored. An association can be made with a CPU address, and a certain length, and another association made with a different CPU address within that range. Since origin addresses are different, you can use `alloc_if` and `free_if` to create distinct target allocations.

Alignment of Dynamic Memory Variables

When memory is allocated for a dynamic memory variable on the target, it is aligned at the natural boundary for the declared type. Sometimes it may be necessary to request that the data be aligned on larger boundaries, for example, when the program expects to use assembly code or intrinsic functions or vectorization, that operate on data with more stringent alignment requirements. In these cases, the `align` modifier may be used to specify an alignment. The operand of the `align` modifier must be an integral expression which evaluates to a power of two. The expression is evaluated on the host and the region of memory allocated for the dynamic memory on the target is aligned at a boundary that is greater than or equal to the value of the expression. When the output value is received on the host, no memory allocation is done. The variables listed in `out` clauses must point to allocated memory of sufficient size to receive the results.
NOTE
For optimal data transfer performance, by default, the target memory address for a transfer through
dynamic memory is made to match the offset within 64 bytes of the CPU data. That is, if the CPU
source address is 16 bytes past a 64 byte boundary, the target data address will also be 16 bytes past
a 64 byte boundary.
The **align** modifier overrides this default and aligns the target memory at the requested alignment. To
get the benefits of fast data transfer and the necessary alignment on the target, ensure that the CPU
data is aligned on the same boundary as the alignment needed on the target. Doing so meets the
requirements for fast data transfer and the requirements for target data alignment.

Examples
The following example illustrates the default behavior, which is no data persistence on the coprocessor.
The compiler allocates and frees data around the offload. No `alloc` or `free` modifiers are necessary.

```fortran
real, dimension(:), pointer :: p
!DIR$ ATTRIBUTES OFFLOAD:mic :: p
real, dimension(10), target :: targ
!DIR$ ATTRIBUTES OFFLOAD:mic :: targ
p->targ
!DIR$ OFFLOAD TARGET (mic) in (p)
```
The following examples illustrate keeping data on the coprocessor between offloads.
The following code allocates memory for `p` as part of this offload, and keeps the memory allocated for `p` after
the offload.
Notice that **ALLOC** is the default, and you do not need to explicitly specify it.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.true.) free_if(.false.))
```
The following code reuses the memory allocated for `p` previously. It only transfers fresh data into that
memory, and after the offload completes, it continues to retain the memory.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.false.) &
!DIR$ free_if(.false.))
```
The following code reuses the memory allocated for `p` previously. However, it frees the memory for `p` after
this offload.
Notice that **FREE** is the default, and you do not need to explicitly specify it.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.false.) free_if(.true.))
```
The following code uses a pointer to create a memory allocation on the target. Then the pointer value is
passed to another function. Through the pointer value, the target memory can be reused. Notice that the
`offload_transfer` directive uses subscript notation. The **length** modifier is not required when a variable is
specified in array notation.

```fortran
! Transfer through a routine argument
Module m
integer, allocatable :: p(:)
!dir$ attributes offload:mic :: p
contains
  subroutine foo (arg_p, count)
!dir$ attributes offload:mic :: foo
  integer, allocatable :: arg_p(:)
```
integer count
   ...
end subroutine foo
end module m

program test
use m
allocate(p(100000))
!dir$ offload_transfer target (mic:0) in(p (100000) : &
!dir$ alloc_if(.true.))
call foo (p, 100000)
end

The following transfers static data to the target. The target static data allocation for the matching CPU
variable is automatically used.

module m
   integer array_both(1000)
!dir$ attributes offload : mic :: array_both
   integer array_cpu_only(1000)
end module m

subroutine foo()
use m
   call bar(array_cpu_only, 1000)
   call bar(array_both, 1000)
end subroutine foo

subroutine bar(iarray, count)
integer iarray(count)
   !dir$ offload begin target (mic:0) in(iarray : &
   !dir$ alloc_if(.false.))
   iarray=4
   !dir$ end offload
end subroutine bar

The following code shows the use of dummy arguments for allocatable arrays mixed between the CPU and
the target.

module mod
   integer, target, allocatable :: arr(:)
   integer, pointer, dimension(:) :: ptr
!dir$ attributes offload:mic :: ptr, arr
end module mod

program main
   use mic_lib
   use mod
   implicit none
   integer i, bar1, bar2

   allocate(arr(1000))
   ptr => arr(1:100)
! copies array to target
! dir$ offload begin target(mic:0) in(arr : free_if(.false.))
   arr = (/ (i, i=1,1000) /) ! 1, 2, 3, ...
! dir$ end offload

! bar2 will use dynamically allocated memory on the target
print *, bar2() ! 0

! bar1 will use allocated "arr" from above
print *, bar1(ptr, 100) ! /= 0

end program main

integer function bar2()
implicit none
integer i, bar1
integer, allocatable :: my_p(:)
allocate (my_p(100))
! first 100 elements of my_p are allocated & transferred to target ("in" implies alloc_if(.true.))
! dir$ offload begin target(mic:0) in(my_p:length(100) &
! dir$ free_if(.false.))
   my_p = (/ (0, i=1,100) /) ! 0, 0, 0, ...
! dir$ end offload

   bar2 = bar1(my_p, 100)
   return
end function bar2

integer function bar1(iarray, len)
implicit none
integer :: iarray(len)
integer len, sum, i

! dir$ offload begin target(mic:0) in(iarray:length(0) &
! dir$ alloc_if(.false.) free_if(.false.))
   sum = 0
   do i = 1, len
      sum = sum + iarray(i)
   end do
! dir$ end offload

   bar1 = sum
   return
end function bar1

**Writing Target-Specific Code Using a Directive**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. The topic will be removed in a future release.

You can write functions that you intend to run on a target, and sections of offloaded code, to take advantage of target-specific functions.

When the compiler generates code for the coprocessor, it defines a directive specific to the coprocessor architecture, for example __TARGET_ARCH_MIC. You can then write target-specific code within a !DIR$ if defined __TARGET_ARCH_MIC section.
NOTE
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Special Cases
offload, Qoffload

Writing Code that Should Not Be Built for CPU-Only Execution
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
You can write code that should not be built when the target is a CPU-only executable.
By default, the compiler defines the macro __INTEL_OFFLOAD. You can write code within an #ifdef __INTEL_OFFLOAD section when the source code is customized for running on the coprocessor heterogeneously.
For example, you can use this macro to protect code on the host that should only be executed for an offload build, such as calls to the omp_set_num_threads_target family of APIs in mic_lib.f90.

Example
The section for the host compiler works only when you compile with the [Q]offload compiler option with the keyword optional.

```fortran
#ifdef __INTEL_OFFLOAD
  #ifdef __MIC__
    PRINT *, "Using offload compiler :  Hello from the coprocessor"
  #elif __TARGET_ARCH_MIC
    PRINT *, "Using offload compiler :  Hello from the coprocessor"
  #else /* __MIC__ */
    PRINT *, "Using offload compiler :  Hello from the CPU"
  #endif /* __MIC__ */
#else
  #ifdef __MIC__
    PRINT *, "Using native compiler :  Hello from the coprocessor"
  #else
    PRINT *, "Using host compiler :  Hello from the CPU"
  #endif
#endif
```

offload, Qoffload

Allocating Memory for Parts of Arrays
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.
This topic discusses using the ALLOC modifier with the OFFLOAD set of directives.
The ALLOC modifier contains an array section reference. When you specify it, then the allocation on the coprocessor is limited to that shape of array. Only unit stride is allowed in the section. When a section has a rank greater than one, the second and subsequent index expressions must specify all elements at that dimension. The array section must be contiguous.
Data is transferred into that portion of the array specified by the **IN** or **OUT** expression. Thus memory allocation and the data transfer can use separate array slice references.

When the lower bound of the first dimension of a section used in the **ALLOC** modifier is non-zero, then the memory allocation begins with that element. The memory preceding the lower bound is unallocated and should not be referenced by your program. By not referencing it, you enable a smaller section of the array to be transferred to the coprocessor without requiring that the entire array be allocated.

**Example**

In the following example,

- The array \( A \) has 15 elements on the CPU, \( A(1:15) \).
- The **ALLOC** modifier allocates 8 elements \( A(3:10) \), the blue and orange regions on the coprocessor.
- On the coprocessor, the elements \( A(1:2) \), the gray region, are uninitialized.
- The **IN** clause transfers elements \( A(4:8) \), the orange region, from the CPU to the coprocessor.

```
INTEGER :: A (15)
  !               8 elements allocated
  !               5 data elements transferred starting at element 4
  !DIR$ OFFLOAD ... IN ( A(4:8) : ALLOC ( (3:10) ) ... 

```

In the diagram below:

- \( B \) is allowed 5 rows, 4 columns on the CPU.
- On the coprocessor, the **ALLOC** modifier allocates rows 2 through 5, the blue and orange regions, all columns.
- On the coprocessor, row 1, the gray region, is not allocated.
- The **IN** clause transfers the third row (3: :), the orange region, to the coprocessor.
Moving Data from One Variable to Another

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This topic discusses using the INTO modifier with the OFFLOAD set of directives.

The INTO modifier enables you to transfer data from a variable on the CPU to another on the coprocessor, and the reverse, from a variable on the coprocessor to another on the CPU. Only one item is allowed in the variable-ref list when using the INTO modifier. Thus a one to one correspondence is established between a single source and destination.

When you use INTO with the IN clause, data is copied from the CPU object to the coprocessor object. The ALLOC_IF, FREE_IF, and ALLOC modifiers apply to the INTO expression.

When you use INTO with the OUT clause, data is copied from the coprocessor object to the CPU object. The ALLOC_IF, FREE_IF, and ALLOC modifiers apply to the OUT expression.

The INTO modifier is not allowed with INOUT and NOCOPY clauses.

When you use the INTO modifier, the source expression generates a stream of elements to be copied into the memory ranges specified by the INTO expression. Overlap between the source and destination memory ranges leads to undefined behavior. No ordering can be assumed between transfers from different IN and OUT clauses.

Example

In the following example:

- The "Partial copy" case copies the first 500 elements of \( P \) to the last 500 elements of \( P_1 \).
- The "Overlapping copy" case copies the first 600 elements of \( P \) into \( P_1 \) but then tries to copy the last 400 elements of \( P \) into \( P_1(100) \) and beyond, but \( P_1(100) \) was initialized by the previous IN clause.
• The "rank change" is an error because rank 2 data on the coprocessor is being copied back to rank 1 data on the CPU, even though the sizes are the same.

```fortran
INTEGER :: P (1000), P1 (2000)
INTEGER :: RANK1 (1000), RANK2 (10, 100)

!          Partial copy
!DIR$ OFLOAD … IN ( P (1:500) : INTO ( P1 (501:1000) ) ) …

!          Overlapping copy; result undefined
!DIR$ OFFLOAD … IN ( P (1:600) : INTO ( P1 (1:600) ) ) … &
&               IN ( P (601:1000) : INTO ( P1 (100:499) ) ) …

!          Rank change is not allowed – error
!DIR $ OFFLOAD … OUT ( RANK1, OUT (RANK2) ) …
```

Restrictions on Offloaded Code Using a Directive

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Offloaded code has the following restrictions:

• Exception handling may be done as usual within code running on the CPU and within code running on the coprocessor. So exceptions can be raised, caught and handled on the CPU, or raised, caught and handled on the coprocessor. However it is not possible to propagate an exception from the coprocessor to the CPU.

• This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Do not use coprocessor-specific directives inside the statement following a `!DIR$ OMP OFFLOAD` statement. You can, however, use them in a subprogram called from the directive.

• The compiler does not inline functions inside statements following an `OFFLOAD` directive statement, including functions marked with the `FORCEINLINE` directive. However, inline function expansion might occur at the compiler’s discretion inside a subprogram called from the `OFFLOAD` directive.

• Multiple host CPU threads can execute concurrently while one host CPU thread offloads a section of code. In this case synchronization mechanisms such as locks, atomics, mutexes, OpenMP atomic operations, OpenMP critical, OpenMP taskwait, OpenMP barriers, etc. do not work between host CPU code and code offloaded to the target. However, if parallelism on the host CPU is enabled using OpenMP, then OpenMP synchronization at the end of a parallel region is guaranteed to work even if some part of the OpenMP parallel region has been offloaded to the target.

• Global variables referenced by functions called from within offloaded code must be declared with matching target attributes to ensure that the variables are available on the target. You must also explicitly send and receive the value of these variables with explicit `in/out/inout` clauses to sync their values between the host and target. Global variables visible within the lexical scope of the offload pragma do not require declaration with matching target attributes, and their associated values are sent and received by default. Global pointer variables used in lexical scope of the offload pragma do require being specified within `in/out/inout` clauses and this is enforced by the compiler.

By default, pointer variables are assumed to point to a single element of the corresponding type. The offloaded code may dereference the pointer and access a single element. The data element pointed to is automatically copied into target memory and the pointer value adjusted accordingly. The `élément-count-expr` expression available with `in / out / inout` parameters enable variable-length data to be copied back and forth.

• Only pointers to non-pointer types are supported. These non-pointer types must have the `TARGET` attribute. Pointers to pointer variables are not supported. The compiler enforces this restriction.
Arrays are supported provided the array element type is a scalar or bitwise copyable derived type. Pointer arrays are supported provided the target is contiguous.

Because pointers are not copied across the host-target interface, but instead the data they point to is copied, do not assume that the relative distance between pointers that point to distinct variables remains the same between the host and target. Pointers within the same data structure still have the same distance between them after offload. Thus, some pointer comparisons and arithmetic that were meaningful on the host CPU can no longer be used reliably on the target.

Unions containing a combination of pointer and non-pointer members are treated as holding the non-pointer value type. Thus, no special treatment is given to the pointer, and the data pointed to is not copied to the target.

Unions consisting entirely of pointer members are not allowed to be copied between the host and the target.

If an offload region calls a function defined in a separate file and that function references global variables, care must be taken to ensure that those global variables are copied in and/or out as needed.

If the global variables are referenced only in the external function and not directly within the offloaded region, then they will not be copied because the references outside the current compilation unit are not known to the compiler.

If the variables referenced from the external function are also referenced in the offloaded region, then they will be copied.

When global variables are file-scope static variables, then they cannot be named in the `in` or `out` clauses. You need to access their values using one of the following methods:

- Make them external and add them to the `in` or `out` clauses in the offload specification.
- Fetch the variable values into local variables using functions designed specifically for that purpose, and then add the local variables to the `in` or `out` clauses.
- You cannot use objects that are not bitwise copyable, inside a `!DIR$ OFFLOAD` region. The compiler enforces this restriction and issues an error.
- The offload region in an internal procedure cannot contain a host associated variable.

Restrictions When Programming on Windows* for Intel® MIC Architecture

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Several programming features that are specific to Windows® might result in errors when you use them in an offload compilation for Intel® MIC Architecture, even if you do not use these features in the code or data that is actually offloaded. When you use code with these features in your application, you must correctly structure the code so that it is not visible in a target compilation.

These features include, but are not limited to:

- Windows calling conventions. For example:

  ```fortran
  !DIR$ ATTRIBUTES STDCALL :: PROCX
  ```

- The attributes `DLLEXPORT` and `DLLIMPORT`. For example:

  ```fortran
  !DIR$ ATTRIBUTES DLLIMPORT :: VARX
  ```

- Module files or libraries that are specific to Windows, such as `IFNLS` or `IFQWIN`.

In addition, you must take care to ensure that code does not depend on specific data size or order of allocation of data, as these can vary between the host and the target.

About Asynchronous Computation (Intel® MIC Architecture)
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

By default, the **OFFLOAD** directive causes the CPU thread that encounters the directive to wait for completion of the offload before continuing to the next statement. You can execute an asynchronous offload computation, which enables the CPU to initiate the offload and immediately continue to the next statement.

To specify an asynchronous offloaded computation, specify a **signal** clause in the **OFFLOAD** directive to initiate the computation, and subsequently use the **OFFLOAD_WAIT** directive to wait for completion of the offloaded computation.

Alternatively, you can use the non-blocking API **OFFLOAD_SIGNALED()** to also determine if a section of offloaded code has completed running on a specific target device.

---

**NOTE**
On Intel® MIC Architecture, the **signal** and **wait** clauses, the **OFFLOAD_WAIT** construct and the **OFFLOAD_SIGNALED()** API refer to a specific target device, so you must specify **target-number** in the **target()** clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where the signal was actually initiated for target device 1. The signal was initiated for target device 1, so there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

---

**Example: Asynchronous Computation**
The following example enables the CPU to issue offloaded computations and continue concurrent activity without using any additional CPU threads:

```fortran
integer signal_var
integer counter
counter = 10000
!DIR$ ATTRIBUTES OFFLOAD:MIC :: long_running_mic_compute
do while (counter .gt. 0)
  !DIR$ OFFLOAD TARGET(MIC:0) SIGNAL(signal_var)
  call long_running_mic_compute()
  call concurrent_cpu_activity()
  !DIR$ OFFLOAD_WAIT TARGET(MIC:0) WAIT (signal_var)
  counter = counter - 1
end do
end
```

**OFFLOAD_TRANSFER**
**OFFLOAD_WAIT**

About Asynchronous Data Transfer (Intel® MIC Architecture)
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
To transfer data between the CPU and the target device, use the **OFFLOAD_TRANSFER** directive with either all **in** clauses or all **out** clauses. Without a **signal** clause the data transfer is synchronous: The next statement is executed only after the data transfer is complete.

**OFFLOAD_TRANSFER** with a **signal** makes the data transfer asynchronous. The tag specified in the **signal** clause is an address expression associated with that dataset. The data transfer is initiated and the CPU can continue past the directive statement.

A later directive written with a **wait** clause causes the activity specified in the directive to begin only after all the data associated with the tag has been received or shared with the target device. The data is placed into the variables specified when the data transfer was initiated. These variables must still be accessible.

Alternatively, you can use the non-blocking API **OFFLOAD_SIGNALED()** to also determine if a section of offloaded code has completed running on a specific target device.

---

**NOTE**

On Intel® MIC Architecture, the **signal** and **wait** clauses, the **OFFLOAD_WAIT** construct and the **OFFLOAD_SIGNALED()** API refer to a specific target device, so you must specify **target-number** in the **target()** clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where the signal was actually initiated for target device 1. The signal was initiated for target device 1, so there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

If, during an asynchronous offload, a signal is created in one thread, Thread A, and waited for in a different thread, Thread B, you are responsible for ensuring that Thread B does not query the signal before Thread A has initiated the asynchronous offload to set up the signal. Thread B querying the signal before Thread A has initiated the asynchronous offload to set up the signal, results in a runtime abort of the application.

If **if-specifier** evaluates to false and you use a **signal (tag)** clause, then the signal is undefined and any wait on this signal has undefined behavior.

---

**Asynchronous Data Transfer From the CPU to the Target**

To transfer data asynchronously from the CPU to the target, use a **signal** clause in an **OFFLOAD_TRANSFER** directive with **in** clauses. The variables listed in the **in** clauses form a data set. The directive initiates the data transfer of those variables from the CPU to the target. A subsequent **OFFLOAD** directive with a **wait** clause that uses the same value for **tag** as that used in the **signal** clause causes the statement controlled by the directive to begin execution on the target only after the data transfer is complete.

---

**Asynchronous Data Transfer from the Target to the CPU**

To transfer data asynchronously from the target to the CPU, use the **signal** and **wait** clauses in two different directives. The first offload directive performs the computation, but only initiates the data transfer. The second directive causes a wait for the data transfer to complete.

---

**Examples: CPU to Target**

In the following example, the data transfer of the floating-point array f1 is initiated at line 10, and f2 is initiated at line 12. The offloads do not initiate a computation. Their only purpose is to start transferring f1 and f2 to the target. At line 14 the CPU initiates the computation of the function foo on the target. The function uses the data f1 and f2, whose transfer was initiated earlier. The execution of the offloaded region on the target begins only after the transfer of f1 and f2 completes. The variable result returns the results of the computation.

```fortran
01   integer, parameter:: n=4086
02   real, allocatable :: f1(:,), f2(:,), result
03   !$dir$ attributes offload:mic :: f1, f2, foo
04   integer :: signal_1, signal_2
```
Multiple independent asynchronous data transfers can occur at any time. The example below uses offload_transfer to send f1 and f2 to the target at different times, first f1 in line 10, and then f2 in line 13.

Examples: Target to CPU

In the following example, the data transfer of the floating-point arrays in1 and in2 is initiated at line 15. The offload does not initiate a computation. Its only purpose is to start transferring in1 to the target. Within the do loop, either in1 or in2 is transferred to the target, and computation starts on whichever set has already been transferred. At line 20 the CPU initiates the computation of the function compute on the target, and tells it to work on in1. At line 24, the CPU initiates the computation of the function compute on the target, but tells it to work on in2, which was transferred at line 23.

The following example double buffers inputs to an offload.

Controlling the Coprocessor's Execution Environment

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can modify the coprocessor's execution environment using the following mechanisms:

- Setting environment variables for the coprocessor on the CPU, and passing them to the coprocessor
- calling functions from the CPU

In general, function calls override environment variables.

Setting Environment Variables on the CPU to Modify the Coprocessor...
Calling Functions on the CPU to Modify the Coprocessor's Execution Environment

Environment Variable for I/O Proxy Control for Offloaded Code

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

The MIC_PROXY_IO=0|1 environment variable controls the proxy of stderr and stdout. It specifies whether the process wants I/O proxy support between the host and coprocessor.

The default is 1 (enable proxy of I/O from coprocessor to host).

Supported Environment Variables

Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Some CPU APIs have offload equivalents, each of which take two additional arguments to specify the target type and target number, defined by the following arguments:

<table>
<thead>
<tr>
<th>target_type</th>
<th>target_type is static. It is recommended to use the following pre-defined default: default_target_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>target_number</td>
<td>The specific coprocessor to target.</td>
</tr>
<tr>
<td></td>
<td>An expression whose value is interpreted as follows:</td>
</tr>
<tr>
<td></td>
<td>&gt;=0</td>
</tr>
<tr>
<td></td>
<td>target = target-number % number_of_targets</td>
</tr>
<tr>
<td></td>
<td>• Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 % 4 and 6 % 4 is 2.</td>
</tr>
<tr>
<td></td>
<td>• Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 % 4 is 0.</td>
</tr>
<tr>
<td>-1 or no value</td>
<td>-1 or no value</td>
</tr>
<tr>
<td>&lt;=1</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

The `mic_lib.f90` header file defines all the function calls that can be made from the CPU to affect the coprocessor’s environment.

This topic uses the CPU API `omp_set_num_threads` and its offload variations as an example. See also the topics listed below for more CPU APIs.

**Example**

**CPU API**

```fortran
subroutine omp_set_num_threads (num_threads) &
   bind (C, name = "omp_set_num_threads")
import :: c_int
integer (kind=c_int), value :: num_threads
end subroutine omp_set_num_threads
```

**Offload API**

```fortran
subroutine omp_set_num_threads_target (target_type, &
   target_number, &
   num_threads) &
```

**Offload API**

```fortran
bind (C, name = "omp_set_num_threads_target")
import :: c_int
integer (kind=c_int), value :: target_type, target_number, num_threads
end subroutine omp_set_num_threads_target
```

```fortran
use mic_lib
use omp_lib

integer :: result, value

value = 66
call omp_set_num_threads_target &
  (TARGET_MIC, 0, value)
!DIR$ OMP OFFLOAD target(mic) out(result)
 !$omp parallel
 !$omp master
 result = omp_get_num_threads()
 !$omp end master
 !$omp end parallel
print ",(A, I)", "Number of threads on target", result
stop
end
```

**Using Libraries With Offloaded Code**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The heterogeneous compilation environment consists of a host CPU compilation environment and a target compilation environment. Each environment consists of the compiler, linker and standard libraries. Code for the host CPU is compiled within the host environment and offloaded code within the target environment. The target environment may supply its own sets of standard libraries and these would be available to be called from offloaded code with no need to use special syntax or runtime features.

Some common libraries, such as the Intel® Math Kernel Library (Intel® MKL) and Intel® Performance Primitives (Intel® IPP) will be available in CPU versions as well as target versions.

When the target is available, the target executable is loaded when the CPU version of the executable is loaded, or when the first offload is attempted. At this time the libraries linked with the target code are initialized. The loaded target executable remains in the target memory until the host program terminates. Thus, any global state maintained by the library is maintained across offload instances.

When you offload code only within shared libraries, you must link the main program with the [Q]offload compiler option.

**NOTE**

Separate copies of libraries are linked or loaded with the host program and the offloaded target code. So there are two sets of global state: One on the host CPU and one on the target. The host CPU code only sees the host CPU state and the offloaded code only sees the state of the library on the target.
Special Cases
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

NOTE This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

Thread-private variables
When a statement is offloaded, thread-private variable values from the CPU thread that does the offload are copied to the target, and then copied back when default in and out are in effect. Copies of thread-private variables in other CPU threads are not modified.

See Also
Writing Target-Specific Code

OpenMP* Considerations

OpenMP* Defaults
This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
The OpenMP* runtime has the following default on Intel® MIC Architecture:

• The OpenMP* runtime creates four threads per core by default under the coprocessor OS.
• If you do not specify the number of threads, the OpenMP* runtime uses the number of logical processors available in the affinity mask of the thread that initially goes parallel.

See Also
Thread Affinity Interface
Supported Environment Variables

OpenMP* Affinity Specifications
The coprocessor OS kernel on the coprocessor uses the logical processor number in /proc/cpuinfo, the calls to sched_(get,set)affinity() and sched_getcpu(), and the taskset command. The OpenMP* runtime library uses the logical processor number if you explicitly specify affinity using a proclist.

The logical processor number used by the coprocessor OS on Intel® MIC Architecture is different from that on the host, and probably not what you expect. There is one logical processor for each hardware thread context. Logical processor 0 is placed on the first hardware context of the highest numbered core. Logical processors from 1 up to the highest, minus three, are placed consecutively on core 0 context 0, core 0 context 1, core 0 context 2, core 0 context 3, core 1, context 0 and so on, with the last three logical processors being on the highest numbered core, with hardware thread contexts 1, 2, and 3.
The simple way to think of this is that you should start enumerating the logical processors to use at logical processor 1, not logical processor 0.

**Balanced Affinity Type**

The affinity type *balanced* is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.

<table>
<thead>
<tr>
<th>NOTE</th>
</tr>
</thead>
<tbody>
<tr>
<td>The OpenMP* environment variable OMP_PROC_BIND=spread is similar to KMP_AFFINITY=balanced and is available on all platforms, including multi-socket CPU systems.</td>
</tr>
</tbody>
</table>

Under this setting, the OpenMP* runtime places threads on separate cores until all cores have at least one thread, similar to the *scatter* type. However, when the runtime must use multiple hardware thread contexts on the same core, the *balanced* type ensures that the OpenMP* thread numbers are close to each other, which *scatter* does not do.

The following diagrams illustrate the allocation of six OpenMP* threads across a 3-core system with the *compact*, *scatter*, and *balanced* affinity types.

**Allocation with the compact affinity type**
On the Intel® MIC Architecture, it is normally beneficial to use cores before threads, so the compact affinity type is unlikely to yield the best results, because it leaves cores unused.

**Allocation with the scatter affinity type**

![Diagram showing thread allocation with scatter affinity type]

The thread allocation under scatter is likely to be better than compact, because it uses cores before threads. However, scatter allocates thread IDs such that threads with IDs in close numerical proximity are on different cores, and therefore do not share caches. Because threads with neighboring IDs often operate on closely related data, placing them on different cores is unlikely to be the best way to allocate them.

**Allocation with balanced affinity type**

![Diagram showing thread allocation with balanced affinity type]
The thread allocation under balanced is balanced over the cores and the threads allocated to a core are neighbors of each other. Therefore, cache utilization should be efficient if the threads access data that is near in store.

**Allocation with balanced affinity type for 9 OpenMP* threads**

![Diagram of thread allocation](image.png)

Tuning affinity is a complicated and machine specific process. Using the balanced affinity type is a reasonable starting point on Intel® MIC Architecture.

The balanced affinity type is also recognized and supported by the OpenMP* runtime on the CPU, but only for single socket systems.

Using the balanced type with the environment variable KMP_AFFINITY propagates to the coprocessor when MIC_ENV_PREFIX is not set. However, this may generate the following runtime warning on a multi-socket CPU:

```
OMP: Warning #230: KMP_AFFINITY: Affinity balanced is not available.
```

To set the balanced affinity type for only the Intel® MIC Architecture environment, assign a specific prefix using the MIC_ENV_PREFIX=prefix and then set prefix_KMP_AFFINITY with balanced.

- Thread Affinity Interface
- Supported Environment Variables
- Setting Environment Variables on the CPU to Modify the Coprocessors Execution Environment

**Setting the Number of OpenMP* Threads on the Coprocessor**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Several methods exist to override the default number of threads per core on the coprocessor.

**Using the OpenMP* API**

The OpenMP* API specification provides the following standard ways to change the desired number of threads on the coprocessor:

- Calling the function `omp_set_num_threads(n)` before the `omp parallel region`
- Using the clause `NUM_THREADS` with OpenMP Fortran directive `PARALLEL`
- Setting the environment variable `OMP_NUM_THREADS=n`

For more information, refer to the OpenMP* API Specification at http://www.openmp.org.
Using the Intel® Compiler

In addition to the standard methods that the OpenMP® API specification provides, listed below, you can use the environment variable MIC_ENV_PREFIX to define a custom-prefixed environment variable to control the number of OpenMP® threads on the coprocessor separately from the host CPU. For example, the following environment variable definitions set OMP_NUM_THREADS on both the CPU and the coprocessor, but with different values.

```
OMP_NUM_THREADS=8
MIC_ENV_PREFIX=ABC
ABC_OMP_NUM_THREADS=124
```

Direct calls on the coprocessor to APIs in libiomp5.so to establish a specific runtime setting override any setting previously set by a CPU environment variable that is replicated on the coprocessor.

Setting Environment Variables on the CPU to Modify the Coprocessor's Execution Environment

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

By default, all environment variables defined in the environment of an executing CPU program are replicated to the coprocessor's execution environment when an offload occurs. You can modify this behavior by defining the environment variable MIC_ENV_PREFIX. When you set MIC_ENV_PREFIX to a specific prefix, then not all CPU environment variables are replicated to the coprocessor, but only those environment variables that begin with the value of the MIC_ENV_PREFIX environment variable. The environment variables set on the coprocessor have the prefix value removed. You thus have independent control of OpenMP® and other execution environments that use common environment variable names.

Setting Multiple Environment Variables on All Coprocessors

You can send multiple variables, each with its own value to all coprocessors.

To do so, use the following form:

```
mic_prefix_VAR=variable1=value1|variable2=value2|variable3=value3|...
```

Where `variableN` is the variable, and `valueN` is its value.

Specifying a Particular Coprocessor

You can specify a particular coprocessor, which is useful when you have multiple coprocessors installed.

To do so, use the following form:

```
mic_prefix_card_number_var=value
```

Where the value of `card_number` is 0 for the first device, 1 for the second, and so on.

Similarly, when setting multiple environment variables, specify a particular coprocessor, using `card_number`.

Example: Setting a Single Environment Variables on All Coprocessors

The following environment variable definitions set OMP_NUM_THREADS on both the CPU and all installed coprocessors, but with different values.

```
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_OMP_NUM_THREADS=124
```

Example: Setting Multiple Environment Variables on All Coprocessors

The following environment variable definition sets `X=x` and `Y=y` on all coprocessors.

```
MIC_ENV_PREFIX=ABC
ABC_VAR=X=x|Y=y
```
Example: Setting a Single Environment Variables on a Particular Coprocessor

The following environment variable definitions set OMP_NUM_THREADS on both the CPU and the fifth coprocessor installed, but with different values.

```
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_4_OMP_NUM_THREADS=124
```

Example: Setting Multiple Environment Variables on a Particular Coprocessor

The following environment variable definition sets X=x and Y=y on the fifth coprocessor installed.

```
MIC_ENV_PREFIX=ABC
ABC_4_VAR=X=x|Y=y
```

Data Alignment for Intel® MIC Architecture

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Unlike the IA-32 and Intel® 64 architectures, the Intel® MIC Architecture requires all data accesses to be properly aligned according to their size, otherwise the program may behave unpredictably.

For example, an integer variable, which requires four bytes of storage, has to be allocated on an address that is a multiple of four. Likewise, a double-precision floating point variable, which requires eight bytes of storage, has to be allocated on an address that is a multiple of eight.

You can align data in the following ways:

- The compiler option `align` can force the alignment of local and global data, arrays, scalars, and fields of defined types, dummy arguments of procedures, data with the ALLOCATABLE or POINTER attribute, common block entities, and fields in SEQUENCE derived types. Natural alignment, where the data is properly aligned according to its size, is usually the default.
- Data objects may be misaligned because of their position in common blocks, because of EQUIVALENCE statements, or because they are fields in SEQUENCE derived types. Even if all of the fields of a defined type are naturally aligned, if the size of the object of defined type is not a multiple of the alignment of the largest field, arrays elements of this defined type would sometimes be misaligned.

Entities in common blocks can be forced onto aligned addresses with the `align *common` compiler options. Fields of a SEQUENCE derived type can be forced onto aligned addresses with the `align sequence` compiler option. Use of these compiler options may affect the correctness of your program unless you apply them consistently to all program units that reference the data being aligned.

- The compiler option `warn alignments` is the default and displays a warning if a data object is misaligned.
- You can use the directives ATTRIBUTES ALIGN, ASSUME_ALIGNED, and ASSUME to align data or tell the compiler that the data should be treated as if aligned.

On the Intel® MIC Architecture, data alignment is so important that alignment warnings are turned into errors so the compilation will fail. Those alignment errors must be corrected before the program will compile.

Using HBW Memory

This topic only applies to Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) and it is only available for Linux® systems.

Certain Intel® Xeon Phi™ coprocessors come equipped with a limited amount of Multi-Channel DRAM (MCDRAM). On Linux®, you can specify use of this high-bandwidth memory for allocatable arrays using the `MEMKIND:HBW` directive or attribute. High bandwidth (HBW) memory is not large so choose the objects you
place there carefully – objects that require repeated and rapid access are best placed in HBW memory. If the
hardware is not available to allocate the object to HBW memory, or if enough HBW memory is not available
to satisfy the allocation, then allocation is performed using non-HBW memory.

When you use the MEMKIND:HBW directive or attribute in a program, you must specify the following on the
compiler or linker command line:

- lmemkind

The memkind library does not ship with Intel Fortran. The memkind webpage is here: http://memkind.github.io/memkind/

From there you can find links to source and binary RPM's: http://download.opensuse.org/repositories/home:/
cmcantalupo/

libmemkind.so must be in the linking path so if you install the binary RPM, it will be in your linking path and
the link option -lmemkind is sufficient when you create a program that uses MEMKIND:HBW. If you build or
put libmemkind.so in some other directory, you must specify that location with -L when you create a
program that uses MEMKIND:HBW.

If the libraries required for HBW memory support are not linked successfully, please refer to the ATTRIBUTES
MEMKIND:HBW directive to determine the action that will be taken.

FOR_GET_HBW_SIZE

Generating an Offload Report

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can measure the amount of time it takes to execute an offload region of code, as well as the amount of
data transferred during the execution of the offload region.

You can print an offload report, which contains information about an offload as the execution proceeds on the
host and on the target. An offload report includes the following information:

• the amount of time it takes to execute an offload region of code
• the amount of data transferred between the host and the target
• additional details, including device initialization, and individual variable transfers

The following mechanisms enable and disable offload reporting:

• the OFFLOAD_REPORT environment variable.
• the _Offload_report API.

A compiler offload report line starts with [Offload] to clearly mark prints from compiler offloads, as
opposed to other offloads, such as those from the Intel® Math Kernel Library.

Activities on the host are marked with [HOST], while activities on the target are marked with [MIC n] where
n is the logical number of the coprocessor to which the offload is sent. The top of the report shows the
mapping of logical devices to physical devices. (Note that

NOTE
An offloaded program can use a subset of physical devices when you specify the OFFLOAD_DEVICES
environment variable.
Because multiple offloads may be in progress concurrently, either when multiple host threads initiate offloads or when asynchronous offloads are used, it is necessary to tag all the output associated with a specific offload directive. Otherwise the reports from several concurrent offloads would be interleaved, making it impossible to determine to which offload a particular line of output belongs. A tag of the form \([\text{Tag } n]\) uniquely identify lines in the offload report that belong to a particular offload.

For each offload, the first two report lines are the source file name and the line number of the offload directive. After that, a line that assigns a Tag to that offload is printed. Subsequent report lines printed for that offload each use the tag \([\text{Tag } n]\) to associate that line with that offload.

The rest of the report contains a line for each major activity. These lines contain an annotation of the activity after the tag that identifies which offload the activity belongs to. The annotations are as follows:

<table>
<thead>
<tr>
<th>Line Marker</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[State]</td>
<td>Activity being performed as part of the offload.</td>
</tr>
<tr>
<td>[Var]</td>
<td>The name of a variable transferred and the direction(s) of transfer.</td>
</tr>
<tr>
<td>[CPU Time]</td>
<td>The total time measured for that offload directive on the host.</td>
</tr>
<tr>
<td>[MIC Time]</td>
<td>The total time measured for executing the offload on the target.</td>
</tr>
<tr>
<td></td>
<td>This excludes the data transfer time between the host and the target, and counts only the execution time on the target.</td>
</tr>
<tr>
<td>[CPU-&gt;MIC Data]</td>
<td>The number of bytes of data transferred from the host to the target.</td>
</tr>
<tr>
<td>[MIC-&gt;CPU Data]</td>
<td>The number of bytes of data transferred from the target to the host.</td>
</tr>
</tbody>
</table>

The various activities printed after [State] describe the internal operation of the Offload Library and are helpful in diagnosing the point at which a runtime failure may occur. In most cases the description is self-explanatory.

**Example**

For this example, example.F90, the offload report output is explained below.

```fortran
1  integer function Hysum(abc,efg,siz)
2    use mic_lib
3
4  integer, dimension(:) :: abc
5  integer, dimension(:) :: efg
6  integer                :: siz
7
8  integer                :: sumT
9  integer                :: k
10
11  !DIR$ OFFLOAD BEGIN target(mic:0) &
12     IN(abc : length(siz )) &
13     OUT(efg : length(siz/2)) &
14     nocopy(k)
15
16  if (OFFLOAD_GET_DEVICE_NUMBER() > -1) then
17     print "(A,I0)","On device : ",OFFLOAD_GET_DEVICE_NUMBER()
18  endif
19
20  sumT = 0
```
The compiler option `OPT:REPORT-PHASE` with the `OFFLOAD` keyword provides summary information about data transfers between the host and the target. There are two reports for each offload code section defined in the source code. The first report beginning with `Offload to target MIC` is from the host compilation. The second report beginning with `Outlined offload region` is from the target compilation. The information in this report option reflects similar information in the output when the `OFFLOAD_REPORT` environment variable is set to 3.

```fortran
21    do k=1,(siz/2)
22       efg(k) = abc(k) + abc(k + (siz/2))
23       sumT = sumT + efg(k)
24    enddo
25    !DIR$ END OFFLOAD
26
27    Hysum = sumT
28
29    return
30  end function Hysum
31
32  program example
33
34  integer, allocatable, dimension(:) :: tuv
35  integer, allocatable, dimension(:) :: xyz
36
37  integer :: j = 10
38  integer :: i = 0
39  integer :: n
40
41  interface
42     integer function Hysum(abc,efg,siz)
43     integer, dimension(:) :: abc
44     integer, dimension(:) :: efg
45     integer                :: siz
46     end function Hysum
47  end interface
48
49     allocate( tuv(j) )
50     allocate( xyz(j/2) )
51
52     do n = 1, j
53        tuv(n) = n - 1
54     enddo
55
56     i = Hysum(tuv,xyz,j)
57
58     do n = 1, (j/2)
59        print "(3X,2(A,I0),$)","xyz("",n,")=",xyz(n)
60     enddo
61     print ",,sum total=",i
62
63  end program example
```
## Intel® Fortran Compiler 19.0 Developer Guide and Reference

Data sent from host to target
- `hysum_abc_v$2d`, pointer to dope-vector with element count `<expr>` elements
- `hysum_ssiz_v$2f`, pointer to `<expr>` elements

Data received by host from target
- `hysum_efg_v$2e`, pointer to dope-vector with element count `<expr>` elements
- `hysum_ssumt_v$31`, scalar size 4 bytes

Data sent from target to host
- `hysum_efg_v$2e`, pointer to dope-vector with element count `<expr>` elements
- `hysum_ssumt_v$31`, scalar size 4 bytes

The rest of this example explains the offload report for the source program shown above.

### NOTE
The host and the target execute independently, so once an offload has been initiated the sequence between host prints and target prints is unpredictable, and can vary from run to run. However, all the host prints will be in the same sequence, as well as all the target prints.

Here, the target device is initialized, and the report shows the mapping between logical and physical devices:

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[HOST]</th>
<th>[State]</th>
<th>Initialize logical card 0 = physical card 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[HOST]</td>
<td>[State]</td>
<td>Initialize logical card 1 = physical card 1</td>
</tr>
</tbody>
</table>

**Offload code in** `example.F90` **at line number 11** **has started executing on the target.**

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[MIC 0]</th>
<th>[File]</th>
<th><code>example.F90</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[MIC 0]</td>
<td>[Line]</td>
<td>11</td>
</tr>
</tbody>
</table>

**Tag value** `Tag0` **is assigned to this offload to enable identifying reports printed for this offload.**

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[MIC 0]</th>
<th>[Tag]</th>
<th><code>Tag0</code></th>
</tr>
</thead>
</table>

The offload is initiated on the host.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[HOST]</th>
<th>[Tag 0]</th>
<th>[State]</th>
<th>Start Offload</th>
</tr>
</thead>
</table>

The target function corresponding to this offload.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[HOST]</th>
<th>[Tag 0]</th>
<th>[State]</th>
<th>Initialize function <code>__offload_entry_example_F90_11hysum_</code></th>
</tr>
</thead>
</table>

Create data transfer buffers for pointer data:
- Four buffers for `abc`: 2 for dope vector and 2 for memory.
- Four buffers for `efg`: 2 for dope vector and 2 for memory.
- Two buffers for `sumt`: This variable was added to the `OUT` clause by default. The variable `sumt` is used in the offload region.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[HOST]</th>
<th>[Tag 0]</th>
<th>[State]</th>
<th>Create buffer from Host memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[HOST]</td>
<td>[Tag 0]</td>
<td>[State]</td>
<td>Create buffer from MIC memory</td>
</tr>
<tr>
<td>[Offload]</td>

<td>[Tag 0]</td>
<td>[State]</td>
<td>Create buffer from MIC memory</td>
</tr>
</tbody>
</table>
Pointer data sent from the host to the target using DMA, for the two dope vectors, and the variables \textit{abc} and \textit{siz}.

Non-pointer data is collected together and sent from host to target.

The offloaded code (line 11) on the target is started.

The offload has completed. Start receiving data from target.

Pointer data from the variable \textit{efg} received from the target using DMA.

This is output from the target. The offload code is invoked on the target.

The variable \textit{abc} is an \textit{IN} for this offload. The two entries are a result of a dope vector for an adjustable array \textit{abc} and memory for \textit{abc}.

The variable \textit{efg} is an \textit{OUT} for this offload. It is a dope vector for an adjustable array \textit{efg} that must be transferred to the target, hence the two entries.

The variable \textit{sumT} is an \textit{OUT} for this offload.

The variable \textit{siz} is an \textit{IN} for this offload.

On the target, non-pointer data is copied into target memory.

User program output:

On device : 0

On the target, non-pointer data, the variable \textit{sumT}, is gathered and sent from the target to the host.

Non-pointer data is copied into target memory.
Host time on the target.

[Offload] [HOST] [Tag 0] [CPU Time] 0.865673 (seconds)

The total amount of pointer and non-pointer data, the variables \textit{abc} and \textit{siz}, transferred from host to target.

[Offload] [MIC 0] [CPU->MIC Data] 188 (bytes)

Computation time on the target.

[Offload] [MIC 0] [MIC Time] 0.000918 (seconds)

The total amount of pointer and non-pointer data, the variables \textit{efg} and \textit{sumT}, transferred from target to
host.

[Offload] [MIC 0] [MIC->CPU Data] 24 (bytes)

User Program output:

\begin{verbatim}
xyz(1)=5  xyz(2)=7  xyz(3)=9  xyz(4)=11  xyz(5)=13
sum total=45
\end{verbatim}

Cleanup at end of program:

[Offload] [MIC 1] [State] Unregister data tables
[Offload] [MIC 0] [State] Unregister data tables
[Offload] [HOST] [State] Unregister data tables

_offload_report

Controls printing offload execution time and the amount of data transferred. This function only applies to Intel® MIC Architecture.

Syntax

\texttt{offload_report(integer)}

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| integer | integer| Possible values: 1, 2 or 3.  
1: Prints the offload computation time, in seconds.  
2: In addition to the information produced with value 1, adds the amount of data transferred between the CPU and the coprocessor, in bytes.  
3: In addition to the information produced at value 2, gives additional details on offload activity, including device initialization, and individual variable transfers. |
**Description**

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

This API enables you to time offload regions and measure the amount of data transferred during their execution.

**Using this API is equivalent to setting the environment variable** `OFFLOAD_REPORT`.

**Example**

In the following example if the `OFFLOAD_REPORT` environment variable is set, the report is produced for offloads before line 19 but suppressed from line 19 to line 28.

Reporting is turned back on at line 28, and subsequent offloads have reporting enabled.

```
01 subroutine foo()
 02   !dir$ ATTRIBUTES OFFLOAD:mic:: foo
      ...
13   !dir$ offload begin target(mic:0) in(SIZ) &
14     in(pc: length(SIZ) alloc_if(.true.) free_if(.false.))
      ...
19   call Offload_report(0)   ! turn off Offload_report
21   !dir$ offload begin target(mic:0) & ...
      ...
28   call Offload_report(1)   ! turn on Offload_report
29   !dir$ offload_transfer target(mic:0) & ...
      ...
40 end
```

The following examples of output are just to give you an idea of the type of output you can expect for each setting. These output examples are not connected to the code examples above.

Here is an example of output for `Offload_report(1)`:

```
[Offload] [MIC 0] [File]            test.f90
[Offload] [MIC 0] [Line]            5
[Offload] [MIC 0] [Tag]             Tag0
sub #1, initial pc: 12345678910
[Offload] [MIC 0] [CPU Time]        0.000000 (seconds)
[Offload] [MIC 0] [MIC Time]        0.000876 (seconds)
```

Here is an example of output for `Offload_report(2)`:

```
[Offload] [MIC 0] [File]            test.f90
[Offload] [MIC 0] [Line]            5
[Offload] [MIC 0] [Tag]             Tag0
sub #1, initial pc: 12345678910
[Offload] [MIC 0] [CPU Time]        0.000000 (seconds)
[Offload] [MIC 0] [CPU->MIC Data]   44 (bytes)
[Offload] [MIC 0] [MIC Time]        0.001131 (seconds)
[Offload] [MIC 0] [MIC->CPU Data]   4 (bytes)
```

Here is an example of output for `Offload_report(3)`:

```
[Offload] [HOST]  [State]   Initialize logical card 0 = physical card 0
[Offload] [HOST]  [State]   Initialize logical card 1 = physical card 1
[Offload] [MIC 0] [File]            test.f90
```

Calling `exit()` From an Offload Region

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**NOTE** This topic is deprecated because it contains information related to Intel® Cilk™ Plus, which is a deprecated feature. This topic will be removed in a future release.

When calling `exit()` from within an offload region, the application reports an offload error stating the process on the device exited unexpectedly.

Building for Intel® MIC Architecture

Setting Stack Size on Coprocessors

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
Each CPU thread that offloads code executes the offloaded code in a coprocessor thread dedicated to that CPU thread. The default stack size for that coprocessor thread is fairly small, 2 MB.

To increase the stack size allocated to offloaded code, set the environment variable `MIC_STACKSIZE` to a size sufficient for the offloaded code. `MIC_STACKSIZE` is always honored. It does not require the variable `MIC_ENV_PREFIX` to be set.

Specify the value for `MIC_STACKSIZE` as follows:

<table>
<thead>
<tr>
<th>integerB</th>
<th>A value, in bytes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>integerK</td>
<td>A value, in kilobytes.</td>
</tr>
<tr>
<td>integerM</td>
<td>A value, in megabytes.</td>
</tr>
<tr>
<td>integerG</td>
<td>A value, in gigabytes.</td>
</tr>
<tr>
<td>integerT</td>
<td>A value, in terabytes.</td>
</tr>
</tbody>
</table>

For example, the following Bash, Dash and C shell commands set the maximum stacksize for the main coprocessor thread to 50MB:

```bash
export MIC_STACKSIZE=50M    #(Bash or Dash shell)
setenv MIC_STACKSIZE 50M    #(C shell)
```

**NOTE**

OpenMP* runtime libraries have their own environment variables for adjusting the sizes of the stacks used by additional OpenMP threads. `MIC_STACKSIZE` does not apply to such threads. For example, to increase the available stack size for every OpenMP thread except the main thread to 3 MB using Bash or Dash, enter: `export OMP_STACKSIZE=3M` (affects OpenMP threads on both host and coprocessor) or `export MIC_ENV_PREFIX=ABC export ABC_OMP_STACKSIZE=3M` (affects coprocessor OpenMP threads only).

**About Building Native Intel® MIC Architecture Applications**

This topic only applies when targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can build a binary to run natively on Intel® MIC Architecture, without building one to run on the CPU at all. To do this, include the `mmic` (Linux*) or `Qmic` (Windows*) compiler option when you invoke the compiler. You can use the `MIC_LIBRARY_PATH` environment variable to add additional paths to search for libraries needed to build the native binary.

**NOTE**
When you specify Windows* option `/Qmic`, you must specify any other options on the command line in the Linux* form. This is because all other options are passed directly to the native compiler for Intel® 64 architecture targeting the Intel® MIC architecture, which is a Windows*-hosted Linux* compiler.

When debugging applications for Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) on Windows*, you should use:

```
ifort /Qmic-avx512 -g
```

See the related links below for information on setting the compiler environment and the class libraries for Intel® Many Integrated Core (Intel® MIC) Architecture. For information on debugging native Intel® MIC Architecture applications, see the debugger documentation.

**Profile-Guided Optimization (PGO)**

Profile-guided Optimization (PGO) improves application performance by shrinking code size, reducing branch mispredictions, and reorganizing code layout to reduce instruction-cache problems. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. **Instrument the program.** The compiler creates and links an instrumented program from your source code and special code from the compiler.
2. **Run the instrumented executable.** Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.
3. **Final compilation.** When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.
See Profile-guided Optimization Options for information about the supported options and Profile an Application for specific details about using PGO from the command line.

PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.
- Detect and do not vectorize loops that execute only a small number of iterations, reducing the run time overhead that vectorization might otherwise add.

Interprocedural optimization (IPO) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about inline function expansion, which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. If you modify your program, the compiler can issue a warning that the dynamic information does not correspond to a modified function when PGO remarks are enabled or found in the optimization report.
• Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.
• Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.
• Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance, execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile-Guided Optimization via HW counters

A lightweight profiling mechanism is available that can be used to achieve many of the benefits of instrumentation based profiling, but without the overhead of inserting instrumentation into the application binary. This mode of operation can be beneficial in cases where increase in code/data size or changes in run time due to instrumentation may make regular Performance-Guided Optimization (PGO) infeasible. This approach requires the use of Intel® VTune™ Amplifier to collect information from the hardware counters. The information is collected with minimal overhead, and combined with debug information produced by the compiler to identify the primary code path for optimizations.

Follow these steps to use this method:

Phase 1: Compile the application with the option `prof-gen-sampling`.

This option will instruct the compiler to generate additional debug information for the application, which is used to map the information collect by the hardware counters to specific source code. However, use of the option does not affect the generated instruction sequence in the way instrumented PGO would. Optimizations may be enabled during this build, however it is recommended to disable function inlining during this build.

Phase 2: Run the generated executable on one or more representative workloads with the Intel VTune Amplifier tool:

```bash
<installation-root>/bin64/amplxe-pgo-report.sh <your application and command line>
```

Additional information regarding options for data collection can be found in the Intel VTune Amplifier documentation. This step will generate files of the form `rNNNpgo.icc.pgo` (where `NNN` is a 3 digit number) which will be used as input to the following phases.

Phase 3: (optional) Merge the report files produced during phase 2.

The tool `profmergesampling` can be used to produce an indexed file of results that will speed up the processing of the data during the next phase.

```
profmergesampling -file <input-file[:input_file]*> -out <output_name>
```

Phase 4: Compile the application with the option `prof-use-sampling:input-file[:input_file]`.

In phase 4, one or more result files produced during phase 2 (or an indexed file from phase 3) can be fed into the compiler to direct the optimizations.

`prof-use-sampling` compiler option
Profile an Application with Instrumentation

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking

   Use \[Q\]prof-gen to produce an executable with instrumented information included. Use \[/Q\]cov-gen (Windows) option to obtain minimum instrumentation only for code coverage.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| Linux and macOS* | ifort -prof-gen -prof-dir /usr/profiled a1.f90 a2.f90 a3.f90  
ifort -oal a1.o a2.o a3.o |
|                   | ifort /Qprof-gen /Qprof-dir:c:\profiled a1.f90 a2.f90 a3.f90  
ifort a1.obj a2.obj a3.obj |
| Windows           | ifort /Qcov-gen /Qcov-dir:c:\cov_data a1.f90 a2.f90 a3.f90  
ifort a1.obj a2.obj a3.obj |

Use the [Q]prof-dir or /Qcov-dir (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

The compiler gathers extra information when you use the -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows) option; however, the extra information is collected to provide support for specific Intel tools, including the code coverage Tool. If you do not expect to use such tools, do not specify -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows); the extended option does not provide better optimization and could slow parallel compile times. If you are interested in using the instrumentation only for code coverage, use the /Qcov-gen (Windows) option, instead of the /Qprof-gen:srcpos (Windows) option, to minimize instrumentation overhead.

PGO data collection is optimized for collecting data on serial applications at the expense of some loss of precision on areas of high parallelism. However, you can specify the threadsafe keyword with the -prof-gen (Linux* and macOS*) or the /Qprof-gen (Windows) compiler option for files or applications that contain parallel constructs using OpenMP* features, for example. Using the threadsafe keyword produces instrumented object files that support the collection of PGO data on applications that use a high level of parallelism but may increase the overhead for data collection. On applications specific to Intel® 64 architecture targeting Intel® MIC Architecture, the only valid mode for using the PGO -prof-gen (Linux and macOS*) or /Qprof-gen (Windows) compiler option is to use the keyword threadsafe.

**NOTE**

Unlike serial programs, parallel programs using OpenMP* may involve dynamic scheduling of code paths, and counts collected may not be perfectly reproducible for the same training data set.

2. Instrumented execution
Run your instrumented program with a representative set of data to create one or more dynamic information files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>./a1.out</td>
</tr>
<tr>
<td>Windows</td>
<td>a1.exe</td>
</tr>
</tbody>
</table>

Executing the instrumented applications generates a dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

By default, the .dyn filename follows this naming convention: `<timestamp>_<pid>.dyn`. The .dyn file is either placed into a directory specified by an environment variable, a compile-time specified directory, or the current directory.

To make it easy to distinguish files from different runs, you can specify a prefix for the .dyn filename in the environment variable, `INTEL_PROF_DYN_PREFIX`. In such a case, executing the instrumented application generates a .dyn filename as follows: `<prefix>_<timestamp>_<pid>.dyn`, where `<prefix>` is the identifier that you have specified. Be sure to set the `INTEL_PROF_DYN_PREFIX` environment variable prior to starting your instrumented application.

**NOTE**
The value specified in `INTEL_PROF_DYN_PREFIX` environment variable must not contain < > : " / \ | ? * characters. The default naming scheme will be used if an invalid prefix is specified.

3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with `[Q]prof-use`; the option instructs the compiler to use the generated dynamic information to guide the optimization:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>ifort -prof-use -ipo -prof-dir /usr/ profiled a1.f90 a2.f90 a3.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /Qprof-use /Qipo /Qprof-dir:c: \profiled a1.f90 a2.f90 a3.f90</td>
</tr>
</tbody>
</table>

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations, `O2`, for phase 1, and specify more advanced optimizations, `[Q]ipo`, during the phase 3 (final) compilation. The example shown above used `O2` in step 1 and `[Q]ipo` in step 3.

**NOTE**
The compiler ignores the `[Q]ipo` or `[Q]ip` option during phase 1 with `[Q]prof-gen.
Profile Function or Loop Execution Time

This topic describes how to profile an application for function or loop execution time. Using the instrumentation method to profile function or loop execution time provides an easy means of getting a view of where cycles are being spent in your application. The Intel® compiler inserts instrumentation code into your application to collect the time spent in various locations. Such data helps you to identify hotspots that may be candidates for optimization tuning or targeting parallelization.

Different levels of instrumentation are available because of the difference in the overhead associated with the inserted probe points that read the CPU cycle counter. The instrumentation levels, in increasing amount of collected data, are grouped as follows:

- Function level
- Function and loop level

You do not need to profile the entire application but it is recommended that the same level of instrumentation is used for all instrumented files. Compile your application with the command line options described below for all the files that require profile information.

After the instrumented application is run, data files containing a summary of the collected data are created in the working directory. View these data files to identify the time proportions of the different parts of your application.

Compiler Options to Obtain Instrumented Program

Use the following command-line compiler options to instrument your application code to profile execution times for functions/loops. When you compile your application using any one of these options, you get an instrumented program.

<table>
<thead>
<tr>
<th>Instrumentation Level</th>
<th>Linux* or macOS* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
</table>
| Function level        | -profile-functions                | /Qprofile-functions        | Instruments function entry/exit points only.  
  - Inserts instrumentation calls on the function entry and exit points to collect the cycles spent within the function.  
  - Data collection is supported for single-threaded applications only.  
  - The collected data from execution of the instrumented application is placed in the file,  
    loop_prof_funcs_<timestamp>.dump in the current working directory. |
| Function and loop level| -profile-loops=<arg>              | /Qprofile-loops:<arg>      | Instruments function and loop entry/exit points:  
  - <arg> argument allows you to specify the types of the loops to be instrumented. The <arg> value must be one of the following:  
    - Inner: Instrument inner loops.  
    - Outer: Instrument outer loops.  
    - All: Instrument both inner and outer loops. |
<table>
<thead>
<tr>
<th>Instrumentation Level</th>
<th>Linux* or macOS* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Inserts instrumentation calls for function entry and exit points, and before and after instrumentable loops as listed in the <code>&lt;arg&gt;</code> argument.</td>
</tr>
</tbody>
</table>

**NOTE**
The compiler may be unable to instrument some loops.

• Data collection is supported for single-threaded applications only.
• The collected data from execution of the instrumented application is placed in the files, `loop_prof_funcs_<timestamp>.dump` and `loop_prof_loops_<timestamp>.dump` in the current working directory for the function data and loop data, respectively.

**NOTE**
Because the instrumentation takes place after many compiler transformations have taken place, loops that have been restructured or replicated by the compiler may result in multiple entries in the generated reports. Additionally, functions may have been inlined into other functions, which may cause the same loop to be listed in multiple functions.

Loop body level `-profile-loops-report=profile-loops-report=<n>`

Controls level of instrumentation for loop bodies where:

• Specifying `n=1` collects the cycle counts on entry and exits of loops. This is the default value if no value is specified for `n`.
• Specifying `n=2` inserts additional instrumentation for collecting loop iteration counts to compute loop min/max and average iteration counts. Such instrumentation increases overhead in the instrumented application.
## Instrumentation Level

<table>
<thead>
<tr>
<th>Linux* or macOS* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
</table>

### NOTE

- Because instrumentation takes place after compiler transformations have taken place, the loop trip count is based on the generated form of the loop, which may be unrolled, and may be different from the original source form.
- This option is effective only when used with the `[Q]profile-loops` option enabled; it acts as a modifier of the `[Q]profile-loops` option.

### Output Formats Obtained on Running Instrumented Program

After compiling your application using the options, you obtain an instrumented program. Run this instrumented program with a representative set of data to create one or more data files.

The output files are produced by a routine that is registered with the `atexit()` routine, and are created only when the program exits via a standard exit procedure. Two formats of the output files are created:

- A plain text file using ‘tab’ delimiters, which can be viewed within a text editor or a spreadsheet.
- An XML data file that can be loaded into the data viewer application.

### Text Output Format

The text output is written into separate files in the current directory. The filenames are `loop_prof_funcs_<timestamp>.dump` and `loop_prof_loops_<timestamp>.dump` for functions and loops respectively. The `<timestamp>` value is the same for both files to indicate they are from the same instrumentation run.

You can load the text files into a spreadsheet by specifying that the data is delimited with ‘tab’ delimiters.

The function report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (abs)</td>
<td>Total accumulated cycles spent between function entry and exit.</td>
</tr>
<tr>
<td>Time %</td>
<td>Percentage of total application time for cycles between function entry and exit.</td>
</tr>
<tr>
<td>Self (abs)</td>
<td>Accumulated cycles spent between function entry and exit less the cycles spent within calls to other instrumented functions.</td>
</tr>
<tr>
<td>Column Heading</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>Time spent in calls to routines or libraries that were not instrumented are included within this cycle count value.</td>
</tr>
<tr>
<td>Self %</td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td>Call count</td>
<td>Number of times the function was entered.</td>
</tr>
<tr>
<td>Exit count</td>
<td>Number of times the function exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a function without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
<tr>
<td>Loop ticks (%)</td>
<td>The percentage of total application time for the self-time cycles of loops within the function. This field is relevant only when you use <code>[Q]profile-loops</code> compiler option.</td>
</tr>
<tr>
<td>Function</td>
<td>Demangled function name</td>
</tr>
<tr>
<td>File:line</td>
<td>Source file containing the code for the function, and the line number the function begins on.</td>
</tr>
</tbody>
</table>

The loop report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (abs)</td>
<td>Total accumulated cycles spent between loop entry and exit.</td>
</tr>
<tr>
<td>Time %</td>
<td>Percentage of total application time for cycles between loop entry and exit.</td>
</tr>
<tr>
<td>Self (abs)</td>
<td>Accumulated cycles spent between loop entry and exit less the cycles spent within calls to other instrumented functions/loops.</td>
</tr>
<tr>
<td>Self %</td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td>Loop entries</td>
<td>Number of times the loop was entered.</td>
</tr>
<tr>
<td>Loop exits</td>
<td>Number of times the loop exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a loop without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
<tr>
<td>Min iteration counts</td>
<td>The smallest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Avg iteration counts</td>
<td>The average iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Max iteration counts</td>
<td>The largest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Function</td>
<td>Demangled function name that executed the loop; this may be different from the function that contained the loop source code, if that function was inlined into another function.</td>
</tr>
<tr>
<td>Function file:line</td>
<td>The name of the source file containing the function that executed the loop, and the line number the function begins on.</td>
</tr>
<tr>
<td>Column Heading</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Loop file:line</td>
<td>The name of the source file containing the loop body, and the line number the loop body begins on.</td>
</tr>
</tbody>
</table>

**XML Output Format**

The `INTEL_LOOP_PROF_XML_DUMP` environment variable is used to control the creation of the XML output format. When `INTEL_LOOP_PROF_XML_DUMP = 0`, no XML file is created.

The XML output file, named `loop_prof_<timestamp>.xml`, is written into the current directory. This file is viewed with the data viewer utility. The XML data file contains both the function and loop level data.

Remember, using the environment variable with a value of 0 implies that the data viewer utility is not going to be used since no XML data files are created.

**Data Viewer Utility**

You must have the Java Runtime Environment, version 1.6 or later installed on your system to use the data viewer utility. The JRE is not included with the Intel® Compiler package.

The Data Viewer displays the data collected for the functions and loops in a sequence of columns that allows for sorting of individual columns. The Data Viewer also provides the ability to filter the function or loops to only display items that meet some threshold amount (total time % or self-time %) of the total application time, or to only show loops that are associated with a particular function.

To launch the Data Viewer utility, or use the following commands from the command line:

On Windows* operating system:

```
loopprofileviewer.bat <datafile>
```

On Linux* and macOS* operating systems:

```
loopprofileviewer.sh <datafile>
```

or

```
loopprofileviewer.csh <datafile>
```
The main user interface displays an upper pane, **Function Profile**, containing function level data, and a lower pane, **Loop Profile**, containing loop level data. If the XML data file is created using only function level instrumentation, the lower pane is not displayed. Drag the separator between individual panes to resize them or click the up/down arrows available on the separator line.

The **Function Profile** pane and **Loop Profile** pane contain the set of columns described in the section, Text Output Format. Click on any of these columns to sort the data based on that column.

The Data Viewer utility has two specific menus - the **View** menu and the **Filter** menu - in the menu bar besides the generic **File** and **Help** menus.

**View Menu**

The **View** menu allows you to open a window that shows the source code for the line you have selected in the table (these menus are grayed out if no line is selected). To use the **View** menu:

1. Select a line in the **Function Profile** pane.
2. Go to **View > Function source for selected function** to see the source code for the selected function.
3. Select a line in the **Loop Profile** pane.
4. Go to **View > Function source for selected loop** to see the source code for the selected function.
5. Go to **View > Loop source for selected loop** to see the source code for the selected loop.
NOTE The source code displayed is the current version of the file, in the directory the file was compiled from when the instrumentation compilation was performed.

When the cursor is within the **Function Profile** pane or the **Loop Profile pane**, right-click on any line to display a popup menu that gives access to these **View** menu options.

By default, the Data Viewer utility displays the most relevant columns based on the data file loaded. Go to **View > Select Columns** to display or hide the columns. In the dialog box that opens, columns not available for the currently loaded data file are grayed out.

**Filter Menu**

The **Filter** menu allows you to limit the data displayed in the tables to items that meet some criteria. As an example, you can use the **Filter** menu as follows:

1. Go to **Filter > Function Profile > “Self time > 1.00%”** to list only the functions in the **Function Profile** pane that represented more than 1.0 % of the application time.
2. Go to **Filter > Set thresholds** to modify the default thresholds used when enabling the filters for total time % or self-time %.

To display only the loops of a particular function, do the following:

1. Select a function in the **Function** column of the **Function Profile** pane.
2. Go to **Filter > Loop Profile > Show loops for selected function** to display the loops for the selected function.

When the cursor is within the **Function Profile** pane or the **Loop Profile pane**, you can right-click any function to display a popup menu that gives access to these **Filter** menu options.

---

### Profile-Guided Optimization Report

The PGO report can help identify where and how the compiler used profile information to optimize the source code. The PGO report can also identify where profile information was discarded due to source code changes made between the time of instrumentation and feedback steps. The PGO report is most useful when combined with the PGO compilation steps outlined in the topic, *[Profile an Application with Instrumentation]*. Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including **-prof-use** (Linux* and macOS*) or **/Qprof-use** (Windows*). The following syntax examples demonstrate how to run the report using the combined options.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -prof-use -qopt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>macOS*</td>
<td>icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c ifort -prof-use -qopt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort pgotools_sample.c /Qprof-use /Qopt-report-phase=pgo</td>
</tr>
</tbody>
</table>

By default the PGO report generates a medium level of detail (where the **[Q]opt-report** argument $n=2$). You can use the **-qopt-report=n** (Linux and macOS*) or **/Qopt-report:n** option along with the **[Q]opt-report-phase** option if you want a greater or lesser level of diagnostic detail.
The output, by default, comes out to a file with the same name as the object file but with an .optrpt extension and is written into the same directory as the object file. Using the entries in the example above, the output file will be pgotools_sample.optrpt. Use the -qopt-report-file (Linux and macOS*) or the /Qopt-report-file (Windows) option to specify any other name for the output file that captures the report results, or to specify that the output should go to stdout or stderr.

High-Level Optimization (HLO)

High-level Optimizations (HLO) exploit the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. While the default optimization level, option O2, performs some high-level optimizations, specifying the O3 option provides the best chance for performing loop transformations to optimize memory accesses.

NOTE
Loop optimizations may result in calls to library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The optimizations performed can also be affected by certain options, such as /arch (Windows*), -m (Linux* and macOS*), or [Q]x options. Additional HLO transformations may be performed for Intel® microprocessors than for non-Intel microprocessors.

Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Predicate Optimization
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Memset Combining, Memory Layout Change
- Loop Rerolling
- Memset and Memcpy Recognition
- Statement Sinking for Creating Perfect Loopnests
- Multiversioning: Checks include Dependency of Memory References, and Trip Counts
- Loop Collapsing
Interprocedural Optimization (IPO)

Interprocedural Optimization (IPO) is an automatic, multi-step process that allows the compiler to analyze your code to determine where you can benefit from specific optimizations.

The compiler may apply the following optimizations:

- Address-taken analysis
- Array dimension padding
- Alias analysis
- Automatic array transposition
- Automatic memory pool formation
- Common block variable coalescing
- Common block splitting
- Constant propagation
- Dead call deletion
- Dead formal argument elimination
- Dead function elimination
- Formal parameter alignment analysis
- Forward substitution
- Indirect call conversion
- Inlining
- Mod/ref analysis
- Partial dead call elimination
- Passing arguments in registers to optimize calls and register usage
- Points-to analysis
- Routine key-attribute propagation
- Specialization
- Stack frame alignment
- Structure splitting and field reordering
- Symbol table data promotion
- Un-referenced variable removal
- Whole program analysis

IPO Compilation Models

IPO supports two compilation models - single-file compilation and multi-file compilation.

Single-file compilation uses the \texttt{-ipo} compiler option, and results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the \texttt{O2} default optimization level; additionally the compiler may perform some inlining for the \texttt{O1} optimization level, such as inlining functions marked with inlining directives.

Multi-file compilation uses the \texttt{-ipo} option, and results in one or more mock object files rather than normal object files. (See the Compilation section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files.

\textbf{NOTE}

Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see \texttt{Profile an Application}.
Compiling with IPO
As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file. The mock object files contain the IR instead of the normal object code. Mock object files can be ten times or more larger than the size of normal object files.
During the IPO compilation phase only the mock object files are visible.

Linking with IPO
When you link with the [Q]ipo compiler option the compiler is invoked a final time. The compiler performs IPO across all mock object files. The mock objects must be linked with the Intel compiler or by using the Intel linking tools. While linking with IPO, the Intel compilers and other linking tools compile mock object files as well as invoke the real/true object files linkers provided on the user’s platform.

Link-time optimization using the -ffat-lto-objects compiler option is provided for GCC compatibility. During IPO compilation, you can specify -ffat-lto-objects option, for the compiler to generate a fat link-time optimization (LTO) object that has both a real/true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.

You can specify the -fno-fat-lto-objects option for the compiler to generate a link-time optimization (LTO) object that only has a discardable intermediate language section; no real/true object is generated. These files are inserted into archives in the form in which they were created. Using this option may improve compilation time and save space for objects.

If you use ld rather than xild to link objects or ar instead of xiar to create an archive, the real/true object, generated during fat link-time optimization guarantees that there will be no impediment to linking/building the archive. However, cross-file optimizations are lost in this case. The extra true object also takes additional space and takes compile time to generate it, so using -fno-fat-lto-objects compiler option is an advantage provided that you link the IPO mock object files with xild and archive them with xiar.

Whole Program Analysis
The compiler supports a large number of IPO optimizations that can be applied or have its effectiveness greatly increased when the whole program condition is satisfied.
During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis - object reader method and table method. Most optimizations can be applied if either type of whole program analysis determines that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

Object reader method
In the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

Table method
In the table method the compiler analyzes the mock object files and generates a call-graph. The compiler contains detailed tables about all of the functions for all important language-specific libraries, like the Fortran runtime libraries. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls by finding an entry for each unresolved function in the compiler tables. If the compiler can resolve the functions call, the whole program condition exists.
Using IPO

This topic discusses how to use IPO from the command line.

Compiling and Linking Using IPO

To enable IPO, you first compile each source file, then link the resulting source files.

First, compile your source files with [Q]ipo compiler as shown below:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*</td>
<td>ifort -ipo -c a.f90 b.f90 c.f90</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort /Qipo /c a.f90 b.f90 c.f90</td>
</tr>
</tbody>
</table>

The output of the above example command differs according to operating system:

- Linux and macOS*: The commands produce a.o, b.o, and c.o object files.
- Windows: The commands produce a.obj, b.obj, and c.obj object files.

Use the c compiler option to stop compilation after generating .o or .obj files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.

Second, link the resulting files. The following example command will produce an executable named app:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>ifort -o app a.o b.o c.o</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:app a.obj b.obj c.obj</td>
</tr>
</tbody>
</table>

The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the xild (Linux and macOS*) or xilink (Windows) tool, with the appropriate linking options.
Combining the Steps

The separate compile and link commands demonstrated above can be combined into a single command, as shown in the following examples:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and macOS*</td>
<td>ifort -ipo -o app a.f90 b.f90 c.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /Qipo /exe:app a.f90 b.f90 c.f90</td>
</tr>
</tbody>
</table>

The `ifort` command, shown in the examples above, calls GCC `ld` (Linux and macOS*) or `link.exe` (Windows only) to link the specified object files and produce the executable application, which is specified by the `-o` (Linux and macOS*) or `/exe` (Windows) option.

Capturing Intermediate IPO Output

The `[-Q]ipo-c` and `[-Q]ipo-S` compiler options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.

- Use the `[-Q]ipo-c` compiler option to optimize across files and produce an object file. The option performs optimizations as described for the `[-Q]ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.o` (Linux and macOS*) or `ipo_out.obj` (Windows).
- Use the `[-Q]ipo-S` compiler option to optimize across files and produce an assembly file. The option performs optimizations as described for `[-Q]ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and macOS*) or `/exe` (Windows) option to specify a different name.

These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and macOS*) or `/exe` (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and macOS*) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `[-Q]ipo-c` option, but you will not get the full benefit of whole program optimizations if you use this option.

The object file created using the `[-Q]ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. Whole program optimizations, which require a knowledge of how the real object file will be linked in with other files to produce and object, are not applied.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

IPO-Related Performance Issues

There are some general optimization guidelines for using IPO that you should keep in mind:

- Using IPO on very large programs might trigger internal limits of other compiler optimization phases.
- Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to these general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

- Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. The Intel® Compiler cannot inspect mock object files generated by other compilers for optimization opportunities.
- Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and macOS*, replace all instances of `ld` with `xild`; for Windows, replace all instances of `link` with `xilink`.

See Also
IPO for Large Programs

IPO for Large Programs

In most cases, IPO generates a single true object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use `[Q]ipo` compiler option on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple true object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

- Use the `[Q]ipoN` compiler option and pass an integer value in the place of `N`.
- Use the `[Q]ipo-separate` compiler option.

The number of true object files generated by the link-time compilation is invisible to you unless the `[Q]ipo-c` or `[Q]ipo-S` compiler option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the desired results then experiment with generating a different number of object files.

You can use the `[Q]ipo-jobs` compiler option to control the number of processes, or jobs, executed during parallel IPO builds.

Using `[Q]ipoN` to Create Multiple Object Files

If you specify `[Q]ipo0`, which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications. If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass a value that exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files.
The following example commands demonstrate how to use [Q]ipo2 option to compile large programs.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td>ifort /Qipo2 /c a.f90 b.f90</td>
</tr>
<tr>
<td>Linux*</td>
<td>ifort -ipo2 -c a.f90 b.f90</td>
</tr>
<tr>
<td>macOS*</td>
<td>ifort -ipo2 -c a.f90 b.f90</td>
</tr>
</tbody>
</table>

In executing the above commands, the compiler generates object files using an OS-dependent naming convention. On Linux* and macOS*, the example command results in object files named ipo_out.o, ipo_out1.o, and ipo_out2.o. On Windows*, the file names follow the same convention; however, the file extensions will be .obj.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

**Creating the Maximum Number of Object Files**

Using [Q]ipo-separate allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation. The maximum number of true object files is the equal to the number of mock object files passed on the link line.

For example, you can pass example commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td>ifort a.obj b.obj c.obj /Qipo-separate /Qipo-c</td>
</tr>
<tr>
<td>Linux*</td>
<td>ifort a.o b.o c.o -ipo-separate -ipo-c</td>
</tr>
<tr>
<td>macOS*</td>
<td>ifort a.o b.o c.o -ipo-separate -ipo-c</td>
</tr>
</tbody>
</table>

The compiler generates multiple object files that use the same naming convention discussed above.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

**Understanding Code Layout and Multi-Object IPO**

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system:
Windows:
- The first routine is placed in `.text$00001`, the second is placed in `.text$00002`, and so on.

Linux:
- The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on.

## Creating a Library from IPO Objects

**Linux* and macOS***

Libraries are often created using a library manager such as `xiar` for Linux*/macOS* or `xilib` for Windows. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

### Example

```
xiar cru user.a a.o b.o
```

The above command creates a library named `user.a` containing the `a.o` and `b.o` objects.

If the objects have been created using `[Q]ipo -c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file.

### Example

```
ifort -ipo -c a.f90 b.f90
```

The commands generate mock objects files, which when placed in archive will also be accompanied by a true object file.

Using `xiar` is the same as specifying `xild -lib`.

**macOS* Only**

When using `xilibtool`, specify `-static` to generate static libraries, or specify `dynamic` to create dynamic libraries. For example, the following command will create a static library named `mylib.a` that includes the `a.o`, `b.o`, and `c.o` objects.

### Example

```
xilibtool -static -o mylib.a a.o b.o c.o
```

Alternately, the following example command will create a dynamic library named `mylib.dylib` that includes the `a.o`, `b.o`, and `c.o` objects.
Example

\texttt{xilibtool -dynamic -o mylib.dylib a.o b.o c.o}

Specifying \texttt{xilibtool} is the same as specifying \texttt{xild -libtool}.

\textbf{Windows* Only}

Create libraries using \texttt{xilib} or \texttt{xilink -lib} to create libraries of IPO mock object files and link them on the command line.

For example, assume that you create three mock object files by using a command similar to the following:

Example

\texttt{ifort /c /Qipo a.obj b.obj c.obj}

Further assume \texttt{a.obj} contains the main subprogram. You can enter commands similar to the following to create a library.

Example

\begin{itemize}
  \item \texttt{xilib -out:main.lib b.obj c.obj}
  \item \texttt{xilink -lib -out:main.lib b.obj c.obj}
\end{itemize}

You can link the library and the main program object file by entering a command similar to the following:

Example

\texttt{xilink -out:result.exe a.obj main.lib}

\section*{Requesting Compiler Reports with the \texttt{xi*} Tools}

The compiler options \texttt{qopt-report (Linux* and macOS*)} and \texttt{[Q]opt-report (Windows*)} generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a file (instead of stderr), and request reports from all routines with names containing a specific string as part of their name.

The \texttt{xi*} tools are used with inter-procedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported \texttt{xi*} tools are:

- Linker tools: \texttt{xilink (Windows*)} and \texttt{xild (Linux* and macOS*)}
- Library tools: \texttt{xilib (Windows*)}, \texttt{xiar (Linux* and macOS*)}, \texttt{xilibtool (macOS*)}

The following tables lists the compiler report options that can be used with the \texttt{xi*} tools during the final IPO compilation.
<table>
<thead>
<tr>
<th>Optimization Report Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-qopt-report[=n] (Linux* and macOS*)</td>
<td>Enables optimization report generation with different levels of detail. Valid values for n are 0 through 5. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail. Higher numbers give greater levels of detail.</td>
</tr>
<tr>
<td>/Qopt-report[=n] (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-qopt-report-file=filename (Linux* and macOS*)</td>
<td>Generates an optimization report and directs the report output to the specified file name. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.</td>
</tr>
<tr>
<td>/Qopt-report-file:filename (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-qopt-report-phase[=list] (Linux* and macOS*)</td>
<td>Specifies a comma separated list of optimization phases to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phases by using the [Q]opt-report-help option.</td>
</tr>
<tr>
<td>/Qopt-report-phase:[=list] (Windows*)</td>
<td>To generate a report for the IPO phase, use the -qopt-report-phase=ipo (Linux* and macOS*) or /Qopt-report-phase:ipo (Windows) option.</td>
</tr>
<tr>
<td>-qopt-report-routine=substring (Linux* and macOS*)</td>
<td>Generates reports for all routines with names containing substring as part of their name. You can also specify a sequence of substrings separated by commas. If you do this, the compiler generates an optimization report for each of the routines whose name contains one or more of these substrings.</td>
</tr>
<tr>
<td>/Qopt-report-routine:substring (Windows*)</td>
<td>If substring is not specified, the compiler generates reports on all routines.</td>
</tr>
<tr>
<td>-qopt-report-filter=string (Linux* and macOS*)</td>
<td>Tells the compiler to find the indicated parts of your application specified by string, and generate optimization reports for them.</td>
</tr>
<tr>
<td>/Qopt-report-filter:string (Windows*)</td>
<td>If both -qopt-report-routines=string1 and qopt-report-filter=string2 are specified, it is treated as -qopt-report-filter=string1;string2.</td>
</tr>
<tr>
<td>-qopt-report-help (Linux* and macOS*)</td>
<td>Displays the optimization phases available to use when using the -qopt-report-phase (Linux* and macOS*) or [Q]opt-report-phase (Windows*) or option.</td>
</tr>
<tr>
<td>/Qopt-report-help (Windows*)</td>
<td></td>
</tr>
<tr>
<td>-qopt-report-names (Linux* and macOS*)</td>
<td>Specifies whether mangled or unmangled names appear in the optimization report. If this option is not specified, unmangled names are used by default.</td>
</tr>
<tr>
<td>/Qopt-report-names (Windows*)</td>
<td>If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing. If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing. If you use this option, you do not have to specify option -qopt-report (Linux* OS and macOS*) or /Qopt-report (Windows* OS).</td>
</tr>
</tbody>
</table>

Inline Expansion of Functions

Inline function expansion does not require that the applications meet the criteria for whole program analysis normally required by IPO; so this optimization is one of the most important optimizations done in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the Intel® compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion is performed on relatively small user functions more often than on functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying the [Q]ip compiler option, single-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying the [Q]ipo compiler option, multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

Caution

Using the [Q]ip and [Q]ipo (Windows*) options can, in some cases, significantly increase compile time and code size.

The Intel compiler does a certain amount of inlining at the default level. Although such inlining is similar to what is done when you use the [Q]ip option, the amount of inlining done is generally less than when you use the option.

Selecting Routines for Inlining

The compiler attempts to select the routines whose inline expansions provide the greatest benefit to program performance. The selection is done using default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use options for Profile-Guided Optimizations (PGO): [Q]prof-use compiler option.

When you use PGO with [Q]ip or [Q]ipo (Windows), the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

Using IPO with PGO
Combining IPO and PGO typically produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.

Compiler Directed Inline Expansion of Functions

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance. See Inline Expansion of Functions for more information.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits.

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>inline-level (Linux* and macOS*) or Ob (Windows*)</td>
<td>Specifies the level of inline function expansion. Note that the option /Ob2 on Windows* is equivalent to -inline-level=2 on Linux* and macOS*. Allowed values are 0, 1, and 2.</td>
<td></td>
</tr>
<tr>
<td>[Q]ip-no-inlining</td>
<td>Disables only inlining enabled by the [Q]ip, [Q]ipo, or Ob2 options.</td>
<td></td>
</tr>
<tr>
<td>[Q]ip-no-pinlining</td>
<td>Disables partial inlining enabled by the [Q]ip or [Q]ipo options. No other IPO optimizations are disabled.</td>
<td></td>
</tr>
<tr>
<td>setting inline-debug-info for the debug option</td>
<td>Indicates that the source position information for an inlined function should be retained, rather than replaced, by that of the call which is being inlined.</td>
<td></td>
</tr>
</tbody>

Developer Directed Inline Expansion of User Functions

In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options and directives that allow you to more precisely direct when and if inline function expansion should occur.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

Typically, the compiler targets functions that have been marked for inlining based on the following:

- **Procedure-specific inlining directives**: indicates to the compiler to inline calls within the targeted procedure if it is legal to do so. For example, `!DIR$ ATTRIBUTES INLINE, !DIR$ ATTRIBUTES FORCEINLINE`.

The following developer directed inlining options and directives provide the ability to change the boundaries used by the inliner to distinguish between small and large functions.

In general, you should use the `|Q|inline-factor` option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

If your code hits an inlining limit, the compiler issues a warning at the highest warning level. The warning specifies which of the inlining limits have been hit, and the compiler option and/or directives needed to get a full report. For example, you could get a message as follows:

```
```

Messages in the report refer directly to the command line options or directives that can be used to overcome the limits.

The following table lists the options you can use to fine-tune inline expansion of functions. The directives associated with the options are documented in the **Effect** column.

<table>
<thead>
<tr>

**Inlining Report**

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler examines the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.
The Inlining Report is part of the Opt Report. The compiler options -qopt-report [Linux* and macOS*] and -Qopt-report [Windows*] generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a specific file, stdout or stderr, and request reports from all routines with names containing a specific string as part of their name.

The inlining report is a description of the inlining choices that were made for each routine that is compiled in the program. It is produced as part of the opt report. To restrict the opt report to contain ONLY the inlining report, use the option -qopt-report-phase=ipo [Linux* and macOS*] or -Qopt-report-phase:ipo [Windows*].

The user can control the amount of information by specifying a level for the inlining report. The level is shown by a number from 1 to 5. Level 1 contains the smallest amount of information, and each level adds information to the report. Level 2 is the default report.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The inlining report gives you an in-depth overview of the compiler's inlining decisions, which occur within five levels of granularity. You can specify levels with -qopt-report=1, -qopt-report=2, etc., [Linux* and macOS*] or -Qopt-report=1, -Qopt-report=2, etc. [Windows*]. See below for specific level details.

**Level 1**

The Inlining Report is activated when you run the Opt Report, using -qopt-report.

For each routine you compile, you get one report with the title INLINE REPORT that shows the calls inlined into that routine.

**Example: Inlining Report Level 1 - Typical Routine**

```
INLINE REPORT: (APPLU)
  -> INLINE: (295,12) SETBV
  -> INLINE: (398,18) EXACT
  -> INLINE: (399,18) EXACT
  -> INLINE: (409,18) EXACT
  -> INLINE: (410,18) EXACT
  -> INLINE: (420,18) EXACT
  -> INLINE: (421,18) EXACT
  -> INLINE: (299,12) SETIV
  -> (303,12) ERHS
  -> (307,12) SSOR
  -> INLINE: (311,12) ERROR
  -> INLINE: (1518,24) EXACT
  -> INLINE: (1552,24) EXACT
  -> INLINE: (315,12) PINTGR
  -> (319,12) VERIFY
```
The report gives the name of the compiled routine (APPLU), and contains one line for each call that the compiler decided to inline or not inline. In the above report, the compiler made 15 inlining decisions for calls in the routine APPLU. It decided to inline 12 of the calls. These decisions are indicated by the lines which start with -> INLINE. It decided not to inline three of the calls. These decisions are indicated by the lines without the word INLINE.

On each line, the position of the call in the source code is given in parentheses, followed by the name of the routine being called. For example:

-> INLINE: (398,18) EXACT

This refers to a call at line 398 column 18 to a routine called EXACT.

Level 2

Level 2 includes the values of important compiler options related to inlining. Unless the user specifies one of these values by using the option on the command line, the default value of the option is shown. You can read more about the meaning of the individual inlining options in the Inlining Options section.

<table>
<thead>
<tr>
<th>Example: Inlining Report Level 2 - Values of Inlining Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>INLINING OPTION VALUES:</td>
</tr>
<tr>
<td>-inline-factor: 100</td>
</tr>
<tr>
<td>-inline-min-size: 30</td>
</tr>
<tr>
<td>-inline-max-size: 230</td>
</tr>
<tr>
<td>-inline-max-total-size: 2000</td>
</tr>
<tr>
<td>-inline-max-per-routine: 10000</td>
</tr>
<tr>
<td>-inline-max-per-compile: 500000</td>
</tr>
</tbody>
</table>

Level 3

Level 3 contains one additional line for each call to an external routine made in the application. Such calls are not candidates for inlining, because the code for these routines is not present in the file or files being compiled.

<table>
<thead>
<tr>
<th>Example: Inlining Report Level 3 - External Linkage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Begin optimization report for: APPLU</td>
</tr>
<tr>
<td>Report from: Interprocedural optimizations [ipo]</td>
</tr>
<tr>
<td>INLINE REPORT: (APPLU) [1] applu.f (1,16)</td>
</tr>
<tr>
<td>-&gt; EXTERN: (1,16) for_set_reentrancy</td>
</tr>
<tr>
<td>-&gt; EXTERN: (80,7) for_read_seq_lis</td>
</tr>
</tbody>
</table>

Level 4

Level 4 adds four additional pieces of information. The specifics are shown below:

- Whole Program values:

<table>
<thead>
<tr>
<th>Example: Whole Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHOLE PROGRAM [SAFE] [EITHER METHOD]: false</td>
</tr>
<tr>
<td>WHOLE PROGRAM [SEEN] [TABLE METHOD]: true</td>
</tr>
<tr>
<td>WHOLE PROGRAM [READ] [OBJECT READER METHOD]: false</td>
</tr>
</tbody>
</table>

An application for which whole program is determined is subject to a higher degree of optimization than one which is not. The Intel compiler uses two methods of determining whole program, a TABLE METHOD and an OBJECT READER METHOD.
• The size of the routine \([sz]\) and the inlined size of the routine \([isz]\). Usually \(isz\) is less than \(sz\):

**Example: Size of the Routine (sz) vs. Inlined Size of the Routine (isz)**

\[
\text{-> INLINE: (295,12) SETBV (isz = 752) (sz = 755)} \\
\text{-> INLINE: (398,18) EXACT (isz = 98) (sz = 109)}
\]

In the above example, the routine SETBV was inlined into the routine that called it. The size of SETBV, before inlining, was 755 units. After inlining, the calling routine was increased by 752 units. The increase in the size of the calling routine is slightly less than the size of SETBV, because some of the overhead of calling SETBV was removed when SETBV was inlined.

• The percentage of time that has passed in the process of compiling the file:

**Example: Percentage of Time Passed During Compilation**

\[
\text{INLINE REPORT: (APPLU) \([1/16=6.2\%]\) applu.f (1,16)}
\]

For example, on the line above, \([1/16 = 6.2\%]\) indicates that APPLU is the first routine out of 16 to be compiled, and when this routine is done being compiled, 6.2% of the compilation is finished. You can use these numbers to estimate how long the compilation is going to take.

• The calls that did not get inlined and the reason why they did not get inlined. The reason is shown in double brackets \([[]]\):

**Example: Calls That Are Not Inlined**

\[
\text{-> (303,12) ERHS (isz = 2125) (sz = 2128)} \\
\text{[[ Inlining would exceed –inline-max-size value (2128>253)]]}
\]

In the above example, the routine ERHS is not inlined, because the size of the routine (2128 units) is larger than the allowable size (253 units). If you wish to inline routines that are this large, you can use the option \(-\text{inline-max-size=2128}\) (or larger).

**Level 5**

Level 5 adds the inlining footnotes.

**Example: Use of Footnote**

\[
\text{-> (303,12) ERHS (isz = 2058) (sz = 2061)} \\
\text{[[ Inlining would exceed –inline-max-size-value (2061>230) <1>]]}
\]

The inlining footnotes explain the text found in the double brackets \([[]]\). They include a description for why an inlining call did not happen, and what you can do to make the inlining of this call happen.

The footnote annotation \(<1>\) refers to the first footnote in the INLINING FOOTNOTES section at the bottom of the inlining report, which is produced when the user selects Level 5. For example, the footnote produced for annotation \(<1>\) above is:

**Example: Footnote Text**

\(<1>\) The subprogram is larger than the inliner would normally inline. Use the option \(-\text{inline-max-size}\) to increase the size of any subprogram that would normally be inlined, add “\text{!DIR$ATTRIBUTES FORCELIN}” to the declaration of the called function, or add “\text{!DIR$ FORCELIN}” before the call site.
Fortran Language Extensions

Intel® Fortran provides a number of additional implementation features designed to simplify or enhance application development. The features in the section are varied; your choice to employ each feature depends on your application and development needs.

The Intel® Fortran Language Reference contains a section showing a summary of all the language extensions (non-standard features).

64-bit Addressing Support (Linux*)

This topic only applies to Linux* systems.

Applications designed to take advantage of Intel® 64 architecture can be built with one of three memory models:

- **small** (-mcmodel=small)
  This causes code and data to be restricted to the first 2GB of address space so that all accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- **medium** (-mcmodel=medium)
  This causes code to be restricted to the first 2GB; however, there is no restriction on data. Code can be addressed with IP-relative addressing, but access of data must use absolute addressing.

- **large** (-mcmodel=large)
  There are no restrictions on code or data; access to both code and data uses absolute addressing.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. This can affect code size and performance. (IP-relative addressing is somewhat faster.)

Additional Notes on Memory Models and on Large Data Objects

- When you specify the medium or large memory models, you must also specify the compiler option `-shared-intel` to ensure that the correct dynamic versions of the Intel run-time libraries are used.
- When you build shared objects (.so), Position-Independent Code (PIC) is specified (that is, `-fpic` is added by the compiler driver) so that a single .so can support all three memory models. However, code that is to be placed in a static library, or linked statically, must be built with the proper memory model specified. Note that there is a performance impact to specifying the medium or large memory models.
- The use of the memory model (medium, large) option and the `-shared-intel` option is required as a by-product of the code models stipulated in the 64-bit Application Binary Interface (ABI), which is written specifically for processors with the 64-bit memory extensions. Both the compiler and the GNU linker (ld) are responsible for generating the proper code and necessary relocations on this platform according to the chosen memory model.
- The 2GB restriction on Intel® 64 architecture involves not only arrays greater than 2GB, but also COMMON blocks and local data with a total size greater than 2GB. The Compiler Options reference contains additional discussion of the supported memory models and offers details about the 2GB restrictions for each model (see the description for option `mcmodel`).
- If, during linking, you fail to use the appropriate memory model and dynamic library options, an error message in this format occurs:

```
<some lib.a library>(some .o): In Function <function>:
  relocation truncated to fit: R_X86_64_PC32 <some symbol>
```
**Traceback**

When a Fortran program terminates due to a severe error condition, the Fortran run-time system displays additional diagnostic information after the run-time message.

The Fortran run-time system attempts to walk back up the call chain and produce a report of the calling sequence leading to the error as part of the default diagnostic message report. This is known as traceback. The minimum information displayed includes:

- The standard Fortran run-time Run-Time Message Display and Format text that explains the error condition.
- A tabular report that contains one line per call stack frame. This information includes at least the image name and a hexadecimal PC in that image.

The information displayed under the Routine, Line, and Source columns depends on whether your program was compiled with the `traceback` option.

For example, if the `traceback` option is specified, the displayed information might resemble the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image           PC        Routine         Line     Source
libifcorert.dll  1000A3B2  Unknown         Unknown  Unknown
libifcorert.dll  1000A184  Unknown         Unknown  Unknown
libifcorert.dll  10009324 Unknown         Unknown  Unknown
libifcorert.dll  10009596 Unknown         Unknown  Unknown
libifcorert.dll  10024193 Unknown         Unknown  Unknown
teof.exe         004011A9   AGAIN            21  teof.for
hteof.exe        004010DD   GO               15  teof.for
hteof.exe        004010A7   WE               11  teof.for
hteof.exe        00401071   HERE             7   teof.for
hteof.exe        00401035   TEOF              3   teof.for
hteof.exe        004013D9   Unknown         Unknown  Unknown
hteof.exe        004012DF   Unknown         Unknown  Unknown
KERNEL32.dll     77F1B304  Unknown         Unknown  Unknown
```

If the same program is not compiled with the `traceback` option:

- The Routine name, Line number, and Source file columns would be reported as "Unknown."
- A link map file is usually needed to locate the cause of the error.

The `traceback` option provides program counter (PC) to source file line correlation information to appear in the displayed error message information, which simplifies the task of locating the cause of severe run-time errors.

For Fortran objects generated with the `traceback` option, the compiler generates additional information used by the Fortran run-time system to automatically correlate PC values to the routine name in which they occur, Fortran source file, and line number in the source file. This information is displayed in the run-time error diagnostic report.

Automatic PC correlation is only supported for Fortran code. For non-Fortran code, only the hexadecimal PC locations are reported.

`traceback` compiler option

**Tradeoffs and Restrictions in Using Traceback**

This topic describes tradeoffs and restrictions that apply to using traceback.
Effect on Image Size

Using the traceback option to get automatic PC correlation increases the size of an image. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PCs with a map file is acceptable.

The approach of providing automatic correlation information in the image was used so that no run-time penalty is incurred by building the information "on the fly" as your application executes. No run-time diagnostic code is invoked unless your application is terminating due to a severe error.

C Compiler Omit Frame Pointer Option on Systems Using IA-32 Architecture

The following routines are used to walk the stack:

- For Windows*, the Windows API routine StackWalk( ) in imagehlp.dll
- For Linux* and for macOS*, _Unwind_ForcedUnwind( ), _Unwind_GetIP( ), _Unwind_GetRegionStart( ) and _Unwind_GetGr( ) routines in libunwind.so

In an environment using IA-32 architecture, there are no firm software calling standards documented. Compiler developers are under no constraints to use machine registers in any particular way or to hook up procedures in any particular way. The stack walking routines listed above use a set of heuristics to determine how to walk the call stack. That is, they make a "best guess" to determine how a program reached a particular point in the call chain. With C code that has been compiled with Visual C++* using the Omit Frame Pointer option -- either -fomit-frame-pointer (Linux and macOS*) or /Oy (Windows) -- this "best guess" is not usually the correct one.

If you are mixing Fortran and C code and you are concerned about stack tracing, consider disabling the -fomit-frame-pointer or /Oy option in your C compilations. Otherwise, traceback will most likely not work for you.

Inlined Routines Will Not Be Displayed

Inlining can cause some routines not to be realized as separate stack frames, so the traceback will not show inlined routines.

Stack Trace Failure

Programs can fail for a number of reasons, often with unpredictable consequences. Memory corruption by erroneously executing code is one possibility. Stack memory can be corrupted in such a way that the attempt to trace the call stack will result in access violations or other undesirable consequences. The stack-tracing run-time code is guarded with a local exception filter. If the traceback attempt fails due to a hard detectable condition, the run-time will report this in its diagnostic output message as:

```
Stack trace terminated abnormally
```

Be forewarned, however: It is also possible for memory to be corrupted in such a way that a stack trace can seem to complete successfully with no hint of a problem. The bit patterns it finds in corrupted memory where the stack used to be, and then uses to access memory, may constitute perfectly valid memory addresses for the program to be accessing. They just do not happen to have any connection to what the stack used to look like. So, if it appears that the stack walk completed normally, but the reported PCs make no sense to you, then consider ignoring the stack trace output in diagnosing your problem.

Another condition that will disable the stack trace process is your program exiting because it has exhausted virtual memory resources.

The stack trace can fail if the run-time system cannot dynamically load libunwind.so (Linux and macOS*) or imagehlp.dll (Windows) or cannot find the necessary routines from that library. In this case, you still get the basic run-time diagnostic message; you will not get any call stack information.
Linker /incremental:no Option on Windows Operating Systems

The following applies to Windows operating systems only.

When incremental linking is enabled, automatic PC correlation does not work. Use of incremental linking always disables automatic PC correlation even if you specify /traceback during compilation.

When you use incremental linking, the default hexadecimal (hex) PC values will still appear in the output. To correlate from the hexadecimal PC values to routine containing the PC addresses requires use of a linker map file. However, if you request a map file during linking, incremental linking becomes disabled. Thus to allow any PC values generated for a run-time problem to be helpful, incremental linking must be disabled.

In the integrated development environment, you can use the Call stack display, so incremental linking is not a problem.

Sample Programs and Traceback Information

The following sections provide sample programs that show the use of traceback to locate the cause of the error:

- Example: End-of-File Condition, Program teof
- Example: Machine Exception Condition, Program ovf

Note that the hex PC's and contents of registers displayed in these program outputs are meant as representative examples of typical output. The PC's will change over time, as the libraries and other tools used to create an image change.

Example: End-of-File Condition, Program teof

In the following example, a READ statement creates an End-Of-File error, which the application has not handled:

```fortran
program teof
  integer*4 i, res
  i = here()
end
integer*4 function here()
  here = we()
end
integer*4 function we()
  we = go()
end
integer*4 function go()
  go = again()
end
integer*4 function again()
  integer*4 a
  open(10, file='xxx.dat', form='unformatted', status='unknown')
  read(10) a
  again = a
end
```

The diagnostic output that results when this program is built with traceback enabled, optimization disabled, and linked against the shared Fortran run-time library on the Intel® 64 architecture platform is similar to the following:

```plaintext
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image                  PC                Routine               Line     Source
libifcorert.dll        00000FED2B232D9  Unknown               Unknown  Unknown
libifcorert.dll        00000FED2B6CEE0  Unknown               Unknown  Unknown
teof.exe               00000013F931193  AGAIN                 17  teof.f90
teof.exe               00000013F93109B  GO                    12  teof.f90
```
If optimization is not disabled (/Od on Windows* or -O0 on Linux* and macOS*), procedure inlining may collapse the call stack and make it more difficult to locate a problem.

The first line of the output is the standard Fortran runtime error message. What follows is the result of walking the call stack in reverse order to determine where the error originated. Each line of output represents a call frame on the stack. Since the application was compiled with the traceback option, the PCs that fall in Fortran code are correlated to their matching routine name, line number and source module. PCs that are not in Fortran code are not correlated and are reported as "Unknown."

The first two frames show the calls to routines in the Fortran runtime library (in reverse order). Since the application was linked against the shared version of the library, the image name reported is either libifcore.so (Linux* and macOS*) or libifcorert.dll (Windows*). These are the runtime routines that were called to do the READ and upon detection of the EOF condition, were invoked to report the error. In the case of an unhandled I/O programming error, there will always be a few frames on the call stack down in runtime code like this.

The stack frame of real interest to the Fortran developer is the first frame in image teof.exe, which shows that the error originated in the routine named AGAIN in source module teof.f90 at line 17. Looking in the source code at line 21, you can see the Fortran READ statement that incurred the end-of-file condition.

The next four frames show the trail of calls in the Fortran user code that led to the routine that got the error (TEOF->HERE->WE->GO->AGAIN).

Finally, the bottom four frames are routines which handled the startup and initialization of the program.

If this program had been linked against the static Fortran runtime library, the output would then look like:

```
fortrl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

Notice that the initial two stack frames now show routines in image teof.exe, not libifcore.so (Linux and macOS*) or libifcorert.dll (Windows). The routines are the same two runtime routines as previously reported for the shared library case but since the application was linked against the archive library libifcore.a (Linux and macOS*) or the static Fortran runtime library libifcore.lib (Windows), the object modules containing these routines were linked into the application image (teof.exe). You can use a Generating Listing and Map Files to determine the locations of uncorrelated PCs.
Now suppose the application was compiled without traceback enabled and, once again, linked against the static Fortran library. The diagnostic output would appear as follows:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image           PC                Routine               Line     Source
  tecf.exe       000000013F851FFB  Unknown               Unknown  Unknown
  tecf.exe       000000013F8480A0  Unknown               Unknown  Unknown
  tecf.exe       000000013F841193  Unknown               Unknown  Unknown
  tecf.exe       000000013F84109B  Unknown               Unknown  Unknown
  tecf.exe       000000013F841072  Unknown               Unknown  Unknown
  tecf.exe       000000013F841049  Unknown               Unknown  Unknown
  tecf.exe       000000013F84101E  Unknown               Unknown  Unknown
  tecf.exe       000000013F87ADCE  Unknown               Unknown  Unknown
  kerne132.dll   0000000076CC59BD  Unknown               Unknown  Unknown
  ntdll.dll      0000000076EFA2E1  Unknown               Unknown  Unknown
```

Without the correlation information in the image that option traceback previously supplied, the Fortran run-time system cannot correlate PC's to routine name, line number, and source file. You can still use the Generating Listing and Map Files to at least determine the routine names and what modules they are in.

Remember that compiling with the traceback option increases the size of your application's image because of the extra PC correlation information included in the image. You can see if the extra traceback information is included in an image (checking for the presence of a .trace section) by entering:

```
objdump -h your_app.exe   ! Linux OS
otool -l your_app.exe     ! macOS
link -dump -summary your_app.exe   ! Windows OS
```

Build your application with and without traceback and compare the file size of each image. Check the file size with a simple directory command.

For this simple teof.exe example, the traceback correlation information adds about 512 bytes to the image size. In a real application, this would probably be much larger. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PC's with a map file is acceptable.

If an error occurs when traceback was requested during compilation, the run-time library will produce the correlated call stack display.

If an error occurs when traceback was disabled during compilation, the run-time library will produce the uncorrelated call stack display.

If you do not want to see the call stack information displayed, you can set the Supported Environment Variable FOR_DISABLE_STACK_TRACE to true. You will still get the Fortran run-time error message:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

**Example: Machine Exception Condition, Program ovf**

The following program generates a floating-point overflow exception when compiled with the fpe option value 0:

```
program ovf
  real*4 a
  a=le37
  do i=1,10
    a=hey(a)
  end do
  print *, 'a= ', a
```

Intel® Fortran Compiler 19.0 Developer Guide and Reference
end
real*4 function hey(b)
  real*4 b
  hey = watch(b)
end
real*4 function watch(b)
  real*4 b
  watch = out(b)
end
real*4 function out(b)
  real*4 b
  out = below(b)
end
real*4 function below(b)
  real*4 b
  below = b*10.0e0
end

Assume this program is compiled with the following:

- Option fpe value 0
- Option traceback
- Option -O0 (Linux and macOS*) or /Od (Windows)

On a system based on IA-32 architecture, the traceback output is similar to the following:

forrtl: error (72): floating overflow

<table>
<thead>
<tr>
<th>Image</th>
<th>PC</th>
<th>Routine</th>
<th>Line</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>ovf.exe</td>
<td>001211A3</td>
<td>BELOW</td>
<td>23</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0012116F</td>
<td>OUT</td>
<td>19</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0012113D</td>
<td>WATCH</td>
<td>15</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0012110B</td>
<td>HEY</td>
<td>11</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0012104E</td>
<td><em>MAIN</em>_</td>
<td>5</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0015B31F</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>0015BADD</td>
<td>Unknown</td>
<td>Unknown</td>

<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>ntdll.dll</td>
<td>770E98D5</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

Notice that unlike the previous example of an unhandled I/O programming error, the stack walk can begin right at the point of the exception. There are no run-time routines on the call stack to dig through. The overflow occurs in routine BELOW at PC 001211A3, which is correlated to line 23 of the source file ovf.f90.

When the program is compiled at a higher optimization level of O2, along with option fpe value 0 and the traceback option, the traceback output appears as follows:

forrtl: error (72): floating overflow

<table>
<thead>
<tr>
<th>Image</th>
<th>PC</th>
<th>Routine</th>
<th>Line</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>ovf.exe</td>
<td>00AE1059</td>
<td><em>MAIN</em>_</td>
<td>7</td>
<td>ovf.f90</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>00B1B75F</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>ovf.exe</td>
<td>00B1BADD</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>kernel32.dll</td>
<td>7515338A</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>ntdll.dll</td>
<td>770E9902</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>ntdll.dll</td>
<td>770E98D5</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

With O2, the entire program has been inlined.

The main program, OVF, no longer calls routine HEY. While the output is not quite what one might have expected intuitively, it is still entirely correct. You need to keep in mind the effects of compiler optimization when you interpret the diagnostic information reported for a failure in a release image.
If the same image were executed again, this time with the environment variable called TBK_ENABLE_VERBOSE_STACK_TRACE set to True, you would also see a dump of the exception context record at the time of the error. Here is an excerpt of how that might appear on a system using IA-32 architecture:

```plaintext
forrtl: error (72): floating overflow
Hex Dump Of Exception Record Context Information:

## Allocating Common Blocks

Use the [Q]dyncom option to dynamically allocate common blocks at run time.

This option designates a common block to be dynamic. The space for its data is allocated at run time rather than at compile time. On entry to each routine containing a declaration of the dynamic common block, a check is performed to see whether space for the common block has been allocated. If the dynamic common block is not yet allocated, space is allocated at that time.

**NOTE**

On macOS* systems, to successfully enable dynamic allocation of common blocks, you must specify the link-time option -undefined dynamic_lookup as well as option -dyncom.

The following command-line example specifies the dynamic common option with the names of the common blocks to be allocated dynamically at run time:

```plaintext
ifort -dyncom "blk1,blk2,blk3" test.f ! Linux and macOS*
ifort /Qdyncom"BLK1,BLK2,BLK3" test.f ! Windows
```

where BLK1, BLK2, and BLK3 are the names of the common blocks to be made dynamic.

**Guidelines for Using the [Q]dyncom Option**

The following are some limitations that you should be aware of when using the [Q]dyncom option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
Only named common blocks can be designated as dynamic COMMON.

An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

Why Use a Dynamic Common Block?

A main reason for using dynamic common blocks is to enable you to control the common block allocation by supplying your own allocation routine. To use your own allocation routine, you should link it ahead of the Fortran run-time library.

The C function prototype is:

```c
void _FTN_ALLOC(void **mem, int *size, char *name);
```

where

- `mem` is the location of the base pointer of the common block that must be set by the routine to point to the block of memory allocated.
- `size` is the integer number of bytes of memory that the compiler has determined are necessary to allocate for the common block as it was declared in the program.

You can ignore this value and use whatever value is necessary for your purpose. You must return the size in bytes of the space you allocate. The library routine that calls the default or Fortran run-time function ensures that all other occurrences of this common block fit in the space you allocated. You can return the size in bytes of the space you allocate by modifying `size`.

- `name` is the name of the common block being dynamically allocated.

The equivalent Fortran INTERFACE specification is:

```fortran
interface subroutine my_ftn_alloc (mem, size, name) bind (C, name="_FTN_ALLOC")
use, intrinsic :: ISO_C_BINDING
implicit none
type(C_PTR), intent(OUT) :: mem
integer(C_INT), intent(INOUT) :: size
character, dimension(*), intent(IN) :: name
end subroutine my_ftn_alloc
end interface
```

You can also use the Fortran run-time function `FOR__SET_FTN_ALLOC` to specify your own allocation routine. This method is especially helpful when you are using shared libraries. If you choose this method, it overrides the default routine `_FTN_ALLOC`.

**NOTE**

Routines `FOR__SET_FTN_ALLOC` and `_FTN_ALLOC` will work on applications running natively on Intel® Xeon Phi™ processors.

However, they will not work across the boundary between a host CPU and an Intel® Xeon Phi™ processor. For example, if you use `FOR__SET_FTN_ALLOC` in the host-side code, it will work on COMMON allocations in other host-side code. The same is true if both are running on Intel® Xeon Phi™ processors.

But if you change the allocation routine on the host, it won't be changed on the processor and vice versa.
Allocating Memory to Dynamic Common Blocks

The run-time library routine, `f90_dyncom`, performs memory allocation. The compiler calls this routine at the beginning of each routine in a program that contains a dynamic common block. In turn, this library routine calls `_FTN_ALLOC` to allocate memory. By default, the compiler passes the size in bytes of the common block as declared in each routine to `f90_dyncom`, and then on to `_FTN_ALLOC`. The Fortran run-time library contains a default version of `_FTN_ALLOC`, which simply allocates the requested number of bytes and returns.

If you use the nonstandard extension having the common block of the same name declared with different sizes in different routines, you may get a run-time error depending on the order in which the routines containing the common block declarations are invoked.

You can now create your own routine to dynamically allocate common blocks, which is especially useful when you are sharing libraries. To use your own routine, you must specify the run-time function `FOR__SET_FTN_ALLOC`.

`FOR__SET_FTN_ALLOC`

Generating Listing and Map Files

Compiler-generated assembler output listings and linker-generated map files can help you understand the effects of compiler optimizations and see how your application is laid out in memory. They may also help you interpret the information provided in a stack trace at the time of an error.

How to Generate Assembler Output

When compiling from the command line, specify the `S` option:

```
ifort -S file.f90 ! Linux and macOS
ifort file.f90 /S ! Windows OS
```

On Linux* and macOS* systems, the resulting assembly file name has a .s suffix. On Windows* systems, the resulting assembly file name has an .asm suffix.

On Windows*, you can also use the Microsoft Visual Studio* integrated development environment:

1. Select Project > Properties.
2. Click the Fortran tab.
3. In the Output Files category, change the Assembler Output settings according to your needs. You can choose from a number of options such as No Listing, Assembly-only Listing, and Assembly, Machine Code and Source.

How to Generate a Link Map (.map) File

When compiling from the command line, specify the `-Xlinker` and `-M` options (Linux and macOS*) or the `/map` (Windows) option:

```
ifort file.f90 -Xlinker -M  ! Linux and macOS
ifort file.f90 /map ! Windows
```

On Windows systems, you can also use the Visual Studio integrated development environment:

1. Select Project > Properties.
2. Click the Linker tab.
3. In the Debug category, select Generate Map File.
How to Generate a Source File Listing

You can use the `list` compiler option to create a listing of the source file. The listing can contain the following information: a display of INCLUDE files, a symbol list with a line number cross reference for each routine, and a list of compiler options used for the compilation.

Use the `show` compiler option to control the contents of the listing file.

Additionally, on Windows systems, you can use the Visual Studio integrated development environment to create a source file listing:

1. Select `Project > Properties`.
2. Click the `Fortran` tab.
3. In the `Output Files` category, change the `Source Listing` setting to `Yes`.

See Also

- `show` compiler option
- `list` compiler option

Ability to Create Shared Libraries

You can create a shareable library by using one of the following compiler options.

<table>
<thead>
<tr>
<th>Compiler Option</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-shared</code> (Linux*)</td>
<td><code>mylib.so</code></td>
</tr>
<tr>
<td><code>/libs: dll</code> (Windows*)</td>
<td><code>mylib.dll</code></td>
</tr>
<tr>
<td><code>-dynamiclib</code> (macOS*)</td>
<td><code>mylib.dylib</code></td>
</tr>
</tbody>
</table>

When you use any of these options, do not specify the `c` option.

See Also

- `shared` compiler option
- `dynamiclib` compiler option
- `libs: dll` compiler option

- Storing Routines in Shareable Libraries
- macOS*: Using Shared Libraries on macOS*

Specifying Alternative Tools and Locations

The default tools are summarized in the table below.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Default</th>
<th>Provided with Intel® Fortran Compiler?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assembler for IA-32 architecture-based applications and Intel® 64 architecture-based applications</td>
<td>MASM* (Windows*) operating system assembler, as (Linux* and macOS*)</td>
<td>No</td>
</tr>
<tr>
<td>Linker</td>
<td>Microsoft* linker (Windows)</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>System linker, <code>ld(1)</code> (Linux and macOS*)</td>
<td>No</td>
</tr>
</tbody>
</table>
The Intel® Fortran Compiler lets you specify alternatives to default tools and locations for preprocessing, compilation, assembly, and linking. In addition, you can invoke options specific to the alternate tools on the command line. This functionality is provided by the Qlocation and Qoption options.

See Also
- Qlocation compiler option
- Qoption compiler option

**Temporary Files Created by the Compiler or Linker**

Temporary files created by the compiler or linker reside in the directory used by the operating system to store temporary files.

To store temporary files, the driver first checks for the TMP environment variable. If defined, the directory that TMP points to is used to store temporary files.

If the TMP environment variable is not defined, the driver then checks for the TMPDIR environment variable. If defined, the directory that TMPDIR points to is used to store temporary files.

If the TMPDIR environment variable is not defined, the driver then checks for the TEMP environment variable. If defined, the directory that TEMP points to is used to store temporary files.

For Windows®, if the TEMP environment variable is not defined, the current working directory is used to store temporary files. For Linux® and macOS®, if the TEMP environment variable is not defined, the /tmp directory is used to store temporary files.

Temporary files are usually deleted. Use the [Q]save-temps compiler option to save temporary files created by the compiler in the current working directory. This option only saves intermediate files that are normally created during compilation.

For performance reasons, use a local drive (rather than a network drive) to contain temporary files.

To view the file name and directory where each temporary file is created, use the all keyword for the watch option.

To create object files in your current working directory, use the c option.

Any object files that you specify on the command line are retained.

**Using the Intel® Fortran COM Server (Windows*)**

This topic only applies to Windows* operating systems.

The Component Object Model (COM) supports a model of client server interaction between a user of an object, the client, and the implementor of the object, the server.

This section discusses creating a COM server using Intel Fortran.

The following section, Using the Intel(R) Fortran Module Wizard (COM Client), discusses using COM and Automation objects from an Intel® Fortran application, using the Fortran COM Server.

**Advantages of a COM Server (Windows*)**

This topic only applies to Windows* operating systems.
A COM server consists of the implementation of one or more object classes. An object class is a type that describes the complete public calling interface ("signature") of an object. It describes the functionality that you want to make available to the users of the object. The COM server creates instances of the class, called objects, at the request of clients.

Some of the advantages of implementing your Fortran code as a COM server include:

- A COM server is a reusable component, which allows multiple applications to use the server. The classes specified by the server define a "contract" between the server and its clients. The server can change the specific implementation of the functionality without breaking the contract. That is, without requiring clients to be changed or rebuilt.
- A COM server is programming-language independent. Multiple development tools can be used to access the server's functionality, including Microsoft Visual Basic*, C++, and Fortran.
- A COM server is self-describing. The server provides a type library that describes the classes and interfaces. Many tools can take advantage of this information and relieve the client programmer from needing to understand low-level invocation details, such as calling conventions. This is a great improvement over multi-language programming with DLLs, where the client programmer has to understand the details of data types and calling conventions.
- A COM server is self-registering. The clients do not need to worry about where the server is located on their system, as COM finds this information in the system registry.
- A COM server can be implemented as an in-process server. Like a DLL, it is loaded into the client's process. A COM server can also be implemented as a separate application and can even reside on a separate machine.

Intel Fortran provides the Fortran COM Server application wizard and special editor for modifying the COM Server structure and generating Fortran code necessary to implement a COM server. This allows you to concentrate on the code that is specific to the functionality that your server provides to its clients.

As explained in Understanding COM and Automation Objects, COM supports two types of servers: COM servers and Automation servers. The Fortran COM Server Wizard can only create a COM server or a server that supports dual interfaces. The wizard cannot create an Automation-only interface.

For more information about creating COM servers, see Creating the Fortran COM Server.

Understanding COM Server Concepts (Windows*)

This topic only applies to Windows* operating systems.

The Fortran COM Server application wizard generates an initial Visual Studio project and creates a COM Hierarchy file, which describes the infrastructure of a COM server. You can modify this file with the COM Server Hierarchy Editor to define the implementation of one or more object classes, including its interface(s), and method(s).

When you save the hierarchy file, the Fortran source files are generated. You then need to write code to implement each method.

What Information You Need to Provide

When you create the COM Server project, you will need to describe the COM server classes that you want to implement.

A class implements one or more COM interfaces. In COM terminology, an interface is a semantically related set of functions. The interface as a whole represents a "feature", or set of related functionality, that is implemented by the class. An interface contains methods, otherwise known as member functions. A method is a routine that performs one of the actions that make up the feature. As far as the Fortran COM Server is concerned, methods are Fortran functions that take arguments and return a value like any other Fortran function.

Consider a simple example of a class that you will create using the Fortran COM Server Application Wizard, called AddingMachine. The class contains a single interface that we call IAdd. By convention, all interface names begin with a capital letter "I". You can define three methods in the IAdd interface:

- **Clear**, which takes no arguments and sets the current value of the adding machine to 0.
Add, which takes a single REAL argument, the amount to add to the current value.
GetValue, which returns the current value.

These methods allow you to perform specific, distinct tasks with the IAdd interface from any language that supports a COM client. The Fortran COM Server Editor provides a user interface to enter this information about the class (in this case the AddingMachine class), which is discussed later in Creating the Fortran COM Server.

An interface can also contain properties. Properties are method pairs that set or return information about the state of an object. Properties must currently be implemented using the get_METHOD and put_METHOD and the same DISPID property.

In terms of the data associated with an object, a key concept of object-oriented programming is encapsulation. Encapsulation means that all of the details about how the object is implemented, including the data that it uses and the logic that it uses to perform its work, is hidden from the client. The client's only access to the object is through the interfaces that the object supports.

You need to define the data that the object uses and code the logic of the methods. For the data, the Fortran COM Server Application Wizard uses the model that each instance of the object has an associated instance of a Fortran derived-type. The code generated by the wizard takes care of creating and destroying the instances of the derived-type as objects are created and destroyed.

You define the fields of the derived-type. For example, with our AddingMachine, each AddingMachine object needs to store the current value. The derived-type associated with each AddingMachine object would contain a single field of type REAL. We name it CurrentValue. Note that each instance of the AddingMachine object has its own instance of the derived-type and its own CurrentValue. This means that the server could support multiple clients simultaneously and each client would see its own AddingMachine. That is, each client is unaffected by the existence of other clients. The derived-type associated with each object is discussed in detail in Creating the Fortran COM Server.

To summarize, at a high level, what you need to do to create a COM server:
- Create the COM Server project using the COM Server Application Wizard.
- Define the class(es), interface(s), method(s), and properties using the COM Server Hierarchy Editor to create the Hierarchy file.
- Define the fields in the derived-type that is associated with each instance of a class.
- Write code that initializes the fields in the derived-type (if necessary), and code that releases any resources used by the fields in the derived-type (if necessary).
- Write the code that implements the methods.

What the COM Server Will Provide

The Fortran COM Server Editor generates source files that implement all of the infrastructure, or "plumbing", of the COM server. The generated files take care of such tasks as:
- Defining the GUIDs that uniquely identify your classes and interfaces. For a discussion of GUIDs, see Getting a Pointer to an Objects Interface.
- Registering the server and your classes and interfaces on the system.
- Implementing the class factory that creates instances of your object.
- Creating the Interface Definition Library (IDL) and type library that describes your classes and interfaces. For a discussion of type libraries, see Using the Module Wizard to Generate Code.
- Implementing the IUnknown and IDispatch interfaces for your object. All of the interfaces created by the Fortran COM Server Editor are derived from IUnknown or IDispatch (dual interfaces).
- Creating and destroying instances of the derived-type associated with your object.
- Invoking the Fortran routines that implement your object’s methods.

The majority of these source files are generated fully by the Fortran COM Server Editor and are not modified by you. Other files contain the skeleton or template of your derived-type and methods. You edit these Fortran source files to fill in your implementation. A walk-through of the AddingMachine example will show you how it's done.
Creating the Fortran COM Server (Windows*)

This topic only applies to Windows* operating systems.

This section shows how to create a project, specify the COM server characteristics, generate code for, and implement a sample Fortran COM server project called Adder.

The first step in creating a Fortran COM Server is to create a new project.

Creating a Fortran COM Server Project using the Visual Studio* IDE:

2. In the New Project dialog box, expand the Intel(R) Visual Fortran item and click COM Server.

To create the sample project, choose In-process Server (DLL). Now do the following:

1. Enter Adder as the name of the project.
2. Accept or modify the project folder location.
3. Click OK.

You can use the project AppWizard once per project to create the project files and skeleton template. The Fortran COM Server AppWizard displays default text for the interface name and class derived type name.
Now do the following:

1. Enter class name AddingMachine.
2. Shorten the default interface name to IAdd.
3. Accept the default class derived type name.
4. Click Finish. (If you click Cancel, project creation is terminated.)

The project is created and the COM Server Hierarchy file (adder.hie) is opened in the COM Hierarchy Editor.

**Using the COM Hierarchy Editor to Define your COM Server**

The COM Hierarchy Editor lets you interactively define the attributes (for example, classes, interfaces, and methods) for your COM server. The user interface contains two panes:

- The top pane is a tree control that displays attribute information in a hierarchy.
- The bottom pane is a panel that displays the IDL definition for a selected element in the hierarchy.

You can use "right-click" context menus to insert, delete, and modify items in the hierarchy. Context menus also let you change item properties. For example, you can right-click the IAdd element and select Properties to see the IAdd interface properties. You could then change the Is Dual property value to False; this indicates that the Adder example only supports a COM server interface.

An explanation of the hierarchy follows:

- The root is the COM server itself.
• The immediate children of the COM server are classes. The hierarchy initially contains a single class, *AddingMachine*. You can add additional classes to the COM server.
• The immediate children of a class are interfaces and the class derived-type. In the example, the hierarchy contains the interface *IAdd* and the class derived-type *AddingMachine_InstanceData*. Each class contains one, and only one, class derived-type. You can add additional interfaces to the class.
• The immediate children of an interface are methods (one or more).
• The immediate children of a method are the method arguments (one or more).

**To add a class, interface, method, property, or argument:**

1. Select the parent item, right-click and select the appropriate Add... item.

**To delete an item:**

1. Select the item to be deleted, right-click and select Delete.
2. Click the Delete button.

Continuing with the Adder COM server example, add methods to the *IAdd* interface:

1. Right-click the *IAdd* interface and select Add Method.
2. Enter Clear as the name of the method.
3. Repeat steps 1 and 2, this time entering the name of *Add*.

The Add method requires an argument. To add the Operand argument named *Operand*:

1. Right-click on the *Add* method and select Add Argument.
2. Enter the argument name, *Operand*.

The default data type of an argument is INTEGER(4).

Proceeding with this example, use the Properties Window to change the Fortran Type property value to *REAL(4)*:
To add a third (and in this example, the last) method:

1. Right-click on the IAdd interface and select Add Method.
2. Enter GetValue as the name for the method.

The GetValue method requires an argument, CurrentValue. To add the CurrentValue argument:

1. Right-click on the GetValue method and select Add Argument.
2. Enter CurrentValue as the name of the argument.

For the CurrentValue argument:

1. Set Fortran Type property value to REAL(4).
2. Set Intent property values to [out,retval].

The screen appears as follows:
The server definition is now complete for this example. When you save the file using **File > Save adder.hie**, the Fortran sources will be regenerated.

For detailed information about the property pages (right pane) for the server, class, interface, method, argument, or instance properties, see **Description of Property Pages**.

To change the definition of your server, open **adder.hie** in the Editor.

**Working with the Hierarchy Pane**

As you have seen in the **AddingMachine** example, the hierarchy pane represents the definition of your server; that is, the classes, interfaces, methods, and so on. The hierarchy pane's user interface supports the following functionality:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expand/contract an area</td>
<td>Click the plus sign (+) next to an item to display its children and the - to hide the children.</td>
</tr>
<tr>
<td>Add a new entry</td>
<td>Select the entry that will precede the new entry in the hierarchy, right-click and select one of the <strong>New...</strong> menu options.</td>
</tr>
<tr>
<td>Delete an entry</td>
<td>Select the item to be deleted, right-click and select <strong>Delete</strong>. All of an item's children are deleted when the item is deleted.</td>
</tr>
</tbody>
</table>
Rename a member
Select the item to be renamed, right-click and select Rename.

Change the order of items
The hierarchy pane supports drag-and-drop to allow you to change the order of items.
The order of some of the entries in the hierarchy is very important. In particular:

- The order of the methods in an interface defines the order of the methods in the class’
  `VTBL`. Changing the order of the methods will break an existing client.
- The order of the arguments in a method define the order of the arguments in the
  method’s interface. Changing the order of the arguments will break an existing client.

Description of Property Pages
Property pages appear in the Properties Window. Property pages are available for the following:

- Server Properties
- Class Properties
- Interface Properties
- Method Properties
- Argument Properties
- Instance Type Properties

Server Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type Library GUID</td>
<td>The unique identifier of the server’s type library. There is usually no reason to change this from the default value generated by the Fortran COM Server Wizard.</td>
</tr>
<tr>
<td>Type Library Version</td>
<td>The current version of the Type Library.</td>
</tr>
<tr>
<td>HelpString</td>
<td>A string used to set the library’s help string attribute in the IDL file.</td>
</tr>
</tbody>
</table>

Class Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProgID</td>
<td>The version independent program ID (or text alias) for the class. The ProgID can be used in calls such as COMCreateObjectByProgID.</td>
</tr>
<tr>
<td>Version</td>
<td>The current version of the class. It is appended to the ProgID to define the version-specific ProgID.</td>
</tr>
<tr>
<td>Short name</td>
<td>A short name for the class. It is used in some of the generated file names.</td>
</tr>
<tr>
<td>Description</td>
<td>A string used as the default value of the class' ProgID keys in the registry. This string is often used by tools, such as the OLE-COM Object Viewer, that display a list of the objects that are registered on the system.</td>
</tr>
<tr>
<td>Help String</td>
<td>A string used to set the class' help string attribute in the IDL file.</td>
</tr>
<tr>
<td>Threading model</td>
<td>The threading model of the class. The two choices are Apartment and Single. See Threading Models in Advanced COM Server Topics for information about the implications of this choice.</td>
</tr>
<tr>
<td>CLSID</td>
<td>The unique identifier of the class. There is usually no reason to change this from the default value generated by the Wizard.</td>
</tr>
</tbody>
</table>

Interface Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Dual</td>
<td>If true, then the dual interface attribute is set in the IDL file. A dual interface supports both COM and Automation clients.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Is OleAutomation</td>
<td>If true, then the interface uses only Automation-compatible data types as described in Fortran COM Server Interface Design Considerations.</td>
</tr>
<tr>
<td>Is Default</td>
<td>If true, then the default interface attribute is set for this interface in the IDL file. The default attribute represents the default programmability interface of the object, and is intended for use by macro languages.</td>
</tr>
<tr>
<td>Help String</td>
<td>A string used to set the interface's help string attribute in the IDL file.</td>
</tr>
<tr>
<td>IID</td>
<td>The unique identifier of the interface. There is usually no reason to change this from the default value generated by the Wizard.</td>
</tr>
</tbody>
</table>

**Method Properties:**

- **DISPID**: The identifier of the method used by Automation clients.
- **Help string**: A string used to set the method’s help string attribute in the IDL file.
- **Property Method**: If checked, then the method is the get_ or put_ method of a property.

**Argument Properties:**

- **Fortran data type**: The Fortran data type of the argument. Select one of the data types from the list, or type in the data type. See Fortran COM Server Interface Design Considerations for a discussion of the implications of your choice.
- **IDL type**: The IDL data type. If you select one of the Fortran data types from the predefined list, then this field defaults to the corresponding IDL data type. Select one of the data types from the list, or type in the data type. See Fortran COM Server Interface Design Considerations for a discussion of the implications of your choice.
- **Intent**: The INTENT of the argument, one of the following list:
  - [in] - the argument value is read but not modified by the method
  - [out] - the argument value is not read, but is modified by the method
  - [in, out] - the argument value is both read and modified by the method
  - [out, retval] - the argument represents the return value of the method
- **By Reference**: Indicates that an argument is passed by reference rather than by value. Only valid with Intent In. Intent Out and Intent InOut are automatically passed by reference.
- **Is Optional**: If true, then the argument is optional. Optional arguments are passed using the Variant data type.
- **Dimensions**: Number of array dimensions (0 if the argument is scalar).

**Instance Type Properties:**

- **Module name**: The name used for the module defined in the UclassnameTY.f90 file.
- **Constructor name**: The name used for the class constructor defined in the UclassnameTY.f90 file.
- **Destructor name**: The name used for the class destructor defined in the UclassnameTY.f90 file.

**Modifying the Generated Code**
When you save the hierarchy file, Fortran sources are generated (or regenerated). Source files are stored as follows:

- Source files that you will need to modify are placed in the **Source Files** folder.
- Files that are complete and need no modification are placed in the **Do Not Edit** folder.

Modify the following files in the Source Files folder:

- **UAddingMachineTY.f90**, which contains a module that defines your class derived-type.
- **UIAdd.f90**, which contains the implementation of the **IAdd** methods.

Initially, the file **UAddingMachineTY.f90** contains the following code:

The file contains a module named **AddingMachine_USE** (in the form **classname_USE**). There are three places in this module where you may need to add code specific to your class:

- The first entry in the module, marked by `<BnDEF>` and `<EnDEF>`, is your class derived-type. Initially it contains an "integer dummy" field to allow the module to be compiled without error. If your class has per-object data, remove the "integer dummy" field line and add your data to the derived-type. For the *AddingMachine* class, we add the following where the object stores the current value:

```fortran
real (4) CurrentValue
```
The module also contains two module procedures, AddingMachine_CONSTRUCTOR and AddingMachine_DESTRUCTOR (referred to as classname_CONSTRUCTOR and classname_DESTRUCTOR below). The former delineated with <BnCON> and <EnCON>; the latter is delineated with <BnDES> and <EnDES>.

The classname_CONSTRUCTOR procedure is called immediately after an instance of the class derived-type is created because of the creation of a new object. This function is where you initialize the fields of the class derived-type, if necessary. The new derived-type is passed as an argument to the function. For the AddingMachine class, initialize the current value to 0 by adding the following statement:

```
ObjectData%CurrentValue = 0
```

The classname_DESTRUCTOR procedure is called immediately before an instance of the class derived-type is destroyed because an object is being destroyed. This function is where you release any resources used by the fields of the class derived-type, if necessary. The derived-type is passed as an argument to the function. For the AddingMachine class, there is nothing that needs to be added.

Now modify the other source file called UIAdd.f90. The original file UIAdd.f90 contains the following code:

```
function IAdd_GetValue (ObjectData, &
                        CurrentValue) result (hresult)
    use AddingMachine_Types
    implicit none
    type(ObjectData) ObjectData
    REAL(4), intent(out) :: CurrentValue
    integer(long) hresult
    !<B2> DO NOT REMOVE THIS LINE
    !<B2> DO NOT REMOVE THIS LINE
    !<B2> DO NOT REMOVE THIS LINE
end function
```

A file by the name Interfacename.f90 (for example UIAdd.f90) is created for each interface defined by the class. The file contains the methods of the class. Each method is named Interfacename_methodname, for example: IAdd_Clear. Each method is a function that is passed to the class derived-type as the first
argument. This gives the function access to the per-object data. Each function returns a 32-bit COM status code called an HRESULT. S_OK is a parameter that defines a success status. For additional information on COM status codes, see Fortran COM Server Interface Design Considerations.

Replace the ! TODO: Add implementation line in each method with the code for the method. For the IAdd interface, the implementation of its three methods is as follows:

For IAdd_Clear: ObjectData%CurrentValue = 0
For IAdd_Add: ObjectData%CurrentValue = ObjectData%CurrentValue + Operand
For IAdd_GetValue: CurrentValue = ObjectData%CurrentValue

Save the file and, from the Build menu, click Build Solution to build the server. The COM server is now complete.

COM Server Projects and the MIDL Compiler

During the creation of a COM Server project -- either In-process Server (DLL) or Out-of-process Server (EXE), as described in this section -- the application wizard determines whether Visual C++* is installed. If it is installed, the MIDL compiler uses the Visual C++ C preprocessor. This is both the default and recommended setting. If Visual C++ is not installed, the application wizard specifies that the MIDL compiler use the Fortran preprocessor for preprocessing MIDL source files. It does this by setting the Additional Options property of the MIDL compiler to include the following: /cpp_cmdifort /cpp_opt"/nologo /fpp /P /E /Option,fpp,/no-fort-cont".

If, later, you install Visual C++ and want to specify that MIDL use the Visual C++ C preprocessor, remove these options from the MIDL compiler Additional Options property.
Fortran COM Server Interface Design Considerations (Windows*)

This topic only applies to Windows* operating systems.

This section provides information that should be considered when designing a Fortran COM server. It contains the following topics:

- Method and Property Data Types
- COM Status Codes: HRESULT
- Visual Basic*, Visual C++*, and Intel® C++ Client Notes

Method and Property Data Types

COM places some restrictions on the data types used in COM methods and properties. The reason for the restrictions is that COM can pass arguments between threads, processes and machines. This raises issues that are not present in older technologies, such as DLLs, that always run in the same address space as the caller.

COM defines set of data types called Automation-compatible data types. These are the only data types that can be used in Automation and Dual interfaces. There are two advantages to restricting your COM interface to these data types:

- Your server will be usable from clients written in the largest set of languages, including Intel® Fortran, Visual Basic, and Visual C++.
- COM will automatically handle the passing of arguments between threads, processes and machines. This is called Type Library Marshalling. For more information, see Marshalling, Proxies and Stubs in Advanced COM Server Topics.

To restrict your server to Automation-compatible data types:

1. Select Use only Automation data types on the Interface property page. When defining a dual interface, this is automatically set.
2. Use only the following combinations of Fortran data type and Interface data type on the Argument property page.

   Note that Intel Fortran does not support the Currency, Decimal, or User Defined Type, Automation-compatible data types.

</tr>
</tbody>
</table>
Fortran Date Type | Interface Data Type
--- | ---
CHARACTER(1) | unsigned char
CHARACTER(*) | BSTR
BYTE | unsigned char
TYPE(VARIANT) | VARIANT (containing one of the above types or SafeArray)

If you decide not to restrict your interface to Automation-compatible data types, the next approach is to restrict your interface to data types that can be described in the Interface Description Language (IDL). The Fortran COM Server Application Wizard automatically generates the IDL file from the description of your server. The MIDL compiler compiles the IDL file into a type library. MIDL can also automatically generate the code needed handle the passing of arguments between threads, processes and machines. Note, however, that a C compiler is required to use this option. For more information, see Discussion of Wizard Code Generation in Advanced COM Server Topics.

If you decide not to restrict your interface to IDL data types, your only remaining options are:
- Implement Custom Marshalling - For more information, see Marshalling, Proxies and Stubs in Advanced COM Server Topics.
- Decide that you will never use your server across apartment, thread, or process boundaries. The server will not be usable in this manner because there is no way to pass the arguments across these boundaries.

**COM Status Codes: HRESULT**
Each function returns a 32-bit COM status code called an HRESULT. An HRESULT is divided into fields:
- The top bit (31) indicates whether the function succeeded or failed. The bit is set if the function failed. In Fortran, you can compare the HRESULT to < 0 as a test to see if a function failed.
- Bits 16 to 27 contain a facility code to indicate the facility that issued the HRESULT. Microsoft pre-defines a number of facility codes for its own use. If you create your own status codes, use FACILITY_ITF. All other facility codes are reserved by Microsoft.
- The first 16 bits, or low word, contain the error code specific to the error that occurred.

A typical HRESULT error value could be a value such as 0x80070057. The first hex digit, 8, indicates that bit 31 is set and that this is an error value. Bits 16 to 27 contain the value 7. This indicates the facility FACILITY_WIN32. The low word contains the value 0057. This is the specific code that identifies the error as E_INVALIDARG.

To view the text description that corresponds to a system HRESULT value, use the Error Lookup tool in the Intel® Fortran program folder. For example, entering the value 0x80070057 retrieves the text message "The parameter is incorrect ", as shown below:

You can also search for HRESULT values in the WINERROR.H file in the \VC\INCLUDE directory.
Visual Basic*, Visual C++*, and Intel® C++ Client Notes

To use an object from Visual Basic, you must add a "reference" to the object to the Visual Basic project. Use the References item in the Project menu to display a list of the registered objects. Select the object in the list to inform Visual Basic that you will be using the object.

Here are some points to be aware of when writing a server that can be used with Visual Basic clients:

• Use only the Automation-compatible data types (see Method and Property Data Types).
• Arguments to a method can be passed ByVal, ByRef, or they can be the function return value.
• An argument to be passed ByVal, must be defined with Intent set to In.
• An argument to be passed ByRef, must be defined with Intent set to InOut.
• A function return value must be defined with Intent set to Out. It must have the Return Value field checked. The argument must be the final argument of the method.
• An array is always passed as a SafeArray ByRef. Therefore it must be defined with Intent set to InOut.
• To use an argument of the Visual Basic Boolean data type, set the Fortran data type to LOGICAL(2) and set the Interface data type to VARIANT_BOOL.

To use an object from C++, use the #import directive. The syntax of the #import directive is:

```
#import "filename" [attributes]
#import <filename> [attributes]
```

The filename is the name of the file containing the type library information. The directive makes the information in the type library available to your source file as a set of C++ classes.

Advanced COM Server Topics (Windows*)

This topic only applies to Windows* operating systems.

Advanced topics about Fortran COM Servers described in this section include:

• Choosing Between DLL or EXE COM Servers
• DLL Server Surrogates
• Discussion of Wizard Code Generation
• Threading Models
• Marshalling, Proxies and Stubs
• A Map of the Generated "Do Not Edit" Code

Choosing Between DLL or EXE COM Servers

The basic tradeoff in choosing between a DLL (in-process) COM server and an EXE (out-of-process) COM server is one of performance vs. robustness:

• A DLL server provides the advantage of performance over an EXE server. Since the DLL server is loaded into the client's address space, there is less overhead involved in method calls. If the client code and the server object live in the same COM apartment, method calls are as efficient as DLL routine calls.
• An EXE server provides the advantage of robustness over a DLL server. Since the server object lives in a separate address space, the object cannot be affected by client memory handling bugs, and vice-versa. If the server crashes, the client doesn't necessarily crash – as long as the client checks the results of all method calls and takes steps to recover from a "dead" object.

In addition to the tradeoff between performance and robustness, the following factors should also be considered:

• With an EXE server, the object can run in a separate security context from the client. With a DLL server, the code of the object's methods executes using the client's access token.
• An EXE server can be run on a remote machine using COM distributed object support.

You can load a DLL server into a surrogate to gain the benefits of an EXE server. This is explained in the next section.
**DLL Server Surrogates**

An in-process DLL server can be run in a separate process with the help of a *surrogate*. A surrogate runs as a separate process, loads the DLL server, and provides all of the mechanism that allows the DLL server to act as a local server. Windows provides a standard surrogate named DLLHOST.EXE. The primary advantage of using a surrogate is fault isolation. That is, if the server crashes it does not crash the client, and vice versa. The disadvantage is performance. There is significant performance overhead in executing methods in a separate application, as opposed to in a DLL.

A DLL server is associated with a surrogate via entries in the system registry. This is done by associating the DLL server with an AppID. An AppID is a GUID. When using the standard surrogate, you can use the CLSID of a class in the DLL as the AppID, or a newly generated GUID. To generate a new GUID, use GUIDGEN.EXE in the Developer Studio Tools subdirectory:

1. Under the HKEY_CLASSES_ROOT\CLSID\{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx} key of the class, add an AppID entry with the value of the CLSID. Using the AddingMachine class as an example, the registry key would be HKEY_CLASSES_ROOT\CLSID\{904245FC-DD6D-11D3-9835-0000F875E193} and the AppID value would be {904245FC-DD6D-11D3-9835-0000F875E193}.
2. Under the HKEY_CLASSES_ROOT\AppID key, add a key using the AppID. Using the AddingMachine class as an example, the registry key would be HKEY_CLASSES_ROOT\AppID\{904245FC-DD6D-11D3-9835-0000F875E193}. Use the class name for the default value of the key, for example, "AddingMachine Class". Add a "DllSurrogate" entry with an empty string for the value.

The client must request CLSCTX_LOCAL_SERVER rather than CLSCTX_INPROC_SERVER to use the surrogate rather than loading the DLL server in-process. Using a surrogate requires that the DLL server have a proxy/stub registered since the method invocations are between different processes. For information on proxies/stubs, see Marshalling, Proxies and Stubs.

It is also possible to write a custom surrogate. See the Windows Platform SDK documentation for information.

**Discussion of Wizard Code Generation**

The COM Server Application Wizard generates the code for your project from the files in the subdirectory of your project named templates. The project-name.hie file contains the definition of your COM server in an undocumented text language. You should not manually edit the project-name.hie file; the Wizard does this for you.

Most of the other files in the templates directory are templates of the source files generated for your project. These templates contain source code that is copied "as-is" to the generated sources, and embedded directives that guide the Wizard in generating the code specific to the COM server that you define. The directives use the information in the project-name.hie file. The directives are undocumented and subject to change.

When you create a new Fortran COM Server project, the AppWizard creates the templates directory and copies the templates from the Fortran COM Server templates directory, ...\Intel Fortran\Templates \COMServer.

The files in the templates directory may change with each release, but the templates in your templates directory are never automatically updated. For example, if you create a COM server using Intel® Fortran Version 13.0 and the next release of Intel® Fortran (such as Version 13.1) contains updated templates, the templates for your COM server are not automatically updated to the new 13.1 templates. If you modify the definition of your server, your project continues to use the templates that it was created with. This has the advantage of not introducing different code into a project that you have developed and tested.

However, there are two cases where you may want to modify the templates that are used by your project:

- A new release of Intel® Fortran may contain additional features that can be used in your COM server project. Some of the new features may depend upon the new templates. These features will not be available to a pre-existing project unless you update the templates in the templates directory. You do
this by copying all of the files in the Fortran COM Server templates directory \Intel Fortran \Templates\COMServer into the templates directory, replacing all files with the same name. Your project will then use the new templates the next time that the definition of your server is modified and the project sources are regenerated.

• When you want to modify the code generated by the Wizard. You may edit a template in your templates directory. Editing code that is copied "as-is" is straightforward. Attempting to modify the embedded directives is unsupported and could cause the Wizard to fail when using the modified template. The embedded directives begin with an @ (at-sign) character. The next character determines the type of directive. The end of many directives is also delimited by an @ character followed by the matching end character for the type of directive. For example, @[ and @] are the delimiters for one type of directive.

The advantage of modifying a template is that you can customize the code generated by the Wizard. The disadvantages of modifying a template are:

• You must be very careful not to modify a template in a manner that causes the Wizard to generate bad code or fail.
• You will not be able to update the project templates with the templates from a new release of Intel Fortran without having to re-apply your modifications to the new templates.

**Threading Models**

The Wizard supports two COM threading models for the classes that you create in a DLL COM server, Apartment and Single. The Wizard uses the Apartment threading model (also known as the Single Threaded Apartment model "STA") by default. The basic rules of the Apartment threading model are:

• If two objects, A and B, are created in the same STA thread, and A is processing a method call, no other client can call either A or B until A completes.

• If B is created in a different thread from A, B can accept a method call while A is still processing and vice versa.

This means that if the class shares any global data among its objects, the global data must be protected from simultaneous access using thread synchronization primitives. This is because two instances of the class could be running in different threads. However the per-object instance data, that is, the fields in the class derived-type, are protected from simultaneous access by COM mechanisms. This is true except in the case where an object calls out to another object that triggers a reentrant invocation of the first object.

A class using the Single threading model need not worry about simultaneous access to class global data, as well as per-object data. All objects of the class are created in a single thread and therefore only a single object of the class can be executing at any time.

An EXE COM server generated by the wizard is single threaded. All method invocations are serialized by the server's message queue. Therefore, with an EXE server, you need not worry about simultaneous access to class global data, as well as per-object data.

Explaining the COM threading models in detail is beyond the scope of this documentation. See the Windows Platform SDK documentation for additional information.

**Marshalling, Proxies and Stubs**

COM supports the use of objects in separate processes (as when using an EXE server or a DLL surrogate), and the threading models described above, by the use of marshalling, proxies and stubs. This section presents an overview of marshalling, proxies and stubs.

Marshalling is the process of reading the parameters for a method call and preparing them for transmission to another execution context (for example, thread, process, or machine). Marshalling is done by a proxy. From the client's perspective, a proxy has the same interface as the object itself. The proxy's job is to make the object look like an object in the same execution context as the client.
Proxies allow client code to be unconcerned about where the object actually lives. A proxy marshalls method parameters and transmits them to a stub associated with the object in the server. The stub unmarshalls the parameters and invokes the method in the server. From the server’s perspective, this is no different than when it is called from a client in the same execution context. A server that is not an in-process DLL server always requires a proxy/stub pair. An in-process DLL server requires a proxy/stub pair when the client and object are in different apartments.

There are three ways to assign a proxy/stub pair to a server:

- **Type Library Marshalling:** If you use only Automation-compatible data types in your methods and properties, COM can automatically use the "Universal Marshaller" as the proxy/stub for the server. The Universal Marshaller uses the description of the server in the type library to decide how to marshall the parameters. This is known as type library marshalling. Using type library marshalling requires no effort on your part, other than restricting your server to Automation-compatible data types.

- **MIDL-based Marshalling:** Your project uses the MIDL compiler to compile the IDL description of the server into a type library. At the same time, the MIDL compiler also generates the C source code necessary to build a proxy/stub DLL for the server. You must have a C compiler to build a proxy/stub DLL from the MIDL generated code. The proxy/stub DLL is itself an in-process DLL server and needs to be registered with the system. You would need to use MIDL-based marshalling if your server uses non-Automation-compatible data types, and is used by a client in a different execution context.

- **Custom Marshalling:** Your server can implement its own marshalling by implementing the IMarshall interface. This approach typically involves a lot of work and is done for performance reasons.

---

**A Map of the Generated "Do Not Edit" Code**

This section presents an overview of which parts of the COM server functionality are implemented as "Do Not Edit" source files generated by the application wizard:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server.idl</td>
<td>Contains the IDL description of the server. It is compiled by the MIDL compiler to produce the server’s type library.</td>
</tr>
<tr>
<td>servernameglobal.f90</td>
<td>Contains the global data and functions for the server.</td>
</tr>
<tr>
<td>dllmain.f90</td>
<td>(DLL server) Contains the exported functions that are required of all COM Server DLLs. This includes DllMain, DLLRegisterServer, DLLUnloadServer, DllCanUnloadNow.</td>
</tr>
<tr>
<td>exemain.f90</td>
<td>(EXE server) Contains the main entry point of an EXE server. It also processes the command-line argument.</td>
</tr>
<tr>
<td>serverhelper.f90</td>
<td>Contains helper functions for the server.</td>
</tr>
<tr>
<td>clsfactty.f90</td>
<td>Contains definitions of the IClassFactory interface that is used to create instances of the classes defined by the server.</td>
</tr>
<tr>
<td>clsfact.f90</td>
<td>Contains methods of the IClassFactory interface that is used to create instances of the classes defined by the server.</td>
</tr>
</tbody>
</table>
### File Name

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>classnameTY.f90</code></td>
<td>Defines a module that contains definitions of parameters and types used in the implementation of the class. It also contains the implementation of the IUnknown methods of the class. A separate instance of this file is generated for each class defined in the server.</td>
</tr>
<tr>
<td><code>interfacename.f90</code></td>
<td>Defines a module that contains the Fortran interfaces of the methods in the interface. It also contains the implementation of the Fortran &quot;wrappers&quot; that are called directly from the class' Vtbl and call the methods implemented by the user. A separate instance of this file is generated for each interface defined in the class.</td>
</tr>
</tbody>
</table>

### Deploying the COM Server on Another System (Windows*)

This topic only applies to Windows* operating systems.

When you have finished developing the COM server, you may want to deploy it on another system. Besides the server itself, you need to install the Fortran run-time DLLs and register the server:

1. Install (or copy) the COM server to an appropriate directory.
2. Register the server:
   - To register a DLL server, use the REGSVR32.EXE system tool, a command-line tool. To register the DLL server, specify the path to the DLL and its file name (`dll_path`) by typing the following command:

```
REGSVR32 dll_path
```

   - The file REGSVR32.EXE is in your system directory, such as the `\Winnt\System32` on Windows NT* or Windows 2000 systems. If this directory is not in your PATH, include its path before the REGSVR32 command.
   - To register a an EXE server, run the server with the `/REGSERVER` command-line option. For example:

```
exe_path /REGSERVER
```

If you are using MIDL-based Marshalling or Custom Marshalling, then the marshalling DLL also needs to be installed and registered. For information on marshalling, see Advanced COM Server Topics.

### Using the Intel® Fortran Module Wizard (COM Client) (Windows*)

This topic only applies to Windows* operating systems.

Intel® Fortran provides a wizard to simplify the use of Component Object Model (COM) and Automation (formerly called OLE Automation) objects. The Intel® Fortran Module Wizard generates Standard Fortran modules that simplify calling COM and Automation services from Fortran programs. This Fortran code lets you invoke methods of an Automation object and member functions of a Component Object Model (COM) object.

The following sections describe the use of COM and Automation objects as clients with Intel Fortran.

#### Understanding COM and Automation Objects (Windows*)

This topic only applies to Windows* operating systems.

This section provides a brief overview of:

- COM Objects
- Automation Objects
- Object Servers

**COM Objects**
The Component Object Model (COM) provides mechanisms for creating reusable software components. COM is an object-based programming model designed to promote software interoperability; that is, to allow two or more applications or components to easily cooperate with one another, even if they were written by different vendors at different times, in different programming languages, or if they are running on different machines running different operating systems.

With COM, components interact with each other and with the system through collections of function calls, also known as methods or member functions or requests, called interfaces. An interface is a semantically related set of member functions. The interface as a whole represents a feature of an object. The member functions of an interface represent the operations that make up the feature. In general, an object can support multiple interfaces and you can use COMQueryInterface (W*32 W*64) to get a pointer to any of them.

The Intel Fortran COM routines provide a Fortran interface to basic COM functions.

**Automation Objects**

The capabilities of an Automation object resemble those of a COM object. An Automation object is in fact a COM object that implements the interface IDispatch. An Automation object exposes:

- **Methods**, which are functions that perform an action on an object. These are very similar to the member functions of COM objects.
- **Properties**, which hold information about the state of an object. A property can be represented by a pair of methods; one for getting the property's current value, and one for setting the property's value.

The Intel® Visual Fortran AUTO routines provide a Fortran interface to invoking an automation object's methods and setting and getting its properties.

**Object Servers**

COM and Automation objects are made available to users by COM and Automation servers. A COM or Automation server can be implemented either as:

- A DLL that is loaded into your process
- A separate executable program. The separate executable program can reside on the same system as your application or on a different system.

**The Role of the Module Wizard (Windows*)**

This topic only applies to Windows* operating systems.

**To use COM and Automation objects from a Fortran program:**

1. Find or install the object server on the system. COM and Automation objects can be registered:
   - By other programs you install.
   - By creating the object server yourself, for example, by using Visual C++*, or Visual Basic*.
   
   For example, the Microsoft visual development environment registers certain objects during installation (see the documentation on the Common Environment Object Model).

   Creating an object server involves deciding what type of object and what type of interfaces or methods should be available. The object's server must be designed, coded, and tested like any other application. For information about object server creation, see Creating the Fortran COM Server.

2. Determine:
   - Whether the object has a COM interface, Automation interface, or both.
   - Where the object's type information is located.

   You should be able to obtain this information from the object's documentation. You can use the OLE/COM Object Viewer tool from the development environment Tools menu to determine the characteristics of an object on your system.

3. Use the Intel® Fortran Module Wizard to generate code.

   The module wizard is an application that allows you to select a COM or Automation object and set generated code options. The information collected by the module wizard is used in the generated code. To learn about using the Intel® Fortran module wizard, see Using the Module Wizard to Generate Code.

4. Write a Fortran program to invoke the code generated by the Intel® Fortran module wizard.
To understand more about calling the interfaces and jacket routines created by the module wizard, see "Calling the Routines Generated by the Module Wizard."

**Using the Module Wizard to Generate Code (Windows*)**

This topic only applies to Windows* operating systems.

To run the Intel® Fortran Module Wizard, select **Tools > Intel Compiler > Intel® Fortran Module Wizard**.

The module wizard displays a series of dialog boxes allowing you to select the COM or Automation object and provide additional information.

COM and automation objects are self-describing, using type information. An object’s type information contains programming language independent descriptions of the object’s interfaces. Type information can be obtained from the object’s type library.

A type library is a collection of type information for any number of object classes, interfaces, and so on. You can store a type library in a file of its own (usually with an extension of .TLB) or it can be part of another file. For example, the type library that describes a DLL can be stored in the DLL itself.

After you start the module wizard, the COM tab of the dialog box displays the list of type libraries that are registered on your system. (There is also a .NET tab, which is explained in Using .NET Components.)

The list has three columns:

- The component name
- The component version number
- The path to the type library
You may select a single component from the list, or click the **Browse for Type Library...** button to find a type library on your system.

The dialog box also provides the Generate code that uses **Automation interfaces** option. If the option is not selected, the Wizard will generate code to use the COM interfaces of the component.

The documentation of the component should tell you whether the component implements COM interfaces, Automation interfaces, or dual interfaces. A dual interface supports both COM and Automation interfaces. For a component that supports dual interfaces, you can check the Generate code that uses Automation interfaces option, or leave it unchecked. The COM interfaces tend to be more efficient (better run-time performance).

ActiveX controls implement an Automation interface. When using an ActiveX control, check the **Generate code** that uses Automation interfaces option.

After you select a component from the list or by browsing using the **Browse for Type Library...** button, click **Next>**.

This dialog box lists the members that are defined in the type library. Click the **Select All** button to select all of the members of the type library, or select individual members from the list. The Wizard uses the selected members.

This dialog box also contains two options regarding the code to be generated by the Wizard:

- **Select Generate DLLEXPORT statements** if you plan to place the generated module in a DLL for use by other projects. The Wizard will generate the DLLEXPORT statements to make the routines in the module visible outside of the DLL.
- **Check for exception return status (Automation only)** is active if you checked the Generate code that uses Automation interfaces option in the first dialog box. Select this option if you want the Wizard to generate code to check the return status of each Automation method or property invocation, and to display a dialog box when an error is generated.
Change the module name if desired and select **Finish**.

**Using .NET Components**

The .NET tab is available on the first dialog box. The module wizard cannot directly read the type information of a .NET component. However, the .NET Framework Tools (provided with Visual Studio*) contain the Type Library Exporter (**Tlbexp.exe**). The Type Library Exporter generates a COM type library that describes the types defined in a .NET component (also known as a common language runtime assembly).

Select the .NET tab to view the assemblies that are registered in your system’s Global Assembly Cache (GAC). The list contains the same three columns as the COM tab, as well as a Browse for Assembly button. Select a .NET component from the list, or use the **Browse for Assembly** button to select a .NET component on your system.

Press **Next >** to run the Type Library Exporter tool to create a type library from the .NET component. If the tool returns an error message, the message is displayed in a dialog box and the Wizard returns to its first dialog box. In this case, no Fortran module is generated. If the tool succeeds, the second Wizard dialog box is displayed with the members found in the type library. There are restrictions on the .NET components that can be used with the Type Library Exporter tool. For example, a common error message returned by Type Library Exporter tool is:

You cannot use Tlbexp.exe to produce a type library from an assembly that was imported using the Type Library Importer (**Tlbimp.exe**). Instead, you should refer to the original type library that was imported with Tlbimp.exe.

In this case, the .NET assembly was created from the information in a type library, and you must obtain the original type library from the assembly provider in order to use it with the Module Wizard.

See the .NET Framework Tools documentation for details.

The Wizard runs the Type Library Exporter tool with the **/nologo/silent** options. You can also run the tool to create a type library before running the Module Wizard if you prefer.

**Intel® Fortran Module Wizard Command Line Interface**

The Intel® Fortran Module Wizard also has a command-line interface. The MODWIZ command has the following form:

```
MODWIZ [options] typeinfo-name
```

For a list of MODWIZ command options and an explanation of typeinfo-name, type the following command in a Fortran command prompt (available from the Intel® Fortran Compiler program folder):

```
MODWIZ /?
```

**See Also**

Using .NET Components

**Calling the Routines Generated by the Module Wizard (Windows*)**

This topic only applies to Windows* operating systems.

Although Standard Fortran does not support objects, it does provide Standard Fortran modules. A module is a set of declarations that are grouped together under a global name, and are made available to other program units by using the **USE** statement.

The Intel® Fortran Module Wizard generates a source file containing one or more modules. The types of information placed in the modules include:

- **Derived-type definitions** are Fortran equivalents of data structures that are found in the type information.
- **Constant definitions** are Fortran PARAMETER declarations that include identifiers and enumerations found in the type information.
Procedure interface definitions are Fortran interface blocks that describe the procedures found in the type information.

Procedure definitions are Fortran functions and subroutines that are jacket routines for the procedures found in the type information.

The jacket routines make the external procedures easier to call from Fortran by handling data conversion and low-level invocation details.

The use of modules allows the Intel® Fortran Module Wizard to encapsulate the data structures and procedures exposed by an object or DLL in a single place. You can then share these definitions in multiple Fortran programs.

The appropriate USE statement needs to be added in your program, as well as function invocations or subroutine calls.

The routines generated by the Intel® Fortran Module Wizard are designed to be called from Fortran. These routines in turn call the appropriate system routines (not designed to be called from Fortran), thereby simplifying the coding needed to use COM and Automation objects.

Intel® Visual Fortran provides a set of run-time routines that present to the Fortran programmer a higher level abstraction of the COM and Automation functionality. The Fortran interfaces that the wizard generates hide most of the differences between Automation objects and COM objects.

Depending on the options specified, the following routines can be present in the generated code:

**IFCOM Routines (COMxxxxx)**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMAddObjectReference</td>
<td>Adds a reference to an object's interface.</td>

</tbody>
</table>

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard. This code is generated from the COM type information for the Save method of the IGeneric Document interface.

```fortran
INTERFACE
  ! Saves the document to disk.
  INTEGER*4 FUNCTION IGenericDocument_Save($OBJECT, vFilename, &
                  vBoolPrompt, pSaved)
    USE IFWINTY
    INTEGER (INT_PTR_KIND()), INTENT(IN) :: $OBJECT ! Object Pointer
    !DIR$ ATTRIBUTES VALUE :: $OBJECT ! Object Pointer
    TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename ! (Optional Arg)
    !DIR$ ATTRIBUTES REFERENCE :: vFilename
    TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt ! (Optional Arg)
    !DIR$ ATTRIBUTES REFERENCE :: vBoolPrompt
    INTEGER, INTENT(OUT) :: pSaved ! DsSaveStatus
    !DIR$ ATTRIBUTES REFERENCE :: pSaved
    !DIR$ ATTRIBUTES STDCALL :: IGenericDocument_Save
```

---

2521
END FUNCTION IGenericDocument_Save
END INTERFACE
POINTER(IGenericDocument_Save_PTR, IGenericDocument_Save) ! routine pointer

Notes for this example:

1. If the type information provides a comment that describes the member function, then the comment is placed before the beginning of the procedure.

2. The first argument to the procedure is always $OBJECT. It is a pointer to the object's interface. The remaining argument names are determined from the type information. For information on how to get a pointer to an object's interface, see Getting a Pointer to an Objects Interface.

3. This is an example of an ATTRIBUTES directive statement used to specify the calling convention of an argument.

4. A VARIANT is a data structure that can contain any type of Automation data. It contains a field that identifies the type of data and a union that holds the data value. The use of a VARIANT argument allows the caller to use any data type that can be converted into the data type expected by the member function.

5. Nearly every COM member function returns a status of type HRESULT. Because of this, if a COM member function produces output, it uses output arguments to return the values. In this example, the "pSaved" argument returns a routine specific status value.

6. The interface of a COM member function looks very similar to the interface for a dynamic link library function with one major exception. Unlike a DLL function, the address of a COM member function is never known at program link time. You must get a pointer to an object's interface at run-time, and the address of a particular member function is computed from that.

The following code shows an annotated version of the wrapper generated by the Intel® Fortran Module Wizard for the "Save" function. The name of a wrapper is the same as the name of the corresponding member function, prefixed with a "$" character.

```fortran
! Saves the document to disk.
INTEGER*4 FUNCTION $IGenericDocument_Save($OBJECT, vFilename, &
   vBoolPrompt, pSaved)
IMPLICIT NONE
INTEGER(INT_PTR_KIND()), INTENT(IN) :: $OBJECT ! Object Pointer
!DIR$ ATTRIBUTES VALUE :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename
!DIR$ ATTRIBUTES REFERENCE :: vFilename
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt
!DIR$ ATTRIBUTES REFERENCE :: vBoolPrompt
INTEGER, INTENT(OUT) :: pSaved ! DsSaveStatus
!DIR$ ATTRIBUTES REFERENCE :: pSaved
INTEGER(4) $RETURN
INTEGER(INT_PTR_KIND()) $VTBL ! Interface Function Table
POINTER($VPTR, $VTBL)
TYPE (VARIANT) :: $VAR_vFilename
TYPE (VARIANT) :: $VAR_vBoolPrompt
IF (PRESENT(vFilename)) THEN
   $VAR_vFilename = vFilename
ELSE
   $VAR_vFilename = OPTIONAL_VARIANT
ENDIF
IF (PRESENT(vBoolPrompt)) THEN
   $VAR_vBoolPrompt = vBoolPrompt
ELSE
   $VAR_vBoolPrompt = OPTIONAL_VARIANT
ENDIF
$VPTR = $OBJECT ! Interface Function Table
$VPTR = $VTBL + 84 ! Add routine table offset
IGenericDocument_Save_PTR = $VTBL
```
Notes for this example:

1. The wrapper takes the same argument names as the member function interface.

2. The wrapper computes the address of the member function from the interface pointer and an offset found in the interface's type information. In implementation terms, an interface pointer is a pointer to a pointer to an array of function pointers called an "Interface Function Table."

3. Arguments to a COM or Automation routine can be optional. The wrapper handles the invocation details for specifying an optional argument that is not present in the call.

4. The offset of the "Save" member function is 84. The code assigns the computed address to the function pointer IGenericDocument_Save_PTR, which was declared with the interface shown above, and then calls the function.

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard from Automation type information for the Rebuild All method of the IApplication interface.

```fortran
SUBROUTINE IApplication_RebuildAll($OBJECT, Configuration, $STATUS)  
IMPLICIT NONE
INTEGER(INT_PTR_KIND()), INTENT(IN) :: $OBJECT ! Object Pointer
!DIR$ ATTRIBUTES VALUE :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: Configuration
!DIR$ ATTRIBUTES REFERENCE :: Configuration
INTEGER(4), INTENT(OUT), OPTIONAL :: $STATUS ! Method status
!DIR$ ATTRIBUTES REFERENCE :: $STATUS
INTEGER (INT_PTR_KIND) invokeargs
invokeargs = AUTOALLOCATEINVOKEARGS()  
IF (PRESENT(Configuration)) CALL AUTOADDARG(invokeargs, '$ARG1', &
    Configuration, AUTO_ARG_IN)
$$STATUS = AUTOINVOKE($OBJECT, 28, invokeargs)  
IF (PRESENT($STATUS)) $STATUS = $$STATUS  
CALL AUTODEALLOCATEINVOKEARGS (invokeargs)
END SUBROUTINE IApplication_RebuildAll
```

Notes for this example:

1. The first argument to the procedure is always $OBJECT. It is a pointer to an Automation object's IDispatch interface. The last argument to the procedure is always $STATUS. It is an optional argument that you can specify if you wish to examine the return status of the method. The IDispatch Invoke member function returns a status of type HRESULT. An HRESULT is a 32-bit value. It has the same structure as a Windows error code. In between the $OBJECT and $STATUS arguments are the method arguments' names determined from the type information. Sometimes, the type information does not provide a name for an argument. The Fortran Module Wizard creates a "$ARGn" name in this case.

2. AUTOAllocateInvokeArgs allocates a data structure that is used to collect the arguments that you will pass to the method. AUTOAddArg adds an argument to this data structure.

3. AUTOInvoke invokes the named method passing the argument list. This returns a status result.

4. If the caller supplied a status argument, the code copies the status result to it.

5. AUTODeallocateInvokeArgs deallocates the memory used by the argument list data structure.

**Getting a Pointer to an Object's Interface (Windows*)**

This topic only applies to Windows* operating systems.
To get a pointer to an object's interface, you need to know the object's unique identifier.

**Object Identification**

Object identification enables the use of COM objects created by disparate groups of developers. To provide a method of uniquely identifying an object class regardless of where it came from, COM uses **globally unique identifiers** (GUIDs). A GUID is a 16-byte integer value that is guaranteed (for all practical purposes) to be unique across space and time. COM uses GUIDs to identify object classes, interfaces, and other things that require unique identification.

To create an instance of an object, you need to tell COM what the GUID of the object is. While using 16-byte integers for identification is fine for computers, it poses a challenge for the typical developer. So, COM also supports the use of a less precise, textual name called a **programmatic identifier** (ProgID). A ProgID takes the form:

```
application_name .object_name .object_version
```

**Obtaining the Pointer to an Object's Interface**

To use the routines generated by the Module Wizard, your application must get a pointer to an object's interface. This pointer is used as the value of the `$OBJECT` argument, which is the first argument of every interface generated by the Module Wizard.

Typically, your application obtains its first pointer to an object's interface by calling the COM routine COMCreateObject. COMCreateObject creates a new instance of an object class and returns a pointer to it. COMCreateObject is the generic name of the two subroutines COMCreateObjectByProgID and COMCreateObjectByGUID.

- Use **COMCreateObjectByProgID** to create Automation objects. It accepts the progID of an object and returns a pointer to the object's IDispatch interface.
- Use **COMCreateObjectByGUID** to create both COM and Automation objects. It takes a GUID and returns a pointer to the object's interface (either Automation or COM - see below)

The arguments to COMCreateObjectByGUID are as follows:

- The first argument is a class identifier (CLSID) that uniquely identifies the object's class. The Module Wizard defines a GUID parameter for each class selected from the Type library. These are given the name in the form: `CLSID_class-name`.
- The second argument allows you to limit the type(s) of server that the call will accept. Most of the time you can use CLSCTX_ALL to accept any type of server.
- The third argument is an interface identifier (IID) that specifies the particular object interface you are requesting:
  - To request an Automation interface, use IID_IDispatch.
  - To request a COM interface, the Module Wizard defines a GUID parameter for each interface selected from the type library. These are given a name in the form: `IID_interface-name`.
- The fourth argument is an output parameter that returns the object's interface pointer.

The COMCreateObjectByProgID and COMCreateObjectByGUID subroutines return an interface pointer of an object that the server has defined as being externally creatable. However, not all objects are externally creatable. Often, a server implements a hierarchy of objects, or **object model**. COMCreateObject is called to obtain a pointer to an interface of the root object in the hierarchy. Methods and/or properties of the root object are used to obtain pointers to child objects, and so on, down the hierarchy.

All objects must implement the IUnknown interface. Every object also implements one or more additional interfaces. You can always get a pointer to any of the object's interfaces from any of the object's interface pointers by using the COMQueryInterface subroutine. It is important that you have a pointer to the correct object interface when calling a routine generated by the Module Wizard. If not, your application will likely terminate unexpectedly.
**Releasing the Pointer to an Object's Interface**

When you have finished using an object's interface pointer, you must call `COMReleaseObject` with the pointer. This includes object pointers that you have received using any method, including `COMCreateObject`, `COMQueryInterface`, or by calling an object's method.

**Additional Resources about COM and Automation (Windows*)**

This topic only applies to Windows* operating systems.

There are a number of published books and articles about COM and Automation. Some of these are listed here as additional resources to assist customers who want to learn more about the subject matter. This list does not comment -- either negatively or positively -- on any documents listed or not yet listed. Books and related resources about COM and Automation include:

- *Inside COM+ Base Services* by Guy Eddon, Henry Eddon. Published by Microsoft Press (Redmond, Washington) 1999
- *Understanding COM+* by David S. Platt. Published by Microsoft Press (Redmond, Washington) 1999
- *Inside COM* by Dale Rogerson. Published by Microsoft Press (Redmond, Washington) 1996
- *Understanding ActiveX and OLE* by David Chappell. Published by Microsoft Press (Redmond, Washington) 1996
- Platform SDK online version. Relevant titles include *Platform SDK, COM and ActiveX Object Services*
- *Visual C++ User's Guide* online version

**IFPORT Portability Library**

Intel® Fortran includes functions and subroutines that ease porting of code to or from a PC, or allow you to write code on a PC that is compatible with other platforms.

The portability library is called `LIBIFPORT.LIB` (Windows*) or `libifport.a` (Linux* and macOS*).

Frequently used functions are included in a portability module called IFPORT.

The portability library also contains IEEE* POSIX library functions. These functions are included in a module called IFPOSIX.

You can use the portability library in one of two ways:

- Add the statement USE IFPORT to your program. This statement includes the IFPORT module.
- Call portability routines using the correct parameters and return value.

The portability library is passed to the linker by default during linking. To prevent this, specify the `fpscomp` compiler option with the `nolibs` keyword.

Using the IFPORT mod file provides interface blocks and parameter definitions for the routines, as well as compiler verification of calls.

**fpp Preprocessing**

The Intel® Fortran Compiler preprocessor, fpp, is provided as part of the Intel® Fortran product. When you use a preprocessor for Intel® Fortran source files, the generated output files are used as input source files by the compiler.

Preprocessing performs such tasks as preprocessor symbol (macro) substitution, conditional compilation, and file inclusion. Intel® Fortran predefined symbols are described in Using Predefined Preprocessor Symbols.

fpp has some of the capabilities of the ANSI C preprocessor and supports a similar set of preprocessor directives. Preprocessor directives must begin in column 1 of any Fortran source files. Preprocessor directives are not part of the Fortran language and not subject to the rules for Fortran statements. Syntax for preprocessor directives is based on that of the C preprocessor.

The compiler includes a limited conditional compilation capability, based on directives, that does not require use of fpp. The IF directive construct provides the capability of limited conditional compilation.

Note that you can also specify an alternate Fortran preprocessor instead of the Intel® Fortran fpp preprocessor. For more information, see option fpp-name.

**Automatic Preprocessing by the Compiler**

By default, the preprocessor is not run on files before compilation. However, the Intel® Fortran Compiler automatically calls fpp when compiling source files that have the .fpp, .f, .F90, .FOR, .FTN, or .FPP. For example, the following command preprocesses a source file that contains fpp preprocessor directives, then passes the preprocessed file to the compiler and linker:

```
ifort source.fpp
```

If you want to preprocess files that have other Fortran extensions than those listed, you have to explicitly specify the preprocessor with the fpp compiler option.

The fpp preprocessor can process both free-form and fixed-form Fortran source files. By default, filenames with the suffix of .f, .f, .for, or .fpp are assumed to be fixed form. Filenames with a suffix of .F90 or .f90 (or any other suffix not specifically mentioned here) are assumed to be free form. You can use the free compiler option to specify free form and the fixed compiler option to explicitly specify fixed form.

The fpp preprocessor recognizes tab format in a source line in fixed form.

**Running fpp to Preprocess Files**

You can explicitly run fpp in these ways:

- On the ifort command line, use the ifort command with the fpp compiler option. By default, the specified files are then compiled and linked. To retain the intermediate (.i or .i90) file, specify the [Q]save-temps compiler option.
- On the command line, use the fpp command. In this case, the compiler is not invoked. When using the fpp command line, you need to specify the input file and the intermediate (.i or .i90) output file. For more information, type fpp -help (Linux and macOS*) or fpp /help (Windows) on the command line.
- In the Microsoft Visual Studio* IDE, set the Preprocess Source File option to Yes in the Fortran Preprocessor Option Category. To retain the intermediate files, add /Qsave-temps to Additional Options in the Fortran Command Line Category.

The following lists some common cpp features that are supported by fpp; it also shows common cpp features that are not supported.
Supported cpp features:
- #define, #undef, #ifdef, #ifndef, #if, #elif, #else, #endif,
- #include, #error, #warning, #line
- # (stringsize) and ## (concatenation) operators
- ! as negation operator

Unsupported cpp features:
- #pragma and #ident
- spaces or tab characters preceding the initial "#" character
- # followed by empty line
- \ backslash-newline

Unlike cpp, fpp does not merge continued lines into a single line when possible.

You do not usually need to specify preprocessing for Fortran source programs unless your program uses fpp preprocessing commands, such as those listed above.

**Caution**

Using a preprocessor that does not support Fortran can damage your Fortran code, especially with "FORMAT (\I4)" with cpp changes the meaning of the program because the double backslash "\\" indicates end-of-record with most C/C++ preprocessors.

### fpp Source Files

A source file can contain fpp tokens in the following forms:

- fpp preprocessor directive names
  
  For more information on fpp preprocessor directives, see [Using fpp Preprocessor Directives](#).
- symbolic names including Fortran keywords
  
  fpp permits the same characters in names as Fortran. For more information on symbolic names, see [Using Predefined Preprocessor Symbols](#).
- constants
  
  Integer, real, double, and quadruple precision real, binary, octal, hexadecimal (including alternate notation), character, and Hollerith constants are allowed.
- special characters, space, tab, and newline characters
- comments, including:
  
  - Fortran language comments. A fixed form source line containing one of the symbols C, c, *, d, or D in the first position is considered a comment line. The ! symbol is interpreted as the beginning of a comment extending to the end of the line except when the ! occurs within a constant-expression in an #if or #elif directive. Within such comments, macro expansions are not performed, but they can be switched on by `-f-com=no`.
  
  - fpp comments between /* and */. They are excluded from the output and macro expansions are not performed within these symbols. fpp comments can be nested: for each */ there must be a corresponding */. fpp comments are useful for excluding from the compilation large portions of source instead of commenting every line with a Fortran comment symbol.
  
  - C++ -like line comments that begin with // (double-slash).

A string that is a token can occupy several lines, but only if its input includes continued line characters using the Fortran continuation character &. fpp will not merge such lines into one line.

Identifiers are always placed on one line by fpp. For example, if an input identifier occupies several lines, it will be merged by fpp into one line.
**fpp Output**
Output consists of a modified copy of the input, plus lines of the form:

```
#line_number  file_name
```

These are inserted to indicate the original source line number and filename of the output line that follows. Use the fpp preprocessor option `P` to disable the generation of these lines.

**Diagnostics**
There are three kinds of fpp diagnostic messages:

- **warnings**: preprocessing of source code is continued and the fpp return value is 0
- **errors**: fpp continues preprocessing but sets the return value to a nonzero value which is the number of errors
- **fatal errors**: fpp stops preprocessing and returns a nonzero return value.

The messages produced by fpp are intended to be self-explanatory. The line number and filename where the error occurred are displayed along with the diagnostic on stderr.

**See Also**
- fixed compiler option
- fpp compiler option
- fpp-name compiler option
- free compiler option
- IF Directive Construct
- save-temps, Qsave-temps compiler option
- Understanding File Extensions

**Using fpp Preprocessor Directives**
All fpp preprocessor directives start with the number sign (`#`) as the first character on a line. White space (blank or tab characters) can appear after the initial "#" for indentation.

fpp preprocessor directives can be placed anywhere in source code, in particular before a Fortran continuation line. However, fpp preprocessor directives within a macro call can not be divided among several lines by means of continuation symbols.

fpp preprocessor directives can be grouped according to their purpose.

**Preprocessor directives for string substitution**
The following fpp preprocessor directives cause substitutions in your program:

<table>
<thead>
<tr>
<th>Preprocessor Directive</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>FILE</strong></td>
<td>Replaces a string with the input file name (a character string literal).</td>
</tr>
<tr>
<td><strong>LINE</strong></td>
<td>Replaces a string with the current line number in the input file (an integer constant).</td>
</tr>
<tr>
<td><strong>DATE</strong></td>
<td>Replaces a string with the date that fpp processed the input file (a character string literal in the form <code>Mmm dd yyyy</code>).</td>
</tr>
<tr>
<td><strong>TIME</strong></td>
<td>Replaces a string with the time that fpp processed the input file (a character string literal in the form <code>hh:mm:ss</code>).</td>
</tr>
</tbody>
</table>
Preprocessor Directive | Result
---|---
__TIMESTAMP__ | Replaces a string with the timestamp that fpp processed the input file (a character string literal in the form "day date time year", where day is a 3-letter abbreviation, date is Mmm dd, time is hh:mm:ss and year is yyyy).

Preprocessor directive for inclusion of external files
To include external files, preprocessor directive `#include` can be specified in one of the following forms:

- `#include "filename"
- `#include <filename>`

`#include` reads in the contents of the named file into the specified or default location in the source. The lines read in from the file are processed by fpp just as if they were part of the current file.

When the `<filename>` notation is used, filename is only searched for in the standard "include" directories. For more information, see the fpp `-I` and the `-Y` options in Using Fortran Preprocessor Options. No additional tokens are allowed on the directive line after the final '"' or '>'.

For `#include "filename"`, filenames are searched for in the following order:
- In the directory in which the source file resides
- In the directories specified by the `-I` or `-Y` option
- In the default directory

For `#include <filename>`, filenames are searched for in the following order:
- In the directories specified by the `-I` or `-Y` option
- In the default directory

Preprocessor directive for line control
The preprocessor directive `#line-number` generates line control information for the Fortran compiler. It takes the following form:

- `#line-number "filename"
- `#line-number "filename"

`#line-number` is an integer constant that is the line number of the next line. "filename" is the name of the file containing the line. If "filename" is not provided, the current filename is assumed.

Preprocessor directive for fpp variable and macro definitions
The preprocessor directive `#define` can be used to define both simple string variables and more complicated macros. It can take two forms.
- Definition of an fpp variable:

  `#define nametoken-string`

  In the above, occurrences of name in the source file will be replaced by token-string.
- Definition of an fpp macro:

  `#define name(argument[,argument] ...) token-string`

  In the above, occurrences of the macro name followed by the comma-separated list of actual arguments within parentheses will be replaced by token-string. Each occurrence of argument in token-string is replaced by the token sequence representing the corresponding "actual" argument in the macro call.
An error occurs if the number of macro call arguments is not the same as the number of arguments in the corresponding macro definition. For example, consider this macro definition:

```
#define INTSUB(m, n, o) call mysub(m, n, o)
```

Any use of the macro INTSUB must have three arguments. In macro definitions, spaces between the macro name and the open parenthesis "(" are prohibited to prevent the directive from being interpreted as an fpp variable definition with the rest of the line beginning with the open parenthesis "(" being interpreted as its token-string.

An fpp variable or macro definition can be of any length and is limited only by the newline symbol. It can be defined in multiple lines by continuing it to the next line with the insertion of \\". For example:

```
#define long_macro_name(x, \y) x*y
```

The occurrence of a newline without a macro-continuation signifies the end of the macro definition.

The scope of a definition begins from the #define and encloses all the source lines (and source lines from #include files) to the end of the current file, except for:

- Files included by Fortran INCLUDE statements
- fpp and Fortran comments
- Fortran IMPLICIT statements that specify a single letter
- Fortran FORMAT statements
- Numeric, typeless, and character constants

**Preprocessor directive for undefining a macro**

The preprocessor directive #undef takes the following form:

```
#undef name
```

This preprocessor directive removes any definition for name produced by the D options, the #define preprocessor directives, or by default. No additional tokens are permitted on the directive line after name.

If name has not been previously defined, then #undef has no effect.

**Preprocessor directive for macro expansion**

If, during expansion of a macro, the column width of a line exceeds column 72 (for fixed format) or column 132 (for free format), fpp inserts appropriate Fortran continuation lines.

For fixed format, there is a limit on macro expansions in label fields (positions 1-5):

- A macro call (together with possible arguments) should not extend beyond column 5.
- A macro call whose name begins with one of the Fortran comment symbols is considered to be part of a comment.
- A macro expansion may produce text extending beyond column 5. In this case, a warning will be issued.

In fixed format, when the fpp option -Xw has been specified, an ambiguity may occur if a macro call occurs in a statement position and a macro name begins or coincides with a Fortran keyword. For example, consider the following:

```
#define callp(x)   call f(x)
call p(0)
```

fpp cannot determine how to interpret the callp token sequence above. It could be considered to be a macro name. The current implementation does the following:

- The longer identifier is chosen (callp in this case)
• From this identifier the longest macro name or keyword is extracted
• If a macro name has been extracted a macro expansion is performed. If the name begins with some keyword, fpp issues an appropriate warning
• The rest of the identifier is considered as a whole identifier

In the previous example, the macro expansion is performed and the following warning is produced:

```plaintext
warning: possibly incorrect substitution of macro callp
```

This situation appears only when preprocessing fixed-format source code and when the space symbol is not interpreted as a token delimiter.

In the following case, a macro name coincides with a beginning of a keyword:

```plaintext
#define INT INTEGER*8
    INTEGER k
```

The INTEGER keyword will be found earlier than the INT macro name. There will be no warning when preprocessing such a macro definition.

**Preprocessor directives for conditional selection of source text**

The following three preprocessor directives are conditional constructs that you can use to select source text.

- **#if preprocessor directive**

  When #if is specified, subsequent lines up to the matching #else, #elif, or #endif preprocessor directive appear in the output only if `condition` evaluates to .TRUE.. The following shows an example:

  ```plaintext
  #if condition_1
  block_1
  #elif condition_2
  block_2
  #elif ...
  #else
  block_n
  #endif
  ```

- **#ifdef preprocessor directive**

  When #ifdef is specified, subsequent lines up to the matching #else, #elif, or #endif preprocessor directive appear in the output only if `name` has been defined, either by a #define preprocessor directive or by the D compiler option, with no intervening #undef preprocessor directive. No additional tokens are permitted on the preprocessor directive line after `name`. The following shows an example:

  ```plaintext
  #ifdef name
  block_1
  #elif condition
  block_2
  #elif ...
  #else
  block_n
  #endif
  ```

- **#ifndef preprocessor directive**

  When #ifndef is specified, subsequent lines up to the matching #else, #elif, or #endif preprocessor directive appear in the output only if `name` has not been defined, or if its definition has been removed with an #undef preprocessor directive. No additional tokens are permitted on the preprocessor directive line after `name`. The following shows an example:

  ```plaintext
  #ifndef name
  block_1
  #elif condition
  block_2
  #elif ...
  #else
  block_n
  #endif
  ```
The #else, #elif, or #endif preprocessor directives are optional. They can be used in the above preprocessor directives.

Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if all of the following occur:

- The condition in the preceding #if directive evaluates to .FALSE. or the name in the preceding ifdef directive is not defined, or the name in the preceding ifndef directive is defined.
- The conditions in all of the preceding #elif directives evaluate to .FALSE.
- The condition in the current #elif evaluates to .TRUE.

Any condition allowed in an #if directive is allowed in an #elif directive. Any number of #elif directives may appear between an #if, ifdef, or ifndef directive and a matching #else or #endif directive.

**Conditional expressions**

condition_1, condition_2, etc. are logical expressions involving fpp constants, macros, and intrinsic functions. The following items are permitted in conditional expressions:

- C language operations: <, >, ==, !=, >=, <=, +, -, /, *, %, <<, >>, &, ~, |, &&, and ||
  
  They are interpreted by fpp in accordance to the C language semantics. This facility is provided for compatibility with "old" Fortran programs using cpp.
- Fortran language operations: .AND., .OR., .NEQV., .XOR., .EQV., .NOT., .GT., .LT., .LE., .GE., .NE., .EQ., ** (power).
- Fortran logical constants: .TRUE., .FALSE.
- The fpp intrinsic function "defined": defined(name) or defined(name) which returns .TRUE. if name is defined as an fpp variable or a macro. It returns .FALSE. if the name is not defined.

#ifdef is shorthand for #if defined(name) and #ifndef is shorthand for #if .not. defined(name).

Only these items, integer constants, and names can be used within a constant expression. A name that has not been defined with the -D option, a #define preprocessor directive, or defined by default, has a value of 0. The C operation != (not equal) can be used in the #if or #elif preprocessor directive, but not in the #define preprocessor directive, where the symbol ! is considered to be the Fortran comment symbol by default.

fpp compiler option
Using Fortran Preprocessor Options

**Using Predefined Preprocessor Symbols**

Preprocessor symbols (macros) let you substitute values in a program before it is compiled. The substitution is performed in the preprocessing phase.

The preprocessor symbols shown in the table below are predefined by the compiler system and are available to compiler directives and to fpp. If you want to use other symbol names, you need to specify them on the command line.

You can use the D compiler option to define the symbol names to be used during preprocessing. This option performs the same function as the #define preprocessor directive.

Preprocessing with fpp replaces every occurrence of the defined symbol name with the specified value. Preprocessing compiler directives only allow IF and IF DEFINED.

If you want to disable symbol replacement (also known as macro expansion) during the preprocessor step, you can specify the macro=no preprocessor option for the fpp compiler option.

Disabling preprocessor symbol replacement is useful for running fpp to perform conditional compilation (using ifdef, etc.) without replacement.
You can use the `U` preprocessor option to suppress an automatic definition of a preprocessor symbol. This option suppresses any symbol definition currently in effect for the specified name. This option performs the same function as an `#undef` preprocessor directive.

The symbols in the following table can be used in both fpp and the Fortran compiler conditional compilations.

<table>
<thead>
<tr>

</table>
**Using Fortran Preprocessor Options**

The Fortran preprocessor (fpp) may be invoked automatically or by specifying the `fpp` compiler option.

The following preprocessor options are available if you use the `fpp` compiler option. On Linux* and macOS* systems, the preprocessor options must start with a dash (`-`); for example, `-macro=no`. On Windows* systems, the preprocessor options must start with a slash (`/`); for example, `/macro=no`.

<table>
<thead>
<tr>
<th>Preprocessor Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Specifies that C++-style comments should not be recognized.</td>
</tr>
<tr>
<td>C</td>
<td>Specifies that C-style comments should not be recognized. This is the same as specifying <code>c_com=no</code>.</td>
</tr>
<tr>
<td>c_com={yes</td>
<td>no}</td>
</tr>
<tr>
<td>D name</td>
<td>Defines the preprocessor variable <code>name</code> as 1 (one). This is the same as if a <code>Dname=1</code> option appeared on the fpp command line. This is the same as specifying the following line in the source file processed by fpp: <code>#define name 1</code></td>
</tr>
<tr>
<td>D name=val</td>
<td>Defines <code>name</code> as if by a <code>#define</code> directive. This is the same as specifying the following line in the source file processed by fpp: <code>#define name var</code> The <code>Dname=val</code> will be ignored if there are any non-alphabetic, non-numeric characters in <code>name</code>.</td>
</tr>
<tr>
<td>Preprocessor Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>The ( D ) option has lower precedence than the ( U ) option. That is, if the same name is used in both a ( U ) option and a ( D ) option, the name will be undefined regardless of the order of the options.</td>
<td></td>
</tr>
<tr>
<td>e</td>
<td>For fixed-form source files, tells the compiler to accept extended source lines, up to 132 characters long.</td>
</tr>
<tr>
<td>e80</td>
<td>For fixed-form source files, tells the compiler to accept extended source lines, up to 80 characters long.</td>
</tr>
<tr>
<td>( f_{-\text{com}}={\text{yes}</td>
<td>\text{no}} )</td>
</tr>
<tr>
<td>#define max 100 ! max number</td>
<td></td>
</tr>
<tr>
<td>do i = 1, max + 1</td>
<td></td>
</tr>
<tr>
<td>If you specify ( f_{-\text{com}}=\text{yes} ), fpp will output the following:</td>
<td></td>
</tr>
<tr>
<td>do i = 1, 100 + 1</td>
<td></td>
</tr>
<tr>
<td>If you specify ( f_{-\text{com}}=\text{no} ), fpp will output the following:</td>
<td></td>
</tr>
<tr>
<td>do i = 1, 100 ! max number + 1</td>
<td></td>
</tr>
<tr>
<td>f77</td>
<td>Tells the compiler to assume FORTRAN 77 language input source.</td>
</tr>
<tr>
<td>f90</td>
<td>Tells the compiler to assume Fortran 90 language input source.</td>
</tr>
<tr>
<td>fixed</td>
<td>Tells the compiler to assume fixed format in the source file.</td>
</tr>
<tr>
<td>free</td>
<td>Tells the compiler to assume free format in the source file.</td>
</tr>
<tr>
<td>help</td>
<td>Displays information about fpp options.</td>
</tr>
<tr>
<td>I dir</td>
<td>Inserts directory ( \text{dir} ) into the search path for files with names not beginning with &quot;/&quot;. The #include ( \text{dir} ) is inserted ahead of the standard list of &quot;include&quot; directories so that #include files with names enclosed in double-quotes (&quot;&quot;) are searched for first in the directory of the file with the #include line, then in directories named with ( \text{i} ) options, and lastly,</td>
</tr>
<tr>
<td>Preprocessor Option</td>

<tr>
<td>Preprocessor Option</td>
<td>Description</td>
</tr>
<tr>
<td>Preprocessor Option</td>
<td>Description</td>
</tr>
<tr>
<td>Preprocessor Option</td>
<td>Description</td>
</tr>
</tbody>
</table>

The preprocessor option `#include` searches for files with names enclosed in angle-brackets (`< >`), and the directory of the file with the `#include` line is not searched.

- **M** Generates make dependencies.
- **m** Expands macros everywhere. This is the same as specifying `macro=yes`.
- **macro={yes|no_com|no}** Determines the behavior of macro expansion. If you specify `macro=no_com`, macro expansion is turned off in comments. If you specify `macro=no`, no macro expansion occurs anywhere. By default, macros are expanded everywhere; that is, `macro=yes`.
- **macro_expand={vc|cpp}** Determines the mode of macro expansion. If you specify `macro_expand=vc`, macros are expanded in Microsoft Visual C/C++ order. If you specify `macro_expand=cpp`, macros are expanded in GNU CPP order.
- **MF=file** Makes `fpp` append dependencies to `file`.
- **noB** Specifies that C++-style comments should be recognized.
- **noC** Specifies that C-style comments should be recognized. This is the same as `c_com=yes`.
- **noJ** Specifies that F90-style comments should be recognized in a `#define` line. This is the same as `f_com=no`.
- **no-fort-cont** Specifies that IDL-style format should be recognized. This option is only for the IDE. Note that macro arguments in IDL may have a C-like continuation character \ which is different from the Fortran continuation character &. The `fpp` preprocessor should recognize the C-like continuation character and process some other non-Fortran tokens so that the IDL processor can recognize them.
- **P** Tells the compiler that line-numbering directives should not be added to the output file. This line-numbering directive appears as `#line-number file-name`
### Preprocessor Option

<table>
<thead>
<tr>
<th>Preprocessor Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#name</code></td>
<td>Removes any initial definition of name, where name is an fpp variable that is predefined on a particular preprocessor. The following shows an example of symbols that may be predefined, depending upon the architecture of the system:</td>
</tr>
<tr>
<td></td>
<td>Operating System: <code>__APPLE__</code>, <code>__unix</code>, and <code>__linux</code></td>
</tr>
<tr>
<td></td>
<td>Hardware: <code>__i386</code>, <code>__x86_64</code></td>
</tr>
<tr>
<td><code>#undef</code></td>
<td>Removes initial definitions for all predefined symbols.</td>
</tr>
<tr>
<td><code>#v</code></td>
<td>Displays the fpp version number.</td>
</tr>
<tr>
<td><code>#w[0]</code></td>
<td>Prevents warnings from being output. By default, warnings are output to standard error stream (stderr).</td>
</tr>
<tr>
<td><code>#what</code></td>
<td>Displays detailed version information.</td>
</tr>
<tr>
<td><code>#xu</code></td>
<td>Converts uppercase letters to lowercase, except within character-string constants. The default is to leave the case as is.</td>
</tr>
<tr>
<td><code>#xw</code></td>
<td>Tells the compiler that in fixed-format source files, the blank or space symbol &quot; &quot; is insignificant. By default, the space symbol is the delimiter of tokens for this format.</td>
</tr>
<tr>
<td><code>#ydir</code></td>
<td>Adds directory <code>dir</code> to the end of the system include paths.</td>
</tr>
</tbody>
</table>

### Methods to Optimize Code Size

This section provides some guidance on how to achieve smaller object and smaller executable size when using the optimizing features of Intel compilers.

To begin, there are two compiler options that are designed to prioritize code size over performance:

- **Favors size over speed**
  - Linux* and macOS*: `-Os`
  - Windows*: `/Os`
  - This option enables optimizations that do not increase code size; it produces smaller code size than option `O2`.
  - Option `Os` disables some optimizations that may increase code size for a small speed benefit.

- **Minimizes code size**
  - Linux* and macOS*: `-O1`
  - Windows*: `/O1`
  - Compared to option `Os`, option `O1` disables even more optimizations that are generally known to increase code size. Specifying option `O1` implies option `Os`. 

---

*Disclaimer: Intel technologies may require enabled hardware and software features to exploit performance.

2539
As an intermediate step in reducing code size, you can replace option `{opt}O3` with option `{opt}O2` before specifying option `{opt}O1`.

Option `{opt}O1` may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.

For more information about the above options, see their full descriptions in the Compiler Reference.

The rest of this section briefly discusses methods that may help you further improve code size even when compared to the default behaviors of options `{opt}Os` and `{opt}O1`.

The following table summarizes the topics in this section.

**Most Common Methods to Reduce Code Size:**
- Disable or Decrease the Amount of Inlining
- Strip Symbols from Your Binaries
- Dynamically Link Intel-Provided Libraries
- Disable Inline Expansion of Standard Library or Intrinsic Functions

**Methods to Use Only When Code Size is Very Important:**
- Disable Passing Arguments in Registers Instead of On the Stack
- Disable Loop Unrolling
- Disable Automatic Vectorization

**Method to Use Under Special Circumstances:**
- Avoid Unnecessary 16-Byte Alignment

The following are important considerations:

- Some of these methods may already be applied by default when options `{opt}Os` and `{opt}O1` are specified. All the methods mentioned in subsequent topics can be applied at higher optimization levels.
- Some of the options referred to in these topics will not necessarily cause code size reduction, and they may provide varying results (good, bad, or neutral) based on the characteristics of the target code. Still, these are the recommended things to try to see if they cause your binaries to become smaller while maintaining acceptable performance.
- You should read the full description of compiler options that are mentioned in these topics to get complete information about their behavior, syntax, and target platforms.

**See Also**
- `compiler option`
- `{opt}Os` compiler option

**Disable or Decrease the Amount of Inlining**

Inlining replaces a call to a function with the body of the function. This lets the compiler optimize the code for the inlined function in the context of its caller, usually yielding more specialized and better performing code. This also removes the overhead of calling the function at run-time.

However, replacing a call to a function by the code for that function usually increases code size. The code size increase can be substantial. To eliminate this code size increase, at the cost of the potential performance improvement, inlining can be disabled.
As an alternative to completely disabling inlining, the default amount of inlining can be decreased by using an inline factor less than the default value of 100. It corresponds to scaling the default values of the main inlining parameters by $n\%$.

**Options to specify:**

| To disable inlining:                  | Linux* and macOS*: -fno-inline  |
|                                       | Windows*: /Ob0                  |
| To reduce inlining and factor the main inlining parameters: | Linux* and macOS*: -inline-factor=$n$  |
|                                       | Windows*: /Qinline-factor:$n$  |
| To fine tune the main inlining parameters: | Linux* and macOS*:  |
|                                       | • -inline-factor  |
|                                       | • -inline-max-per-compile  |
|                                       | • -inline-max-per-routine  |
|                                       | • -inline-max-size  |
|                                       | • -inline-max-total-size  |
|                                       | • -inline-min-size  |
| Windows*:                            | • /Qinline-factor  |
|                                       | • /Qinline-max-per-compile  |
|                                       | • /Qinline-max-per-routine  |
|                                       | • /Qinline-max-size  |
|                                       | • /Qinline-max-total-size  |
|                                       | • /Qinline-min-size  |

For further details about the compiler options, see the compiler option descriptions.

**Advantages of this method:** Disabling or reducing this optimization can reduce code size.

**Disadvantages of this method:** Performance is likely to be sacrificed by disabling or reducing inlining especially for applications with many small functions.

**Strip Symbols from Your Binaries**

You can specify a compiler option to omit debugging and symbol information from the executable without sacrificing its operability.

**Options to specify:**

| Linux* and macOS*: | -Wl, --strip-all  |
| Windows*:          | None               |

**Advantages of this method:** This method noticeably reduces the size of the binary.

**Disadvantages of this method:** It may be very difficult to debug a stripped application.

**Dynamically Link Intel-Provided Libraries**

By default, some of the Intel support and performance libraries are linked statically into an executable. As a result, the library codes are linked into every executable being built. This means that codes are duplicated. It may be more profitable to link them dynamically.
Options to specify:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*:</td>
<td>-shared-intel</td>
</tr>
<tr>
<td>Windows*:</td>
<td>/MD or /libs:dll</td>
</tr>
</tbody>
</table>

Advantages of this method:

- Performance of the resulting executable is normally not significantly affected.
- Library codes that are otherwise linked in statically into every executable will not contribute to the code size of each executable with this option. These codes will be shared between all executables using them, and will be available independent of those executables.

Disadvantages of this method:

- The libraries on which the resulting executable depends must be re-distributed with the executable in order for it to work properly.
- When libraries are linked statically, only library content that is actually used is linked into the executable. Dynamic libraries, on the other hand, contain all the library content. Therefore, it may not be beneficial to use this option if you only need to build and/or distribute a single executable.
- The executable itself may be much smaller when linked dynamically, compared to a statically linked executable. However, the total size of the executable plus shared libraries or DLLs may be much larger than the size of the statically linked executable.

Disable Inline Expansion of Standard Library or Intrinsic Functions

In some cases, disabling the inline expansion of standard library or intrinsic functions may noticeably improve the size of the produced object or binary.

Options to specify:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*:</td>
<td>-nolib-inline</td>
</tr>
<tr>
<td>Windows*:</td>
<td>None</td>
</tr>
</tbody>
</table>

Disable Passing Arguments in Registers Instead of On the Stack

You can specify an option that causes the compiler to pass arguments in registers rather than on the stack. This can yield faster code.

However, doing this may require the compiler to create an additional entry point for any function that can be called outside the code being compiled.

In many cases, this will lead to an increase in code size. To prevent this increase in code size, you can disable this optimization.

Options to specify:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and macOS*:</td>
<td>-qopt-args-in-regs=none</td>
</tr>
<tr>
<td>Windows*:</td>
<td>/Qopt-args-in-regs:none</td>
</tr>
</tbody>
</table>

Advantages of this method:

Disabling this optimization can reduce code size.
Disadvantages of this method: The amount of code size saved may be small when compared to the corresponding performance loss of disabling the optimization.

Notes:
If you do not specify "none" for option [q or Q]opt-args-in-regs, the default behavior for the option is that parameters are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.
Depending on code characteristics, this option can sometimes increase binary size.

**Disable Loop Unrolling**

Unrolling a loop increases the size of the loop proportionally to the unroll factor.
Disabling (or limiting) this optimization may help reduce code size at the expense of performance.

**Options to specify:**

<table>
<thead>
<tr>
<th><em><em>Linux</em> and macOS</em>**:</th>
<th>-unroll=0</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Windows</strong>*:</td>
<td>/Qunroll:0</td>
</tr>
</tbody>
</table>

Advantages of this method: Code size is reduced.
Disadvantages of this method: Performance of otherwise unrolled loops may noticeably degrade because this limits other possible loop optimizations.

Notes:
This option is already the default if you specify option Os or option O1.

**Disable Automatic Vectorization**

The compiler finds possibilities to use SIMD (SSE/AVX) instructions to improve performance of applications. This optimization is called automatic vectorization.
In most cases, this optimization involves transformation of loops and increases code size, in some cases significantly.
Disabling this optimization may help reduce code size at the expense of performance.

**Options to specify:**

<table>
<thead>
<tr>
<th><em><em>Linux</em> and macOS</em>**:</th>
<th>-no-vec</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Windows</strong>*:</td>
<td>/Qvec-</td>
</tr>
</tbody>
</table>

Advantages of this method: Compile-time is also improved significantly.
Disadvantages of this method: Performance of otherwise vectorized loops may suffer significantly. If you care about the performance of your application, you should use this option selectively to suppress vectorization on everything except performance-critical parts.

Notes:
Depending on code characteristics, this option can sometimes increase binary size.

**Avoid Unnecessary 16-Byte Alignment**

This method should only be used in certain situations that are well understood. It can potentially cause correctness issues when linking with other objects or libraries that aren't built with this option. This topic only applies to Linux systems on IA-32 architecture.
The 32-bit Linux ABI states that stacks need only maintain 4-byte alignment. However, for performance reasons in modern architectures, GCC and ICC maintain an alignment of 16-bytes on the stack. Maintaining 16-byte alignment may require additional instructions to adjust the stack on function entries where no stack adjustment would otherwise be needed. This can impact code size, especially in code that consists of many small routines.

You can specify a compiler option that will revert ICC back to maintaining 4-byte alignment, which can eliminate the need for extra stack adjust instructions in some cases.

Use this option only if one of the following is true:

- Your code does not call any other object or library that can be built without this option and, therefore, may rely on the stack being aligned to 16-bytes when called.
- Your code is targeted for architectures that do not have or support SSE instructions; therefore, it would never need 16-byte alignment for correctness reasons.

Options to specify:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>-falign-stack=assume-4-byte</td>
</tr>
<tr>
<td>macOS*</td>
<td>None</td>
</tr>
<tr>
<td>Windows*</td>
<td>None</td>
</tr>
</tbody>
</table>

Advantages of this method:

- Code size can be smaller because you do not need extra instructions to maintain 16-byte alignment when not needed.
- This method can improve performance in some cases because of this reduction of instructions.

Disadvantages of this method:

This method can cause incompatibility when linked with other objects or libraries that rely on the stack being 16-byte aligned across the calls.

Notes:

Depending on code characteristics, this option can sometimes increase binary size.

National Language Support (NLS) Routines

Intel® Fortran provides a complete National Language Support (NLS) library of language-localization routines and multibyte-character routines. You can use these routines to write applications in many different languages.

In many languages, the standard ASCII character set is not enough because it lacks common symbols and punctuation (such as the British pound sign), or because the language uses a non-ASCII script (such as Cyrillic for Russian) or because the language consists of too many characters for each to be represented by a single byte (such as Chinese).

In the case of many non-ASCII languages, such as Arabic and Russian, an extended single-byte character set is sufficient. You need only change the language locale and codepage, which can be done at a system level or within your program. However, Eastern languages such as Japanese and Chinese use thousands of separate characters that cannot be encoded as single-byte characters. Multibyte characters are needed to represent them.

Character sets are stored in tables called code sets. There are three components of a code set: the locale, which is a language and country (since, for instance, the language Spanish may vary among countries), the codepage, which is a table of characters to make up the computer’s alphabet, and the font used to represent the characters on the screen. These three components can be set independently. Each computer running Windows operating systems comes with many code sets built into the system, such as English, Arabic, and Spanish. Multibyte code sets, such as Chinese and Japanese, are not standard but come with special versions of the operating system (for instance, Windows NT-J comes with the Japanese code set).
The default code set is obtained from the operating system when a program starts up. When you install your operating system, you should install the system supplied code sets. Thereafter, they are always available. You can switch among them by:

- Open the Control Panel (available from Settings)
- Click the Regional Settings icon
- Choose from the dropdown list of available locales (languages and countries).

When you select a new locale, it becomes the default system locale, and will remain the default locale until you change it. Each locale has a default codepage associated with it, and a default currency, number, and date format.

**NOTE**
The default codepage does not change when you select a new locale until you reboot your computer.

You can change the currency, number, and date format in the International dialog box or the Regional Setting dialog box independently of the locale.

The locale determines the character set available to the user. The locale you select becomes the default for the NLS routines described in this section, but the NLS routines allow you to change locales and their parameters from within your programs. These routines are useful for creating original foreign-language programs or different versions of the same program for various international markets. Changes you make to the locale from within a program affect only the program. They do not change the system default settings.

The codepage you select, which can be set independently, controls the multibyte (MB routines) character routines described in this section. Only users with special multibyte-character code sets installed on their computers need to use MB routines. The standard code sets all use single-byte character code sets.

Note that in Intel Fortran source code, multibyte characters can be used only in character strings and source comments. They cannot be used within variable names or statements. Like program changes to the locale, program changes to codepages affect only the program, not the system defaults.

To access the routines, the following statement should be present in any program unit that uses NLS or MB routines:

```
USE IFNLS
```

Program Units and Procedures

**Understanding Single and Multibyte Character Sets (Windows*)**

The ASCII character set defines the characters from 0 to 127 and an extended set from 128 to 255. Several alternative single-byte character sets, primarily European, define the characters from 0 to 127 identically to ASCII, but define the characters from 128 to 255 differently. With this extension, 8-bit representation is sufficient for defining the needed characters in most European-derived languages. However, some languages, such as Japanese Kanji, include many more characters than can be represented with a single byte. These languages require multibyte coding.

A multibyte character set consists of both one-byte and two-byte characters. A multibyte-character string can contain a mix of single and double-byte characters. A two-byte character has a lead byte and a trail byte. In a particular multibyte character set, the lead and trail byte values can overlap, and it is then necessary to use the byte's context to determine whether it is a lead or trail byte.
Tools

PGO Tools

PGO Tools Overview
This section describes the tools that take advantage of or support the Profile-guided Optimizations (PGO) available in the compiler.

- Code coverage Tool
- Test prioritization Tool
- Profmerge and proforder Tools

Code Coverage Tool
The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are listed below:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- Code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate an HTML-formatted report and export data in both text- and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on all supported Intel architectures on Linux*, Windows*, and macOS* operating systems.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.

Code Coverage Tool Requirements
To run the code coverage tool on an application, you must have following items:
• The application sources.
• The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows) option.

**NOTE**
Use the -[Q]prof-gen:srcpos option if you intend to use the collected data for code coverage and profile feedback. If you are only interested in using the instrumentation for code coverage, use the /Qcov-gen option. Using the /Qcov-gen option saves time and improves performance. This option can be used only on Windows platform for all architectures.

• A pgopti.dpi file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge tool. This file is also generated implicitly by the Intel® compilers when compiling an application with [Q]prof-use options with available .dyn and .dpi files.

**Using the Tool**
The tool uses the following syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov [-codecov_option]</td>
</tr>
</tbody>
</table>

where -codecov_option is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in the code coverage tools Options section. If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using -prof-gen=srcpos (Linux and macOS*) or /Qprof-gen:srcpos (Windows), and/or /Qcov-gen (Windows) option.

   This step generates an instrumented executable and a corresponding static profile information (pgopti.spi) file when the [Q]prof-gen=srcpos option is used. When the /Qcov-gen option is used, minimum instrumentation only for code coverage and generation of .spi file is enabled.

   **NOTE**
   You can specify both the /Qprof-gen=srcpos and /Qcov-gen options on the command line. The higher level of instrumentation needed for profile feedback is enabled along with the profile option for generating the .spi file, regardless of the order the options are specified on the command line.

2. Run the instrumented application.

   This step creates the dynamic profile information (.dyn) file. Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by the -prof-dir (Linux or macOS*) or /Qprof-dir (Windows) option, or PROF_DIR environment variable. On Windows, you can use the /Qcov-dir or COV_DIR environment variable. These have the same meaning as /Qprof-dir and PROF_DIR.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (pgopti.dpi) file.

   This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.

   You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the profmerge -a option. Select an alternate name for the output .dpi file using the profmerge -prof_dpi option.
Caution
The promerge tool merges all .dyn files that exist in the given directory. Confirm that unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. The valid syntax and tool options are shown below.
This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.

NOTE
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

<table>
<thead>
<tr>
<th>Example: specify .dpi and .spi files</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi</td>
</tr>
</tbody>
</table>

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

<table>
<thead>
<tr>
<th>Example: add contact information</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov -prj myProject -mname JoeSmith -maddr <a href="mailto:js@company.com">js@company.com</a></td>
</tr>
</tbody>
</table>

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

<table>
<thead>
<tr>
<th>Example: export data to text</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt</td>
</tr>
</tbody>
</table>

Code Coverage Tool Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bcolor color</td>
<td>#FFFF99</td>
<td>Specifies the HTML color name for code in the uncovered blocks.</td>
</tr>
<tr>
<td>-beginblkdsbl string</td>
<td></td>
<td>Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-ccolor color</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the covered code.</td>
</tr>
<tr>
<td>-comp file</td>
<td></td>
<td>Specifies the file name that contains the list of files being (or not) displayed.</td>
</tr>
<tr>
<td>-counts</td>
<td></td>
<td>Generates dynamic execution counts.</td>
</tr>
<tr>
<td>-demang</td>
<td></td>
<td>Demangles both function names and their arguments.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-dpi file</td>
<td>pgopti.dpi</td>
<td>Specifies the file name of the dynamic profile information file (.dpi).</td>
</tr>
<tr>
<td>-endblkdsbl string</td>
<td></td>
<td>Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-fcolor color</td>
<td>#FFCCCC</td>
<td>Specifies the HTML color name for code of the uncovered functions.</td>
</tr>
<tr>
<td>-help, -h</td>
<td></td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-icolor color</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.</td>
</tr>
<tr>
<td>-include-nonexec</td>
<td></td>
<td>Block details will also be listed for functions that did not execute, when used with -xmlbcvrg[full] or -txtbcvrg[full] options.</td>
</tr>
<tr>
<td>-maddr string</td>
<td>Nobody</td>
<td>Sets the email address of the web-page owner</td>
</tr>
<tr>
<td>-mname string</td>
<td>Nobody</td>
<td>Sets the name of the web-page owner.</td>
</tr>
<tr>
<td>-nopartial</td>
<td></td>
<td>Treats partially covered code as fully covered code.</td>
</tr>
<tr>
<td>-nopmeter</td>
<td></td>
<td>Turns off the progress meter. The meter is enabled by default.</td>
</tr>
<tr>
<td>-nounwind</td>
<td></td>
<td>Ignores compiler-generated unwind handlers for exception handling cleanup when computing and displaying basic block coverage.</td>
</tr>
<tr>
<td>-onelinedsbl string</td>
<td></td>
<td>Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-pcolor color</td>
<td>#FAFAD2</td>
<td>Specifies the HTML color name or code of the partially covered code.</td>
</tr>
<tr>
<td>-prj string</td>
<td></td>
<td>Sets the project name.</td>
</tr>
<tr>
<td>-ref</td>
<td></td>
<td>Finds the differential coverage with respect to ref_dpi_file.</td>
</tr>
<tr>
<td>-showdirnames</td>
<td></td>
<td>Displays the full path name for source files in the HTML report, instead of just the base filename.</td>
</tr>
<tr>
<td>-spifile</td>
<td>pgopti.spi</td>
<td>Specifies the file name of the static profile information file (.spi).</td>
</tr>
<tr>
<td>-srcroot dir</td>
<td></td>
<td>Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NOTE</td>
<td></td>
<td>In order for the substitution to take place, the sources need to be compiled with one of the following options: [Q]prof-src-root, [Q]prof-src-root-cwd. This option specifies the base directory that is to be treated as the project root directory.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>An example of use is:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; ifort -Qprof-gen:srcpos -Qprof-src-root c:\workspaces\orig_project_dir test1.f90 test2.f90</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; test1.exe</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; profmerge</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; cd \workspaces\</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; mv orig_project_dir new_project_dir</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; cd new_project_dir\src</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C:&gt; codecov -srcroot C:\workspaces\new_project_dir</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Now, &quot;C:\workspaces\new_project_dir&quot; will be substituted for &quot;c:\workspaces\orig_project_dir&quot; when looking for the source files.</td>
</tr>
<tr>
<td>-txtbcvrgfile</td>
<td></td>
<td>Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtbcvrgfullfile</td>
<td></td>
<td>Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtdcgfile</td>
<td></td>
<td>Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtfcvrgfile</td>
<td></td>
<td>Export function coverage for covered function in text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-ucolorcolor</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the unknown code.</td>
</tr>
<tr>
<td>-xcolorcolor</td>
<td>#90EE90</td>
<td>Specifies the HTML color of the code ignored.</td>
</tr>
<tr>
<td>-xmlbcvrgfile</td>
<td></td>
<td>Export the block-coverage for the covered function in XML format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-xmlbcvrgfullfile</td>
<td></td>
<td>Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-xmlfcvrgfile</td>
<td></td>
<td>Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.</td>
</tr>
</tbody>
</table>
Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application's critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

**Top-Level Coverage**

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest.
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.
- By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  - Basic-block coverage
  - Function coverage
  - Function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.
The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. With one click you can see the least-covered function in the list, and with another click you can see the body of the function. You can scroll down in the source view and browse through the function body.

**Individual Module Source View**

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

**Setting the Coloring Scheme for the Code Coverage**

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covered code</td>
<td>#FFFFFF</td>
<td>Indicates code was exercised by the tests. You can override the default color with the <code>-ccolor</code> tool option.</td>
</tr>
<tr>
<td>Uncovered basic block</td>
<td>#FFFF99</td>
<td>Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed during the tests. You can override the default color with the <code>-bcolor</code> tool option.</td>
</tr>
<tr>
<td>Uncovered function</td>
<td>#FFCCCC</td>
<td>Indicates functions that were never called during the tests. You can override the default color with the <code>-fcolor</code> tool option.</td>
</tr>
<tr>
<td>Partially covered code</td>
<td>#FAFAD2</td>
<td>Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the <code>-pcolor</code> tool option.</td>
</tr>
<tr>
<td>Ignored code</td>
<td>#90EE90</td>
<td>Indicates code that was specifically marked to be ignored. You can override this default color using the <code>-xcolor</code> tool option.</td>
</tr>
<tr>
<td>Information lines</td>
<td>#FFFFFF</td>
<td>Indicates basic-block markers and dynamic counts. You can override the default color with the <code>-icolor</code> tool option.</td>
</tr>
<tr>
<td>Unknown</td>
<td>#FFFFFF</td>
<td>Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the <code>-ucolor</code> tool option.</td>
</tr>
</tbody>
</table>
The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

**NOTE**
You need to interpret the colors in the context of the code. For example, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks.

### Dynamic Counters

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the code is an `IF` statement:

```plaintext
11 IF ((N .EQ. 1).OR. (N .EQ. 0))
    ^ 10 (1/2)
12 PRINT N
    ^ 7
```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.
- Only one of the two blocks was executed, resulting in the partial coverage color.
- Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

### Differential Coverage

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run, and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

### Generating Reference Data
Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the -ref option. The following command demonstrate a typical command for generating the reference data:

**Example: generating reference data**

```
codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code with the same coverage property (covered or not covered) on both runs is considered covered code. Otherwise, if the new run indicates that the code was executed, while in the reference run the code was not executed, then the code is treated as uncovered. Alternately, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

**Running Differential Coverage**

To run the code coverage tool for differential coverage, you must have the application sources, the .spi file, and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of differential coverage analysis:

**Example**

```
codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi
```

Specify the .dpi and .spi files using the `-spi` and `-dpi` options.

**Excluding Code from Coverage Analysis**

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will be unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, lack of a test case is preferred. You may want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking portions of the code infeasible and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

**Including and Excluding Coverage at the File Level**

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the `-comp` option. The following example shows the general command:

**Example: specifying a component file**

```
codecov -comp file
```

where `file` is the name of a text file containing strings that act as file/directory name masks for including and excluding file-level analysis. For example, assume the following:

- You want to include all files with the string "source" in the file name or directory name.
- You create a component text file named `myComp.txt` with the selective inclusion string "source".
Once you have a component file, enter a command similar to the following:

```
Example

codecov -comp myComp.txt
```

In this example, filenames with string "source" (like source1.f and source2.f) and all files within directories where the directory name contains the string "source" (like source/file1.f and source2\file2.f) are included in the analysis.

To exclude files or directories, add the tilde (~) prefix to the string. You can specify inclusion and exclusion in the same component file. For example, assume you want to analyze all individual files or files in a directory where the file/directory name includes the string "source", and you want to exclude all individual files and files in directories where the file/directory name includes the string "skip". You add content similar to the following to the component file (myComp.txt) and pass it to the -comp option:

```
Example: inclusion and exclusion strings in the myComp.txt file

source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file, myComp.txt, instructs the tool to:

- Include files with filename containing "source" (like source1.f and source2.f)
- Include all files in directories with the directory name containing "source" (like source/file1.f and source2\file2.f)
- Exclude all files with filename containing "skip" (like skipthis1.f and skipthis2.f)
- Exclude all files in directories with the directory name containing "skip" (like skipthese1\debug1.f and skipthese2\debug2.f)

### Excluding Coverage at the Line and Function Level

You can mark individual lines for exclusion my passing string values to the -onelinedsbl option. For example, assume that you have some code similar to the following:

```
Sample code

print*, "ERROR: n  = ", n  ! NO_COVER
print*, "       n2 = ", n2  ! INF IA-32 architecture
```

If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following:

```
Example

codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.
Sample code

```fortran
subroutine dumpInfo (n)
  integer n ! NO_COVER
  ...
end subroutine
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the `-onelinedsbl` and `-xcolor` options. The following example commands demonstrate the combination:

Example: combining tool options

```bash
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

Excluding Code by Defining Arbitrary Boundaries

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the `-beginblkdsbl` and `-endblkdsbl` options to mark the beginning and end (respectively) of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

Sample code

```fortran
integer n, n2
n = 123
n2 = n*n
if (n2 .lt. 0) then
  ! /* BINF */
  print*, "ERROR: n  = ", n
  print*, "       n2 = ", n2
  ! // EINF
else if (n2 .eq. 0) then
  print*, "zero: n = ", n, " n2 = ", n2
else
  print*, "positive: n = ", n, " n2 = ", n2
endif
end
```

The following example commands demonstrate how to use the `-beginblkdsbl` option to mark the beginning and the `-endblkdsbl` option to mark the end of code to exclude from the sample shown above.

Example: arbitrary code marker commands

```bash
codecov -xcolor #CCFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the `-xcolor` option.
Exporting Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool:

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The -xmlfcvrg, -txtfcvrg, -xmlbcvrg and -txtbcvrg options support the first method.

- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The -xmlbcvrgfull and -txtbcvrgfull options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

**Quick Export**

The profile of covered functions of an application can be exported quickly using the -xmlfcvrg, -txtfcvrg, -xmlbcvrg, and -txtbcvrg options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

```
Example: quick export of function data

codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function, together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report:

```
XML-formatted report example

<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.F">
    <FUNCTION name="f0" freq="2">
      <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
    </FUNCTION>
    ...
  </MODULE>
  <MODULE name = "D:\SAMPLE2.F">
    ...
  </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.f, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.
You can also export the data in text format using the -txtfcvrg option. The generated text report, using this option, for the above example would be similar to the following example:

**Text-formatted report example**

<table>
<thead>
<tr>
<th>Function name</th>
<th>Execution frequency</th>
<th>Line number of the start of the function definition</th>
<th>Column number of the start of the function definition</th>
<th>Percentage of basic-block coverage of the function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;f0&quot;</td>
<td>2</td>
<td>6</td>
<td>5</td>
<td>83.33</td>
</tr>
<tr>
<td>&quot;f1&quot;</td>
<td>1</td>
<td>6</td>
<td>4</td>
<td>66.67</td>
</tr>
<tr>
<td>&quot;f2&quot;</td>
<td>1</td>
<td>6</td>
<td>3</td>
<td>50.00</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the text formatted version of the report, the each line of the report should be read in the following manner:

**Example: quick export of block data to XML**

```bash
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

**XML-formatted report example**

```xml
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cF90">
    <FUNCTION name="f0" freq="2">
      ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1"> </INSTANCE>
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2"> </INSTANCE>
        <INSTANCE id="2" freq="1"> </INSTANCE>
      </BLOCK>
    </FUNCTION>
  </MODULE>
</PROJECT>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.f90. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column 3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the -txtbcvrg option.

**Combined Exports**

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.
Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formats in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

**Dynamic Call Graphs**

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

**Test Prioritization Tool**

The test prioritization tool, also known as the tselect tool, enables the profile-guided optimizations on all supported Intel® architectures, on Linux*, Windows*, and macOS* operating systems, to select and prioritize tests for an application based on prior execution profiles.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool

**Features and Benefits**

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application. The tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing. Instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests' execution time.

See Understanding Profile-guided Optimization and Profile an Application topics for general information on creating the files needed to run this tool.

**Test Prioritization Tool Requirements**

The test prioritization tool needs the following items to work:

- The `.spi` file generated by Intel® compilers when compiling the application for the instrumented binaries with the `-prof-gen=srcpos` (Linux* and macOS*) or `/Qprof-gen:srcpos` (Windows*) option.
- The `.dpi` files generated by the profmerge tool as a result of merging the dynamic profile information `.dyn` files of each of the application tests. Run the profmerge tool on all `.dyn` files that are generated for each individual test and name the resulting `.dpi` in a fashion that uniquely identifies the test.
User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
- Name each test .dpi file so the file names uniquely identify each test.
- Create a .dpi list file, which is a text file that contains the names of all .dpi test files.
  
  Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.
  
  For example: Test1.dpi 00:00:60:35 states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.
  
  The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

Caution
The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code. The tool uses the following general syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
</table>
| tselect -dpi_list

-dpi_list is a required tool option that sets the path to the list file containing the list of all .dpi files. All other tool commands are optional.

**NOTE**
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

Usage Model
The following figure illustrates a typical test prioritization tool usage model.
Test Prioritization Tool Options

The tool uses the options that are listed in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-dpi_list &lt;file&gt;</td>
<td>Required. Specifies the name of the file that contains the names of the dynamic profile information (.dpi) files. Each line of the file must contain only one .dpi file name, which can be followed by its execution time (optional). The name must uniquely identify the test.</td>
</tr>
<tr>
<td>-spifile</td>
<td>Specifies the file name of the static profile information file (.SPI). Default is pgopti.spi</td>
</tr>
<tr>
<td>-ofile</td>
<td>Specifies the file name of the output report file.</td>
</tr>
<tr>
<td>-comp &lt;file&gt;</td>
<td>Specifies the file name that contains the list of files of interest.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-cutoff&lt;value&gt;</td>
<td>Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by value, of pre-computed total coverage. value must be greater than 0.0 (for example, 99.00) but not greater than 100. value can be set to 100.</td>
</tr>
<tr>
<td>-nototal</td>
<td>Instructs the tool to ignore the pre-compute total coverage process.</td>
</tr>
<tr>
<td>-mintime</td>
<td>Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the same line of dpi_list file, after the test name in dd:hh:mm:ss format.</td>
</tr>
<tr>
<td>-srcbasedir&lt;dir&gt;</td>
<td>Specifies a different top-level project directory than was used during compiler instrumentation run with the prof-src-root compiler option to support relative paths to source files in place of absolute paths.</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to generate more logging information about program progress.</td>
</tr>
</tbody>
</table>

### Running the Tool

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

   **Example**
   ```
   set PROF_DIR=c:\myApp\prof-dir
   ```

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

   **Operating System** | **Command** |
   ----------------------|-------------|
   Linux and macOS*      | `ifort -prof-gen=srcpos myApp.f90` |
   Windows               | `ifort /Qprof-gen:srcpos myApp.f90` |

   The commands shown above compile the program and generate instrumented binary `myApp`, as well as the corresponding static profile information `pgopti.spi`.

3. Confirm that unrelated `.dyn` files are not present by issuing a command similar to the following:

   **Example**
   ```
   rm prof-dir \*.*
   ```

4. Run the instrumented files by issuing a command similar to the following:

   **Example**
   ```
   myApp < data1
   ```
The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by the -prof-dir step above.

5. Merge all .dyn file into a single file by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test1.dpi
```

The profmerge tool merges all the .dyn files into one file (Test1.dpi) that represents the total profile information of the application on Test1.

6. Confirm again there are no unrelated .dyn files present a second time by issuing a command similar to the following:

```
Example
rm prof-dir \*.dyn
```

7. Run the instrumented application, and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified in the prof-dir step above by issuing a command similar to the following:

```
Example
myApp < data2
```

8. Merge all .dyn files into a single file by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test2.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test2.dpi) that represents the total profile information of the application on Test2.

9. Confirm that there are no unrelated .dyn files present for the final time by issuing a command similar to the following:

```
Example
rm prof-dir \*.dyn
```

10. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified by -prof-dir by issuing a command similar to the following:

```
Example
myApp < data3
```

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test3.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test3.dpi) that represents the total profile information of the application on Test3.

12. Create a file named tests_list with three lines. The first line contains Test1.dpi, the second line contains Test2.dpi, and the third line contains Test3.dpi.

Tool Usage Examples
When these items are available, the test prioritization tool may be launched from the command line in the prof-dir directory as described in the following examples.

**Example 1: Minimizing the Number of Tests**
The following example describes how minimize the number of test runs.

**Example Syntax**
```
tselect -dpi_list tests_list -spi pgopti.spi
```
where the `-spi` option specifies the path to the `.spi` file.

The following sample output shows typical results.

**Sample Output**
```
Total number of tests   =  3
Total block coverage    ~  52.17
Total function coverage ~  50.00

num  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
---  --------  --------  --------  -------------------
 1   87.50     45.65     37.50    Test3.dpi
 2   100.50    52.17     50.00    Test2.dpi

In this example, the results provide the following information:

- By running all three tests, you achieve 52.17% block coverage and 50.00% function coverage.
- Test3 alone covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, you achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

**Example 2: Minimizing Execution Time**
Assume you have the following execution time of each test in the `tests_list` file:

**Sample Output**
```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `-mintime` option:

**Sample Syntax**
```
tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:
Sample Output

<table>
<thead>
<tr>
<th>Total number of tests</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total block coverage</td>
<td>~ 52.17</td>
</tr>
<tr>
<td>Total function coverage</td>
<td>~ 50.00</td>
</tr>
<tr>
<td>Total execution time</td>
<td>1:41:35</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>num</th>
<th>elapsedTime</th>
<th>%RatCvrg</th>
<th>%BlkCvrg</th>
<th>%FncCvrg</th>
<th>Test Name @ Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10:15</td>
<td>75.00</td>
<td>39.13</td>
<td>25.00</td>
<td>Test2.dpi</td>
</tr>
<tr>
<td>2</td>
<td>41:00</td>
<td>100.00</td>
<td>52.17</td>
<td>50.00</td>
<td>Test3.dpi</td>
</tr>
</tbody>
</table>

In this case, the results indicate that running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests when based on minimizing time (first Test2, then Test3) may be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

Using Other Options

The `-cutoff` enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to use the option:

```
Example
tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-cutoff` enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

Profmerge and Proforder Tools

Profmerge Tool

Use the profmerge tool to merge dynamic profile information (.dyn) files and any specified summary files (.dpi). The compiler executes profmerge automatically during the feedback compilation phase when you specify the `-prof-use` option.

The command-line usage for profmerge is as follows:

```
Syntax
profmerge [-prof_dir dir_name]
```

The tool merges all .dyn files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: pgopti.dpi.
NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example [Q]prof-dir) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-") unlike Windows* compiler options, which are preceded by a forward slash ("/").

You can use profmerge tool to merge .dyn files into a .dpi file without recompiling the application. You can run the instrumented executable file on multiple systems to generate .dyn files, and optionally use profmerge with the -prof_dpi option to name each summary .dpi file created from the multiple .dyn files.

Because the profmerge tool merges all the .dyn files that exist in the given directory, confirm that unrelated .dyn files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

Profmerge Options
The profmerge tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dump</td>
<td>Displays profile information.</td>
</tr>
<tr>
<td>-help</td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-exclude_filesfiles</td>
<td>Excludes functions from the profile if the function comes from one of the listed files. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot;) as a wild card character in function names.</td>
</tr>
<tr>
<td>-exclude_funcsfunctions</td>
<td>Excludes functions from the profile. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot;) as a wild card character in function names.</td>
</tr>
<tr>
<td>-prof_dirdir</td>
<td>Specifies the directory from which to read .dyn and .dpi files, and write the .dpi file. Alternatively, you can set the environment variable PROF_DIR.</td>
</tr>
<tr>
<td>-prof_dpifile</td>
<td>Specifies the name of the .dpi file being generated.</td>
</tr>
<tr>
<td>-prof_filefile</td>
<td>Merges information from file matching: dpi_file_and_dyn_tag.</td>
</tr>
<tr>
<td>-src_olddir-src_newdir</td>
<td>Changes the directory path stored within the .dpi file.</td>
</tr>
<tr>
<td>-no_src_dir</td>
<td>Uses only the file name and not the directory name when reading dyn/dpi records. If you specify -no_src_dir, the directory name of the source file is ignored.</td>
</tr>
<tr>
<td>Tool Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-src-rootdir</td>
<td>Specifies a directory path prefix for the root directory where the user’s application files are stored. This option is ignored if you specify <code>-no_src_dir</code>.</td>
</tr>
<tr>
<td>-file1.dpi...fileN.dpi</td>
<td>Specifies and merges available .dpi files.</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to display full information during merge.</td>
</tr>
<tr>
<td>-weighted</td>
<td>Instructs the tool to apply an equal weighting (regardless of execution times) to the .dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.</td>
</tr>
<tr>
<td>-gen_weight_spec file</td>
<td>Instructs the tool to generate a text file containing a list of the .dyn and .dpi file that were merged with default weight=1/run_count. The text file is created in the directory specified by the prof_dir option.</td>
</tr>
<tr>
<td>-weight_spec weight_spec.txt</td>
<td>Instructs the profmerge tool to generate and use the text file, weight_spec.txt, listing individual .dyn/.dpi files or directory names along with weight values for them. When the <code>-weight_spec</code> option is used:</td>
</tr>
<tr>
<td></td>
<td>• A new .dpi file is always created</td>
</tr>
<tr>
<td></td>
<td>• Only files called out by the specification file are merged</td>
</tr>
<tr>
<td></td>
<td>• .dyn timestamps are ignored and merge always takes place</td>
</tr>
<tr>
<td></td>
<td>The prof_dir option controls where the input/output weight_spec.txt is located, and the destination of the .dpi file.</td>
</tr>
<tr>
<td></td>
<td>The -weight_spec option overrides:</td>
</tr>
<tr>
<td></td>
<td>• Any values of -a option</td>
</tr>
<tr>
<td></td>
<td>• Any computation from using -weighted option</td>
</tr>
</tbody>
</table>

**Weighting the Runs**

Using the `-weight_spec` option results in a new .dpi file. Only the files listed in the text file are merged. No files in the current directory are used unless they are included in the text file.

**Relocating source files using profmerge**
The Intel® Fortran Compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (.dpi) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading .dyn/.dpi file records by specifying the profmerge option -no_scr_dir. This profmerge option is the same as the compiler option -no-prof-src-dir (Linux* and macOS*) and /Qprof-src-dir- (Windows*).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the profmerge option -src-root to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair -src_old-src_new to modify the data in an existing summary dpi file. For example:

**Example: relocation command syntax**

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where `<dir1>` is the full path to dynamic information file (.dpi), `<dir2>` is the old full path to source files, and `<dir3>` is the new full path to source files. The example command (above) reads the pgopti.dpi file, in the location specified in `<dir1>`. For each routine represented in the pgopti.dpi file, whose source path begins with the `<dir2>` prefix, profmerge replaces that prefix with `<dir3>`. The pgopti.dpi file is updated with the new source path information.

You can run profmerge more than once on a given pgopti.dpi file. For example, you may need to do this if the source files are located in multiple directories:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command Examples</th>
</tr>
</thead>
</table>
| Linux* and macOS*| profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2  
profmerge -prof_dir -src_old /proj_1 -src_new /proj_2 |
| Windows*         | profmerge -src_old "c:/program files" -src_new "e:/program files"  
profmerge -src_old c:/proj/application -src_new d:/app |

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical in Windows. Likewise, forward slash (`/`) and backward slash (`\`) characters are treated as identical.

**NOTE**

Because the source relocation feature of profmerge modifies the pgopti.dpi file, consider making a backup copy of the file before performing the source relocation.

**Proforder Tool**

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the /ORDER linker option in Windows. The tool uses the following syntax:

**Syntax**

```
proforder [-prof_dir dir] [-o file]
```

where `dir` is the directory containing the profile files (.dpi and .spi), and `file` is the optional name of the function order list file. The default name is proford.txt.
NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example `-prof_dir`) instead of the hyphen used by compiler options (for example `[-prof-dir]`) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-"), unlike Windows* compiler options, which are preceded by a forward slash ("/").

**Proforder Options**

The proforder tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-help</code></td>
<td></td>
<td>Lists supported options.</td>
</tr>
<tr>
<td><code>-nologo</code></td>
<td></td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td><code>-omit_static</code></td>
<td></td>
<td>Instructs the tool to omit static functions from function ordering.</td>
</tr>
<tr>
<td><code>-prof_dir</code></td>
<td><code>dir</code></td>
<td>Specifies the directory where the <code>.spi</code> and <code>.dpi</code> file reside.</td>
</tr>
<tr>
<td><code>-prof_dpi</code></td>
<td><code>file</code></td>
<td>Specifies the name of the <code>.dpi</code> file.</td>
</tr>
<tr>
<td><code>-prof_file</code></td>
<td><code>string</code></td>
<td>Selects the <code>.dpi</code> and <code>.spi</code> files that include the substring value in the file name matching the values passed as string.</td>
</tr>
<tr>
<td><code>-prof_spi</code></td>
<td><code>file</code></td>
<td>Specifies the name of the <code>.spi</code> file.</td>
</tr>
<tr>
<td><code>-o</code></td>
<td><code>file</code></td>
<td>Specifies an alternate name for the output file.</td>
</tr>
</tbody>
</table>

**Supported Environment Variables**

Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option `[Q]ipo`, you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the procedures and data in your application. These optimizations are not supported on macOS* systems.

The following table lists each optimization, the type of procedures or global data it applies to, and the operating systems and architectures that it is supported on.

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type of Procedure or Data</th>
<th>Supported OS and Architectures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function Order Lists:</td>
<td><code>EXTERNAL</code> procedures and library procedures only (not other types of static procedures).</td>
<td>Windows: all Intel architectures, Linux: not supported</td>
</tr>
</tbody>
</table>
### Optimization

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type of Procedure or Data</th>
<th>Supported OS and Architectures</th>
</tr>
</thead>
<tbody>
<tr>
<td>by improving code locality and reduce paging. Also see Comparison of Function Order Lists and IPO Code Layout.</td>
<td><strong>EXTERNAL</strong> procedures and static procedures only (not library procedures).</td>
<td>Linux: IA-32 and Intel 64 architectures. Windows: not supported.</td>
</tr>
<tr>
<td><strong>Function Grouping:</strong> Specifies that the linker should place the extern and static routines (procedures) of your program into hot or cold program sections. This optimization can improve application performance by improving code locality and reduce paging.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong> This option will cause functions to be placed into the linker sections named &quot;.text.hot&quot; and &quot;.text.unlikely.&quot; If you are using a custom linker script, you will need to specify memory placement for these sections.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Function Ordering:</strong> Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging.</td>
<td><strong>EXTERNAL</strong> procedures and static procedures only (not library procedures).</td>
<td>Linux and Windows: all Intel architectures.</td>
</tr>
<tr>
<td><strong>Data Ordering:</strong> Enables ordering of static global data items (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.</td>
<td>Static global data (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) only.</td>
<td>Linux and Windows: all Intel architectures.</td>
</tr>
</tbody>
</table>

You can only use one of the function-related ordering optimizations listed above on each application. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the **prof-gen** option keyword **globdata** (needed for Data Ordering) instead of **srcpos** (needed for function-related ordering).
The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the \texttt{\texttt{\texttt{-ipo}}} or equivalent compiler option.

### Generating a Function Order List (Windows)

This section provides an example of the process for generating a function order list. Assume you have a Fortran program that consists of the following files: \texttt{file1.f90} and \texttt{file2.f90}. Additionally, assume you have created a directory for the profile data files called \texttt{c:\profdata}. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the \texttt{/Qprof-gen:srcpos} option. Use the \texttt{/Qprof-dir} option to specify the directory location of the profile files. This step creates an instrumented executable.

   **Example commands**
   
   \begin{verbatim}
   ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90
   \end{verbatim}

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

   **Example commands**
   
   \begin{verbatim}
   myprog.exe
   \end{verbatim}

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the \texttt{profmerge} tool to produce the \texttt{pgopti.dpi} file. Use the \texttt{/prof_dir} option to specify the directory location of the .dyn files.

   **Example commands**
   
   \begin{verbatim}
   profmerge /prof_dir c:\profdata
   \end{verbatim}

4. Generate the function order list using the \texttt{proforder} tool. By default, the function order list is produced in the file \texttt{proford.txt}.

   **Example commands**
   
   \begin{verbatim}
   proforder /prof_dir c:\profdata /o myprog.txt
   \end{verbatim}

5. Compile the application with the generated profile feedback by specifying the \texttt{ORDER} option to the linker. Use the \texttt{/Qprof-dir} option to specify the directory location of the profile files.

   **Example commands**
   
   \begin{verbatim}
   ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /link /ORDER:@MYPROG.txt
   \end{verbatim}

### Using Function Grouping (Linux)

This section provides a general example of the process for using the function grouping optimization. Assume you have a Fortran program that consists of the following files: \texttt{file1.f90} and \texttt{file2.f90}. Additionally, assume you have created a directory for the profile data files called \texttt{profdata}. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the \texttt{-prof-gen} option. Use the \texttt{-prof-dir} option to specify the directory location of the profile files. This step creates an instrumented executable.

   **Example commands**
   
   \begin{verbatim}
   ifort -o myprog -prof-gen -prof-dir ./profdata file1.f90 file2.f90
   \end{verbatim}
2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

```
Example commands

./myprog
```

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the -prof-func-group option to request the function grouping as well as the -prof-use option to request feedback compilation. Again, use the -prof-dir option to specify the location of the profile files.

```
Example commands

ifort /exe:myprog file1.f90 file2.f90 -prof-func-group -prof-use -prof-dir ./profdata
```

**NOTE** On Linux, the –prof-func-group option is on by default when –prof-use is selected.

Finer grain control over the number of functions placed into the hot region can be controlled with the -prof-hotness-threshold compiler option, see the command line reference for more details.

### Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows) option. Use the `-prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

```
Operating System          Example commands

Linux                      ifort -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.f90 file2.f90
Windows                    ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

```
Operating System          Example commands

Linux                      ./myprog
Windows                    myprog.exe
```

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the `-prof-func-order` option to request the function ordering, as well as the `-prof-use` option to request feedback compilation. Again, use the `-prof-dir` option to specify the location of the profile files.
Using Data Ordering

This section provides an example of the process for using the data order optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the -prof-gen=globdata (Linux) or /Qprof-gen:globdata (Windows) option. Use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-gen=globdata -prof-dir ./profdata file1.f90 file2.f90 -prof-func-order-prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-gen:globdata /Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-func-order /Qprof-use</td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
</tbody>
</table>

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the [Q]prof-data-order option to request the data ordering as well as the [Q]prof-use option to request feedback compilation. Again, use the [Q]prof-dir option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-data-order-prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-data-order/Qprof-use</td>
</tr>
</tbody>
</table>
Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the `/Qipo` (Windows) compiler option

Each method has advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions (external and library functions whose names are exposed to the linker).

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Function Order List Effects

<table>
<thead>
<tr>
<th>Function Type</th>
<th>IPO Code Layout</th>
<th>Function Ordering with proforder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static</td>
<td>X</td>
<td>No effect</td>
</tr>
<tr>
<td>Extern</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Library</td>
<td>No effect</td>
<td>X</td>
</tr>
</tbody>
</table>

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
- You must compile with `/Gy` to enable function-level linking. (This option is active if you specify either option `/O1` or `/O2`.)

Compiler Option Mapping Tool

The Intel compiler's Option Mapping Tool provides an easy method to derive equivalent options between Windows* and Linux* operating systems. For example, a Windows developer who is developing an application may want to know the Linux equivalent for the `/Oy`- option. Likewise, the Option Mapping Tool provides Windows OS equivalents for Intel compiler options supported on Linux.

**NOTE**
The Compiler Option Mapping Tool does not support selecting OS* X. However, because Linux and macOS* use the same options in almost all cases, specify "tlinux" if targeting macOS*.

Using the Compiler Option Mapping Tool

You can start the Option Mapping Tool from the command line by:

- Invoking the compiler and using the `/Qmap-opts` option
- Invoking the compiler and using the `-map-opts` option
- Executing the tool directly

**NOTE**
The Compiler Option Mapping Tool only maps compiler options on the same architecture. It will not map an option that is specific to the Intel® 64 architecture to a like option available on the IA-32 architecture.

Calling the Option Mapping Tool with the Compiler
If you use the compiler to execute the Option Mapping Tool, the following syntax applies:

```
<compiler command> <map-opts option> <compiler option(s)>
```

**Example: Finding the Linux equivalent for /Oy-**

```
ifort /Qmap-opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for Fortran
'--map-opts' Windows option maps to
---> '-map-opts' option on Linux
---> '-map_opts' option on Linux
'-Oy-' Windows option maps to
---> '-fomit-frame-pointer-' option on Linux
---> '-fno-omit-frame-pointer' option on Linux
---> '-fp' option on Linux
```

**Example: Finding the Windows equivalent for -fp**

```
ifort -map-opts -fp
Intel(R) Compiler option mapping tool
mapping Linux options to Windows for Fortran
'-map-opts' Linux option maps to
---> '-Qmap-opts' option on Windows
---> '-Qmap_opts' option on Windows
'-fp' Linux option maps to
---> '-Oy-' option on Windows
```

**NOTE**
Output from the Option Mapping Tool also includes:

- Option mapping information (not shown here) for options included in the compiler configuration file
- Alternate forms of the options that are supported but may not be documented

When you call the Option Mapping Tool with the compiler, the source file is not compiled.

**Calling the Option Mapping Tool Directly**

Use the following syntax to execute the Option Mapping Tool directly from a command line environment where the full path to the `map_opts` executable is known (compiler bin directory):

```
map_opts -t<target OS> -l<language> -opts <compiler option(s)>
```

where values for:

- `<target OS> = {l|linux|w|windows}`
- `<language> = {f|fortran|c}`

**Example: Finding the Linux equivalent for /Oy-**

```
map_opts -tl -lf -opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for Fortran
'-Oy-' Windows option maps to
---> '-fomit-frame-pointer-' option on Linux
---> '-fno-omit-frame-pointer' option on Linux
---> '-fp' option on Linux
```

**Example: Finding the Windows equivalent for -fp**
map_opts -tw -lf -opts -fp
Intel(R) Compiler option mapping tool
mapping Linux options to Windows for Fortran
'fp' Linux option maps to
--> '-Oy-' option on Windows

Offload Extract Tool
This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Description
The Offload Extract tool is a standalone tool that extracts embedded target objects from fat objects and embedded target binaries from fat executables on Windows* and Linux* systems. The tool can be used for Intel® MIC Architecture related offload extraction. For simplicity, in this topic, the Intel® MIC Architecture target objects and executables will be referred to as Intel® MIC target objects and executables.

Features and Benefits
By default, you cannot use analyzing and debugging tools like objdump and readelf to directly examine offload Intel® MIC objects/binaries because they are embedded in the host object or binary.

Use the Offload Extract tool to extract Intel® MIC object/binary from a fat object/binary on 64-bit Linux* or 64-bit Windows* systems. The extracted object/binary is an ELF object that can be analyzed with objdump or readelf analyzing tools.

Using the Tool
To extract the target object files, invoke the offload extract tool as follows:

    offload_extract  <fat host object>

The Intel® MIC target objects are extracted into object files with the same name as the input object file but with the substring Intel® MIC appended to the filename. Since the target objects are in ELF format the object file name extension will be .o. For example,

    offload_extract host.obj => hostMIC.o

To extract the target executables, invoke the offload extract tool as follows:

    offload_extract  <fat host binary>

The Intel® MIC target executables are extracted into target executable files with the same name as the input object file but with the file extension Intel® MIC added. For example,

    offload_extract host.exe => hostMIC.mic

NOTE
To extract the target object files from an archived library, you must first extract the individual fat objects from the fat archived library and then invoke the offload extract tool on the individual fat objects. For example:

    ar -x libhost.a
    offload_extract <individual fat host object>
Using Options

There are two options you can use to fine tune your extraction of offload binaries or executables.

Use the \texttt{-o} option to specify target filename or output directory. The syntax for the option is as follows:

\begin{verbatim}
offload_extract <fat host object|binary> [-o <output filename>]
offload_extract <fat host object|binary> [-o <output directory>]
\end{verbatim}

When you use the \texttt{-o} option the target output filename and directory are generated without the Intel® MIC substring.

Use the \texttt{-target} option to select specific target Intel® MIC objects/executables to be extracted. The syntax for the option is as follows:

\begin{verbatim}
offload_extract <fat host object|binary> [-target mic]
\end{verbatim}
Compatibility and Portability

Portability Considerations Overview

This section presents topics to help you understand how language standards, operating system differences, and computing hardware influence your use of Intel® Fortran and the portability of your programs.

Your program is portable if you can implement it on one hardware-software platform and then move it to additional systems with minimum changes to the source code. Correct results on the first system should be correct on the additional systems. The number of changes you might have to make when moving your program varies significantly. You might have no changes at all (strictly portable), or enough that it is more efficient to design or implement a new program (non-portable customization). Most programs in their lifetime will need to be ported from one system to another, and this section can help you write code that makes this easy.

Understanding Fortran Language Standards

Understanding Fortran Language Standards Overview

A language standard specifies the form and establishes the interpretation of programs expressed in the language. Its primary purpose is to promote portability of programs across a variety of systems among vendors and users.
The vendor-user community has adopted a series of major Fortran language standards. The primary organizations that develop and publish the standards are the InterNational Committee for Information Technology Standards (INCITS) and International Standards Organization (ISO).

The major Fortran language standards are:

- **Fortran 2018**
  
  The Fortran Standards group is working on a revision to Fortran 2008, which is called Fortran 2018. There is a Fortran 2018 document in progress, which introduces further support for interoperability with the C language, including assumed type and assumed rank arrays, C descriptors, and the RANK intrinsic.

- **Fortran 2008**
  
  American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2010, Information technology -- Programming languages -- Fortran. This standard introduces support for submodules and coarrays, and includes various performance enhancements such as the DO CONCURRENT construct. For more information on supported Fortran 2008 language features, see the Intel® Fortran Language Reference.

- **Fortran 2003**
  

- **Fortran 95**
  
  American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1: 1997(E), Information technology -- Programming languages -- Fortran. This standard introduces certain language elements and corrections into Fortran 90. Fortran 95 includes Fortran 90 and most features of FORTRAN 77. For information about differences between Fortran 95 and Fortran 90, see the Intel® Fortran Language Reference.

- **Fortran 90**
  

- **FORTRAN 77**
  
  American National Standard Programming Language FORTRAN, ANSI X3.9-1978. This standard added new features based on vendor extensions to FORTRAN IV and addressed problems associated with large-scale projects, such as improved control structures.

- **FORTRAN IV**
  
  American National Standard Programming Language FORTRAN, ANSI X3.9-1966. This was the first attempt to standardize the languages called FORTRAN by many vendors.

Although a language standard seeks to define the form and the interpretation uniquely, a standard may not cover all areas of interpretation. It may also include some ambiguities. You need to carefully craft your program in these cases to insure that you get the desired answers when producing a portable program.

Language Standards Conformance

### Using Standard Features and Extensions

**Standard Features**

Use standard language features to achieve the greatest degree of portability for your Intel® Fortran programs. You can design a robust implementation to improve the portability of your program, or you can choose to use extensions to the standard to increase the readability, functionality, and efficiency of your programs.
You can request that the compiler warn you about program syntax that violates the standard’s numbered syntax rules and constraints. While this does not insure that the program as a whole is standard-conforming, it can help to avoid many possible compatibility issues. The /stand (Windows*) or -std (Linux* and macOS*) options enable this checking, and you can specify the desire standard to check against. If you do not specify a standard, Fortran 2008 is used.

You can use the standard-semantics compiler option to enable all of the options that implement the current Fortran Standard behavior of the compiler where those differ from the compiler’s default.

**Standard Extensions**

Not all extensions to the Fortran standard cause problems when porting to other platforms. Many extensions are supported on a wide range of platforms, and if a system you are porting a program to supports an extension, there is no reason to avoid using it. There is no guarantee, however, that the same feature on another system will be implemented in the same way as with Intel® Fortran. Only the Fortran standard is guaranteed to coexist uniformly on all platforms.

The Intel® Fortran Compiler supports many language extensions on multiple platforms, including Linux*, macOS*, and Microsoft Windows* operating systems. The Intel® Fortran Language Reference Manual identifies whether each language element is supported on other platforms.

It is a good programming practice to declare any external procedures either in an EXTERNAL statement or in a procedure interface block, for the following reasons:

- The newer Fortran standards have added many new intrinsic procedures to the language.
  
  Programs that conformed to earlier Fortran Standards (such as FORTRAN 77) may include non-intrinsic functions or subroutines having the same name as new Fortran Standard procedures.

- Some processors include nonstandard intrinsic procedures that might conflict with procedure names in your program.

If you do not explicitly declare the external procedures and the name duplicates an intrinsic procedure, the processor calls the intrinsic procedure, not your external routine. For more information on how the Intel® Fortran Compiler resolves name definitions, see Resolving Procedure References.

**See Also**

stand compiler option
standard-semantics compiler option
Resolving Procedure References

**Using Compiler Optimizations**

Many Fortran compilers perform code-generation optimizations to increase the speed of execution or to decrease the required amount of memory for the generated code. Although the behaviors of both the optimized and non-optimized programs fall within the language standard specification, different behaviors can occur in areas not covered by the language standard. Compiler optimization can influence floating-point numeric results.

The Intel® Fortran Compiler can perform optimizations to increase execution speed and to improve floating-point numerical consistency.

Floating-point consistency refers to obtaining results consistent with the IEEE binary floating-point standards. For more information, refer to the /fp:consistent option of fp-model.

<table>
<thead>
<tr>

Conformance, Compatibility, and Fortran Features

Language Standards Conformance

The Fortran standard has undergone several revisions since its initial publication as FORTRAN IV (also known as FORTRAN 66). Subsequent revisions have been FORTRAN 77, Fortran 90, Fortran 95, Fortran 2003, Fortran 2008, and Fortran 2018. Each revision has added new features; some revisions have labeled features as "deprecated" (or obsolescent) or they have removed them. Intel® Fortran continues to support deprecated and deleted features.

It also includes support for some features from the Fortran 2018 standard.

The Fortran Standards committee is currently answering questions of interpretation on Fortran 2008 language features. Any answers given by the committee that are related to features implemented in Intel® Fortran may result in changes in future releases of the Intel® Fortran Compiler, even if the changes produce incompatibilities with earlier releases of Intel® Fortran. The Fortran 2018 standard is in the final stages of development but subject to change. Changes to the Fortran 2018 standard may produce incompatibilities in future releases of Intel® Fortran with respect to the Fortran 2018 features included in this release.

Intel Fortran provides a number of extensions to the Fortran 2008 Standard. In the language reference, extensions (non-standard features) are displayed in this color.

Language Compatibility

Intel® Fortran is highly source-compatible with Compaq* Visual Fortran on supported systems, and it is substantially source-compatible with DEC* Fortran 90 and VAX* FORTRAN 77.

Fortran 2018 Features

The following Fortran 2018 features are new in this release:

\(^2\) This is the same as International Standards Organization standard ISO/IEC 1539-1:1997 (E).

\(^3\) This is the same as International Standards Organization standard ISO/IEC 1539:1991 (E).
• The **COSHAPE** intrinsic function
  Returns the cobounds of a coarray argument.
• You can now add module names, OpenMP reduction identifiers, and defined I/O generic specs to **PUBLIC** and **PRIVATE** statements.
• Features to provide synchronization capabilities between images:
  The **EVENT_QUERY** intrinsic subroutine
  The **EVENT_POST** and **EVENT_WAIT** statements
  The derived type **EVENT_TYPE** in the **ISO_FORTRAN_ENV** intrinsic module
• Enhancements to the **IMPORT** statement
  The **IMPORT** statement can now be used in internal subprograms and BLOCK constructs to control host association. There are three new forms:
  IMPORT, ALL
  IMPORT, NONE
  IMPORT, ONLY: *import-name-list*
• Default accessibility of module entities
  A module name that is accessed via used association can appear in a **PUBLIC** or **PRIVATE** *access-id-list*. It can be used to set the default accessibility for all accessible entities from that module.
• C language interoperability
  An assumed-rank array is now permitted to be an argument to the **C_SIZEOF** intrinsic function.
  With the exception of **C_F_POINTER**, all standard procedures in the **ISO_C_BINDING** intrinsic module are now **PURE**.
• Enhancement to the **NON_RECURSIVE** keyword
  This keyword allows procedures to be declared as not recursive. The default in previous Fortran standards was that procedures were non-recursive unless declared **RECURSIVE**. Fortran 2018 changes that default. Intel® Fortran has implemented the **NON_RECURSIVE** keyword, but the default compilation mode for this release remains non-recursive. This will change in a future release.
• I/O enhancement
  The **G0.d** edit descriptor can be used to specify the output of integer, logical, and character data, using the rules for **I0**, **L1**, and **A** edit descriptors, respectively.

The following Fortran 2018 features are also supported:
• Further Interoperability of Fortran with C, including assumed-type, assumed-rank, C descriptors, and the **RANK** intrinsic.
• The **ERROR STOP** statement is allowed in **PURE** procedures

For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.

New Language Features
Fortran 2003 Features
Fortran 2008 Features

**Fortran 2008 Features**

The following Fortran 2008 features are new in this release:
• Specification expressions can now contain user-defined operators.
• Direct access user-defined I/O has been implemented.

The following Fortran 2008 features are also supported:
• The **FINDLOC** intrinsic function
• You can specify optional argument **BACK** in **MAXLOC** and **MINLOC** intrinsic functions.
• You can declare multiple type-bound procedures in a PROCEDURE list.
• Intrinsic assignment to an allocatable polymorphic variable is allowed if the variable is not a coarray. For more information, see Examples of Intrinsic Assignment to Polymorphic Variables.
• The intrinsic module functions COMPILER_OPTIONS and COMPILER_VERSION
• Subscripts and nested implied-DO limits in a data statement can be any constant expression instead of being limited to combinations of constants, implied-DO variables, and intrinsic operations.
• The intrinsic functions ACOS, ACOSH, ASIN, ASINH, ATAN, ATANH, COSH, SINH, TAN, and TANH now take arguments of type COMPLEX. The intrinsic function ATAN(Y, X) is defined as ATAN2(Y, X).
• A pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute.
• A reference to a function that returns a data pointer is treated as a variable and is permitted in any variable-definition context.
• Allocatable components are allowed to be of recursive type, that is, the type being defined, or of a forward type, that is, a derived type that is not yet defined.
• In an ALLOCATE statement, you can specify more than one allocate object for a given SOURCE= or MOLD=. Also, if you do not specify upper and lower bounds in an ALLOCATE statement's s-spec list, the shape of the array is that of SOURCE=source-expr or MOLD=source-expr.
• Initialization expressions are now referred to as constant expressions.
• An EXIT statement can appear in a BLOCK, IF, ASSOCIATE, SELECT CASE, or SELECT TYPE construct.
• You can specify intrinsic types in a TYPE statement.
• You can specify implied-shape array specifications for named constant arrays.
• You can specify %re and %im designators for the real and imaginary parts of values of COMPLEX type.

• Pointer Initialization
• Binary, octal, and hexadecimal constants are allowed for one or more arguments in intrinsic routines BGE, BGT, BLE, BLT, CMPLX, DBLE, DSHIFTL, DSHIFTR, IAND, IEOR, INT, IOR, MERGE_BITS, and REAL.
• You can specify an optional integer datatype for the subscript-name in the triplet-spec in the FORALL statement.
• An ALLOCATE statement can give a polymorphic variable the shape and type of another variable without copying the value. This is done with MOLD= replacing SOURCE=.
• Except for procedure arguments and pointer dummy arguments, a PURE function may have a dummy argument with the VALUE attribute without the explicit INTENT(IN) attribute.
• Dummy arguments of ELEMENTAL procedures may appear in specification expressions in the procedure.
• You can specify an optional RADIX argument for the intrinsic function SELECTED_REAL_KIND and the intrinsic module procedure IEEE_SELECTED_REAL_KIND.
• Submodules
• IMPURE keyword
• The EXECUTE_COMMAND_LINE subroutine
• The BLOCK construct
• The FUNCTION and SUBROUTINE keywords on the END statement are optional for internal procedures and module procedures.
• A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign.
• Generic resolution of procedures where one dummy argument has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN), or where one is a procedure and the other is a data object.
• The ENTRY statement is an obsolescent feature.
• A source statement can begin with one or more semicolon characters.
• Coarray intrinsic routines: ATOMIC_DEFINE and ATOMIC_REF
• A polymorphic MOLD= specifier for ALLOCATE
• Coarrays (Windows* and Linux* only)
• Image control statements: SYNC ALL, SYNC IMAGES, SYNC MEMORY, CRITICAL, LOCK, and UNLOCK
• Coarray intrinsic routines: IMAGE_INDEX, LCOBOUND, NUM_IMAGES, THIS_IMAGE, and UCOBOUND
• CRITICAL construct
• Maximum array rank of 15 (Intel® Fortran allows 31 dimensions)
• G0 and G0.d format edit descriptors
• FINAL routines
• GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
• A generic interface may have the same name as a derived type.
• Bounds specification and bounds remapping list on a pointer assignment
• In formatting, a * indicates an unlimited repeat count
• NEWUNIT= specifier in OPEN
• A CONTAINS section can be empty
• Attributes CODIMENSION and CONTIGUOUS
• Coarrays can be specified in ALLOCATABLE, ALLOCATE, and TARGET statements
• MOLD keyword in ALLOCATE
• DO CONCURRENT statement
• ERROR STOP statement
• Intrinsic functions BESSEL_J0, BESSEL_J1, BESSEL_JN, BESSEL_Y0, BESSEL_Y1, BESSEL_YN, BGE, BGT,
BLE, BLT, DSHIFTL, DSHIFTR, ERF, ERFC, ERFC_SCALED, GAMMA, HYPOT, IALL, IANY, IPARITY,
IS_CONTIGUOUS, LEADZ, LOG_GAMMA, MASKL, MASKR, MERGE_BITS, NORM2, PARITY, POPCNT,
POPPAR, SHIFTA, SHIFTL, SHIFTR, STORAGE_SIZE, TRAILZ
• ISO_FORTRAN_ENV module constants ATOMIC_INT_KIND, ATOMIC_LOGICAL_KIND, CHARACTER_KINDS,
INTEGER_KINDS, INT8, INT16, INT32, INT64, LOGICAL_KINDS, REAL_KINDS, REAL32, REAL64, REAL128,
STAT_LOCKED, STAT_LOCKED_OTHER_IMAGE, STAT_UNLOCKED
• ISO_FORTRAN_ENV type LOCK_TYPE
• SCALAR keyword for ALLOCATED

For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.

Fortran 2003 Features
Fortran 2018 Features

Fortran 2003 Features

Fortran 2003 is fully supported, including the following features:
• Parameterized derived types with KIND and LENGTH type parameters and the %KIND and %LEN type
parameter designators
• A polymorphic dummy argument that has the attribute INTENT(OUT) becomes UNDEFINED or it will have
DEFAULT INITIALIZATION applied.
• User-Defined Derived-Type I/O
• A polymorphic SOURCE= specifier for ALLOCATE
• Bounds specification and bounds remapping list on a pointer assignment
• FINAL routines
• GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
• Enumerators
• Type extension (not polymorphic)
• Type-bound procedures
• Allocatable scalar variables (not deferred-length character)
• ERRMSG keyword for ALLOCATE and DEALLOCATE
• SOURCE= keyword for ALLOCATE
• Character arguments for MAX, MIN, MAXVAL, MINVAL, MAXLOC, and MINLOC
• Intrinsic modules IEEE_EXCEPTIONS, IEEE_ARITHMETIC and IEEE_FEATURES
• ASSOCIATE construct
• DO CONCURRENT construct
• PROCEDURE declaration
• Procedure pointers
• ABSTRACT INTERFACE
• PASS and NOPASS attributes
• CONTIGUOUS attribute
• Structure constructors with component names and default initialization
• Array constructors with type and character length specifications
• I/O keywords BLANK, DECIMAL, DELIM, ENCODING, IOMSG, PAD, ROUND, SIGN, and SIZE
• Format edit descriptors DC, DP, RD, RC, RN, RP, RU, and RZ
• The COUNT_RATE argument to the SYSTEM_CLOCK intrinsic may be a REAL of any kind.
• NAMELIST I/O for internal files
• Intrinsic functions EXTENDS_TYPE_OF and SAME_TYPE_AS
• SELECT TYPE construct
• CLASS declaration
• PUBLIC types with PRIVATE components and PRIVATE types with PUBLIC components
• RECORDTYPE setting STREAM_CRLF
• A file can be opened for stream access (ACCESS='STREAM')
• Specifier POS can be specified in an INQUIRE, READ, or WRITE statement
• BIND attribute and statement
• Language binding can be specified in a FUNCTION or SUBROUTINE statement, or when defining a derived type
• IS_IOSTAT_END intrinsic function
• IS_IOSTAT_EOR intrinsic function
• INTRINSIC and NONINTRINSIC can be specified for modules in USE statements
• ASYNCHRONOUS attribute and statement
• VALUE attribute and statement
• Specifier ASYNCHRONOUS can be specified in an OPEN, INQUIRE, READ, or WRITE statement
• An ID can be specified for a pending data transfer operation
• FLUSH statement
• WAIT statement
• IMPORT statement
• NEW_LINE intrinsic function
• SELECTED_CHAR_KIND intrinsic function
• Intrinsic modules ISO_C_BINDING and ISO_FORTRAN_ENV
• Specifiers ID and PENDING can be specified in an INQUIRE statement
• User-defined operators can be renamed in USE statements
• MOVE_ALLOC intrinsic subroutine
• PROTECTED attribute and statement
• Pointer objects can have the INTENT attribute
• GET_COMMAND intrinsic
• GET_COMMAND_ARGUMENT intrinsic
• COMMAND_ARGUMENT_COUNT intrinsic
• GET_ENVIRONMENT_VARIABLE intrinsic
• Allocatable components of derived types
• Allocatable dummy arguments
• Allocatable function results
• VOLATILE attribute and statement
• Names of length up to 63 characters
• Statements up to 256 lines
• A named PARAMETER constant may be part of a complex constant
• In all I/O statements, the following numeric values can be of any kind: UNIT=, IOSTAT=
• The following OPEN numeric values can be of any kind: RECL=
• The following READ and WRITE numeric values can be of any kind: REC=, SIZE=
• The following INQUIRE numeric values can be of any kind: NEXTREC=, NUMBER=, RECL=, SIZE=
• Recursive I/O is allowed when the new I/O being started is internal I/O that does not modify any internal file other than its own
• IEEE infinities and Nans are displayed by formatted output as specified by Fortran 2003
• In an I/O format, the comma after a P edit descriptor is optional when followed by a repeat specifier
• The following intrinsics take an optional KIND= argument: ACHAR, COUNT, IACHAR, ICHAR, INDEX, LBOUND, LEN, LEN_TRIM, MAXLOC, MINLOC, SCAN, SHAPE, SIZE, UBOUND, VERIFY
• Square brackets [ ] are permitted to delimit array constructors instead of (/ /)
• The Fortran character set has been extended to contain the 8-bit ASCII characters ~ \ [ ] ` ^ { } | # @

Fortran 2018 Features
Minimizing Operating System-Specific Information

The operating system influences your program both externally and internally. For increased portability, you need to minimize the amount of operating-system-specific information required by your program. The Fortran language standards do not specify this information.

Operating-system-specific information consists of non-intrinsic extensions to the language, compiler and linker options, and possibly the graphical user interface of Windows®. Input and output operations use devices that may be system-specific and may involve a file system with system-specific record and file structures.

The operating system also governs resource management and error handling. You can depend on default resource management and error handling mechanisms or provide mechanisms of your own. For information on special library routines to help port your program from one system to another, see IFPORT Portability Library and related topics.

The minimal interaction with the operating system is for input/output (I/O) operations and usually consists of knowing the standard units preconnected for input and output. You can use default file units with the asterisk (*) unit specifier.

To increase the portability of your programs across operating systems, consider the following:

- Do not assume the use of a particular type of file system.
- Do not embed filenames or paths in the body of your program. Define them as constants at the beginning of the program or read them from input data.
- Do not assume a particular type of standard I/O device or the "size" of that device (number of rows and columns).
- Do not assume display attributes for the standard I/O device. Some environments do not support attributes such as color, underlined text, blinking text, highlighted text, inverse text, protected text, or dim text.

IFPORT Portability Library

Storing and Representing Data

The Fortran language standard specifies little about the storage of data types.

This loose specification of storage for data types results from a great diversity of computing hardware. This diversity poses problems in representing data and especially in transporting stored data among a multitude of systems. The size (as measured by the number of bits) of a storage unit (a word, usually several bytes) varies from machine to machine. In addition, the ordering of bits within bytes and bytes within words varies from one machine to another. Furthermore, binary representations of negative integers and floating-point representations of real and complex numbers take several different forms.

The simplest and most reliable means of transferring data between dissimilar systems is in character and not binary form. Simple programming practices ensure that your data as well as your program is portable.

Supported Native and Nonnative Numeric Formats
Data Portability

Formatting Data for Transportability

You can achieve the highest transportability of your data by formatting it as 8-bit character data. Use a standard character set, such as the ASCII standard, for encoding your character data. Although this practice is less efficient than using binary data, it will save you from shuffling and converting your data.

If you are transporting your data by means of a record-structured medium, it is best to use the Fortran sequential files. See Record Types in the reference guide for more information.

Remember also that some systems use a carriage return/linefeed pair as an end-of-record indicator, while other systems use linefeed only. There might be system-dependent values embedded within your data that complicate its transport.

Implementing a strictly portable solution requires a careful effort. Maximizing portability may also mean making compromises to the efficiency and functionality of your solution. If portability is not your highest priority, you can use some of the techniques that appear in later sections to ease your task of customizing a solution.

Record Types
Supported Native and Nonnative Numeric Formats

Supported Native and Nonnative Numeric Formats

Data storage in different computers uses a convention of either little endian or big endian storage. The storage convention generally applies to numeric values that span multiple bytes, as follows:

Little endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the lowest address.
- The most significant bit (MSB) value is in the byte with the highest address.
- The address of the numeric value is the byte containing the LSB. Subsequent bytes with higher addresses contain more significant bits.

Big endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the highest address.
- The most significant bit (MSB) value is in the byte with the lowest address.
- The address of the numeric value is the byte containing the MSB. Subsequent bytes with higher addresses contain less significant bits.

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte).
The following figures show the difference between the two byte-ordering schemes:

**Little and Big Endian Storage of an INTEGER Value**

The following figure illustrates the difference between the two conventions for the case of addressing bytes within words.

**Byte Order Within Words: (a) Big Endian, (b) Little Endian**

Data types stored as subcomponents (bytes stored in words) end up in different locations within corresponding words of the two conventions. The following figure illustrates the difference between the representations of several data types in the two conventions. Letters represent 8-bit character data, while numbers represent the 8-bit partial contribution to 32-bit integer data.

**Character and Integer Data in Words: (a) Big Endian, (b) Little Endian**
If you serially transfer bytes now from the big endian words to the little endian words (BE byte 0 to LE byte 0, BE byte 1 to LE byte 1, and so on), the left half of the figure shows how the data ends up in the little endian words. Note that data of size one byte (characters in this case) is ordered correctly, but that integer data no longer correctly represents the original binary values. The right half of the figure shows that you need to swap bytes around the middle of the word to reconstitute the correct 32-bit integer values. After swapping bytes, the two preceding figures are identical.

**Data Sent from Big to Little: (a) After Transfer, (b) After Byte Swaps**

You can generalize the previous example to include floating-point data types and to include multiple-word data types.

Moving unformatted data files between big endian and little endian computers requires that the data be converted.

Intel Fortran provides the capability for programs to read and write unformatted data (originally written using unformatted I/O statements) in several nonnative floating-point formats and in big endian INTEGER or floating-point format. Supported nonnative floating-point formats include Compaq* VAX* little endian.
floating-point formats supported by Digital* FORTRAN for OpenVMS* VAX Systems, standard IEEE big endian floating-point format found on most Sun Microsystems* systems and IBM RISC* System/6000 systems, IBM floating-point formats (associated with the IBM's System/370 and similar systems), and CRAY* floating-point formats.

Converting unformatted data instead of formatted data is generally faster and is less likely to lose precision of floating-point numbers. For unformatted files that contain record lengths before and after the data, specifying big-endian conversion will interpret the lengths as big-endian.

Caution:

Intel Fortran support of data conversion applies only to I/O list items of intrinsic type (REAL, INTEGER, and so on). I/O list items of derived type are not converted.

The native memory format includes little endian integers and little endian IEEE floating-point formats, IEEE binary32 for REAL(KIND=4) and COMPLEX(KIND=4) declarations, IEEE binary64 for REAL(KIND=8) and COMPLEX(KIND=8) declarations, and IEEE binary128 for REAL(KIND=16) and COMPLEX(KIND=16) declarations.

The keywords for supported nonnative unformatted file formats and their data types are listed in the following table:

**Nonnative Numeric Formats, Keywords, and Supported Data Types**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG_ENDIAN</td>
<td>Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian IEEE floating-point formats for REAL and COMPLEX single-, double-, and extended-precision numbers. INTEGER(KIND=1) data is the same for little endian and big endian.</td>
</tr>
<tr>
<td>CRAY</td>
<td>Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian CRAY proprietary floating-point format for REAL and COMPLEX single- and double-precision numbers.</td>
</tr>
</tbody>
</table>
| FDX         | Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats:  
• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
• VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8)  
• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16) |
| FGX         | Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats:  
• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
• VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8)  
• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16) |
| IBM         | Big endian integer data of the appropriate INTEGER size (one, two, or four bytes) and big endian IBM proprietary (System/370 and similar) floating-point format for REAL and COMPLEX single- and double-precision numbers. |
| LITTLE_ENDIAN      | Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following native little endian IEEE floating-point formats:  
• IEEE binary32 for REAL (KIND=4) and COMPLEX (KIND=4)  
• IEEE binary64 for REAL (KIND=8) and COMPLEX (KIND=8)  
• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16)  
For additional information on supported ranges for these data types, see Native IEEE Floating-Point Representations. |
| NATIVE      | No conversion occurs between memory and disk. This is the default for unformatted files. |
| VAXD        | Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: |
Porting non-Native Data

When porting nonnative data, consider the following:

• Vendors might use different units for specifying the record length (RECL specifier) of unformatted files. While formatted files are specified in units of characters (bytes), unformatted files are specified in longword units for Intel® Fortran (default) and some other vendors.

To allow you to specify RECL units (bytes or longwords) for unformatted files without source file modification, use the assume byterecl compiler option.

• Certain vendors apply different OPEN statement defaults to determine the record type. The default record type (RECORDTYPE) with Intel® Fortran depends on the values for the ACCESS and FORM specifiers for the OPEN statement.

• Certain vendors use a different identifier for the logical data types, such as hex FF and hex 00 instead of 01 to denote .TRUE. and .FALSE. See the fpscomp:logicals compiler option.

• Source code being ported may be coded specifically for big endian use.

assume compiler option

Specifying the Data Format

Methods of Specifying the Data Format

There are a number of methods for specifying a nonnative numeric format for unformatted data:

• Set an environment variable for a specific unit number before the file is opened. The environment variable is named FORT_CONVERTn, where n is the unit number.

• Set an environment variable for a specific file name extension before the file is opened. The environment variable is named FORT_CONVERT.ext or FORT_CONVERT_ext, where ext is the file name extension (suffix).

• Set an environment variable for a set of units before the application is executed. The environment variable is named F_UFMTENDIAN.

• Specify the CONVERT keyword in the OPEN statement for a specific unit number.

• Compile the program with an OPTIONS statement that specifies the CONVERT=keyword qualifier. This method affects all unit numbers using unformatted data specified by the program.

• Compile the program with the appropriate compiler option, which affects all unit numbers that use unformatted data specified by the program. Use the convert compiler option.
If none of these methods are specified, the native LITTLE_ENDIAN format is assumed (no conversion occurs between disk and memory).

Any keyword listed in Supported Native and Nonnative Numeric Formats can be used with any of these methods, except for the Environment Variable F_UFMTENDIAN Method, which supports only LITTLE_ENDIAN and BIG_ENDIAN.

If you specify more than one method, the order of precedence when you open a file with unformatted data is below:

1. Check for an environment variable (FORT_CONVERTn) for the specified unit number (applies to any file opened on a particular unit).
2. Check for an environment variable (FORT_CONVERT.ext is checked before FORT_CONVERT_ext) for the specified file name extension (applies to all files opened with the specified file name extension).
3. Check for an environment variable (F_UFMTENDIAN) for the specified unit number (or for all units).

**NOTE**
This environment variable is checked only when the application starts executing.

4. Check the OPEN statement CONVERT specifier.
5. Check whether an OPTIONS statement with a CONVERT:keyword qualifier was present when the program was compiled.
6. Check whether the convert compiler option was present when the program was compiled.

**See Also**
convert

Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method
Environment Variable FORT_CONVERTn Method
OPEN Statement CONVERT Method
OPTIONS Statement Method
Supported Native and Nonnative Numeric Formats

**Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method**

Use this method to specify a non-native numeric format for each specified file name extension (suffix). Specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit OPEN to one or more unformatted files. Use the format FORT_CONVERT.ext or FORT_CONVERT_ext (where ext is the file extension or suffix). The FORT_CONVERT.ext environment variable is checked before FORT_CONVERT_ext environment variable (if ext is the same).

For example, assume you have a previously compiled program that reads numeric data from one file and writes to another file using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from a file with a .dat file extension and write that data in native little endian format to a file with an extension of .data. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format (IEEE binary32 and IEEE binary64) when read from file.dat, and then written without conversion in native little endian IEEE format to the file with a suffix of .data, assuming that environment variables FORT_CONVERT_DATA and FORT_CONVERTn (for that unit number) are not defined.

Without requiring source code modification or recompilation of a program, the following command sets the appropriate environment variables before running the program:

**Example**

```plaintext
// Linux*
setenv FORT_CONVERT.DAT BIG_ENDIAN
```
The FORT_CONVERTn method takes precedence over this method. When the appropriate environment variable is set when you open the file, the FORT_CONVERT.ext or FORT_CONVERT_ext environment variable is used if a FORT_CONVERTn environment variable is not set for the unit number.

The FORT_CONVERTn and the FORT_CONVERT.ext or FORT_CONVERT_ext environment variable methods take precedence over the other methods. For instance, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

You can set the appropriate environment variable using the format FORT_CONVERT.ext or FORT_CONVERT_ext. If you also use Intel® Fortran on Linux* systems, consider using the FORT_CONVERT_ext form, because a dot (.) cannot be used for environment variable names on certain Linux* command shells. If you do define both FORT_CONVERT.ext and FORT_CONVERT_ext for the same extension (ext), the file defined by FORT_CONVERT.ext is used.

On Windows* systems, the file name extension (suffix) is not case-sensitive. The extension must be part of the file name (not the directory path).

### Environment Variable FORT_CONVERTn Method

You can use this method to specify a nonnative numeric format for each specified unit number. You specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit OPEN to that unit number.

When the appropriate environment variable is set when you open the file, the environment variable is always used because this method takes precedence over the other methods. For example, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

For example, assume you have a previously compiled program that reads numeric data from unit 28 and writes it to unit 29 using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from unit 28 and write that data in native little endian format to unit 29. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format when read from unit 28, and then written without conversion in native little endian IEEE format to unit 29.

Without requiring source code modification or recompilation of this program, the following command sequence sets the appropriate environment variables before running a program.

Linux:

```bash
setenv FORT_CONVERT28 BIG_ENDIAN
setenv FORT_CONVERT29 NATIVE
```

Windows:

```bash
set FORT_CONVERT28=BIG_ENDIAN
set FORT_CONVERT29=NATIVE
```
The following figure shows the data formats used on disk and in memory when the program is run after the environment variables are set.

**Sample Unformatted File Conversion**

![Diagram showing data formats](image)

This method takes precedence over other methods.

**Environment Variable F_UFMTENDIAN Method**

This little-endian-big-endian conversion feature is intended for Fortran unformatted input/output operations. It enables the development and processing of files with little-endian and big-endian data organization.

The **F_UFMTENDIAN** environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units or for all units continues for the rest of the execution.

Specify the numbers of the units to be used for conversion purposes by setting **F_UFMTENDIAN**. Then, the READ/WRITE statements that use these unit numbers will perform relevant conversions. Other READ/WRITE statements will work in the usual way.

**General Syntax for F_UFMTENDIAN**

In the general case, the variable consists of two parts divided by a semicolon. No spaces are allowed inside the **F_UFMTENDIAN** value:

\[
\text{F\_UFMTENDIAN=} \text{MODE} \mid [\text{MODE;} \text{ EXCEPTION}]
\]

where:

- **MODE** = big | little
- **EXCEPTION** = big:ULIST | little:ULIST | ULIST
- **ULIST** = U | ULIST,U
- **U** = decimal | decimal -decimal

- **MODE** defines current format of data, represented in the files; it can be omitted.
  
  The keyword **little** means that the data has little endian format and will not be converted. This is the default.

  The keyword **big** means that the data has big endian format and will be converted.

- **EXCEPTION** is intended to define the list of exclusions for **MODE.EXCEPTION** keyword (little or big)
  defines data format in the files that are connected to the units from the **EXCEPTION** list. This value overrides **MODE** value for the units listed.
The **EXCEPTION** keyword and the colon can be omitted. The default when the keyword is omitted is `big`.

- Each list member $U$ is a simple unit number or a number of units. The number of list members is limited to 64.
- `decimal` is a non-negative decimal number less than 232.

Converted data should have basic data types or arrays of basic data types. Derived data types are disabled. Error messages may be issued during the little-endian-to-big-endian conversion. They are all fatal.

On Linux* systems, the command line for the variable setting in the shell is:

```bash
Sh: export F_UFMTENDIAN=MODE; EXCEPTION
```

**NOTE**
The environment variable value should be enclosed in quotes if the semicolon is present.

The environment variable can also have the following syntax:

```
F_UFMTENDIAN=u[,u] . . .
```

**Examples**

1. `F_UFMTENDIAN=big`
   
   All input/output operations perform conversion from `big-endian` to `little-endian` on READ and from `little-endian` to `big-endian` on WRITE.

2. `F_UFMTENDIAN="little;big:10,20"
   
   or `F_UFMTENDIAN=big:10,20`
   
   or `F_UFMTENDIAN=10,20`

   The input/output operations perform big-endian to little endian conversion only on unit numbers 10 and 20.

3. `F_UFMTENDIAN="big;little:8"
   
   No conversion operation occurs on unit number 8. On all other units, the input/output operations perform big-endian to little-endian conversion.

4. `F_UFMTENDIAN=10-20`
   
   The input/output operations perform big-endian to little-endian conversion on units 10, 11, 12, ... 19, 20.

5. Assume you set `F_UFMTENDIAN=10,100` and run the following program.

   ```fortran
   integer*4   cc4
   integer*8   cc8
   integer*4   c4
   integer*8   c8
   c4 = 456
   c8 = 789
   
   ! prepare a little endian representation of data
   open(11,file='lit.tmp',form='unformatted')
   write(11) c8
   write(11) c4
   close(11)
   
   ! prepare a big endian representation of data
   ```
open(10, file='big.tmp', form='unformatted')
write(10) c8
write(10) c4
close(10)

! read big endian data and operate with them on
! little endian machine.

open(100, file='big.tmp', form='unformatted')
read(100) cc8
read(100) cc4

! Any operation with data, which have been read

!...
close(100)
stop
end

Now compare lit.tmp and big.tmp files with the help of the od utility:

> od -t x4 lit.tmp
0000000 00000008 00000315 00000000 00000008
0000020 00000004 000001c8 00000004
0000034

> od -t x4 big.tmp
0000000 08000000 00000000 15030000 08000000
0000020 04000000 c8010000 04000000
0000034

You can see that the byte order is different in these files.

**OPEN Statement CONVERT Method**

Use this method to specify a nonnative numeric format for each specified unit number. This method requires an explicit file OPEN statement to specify the numeric format of the file for that unit number.

This method takes precedence over the OPTIONS statement and the compiler option CONVERT[: ] keyword method, but has a lower precedence than the environment variable methods.

For example, the following source code shows how the OPEN statement would be coded to read unformatted VAXD numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20 (the absence of the CONVERT keyword or environment variables FORT_CONVERT20, FORT_CONVERT.dat, or FORT_CONVERT.dat indicates native little endian data for unit 20):

```
OPEN (CONVERT='VAXD', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
...
OPEN (FILE='graph3_t.dat', FORM='UNFORMATTED', UNIT=20)
```

A hard-coded OPEN statement CONVERT keyword value cannot be changed after compile time. However, to allow selection of a particular format at run time, equate the CONVERT keyword to a variable and provide the user with a menu that allows selection of the appropriate format (menu choice sets the variable) before the OPEN occurs.

You can also select a particular format at run time for a unit number by using one of the environment variable methods (Environment Variable FORT_CONVERTn Method, Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method, or Environment Variable F_UFMTENDIAN Method), which take precedence over the OPEN statement CONVERT keyword method.

OPEN
Environment Variable FORT_CONVERTn Method
Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method
Environment Variable F_UFMTENDIAN Method

OPTIONS Statement Method

You can only specify one numeric file format for all unformatted file unit numbers using this method unless you also use one of the environment variable methods or OPEN statement CONVERT keyword method.

You specify the numeric format at compile time and must compile all routines under the same OPTIONS statement CONVERT=keyword qualifier. You could use one source program and compile it using different ifort commands to create multiple executable programs that each read a certain format.

The environment variable methods and the OPEN statement CONVERT=keyword method take precedence over this method. For example, you might use the FORT_CONVERTn environment variable or OPEN CONVERT=keyword method to specify each unit number that will use a format other than that specified using the ifort option method.

This method takes precedence over the ifortconvert[:]:keyword compiler option method.

You can use OPTIONS statements to specify the appropriate floating-point formats (in memory and in unformatted files) instead of using the corresponding ifort command qualifiers. For example, to use VAX F_floating, G_floating, and H_floating as the unformatted file format, specify the following OPTIONS statement:

OPTIONS /CONVERT=VAXG

Because this method affects all unit numbers, you cannot read data in one format and write it in another format, unless you use it in combination with one of the environment variable methods or the OPEN statement CONVERT keyword method to specify a different format for a particular unit number.

For more information, see the OPTIONS statement.

See Also
OPTIONS Statement

Compiler Option -convert or /convert Method

You can only specify one numeric format for all unformatted file unit numbers using the convert compiler option unless you also use one (or more) of the previous methods shown in Methods of Specifying the Data Format.

You specify the numeric format at compile time and must compile all routines under the same convert keyword compiler option. You can use the same source program and compile it using different ifort commands (or the equivalent in the IDE) to create multiple executable programs that each read a certain format.

If you specify other methods, the other methods take precedence over using this method. For instance, you might use the environment variable or OPEN statement CONVERT specifier method to specify each unit number that will use a format different than that specified using the convert keyword compiler option method for all other unit numbers.

For example, the following command compiles program file.for to use VAX D_floating (and F_floating) floating-point data for all unit numbers (unless superseded by one of the other methods). Data is converted between the file format and the little endian memory format (little endian integers, IEEE binary32, IEEE binary64, and IEEE binary128 little endian IEEE* floating-point format). The created file, vconvert.exe, can then be run:
Because this method affects all unformatted file unit numbers, you cannot read data in one format and write it in another file format using the `convert` keyword compiler option alone. You can if you use it in combination with the environment variable methods or the OPEN statement CONVERT specifier method to specify a different format for a particular unit number.

Fortran 88
Windows
function converting unit number to handle 1535
function returning position of 1558
function returning properties of 1555
function returning size of 1558
function returning unit number of 1554
function setting position of 2055
function setting properties of child 2049
function setting size of 2055
setting focus to 1465
subroutine returning boundaries of text 1551
subroutine scrolling the contents of text 2001
subroutine setting boundaries of text 2045
Windows* API
BitBlt 1867
CreateFile 1053, 2082
CreateFontIndirect 2028, 2049
CreateProcess 2126, 2128
EscapeCommFunction 2095
GetEnvironmentVariable 1525
GetExceptionInformation 2164
PurgeComm 2088

Windows* API (continued)
SetEnvironmentVariable 1525
SetFileApisToANSI 1761
SetFileApisToOEM 1761
SetROP2 2053
Windows* API modules 588
Windows* APIs 88, 586
Windows* applications
option creating and linking 542
Windows* bitmap file
function saving an image into 1998
Windows* coordinates
functions filling (color index) 1459
functions filling (RGB) 1460
subroutine converting from viewport coordinates 1556
subroutines converting from physical coordinates 1554
Windows* data types
translated to Fortran types 586
Windows* fonts
initializing 1627
Windows* properties
function returning 1555
function setting 2049, 2055
Windows* structured exception handling 726
Windows* structures
compared to Fortran derived types 586
WINEXIT
predefined QuickWin routine 1199
WINFULLSCREEN
predefined QuickWin routine 1199
WININDEX
predefined QuickWin routine 1199
WININPUT
predefined QuickWin routine 1199
WinMainCRTStartup run-time function 723, 728
WINPASTE
predefined QuickWin routine 1199
WINPRINT
predefined QuickWin routine 1199
WINSAVE
predefined QuickWin routine 1199
WINSELECTALL
predefined QuickWin routine 1199
WINSELECTGRAPHICS
predefined QuickWin routine 1199
WINSELECTTEXT
predefined QuickWin routine 1199
WINSIZEZOTOFIT
predefined QuickWin routine 1199
WINSTATE
predefined QuickWin routine 1199
WINSTATUS
predefined QuickWin routine 1199
WINTILE
predefined QuickWin routine 1199
WINUSING
predefined QuickWin routine 1199
worker thread 2333
working directory
function returning path of 1520
WORKSHARE 2210
worksharing 1922, 2210, 2319, 2369
WRAPON 2211
WRITE
specifier for INQUIRE 1031
write mode
function returning logical 1557
function setting logical 2053
write operations
  function committing to physical device 1321

X

edit descriptor 994
Xcode*
  building the target 108
  creating a project
    in Xcode* 106
  projects
    Adding a new file 107
    creating 106
    running the executable 109
    selecting the Intel® Fortran Compiler 107
  setting compiler options 109
xiar 2473, 2475
xild 2469, 2473, 2475
xllib 2475
