READ (unit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

For more information on syntax, see READ.

Formatted, internal READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

This form of READ statement behaves as if the format begins with a BN edit descriptor. (You can override this behavior by explicitly specifying the BZ edit descriptor.)

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

Before data transfer occurs, the file is positioned at the beginning of the first record. This record becomes the current record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains.

In list-directed and namelist formatting, character strings have no delimiters.

**Examples**

The following program segment reads a record and examines the first character to determine whether the remaining data should be interpreted as decimal, octal, or hexadecimal. It then uses internal READ statements to make appropriate conversions from character string representations to binary.

```fortran
INTEGER IVAL
CHARACTER TYPE, RECORD*80
CHARACTER*(*) AFMT, IFMT, OFMT, ZFMT
PARAMETER (AFMT='(Q,A)', IFMT= '(I10)', OFMT= '(O11)', &  ZFMT= '(Z8)')
ACCEPT AFMT, ILEN, RECORD
TYPE = RECORD(1:1)
```
IF (TYPE .EQ. 'D') THEN
  READ (RECORD(2:MIN(ILEN, 11)), IFMT) IVAL
ELSE IF (TYPE .EQ. 'O') THEN
  READ (RECORD(2:MIN(ILEN, 12)), OFMT) IVAL
ELSE IF (TYPE .EQ. 'X') THEN
  READ (RECORD(2:MIN(ILEN, 9)), ZFMT) IVAL
ELSE
  PRINT *, 'ERROR'
END IF
END

Forms for WRITE Statements

This section discusses the various forms you can specify for WRITE statements.

Forms for Sequential WRITE Statements

Sequential WRITE statements transfer output data to external sequential access records. The statements can
be formatted by using format specifiers (which can use list-directed formatting) or namelist specifiers (for
namelist formatting), or they can be unformatted.

A sequential WRITE statement takes one of the following forms:

**Formatted:**

**Formatted - List-Directed:**

**Formatted - Namelist:**

**Unformatted:**

See Also
WRITE
I/O control-list specifiers
I/O lists
Rules for Formatted Sequential WRITE Statements

Formatted, sequential WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for sequential access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

The output list and format specification must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples

The following example shows formatted, sequential WRITE statements:

```
WRITE (UNIT=8, FMT='(B)', ADVANCE='NO') C
WRITE (*, "(F6.5)", ERR=25, IOSTAT=IO_STATUS) A, B, C
```

See Also
WRITE statement
Forms for Sequential WRITE Statements

Rules for List-Directed Sequential WRITE Statements

List-directed, sequential WRITE statements transfer data from binary to character form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

The following table shows the default output formats for each intrinsic data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Output Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>I5</td>
</tr>
<tr>

</tr>
<tr>
<td>CHARACTER</td>
<td>Aw¹</td>
</tr>
</tbody>
</table>

¹ Where \( w \) is the length of the character expression.

² If option assume noold_ldout_format is in effect, the compiler uses Fortran 2003 standard semantics for output of integer and real values in list-directed and namelist-directed output. This means that for real and complex values, the output is in E or F format depending on the magnitude of the value. For more information, see the description of option assume.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

**Examples**

Suppose the following statements are specified:

```fortran
DIMENSION A(4)
DATA A/4*3.4/
WRITE (1,*) 'ARRAY VALUES FOLLOW'
WRITE (1,*) A,4
```

The following records are then written to external unit 1:

```
ARRAY VALUES FOLLOW
3.400000 3.400000 3.400000 3.400000 4
```

The following shows another example:

```fortran
INTEGER i, j
REAL a, b
LOGICAL on, off
```
The preceding example produces the following output:

```
  123456         500
  28.22000      1.555500E-03 T F
Here's a string
```

See Also

Rules for Formatted Sequential WRITE Statements
Rules for List-Directed Sequential READ Statements for details on list-directed input

Rules for Namelist Sequential WRITE Statements

Namelist, sequential WRITE statements translate data from internal to external form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control, except for literal character constants that are continued from the previous record.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

Examples

Consider the following statements:

```
CHARACTER*19 NAME(2)/2*' '/
REAL PITCH, ROLL, YAW, POSITION(3)
LOGICAL DIAGNOSTICS
```
INTEGER ITERATIONS

TYPE MYTYPE
  INTEGER X
  REAL Y
  CHARACTER(5) Z
END TYPE MYTYPE

TYPE(MYTYPE) :: TYPEVAR = MYTYPE(1, 2.0, 'ABCDE')

NAMELIST /PARAM/ NAME, PITCH, ROLL, TYPEVAR, YAW, POSITION, ...
  DIAGNOSTICS, ITERATIONS
...
READ (UNIT=1, NML=PARAM)
WRITE (UNIT=2, NML=PARAM)

Suppose the following input is read:

&PARAM
   NAME(2)(10:) = 'HEISENBERG',
   PITCH = 5.0, YAW = 0.0, ROLL = 5.0,
   DIAGNOSTICS = .TRUE.,
   ITERATIONS = 10
/

The following is then written to the file connected to unit 2:

&PARAM
   NAME = ' ', ' ', 'HEISENBERG',,
   PITCH = 5.000000,
   ROLL = 5.000000,
   TYPEVAR = 1, 2.0, 'ABCDE'
   YAW = 0.0000000E+00,
   POSITION = 3*0.0000000E+00,
   DIAGNOSTICS = T,
   ITERATIONS = 10
/

Note that character values are not enclosed in apostrophes unless the output file is opened with DELIM='APOSTROPE'. The value of POSITION is not defined in the namelist input, so the current value of POSITION is written.

The following example declares a number of variables, which are placed in a namelist, initialized, and then written to the screen with namelist I/O:

INTEGE(1) int1
INTEGER int2, int3, array(3)
LOGICAL(1) log1
LOGICAL log2, log3
REAL real1
REAL(8) real2
COMPLEX z1, z2
CHARACTER(1) char1
CHARACTER(10) char2

NAMELIST /example/ int1, int2, int3, log1, log2, log3, &
& real1, real2, z1, z2, char1, char2, array

int1 = 11
int2 = 12
int3 = 14
log1 = .TRUE.
log2 = .TRUE.
log3 = .TRUE.
real1 = 24.0
real2 = 28.0d0
z1 = (38.0,0.0)
z2 = (316.0d0,0.0d0)
char1 = 'A'
char2 = '0123456789'
array(1) = 41
array(2) = 42
array(3) = 43
WRITE (*, example)

The preceding example produces the following output:

&EEXAMPLE
INT1 = 11,
INT2 = 12,
INT3 = 14,
LOG1 = T,
LOG2 = T,
LOG3 = T,
REAL1 = 24.00000,
REAL2 = 28.0000000000000,
Z1 = (38.00000,0.0000000E+00),
Z2 = (316.0000,0.0000000E+00),
CHAR1 = A,
CHAR2 = 0123456789,
ARRAY = 41, 42, 43
/

NAMELIST
Rules for Formatted Sequential WRITE Statements
Rules for Namelist Sequential READ Statements

Rules for Unformatted Sequential WRITE Statements

Unformatted, sequential WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.
Objects of intrinsic or derived types can be transferred.
This form of WRITE statement writes exactly one record. If there is no I/O item list, the statement writes one null record.
If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.
For a discussion of I/O buffering, see Rules for Unformatted Sequential READ Statements.

Examples

The following example shows an unformatted, sequential WRITE statement:

WRITE (UNIT=6, IOSTAT=IO_STATUS) A, B, C

Forms for Direct-Access WRITE Statements

Direct-access WRITE statements transfer output data to external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)
A direct-access WRITE statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

**Unformatted:**
WRITE (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err] [, iomsg]) {io-list}

**See Also**
WRITE  
I/O control-list specifiers  
I/O lists

**Rules for Formatted Direct-Access WRITE Statements**
Formatted, direct-access WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for direct access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is written by that output statement.

**Examples**
The following example shows a formatted, direct-access WRITE statement:

```
WRITE (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

**Rules for Unformatted Direct-Access WRITE Statements**
Unformatted, direct-access WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**
The following example shows unformatted, direct-access WRITE statements:

```
WRITE (1, REC=10) LIST(1), LIST(8)
WRITE (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream WRITE Statements**
The forms for stream WRITE statements take the same forms as sequential WRITE statements. A POS specifier may be present to specify at what file position the WRITE will start.
After a formatted stream WRITE where no error occurred, the output file is truncated after the byte with the largest POS value. An unformatted stream WRITE does not truncate the output file.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

See Also
NEW_LINE

Forms and Rules for Internal WRITE Statements

Internal WRITE statements transfer output data to an internal file.

An internal WRITE statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal WRITE statement takes one of the following forms:

```
WRITE (iunit, format [, iostat] [, err] [, iomsg]) [io-list]
WRITE (iunit, nml-group [, iostat] [, err] [, iomsg]) [io-list]
```

For more information on syntax, see WRITE.

Formatted, internal WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an internal file.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the number of characters written in a record is less than the length of the record, the rest of the record is filled with blanks. The number of characters to be written must not exceed the length of the record.

Character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

Examples

The following example shows an internal WRITE statement:

```fortran
INTEGER J, K, STAT_VALUE
CHARACTER*50 CHAR_50
...
WRITE (FMT=*, UNIT=CHAR_50, IOSTAT=STAT_VALUE) J, K
```

User-Defined Derived-Type I/O

By default, when a derived-type object is in a formatted I/O statement, it is treated as if all of its components were specified in the component order. The components must be accessible in the scope of the I/O statement and they cannot be pointers or allocatables. In an unformatted I/O statement, a derived-type object is treated as a single value in a processor-dependent form.
User-defined derived-type I/O lets you replace the default I/O processing for a derived-type object. For both unformatted and formatted I/O, a procedures can be invoked that will handle the I/O of the derived type. This is similar to defined operators and defined assignment.

For formatted I/O, the replacement occurs for list-directed formatting, namelist formatting, and for an explicit format with the DT edit descriptor. Other edit descriptors in the explicit format do not have any effect on user-defined I/O.

A procedure can be associated with defined I/O through generic bindings or generic interface blocks. The procedure must conform to the interface that specifies its characteristics. It cannot directly or indirectly use OpenMP constructs. A defined I/O procedure can also call itself recursively.

An I/O statement that includes a derived-type object and causes a defined I/O procedure to be invoked is called a parent I/O statement. An I/O statement that is executed while a parent statement is being processed, and specifies the unit passed to a defined I/O procedure, is called a child I/O statement.

A defined I/O procedure can be invoked as a parent I/O statement for an external or internal file opened for sequential, direct, or stream access.

This section also has information about how to resolve user-defined I/O procedure references.

**Specifying the User-Defined Derived Type**

**DT Edit Descriptor in User-Defined I/O**

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

\[
\text{DT } [\text{string}] \ [\{v\text{-list}\}]
\]

The `string` is a default character literal constant delimited by single quotes (‘ ’) or double quotes (" "); no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character. If `string` is not specified, a character string of length zero is passed.

The `v-list` is a list of one or more signed or unsigned integer literal constants; no kind parameter can be specified. If `v-list` is not specified, an integer array of length zero is passed.

A DT edit descriptor must correspond to a list item of a derived type. Also, there should be an accessible interface to a corresponding defined FORMATTED I/O procedure for that derived type.

In a format statement, if the last closing parenthesis of the format string is reached and there are no effective items left, then format processing terminates. But, if there are more items to be processed, then format control reverts to the beginning of the format item which was terminated by the next-to-last right parenthesis.

If there is no such preceding right parenthesis, it reverts to the first left parenthesis of the format specification. During this format reversion, the right parenthesis that is part of a DT edit descriptor is not considered as the next-to-last parenthesis. For example, consider the following:

\[\text{write (10, '@'(F10.3, I5, 'DT "sample" (1, 2) ')') 10.1, 3, obj1, 4.7, 1, obj2}\]

In the above case, format control reverts to the left parenthesis before F10.3 and not to DT.

**Examples**

The following are valid ways to specify the DT edit descriptor:

- DT
- DT "z8, i4, e10.2"
- DT (1, -1, +1000)
- DT 'my type' (0)
Associating a Procedure with Defined I/O

Defined I/O Procedures

For a particular derived type and a particular set of kind-type parameter values, there are four possible sets of characteristics for defined I/O procedures: formatted input, formatted output, unformatted input, and unformatted output.

To specify that an I/O procedure should be used for derived-type I/O, specify one of the following with a defined-io-generic-spec:

- A generic binding
- An interface block

A defined-io-generic-spec is one of the following statements:

- READ (FORMATTED)
- READ (UNFORMATTED)
- WRITE (FORMATTED)
- WRITE (UNFORMATTED)

Generic Bindings

User-defined I/O procedures can be type-bound procedures that use a defined-io-generic-spec (see Defined IO Procedures).

Consider the following:

```
TYPE LIST
  TYPE(NODE), POINTER :: FIRST
  CONTAINS
    PROCEDURE :: FMTREAD => LIST_FMTREAD
    PROCEDURE :: FMTWRITE => LIST_FMTWRITE
    GENERIC,PUBLIC :: READ(FORMATTED) => FMTREAD
    GENERIC,PUBLIC :: WRITE(FORMATTED) => FMTWRITE
  END TYPE LIST
```

In the above example, LIST_FMTREAD and LIST_FMTWRITE are the type-bound defined I/O procedures. If an object of type LIST is an effective item in a formatted READ statement, LIST_FMTREAD will be called to perform the read operation.

See Also

Type-Bound Procedures
Resolving Defined I/O Procedure References

Generic Interface Block

A generic interface block can be used to associate procedures with defined I/O. The generic identifier should be the defined-io-generic-spec (see Defined IO Procedures). This is the only option for sequence or BIND(C) types.

Consider the following:

```
MODULE EXAMPLE
  TYPE LIST
    INTEGER :: X
  END TYPE
  INTERFACE READ (FORMATTED)
    MODULE PROCEDURE R1
  END INTERFACE
  CONTAINS
```

In the above example, R1 is the READ (FORMATTED) defined I/O procedure.
If an object of type LIST is an effective item in a formatted READ statement, R1 will be called.

**See Also**

TYPE Statement (Derived Types)
Defining Generic Names for Procedures

**Characteristics of Defined I/O Procedures**

Shown below are the four interfaces that specify the characteristics of the user-defined I/O procedures. The actual specific procedure names and the names of the dummy arguments in these interfaces are arbitrary. The following names are used in the interfaces:

- **dtv-type-spec**
  Is one of the following:
  - TYPE(d-name) for a sequence or BIND(C) type
  - CLASS(d-name) for an extensible type
  
  d-name is the name of the derived type. It cannot be an abstract type. All length type parameters of the derived type must be assumed.

- **var**
  Is a scalar of the derived type. For output, it holds the value to be written. For input, it will be altered in accordance with the values read.

- **unit**
  Is the scalar integer value of the I/O unit on which input or output is taking place. It is a negative number for an internal file or for an external unit that is a NEWUNIT value. It is a processor-dependent number (which may be negative) for the '*' unit.

- **iotype**
  Is the value 'LISTDIRECTED', 'NAMELIST', or 'DT'//string, where string is the character string from the DT edit descriptor.

- **vlist**
  Is a rank-one assumed-shape integer array whose value comes from the parenthetical list of integers from the DT edit descriptor. For list-directed formatting and namelist formatting, vlist is a zero-sized integer array.

- **iostat**
  Is a scalar integer variable that must be given a positive value if an error condition occurs. If an end-of-file or end-of-record condition occurs, it must be given the value IOSTAT_END or IOSTAT_EOR (from the intrinsic module ISO_FORTRAN_ENV). In all other cases, it must be given the value zero.
The following interfaces specify the characteristics of the user-defined I/O procedures:

```fortran
SUBROUTINE my_read_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_read_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
INTEGER,INTENT(IN) :: unit
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END
```

See Also
ISO_FORTRAN_ENV Module

Defined I/O Data Transfers

The following rules apply to defined I/O data transfers:

- During execution of a defined I/O procedure, there must be no I/O for an external unit except for the unit argument. However, I/O is permitted for internal files.
- You cannot use user-defined I/O in combination with asynchronous I/O.
- No file-positioning commands are permitted in the defined I/O procedure. OPEN, CLOSE, BACKSPACE, ENDFILE, and REWIND statements will not be executed. Any ADVANCE= specifier in a child statement is ignored.
- A record positioning edit descriptor, such as TL and TR, used on the unit by a child data transfer statement will not cause the record position to be positioned before the record position at the time the defined I/O procedure was invoked.
- A child data transfer statement must not specify the ID=, POS=, or REC= specifier in an I/O control list.
- The file position on entry is treated as a left tab limit and there is no record termination on return. However, a child statement with slash (/) edit descriptor, or explicit record termination by a list-directed child I/O, is allowed.
- If the unit is associated with an external file (for example, non-negative, or equal to one of the constants ERROR_UNIT, INPUT_UNIT, or OUTPUT_UNIT from the intrinsic module ISO_FORTRAN_ENV), the current settings for the pad mode, sign mode, etc., can be discovered by using INQUIRE with PAD=, SIGN=, etc. on the unit argument.

Note that INQUIRE must not be used if the unit is an internal unit passed to a user-defined derived-type I/O procedure from a parent I/O statement. When an internal unit is used with the INQUIRE statement, an error condition will occur, and the variable specified in an IOSTAT= specifier in the INQUIRE statement will be assigned the value IOSTAT_INQUIRE_INTERNAL_UNIT from the intrinsic module ISO_FORTRAN_ENV.

User-Defined Derived-Type I/O

Resolving Defined I/O Procedure References

A generic interface for defined I/O of a derived-type object is one that has both of the following:

- A defined-io-generic-spec that is appropriate to the READ or WRITE direction and the form (formatted or unformatted) of the data transfer (see Defined IO Procedures, Generic Bindings, and Generic Interface Block).
- A specific interface whose var argument is compatible with the derived-type item.

Within the scope of a defined-io-generic-spec, if two procedures have that generic identifier, they must be distinguishable.

For defined I/O procedures, only the var argument corresponds to something explicitly written in the program, so it is the var that must be distinguishable.

Because var arguments are required to be scalar, they cannot differ in rank. So, the var must be distinguishable in the type and kind type parameters.

You cannot have two procedures with the same defined-io-generic-spec.

Characteristics of Defined I/O Procedures

Recursive Defined I/O

A defined I/O procedure can invoke itself indirectly.

It can have an I/O statement that includes a derived-type object that results in the invocation of the same procedure. In this case, the defined I/O procedure must be declared RECURSIVE.

Consider the following:

```fortran
! This prints a linked list by calling write on the children
! of the list.

MODULE LIST_MODULE
  IMPLICIT NONE
  TYPE NODE
    ! This type declaration represents a singly-linked list that also
    ! contains a user-defined i/o procedure. The name of the procedure
    ! is arbitrary, but the order of arguments must conform to the
    ! standard definition.
    INTEGER :: VALUE = -1
    TYPE(NODE), POINTER :: NEXT_NODE => NULL()
  CONTAINS
    PROCEDURE :: PWF
    GENERIC :: WRITE(FORMATTED) => PWF ! <=== GENERIC BINDING.
  END TYPE NODE
CONTAINS
  ! This prints a linked list by calling write on the children
  ! of the list.
  INTEGER :: VALUE = -1
  TYPE(NODE), POINTER :: NEXT_NODE => NULL()
  CONTAINS
    PROCEDURE :: PWF
    GENERIC :: WRITE(FORMATTED) => PWF ! <=== GENERIC BINDING.
END MODULE LIST_MODULE
```
RECURSIVE SUBROUTINE PWF( DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG )
! These arguments are defined in the standard.
   CLASS(NODE), INTENT(IN) :: DTV
   INTEGER, INTENT(IN) :: UNIT
   CHARACTER(LEN=*) , INTENT(IN) :: IOTYPE
   INTEGER, DIMENSION(:), INTENT(IN) :: V_LIST
   INTEGER :: IOSTAT
   CHARACTER(LEN=*) , INTENT(INOUT) :: IOMSG

! The following is a child i/o statement that is called when user-defined i/o
! statement is invoked.
   WRITE( UNIT=UNIT, FMT='(I9)' , IOSTAT=IOSTAT ) DTV%VALUE
   PRINT *, ASSOCIATED(DTV%NEXT_NODE)
   IF(IOSTAT /= 0)RETURN

! It is possible to recursively call the user-defined i/o routine.
   IF(ASSOCIATED(DTV%NEXT_NODE)
      WRITE(UNIT=UNIT, FMT='(/,DT)' , IOSTAT=IOSTAT) DTV%NEXT_NODE
   END IF
END SUBROUTINE PWF
END MODULE LIST_MODULE

PROGRAM LISTE
   USE LIST_MODULE
   IMPLICIT NONE
   INTEGER :: UNIT, IOSTAT, I
   TYPE(NODE), POINTER :: CUR, TO_PRINT

! Create the linked list
   ALLOCATE(CUR)
   CUR % VALUE = 999
   ALLOCATE(TO_PRINT)
   TO_PRINT => CUR
   DO I = 1,10
      ALLOCATE(CUR%NEXT_NODE)
      CUR % VALUE = I
      CUR => CUR%NEXT_NODE
   END DO
   CUR % NEXT_NODE => NULL()
! END CREATION OF LINKED LIST
   DO I = 1,15
      IF(ASSOCIATED(TO_PRINT)) THEN
         PRINT *, I, TO_PRINT%VALUE
         TO_PRINT => TO_PRINT % NEXT_NODE
      END IF
   END DO
! Call the user-defined i/o routine with dt format descriptor.
   WRITE( UNIT=UNIT, FMT='(DT)' , IOSTAT=IOSTAT ) CUR
END PROGRAM LISTE

Examples of User-Defined Derived-Type I/O

Example 1
The following example shows formatted defined I/O using the DT edit descriptor and both generic type-bound and explicit interface procedures:

```fortran
MODULE TYPES
  TYPE T
    INTEGER :: K(10)
  CONTAINS

  ! a generic type-bound procedure
  PROCEDURE :: UDIO_READ_ARRAY
    GENERIC :: READ (FORMATTED) => UDIO_READ_ARRAY
  END TYPE T

  ! an explicit interface
  INTERFACE WRITE (FORMATTED)
    MODULE PROCEDURE UDIO_WRITE_ARRAY
  END INTERFACE

  CONTAINS

  SUBROUTINE UDIO_READ_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST (:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG

    ! This is the child I/O that gets performed when the procedure
    ! is called from a parent I/O – it uses list-directed input to read
    ! the array K

    READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K
  END SUBROUTINE UDIO_READ_ARRAY

  SUBROUTINE UDIO_WRITE_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(IN) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST (:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG

    ! This is the child I/O that gets performed when the procedure
    ! is called from a parent I/O – it uses list-directed output to write
    ! the array K

    WRITE (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K
  END SUBROUTINE UDIO_WRITE_ARRAY

END MODULE TYPES
```
PROGRAM TEST1
  USE TYPES
  TYPE (T) :: V
  INTEGER :: COUNTCHAR

  OPEN (1, FILE='TEST.INPUT', FORM='FORMATTED')
  READ (1, FMT='(DT)', ADVANCE='NO', SIZE=COUNTCHAR) V
  CLOSE(UNIT=1)
  WRITE(6, '(DT)') V

END PROGRAM TEST1

Consider that procedure UDIO_READ_ARRAY reads an input file named TEST.INPUT that contains the following:

1, 3, 5, 7, 9, 2, 4, 6, 8, 10

In this case, the program TEST1 in procedure UDIO_WRITE_ARRAY prints:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>5</td>
<td>7</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>

Example 2

The following example shows list-directed formatted output and user-defined I/O:

MODULE M
  TYPE T
    REAL, POINTER :: R (:)
  CONTAINS
    PROCEDURE :: UDIO_WRITE_LD
    GENERIC :: WRITE(FORMATTED) => UDIO_WRITE_LD
  END TYPE T
  CONTAINS
    SUBROUTINE UDIO_WRITE_LD (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
      CLASS(T), INTENT(IN)            :: DTV
      INTEGER, INTENT(IN)             :: UNIT
      CHARACTER(LEN=*) , INTENT(IN)   :: IOTYPE
      INTEGER, INTENT(IN)             :: V_LIST (:)
      INTEGER, INTENT(INOUT)          :: IOSTAT
      CHARACTER(LEN=*) , INTENT(INOUT) :: IOMSG
      IOSTAT = 0
      PRINT *, SIZE (DTV%R)
      WRITE (UNIT, *) DTV%R
    END SUBROUTINE UDIO_WRITE_LD
END MODULE M

PROGRAM TEST2
  USE M
  TYPE (T)     :: X
  REAL, TARGET :: V (3)

  V = [ SIN (1.0), COS (1.0), TAN (1.0) ]
  X = T (R=V)
  PRINT *, X
END PROGRAM TEST2
TEST2 should print "3 0.8414710 0.5403023 1.557408".

Example 3
The following example shows user-defined derived-type NAMELIST input/output:

```fortran
! PROGRAM: udio_nml_read_write.f90
!
! This program tests NAMELIST READ and WRITE. In the WRITE subroutine, there are FORMATTED WRITES as well as NAMELIST WRITES.
!
MODULE UDIO
  TYPE MYDT
    INTEGER F1
    INTEGER F2
  CONTAINS
    PROCEDURE :: MYSUBROUTINE
      GENERIC :: READ (FORMATTED) => MYSUBROUTINE
  END TYPE MYDT

INTERFACE WRITE (FORMATTED)
  MODULE PROCEDURE :: WRITESUBROUTINE
END INTERFACE

CONTAINS

SUBROUTINE WRITESUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
  CLASS (MYDT),    INTENT(IN)    :: DTV
  INTEGER*4,        INTENT(IN)    :: UNIT
  CHARACTER (LEN=*) ,     INTENT(IN)    :: IOTYPE
  INTEGER,             INTENT(IN)    :: V_LIST(:)
  INTEGER*4,        INTENT(OUT)    :: IOSTAT
  CHARACTER (LEN=*) ,    INTENT(INOUT)    :: IOMSG

  INTEGER I, J
  NAMELIST /SUBRT_NML/ I, J

  I=DTV%F1
  J=DTV%F2

  WRITE (UNIT, '(A,2I5.2)', IOSTAT=IOSTAT) IOTYPE, DTV%F1, DTV%F2
  WRITE (UNIT, NML=SUBRT_NML)
END SUBROUTINE WRITESUBROUTINE

SUBROUTINE MYSUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
  CLASS (MYDT),    INTENT(INOUT) :: DTV
  INTEGER*4,        INTENT(IN)    :: UNIT
  CHARACTER (LEN=*) ,     INTENT(IN)    :: IOTYPE
  INTEGER,             INTENT(IN)    :: V_LIST(:)
  INTEGER*4,        INTENT(OUT)    :: IOSTAT
  CHARACTER (LEN=*) ,    INTENT(INOUT)    :: IOMSG

  INTEGER X, Y
  NAMELIST /SUBRT_NML/ X, Y

  READ (UNIT, *) DTV%F1, DTV%F2

! X and Y are aliases for DTV%F1 and DTV%F2 since field references cannot be referenced in a NAMELIST statement
```
X = DTV%F1
Y = DTV%F2

READ (UNIT, NML=SUBRT_NML, IOSTAT=IOSTAT)

END SUBROUTINE MYSUBROUTINE

END MODULE UDIO

PROGRAM UDIO_PROGRAM
  USE UDIO
  TYPE (MYDT) :: MYDTV
  INTEGER        :: A, B
  NAMELIST /MAIN_NML/ A, MYDTV, B

  OPEN (10, FILE='udio_nml_read_write.in')
  READ (10, NML=MAIN_NML)
  WRITE (6, NML=MAIN_NML)
  CLOSE (10)

END PROGRAM UDIO_PROGRAM

The following shows input file 'UDIO_NML_READ_WRITE.IN' on unit 10 read by MYSUBROUTINE:

&MAIN_NML
A=100
MYDTV=20 30
&SUBRT_NML
X=20
Y=30
/
/B=200
/

The following shows output to unit 6 by WRITESUBROUTINE:

&MAIN_NML
A = 100,
MYDTV=NAMELIST 20 30
&SUBRT_NML
I = 20,
J = 30
/
/B = 200
/

Example 4
The following example shows user-defined derived-type UNFORMATTED input/output:

! PROGRAM: UDIO_UNFORMATTED_1.F90
!
! This test first writes unformatted data to a file via user-defined derived type output
! and then reads the data from the file via user-defined derived type input.
!
MODULE UNFORMATTED_TYPE

  TYPE UNFORMATTED_TYPE
    INTEGER :: I

END PROGRAM UDIO_PROGRAM

The following shows input file 'UDIO_NML_READ_WRITE.IN' on unit 10 read by MYSUBROUTINE:
CHARACTER*25 :: CHAR
CONTAINS
    PROCEDURE :: MY_UNFMT_WRITE
    GENERIC :: WRITE (UNFORMATTED) => MY_UNFMT_WRITE
END TYPE UNFORMATTED_TYPE

INTERFACE READ (UNFORMATTED)
    MODULE PROCEDURE :: MY_UNFMT_READ
END INTERFACE

CONTAINS

SUBROUTINE MY_UNFMT_WRITE (DTV, UNIT, IOSTAT, IOMSG)
    CLASS (UNFORMATTED_TYPE), INTENT(IN) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(LEN=*), INTENT(INOUT) :: IOMSG

    WRITE (UNIT=UNIT, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%I+1, DTV%CHAR
END SUBROUTINE MY_UNFMT_WRITE

SUBROUTINE MY_UNFMT_READ (DTV, UNIT, IOSTAT, IOMSG)
    CLASS (UNFORMATTED_TYPE), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER (LEN=*), INTENT(INOUT) :: IOMSG

    READ (UNIT=UNIT, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%I, DTV%CHAR
    DTV%I = 1-DTV%I
END SUBROUTINE MY_UNFMT_READ

END MODULE UNFORMATTED

PROGRAM UNFORMATTED_WRITE_PROGRAM
    USE UNFORMATTED

    TYPE (UNFORMATTED_TYPE) :: READ_UNFORMATTED (1,2), UNFORMATTED_OBJECT (3:3,0:1)
    INTEGER :: IOSTAT
    CHARACTER(LEN=100) :: IOMSG

    UNFORMATTED_OBJECT (3, 1) = UNFORMATTED_TYPE (I=71, CHAR='HELLO WORLD.')
    UNFORMATTED_OBJECT (3, 0) = UNFORMATTED_TYPE (I=72, CHAR='WORLD HELLO.')

    OPEN (UNIT=71, FILE='MYUNFORMATTED_DATA.DAT', FORM='UNFORMATTED')
    WRITE (UNIT=71) UNFORMATTED_OBJECT
    CLOSE (UNIT=71)

    OPEN (UNIT=77, FILE='MYUNFORMATTED_DATA.DAT', FORM='UNFORMATTED')
    READ (UNIT=77) READ_UNFORMATTED
    CLOSE (UNIT=77)

    PRINT *, -READ_UNFORMATTED (:,1:2)%I .EQ. UNFORMATTED_OBJECT%I
    PRINT *, READ_UNFORMATTED%CHAR .EQ. UNFORMATTED_OBJECT%CHAR

END PROGRAM UNFORMATTED_WRITE_PROGRAM

The following shows output to unit * from program UNFORMATTED_WRITE_PROGRAM:
T T
T T
I/O Formatting

A format appearing in an input or output (I/O) statement specifies the form of data being transferred and the data conversion (editing) required to achieve that form. The format specified can be explicit or implicit.

Explicit format is indicated in a format specification that appears in a FORMAT statement or a character expression (the expression must evaluate to a valid format specification).

The format specification contains edit descriptors, which can be data edit descriptors, control edit descriptors, or string edit descriptors.

Implicit format is determined by the processor and is specified using list-directed or namelist formatting.

List-directed formatting is specified with an asterisk (*); namelist formatting is specified with a namelist group name.

List-directed formatting can be specified for advancing sequential files and internal files. Namelist formatting can be specified only for advancing sequential files.

See Also

Rules for List-Directed Sequential WRITE Statements for details on list-directed output
Rules for Namelist Sequential READ Statements for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Format Specifications

A format specification can appear in a FORMAT statement or a character expression. In a FORMAT statement, it is preceded by the keyword FORMAT. A format specification takes one of the following forms:

( [format-items])
( [format-items, ] unlimited-format-item)

format-items  Is format-items [[,] format-item]...
where format-item is one of the following:

[r] data-edit-desc
control-edit-desc
char-string-edit-desc
[r] (format-items)

r  (Optional) Is an integer literal constant. This is called a repeat specification. The range of r is 1 through 2147483647 (2**31-1). If r is omitted, it is assumed to be 1.

data-edit-desc  Is one of the data edit descriptors: I, B, O, Z, F, E, EN, ES, D, DT, G, L, or A.
A repeat specification can precede any data edit descriptor.

control-edit-desc  Is one of the control edit descriptors: T, TL, TR, X, S, SP, SS, BN, BZ, P, ;, /, $, \, and Q.
A repeat specification can precede the slash (/) edit descriptor.

char-string-edit-desc  Is one of the string edit descriptors: H, 'c', and "c", where c is a character constant.

unlimited-format-item  Is * (format-items). The * indicates an unlimited repeat count.
If more than one edit descriptor is specified, they must be separated by commas or slashes (/).

A comma can be omitted in the following cases:
- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

**Description**

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see BLANK Specifier in OPEN statements.)

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The following table summarizes the edit descriptors that can be used in format specifications.

**Summary of Edit Descriptors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>

</table>
Character Format Specifications

In data transfer I/O statements, a format specifier ([FMT=]format) can be a character expression that is a character array, character array element, or character constant. This type of format is also called a run-time format because it can be constructed or altered during program execution.

The expression must evaluate to a character string whose leading part is a valid format specification (including the enclosing parentheses).

If the expression is a character array element, the format specification must be contained entirely within that element.

If the expression is a character array, the format specification can continue past the first element into subsequent consecutive elements.

If the expression is a character constant delimited by apostrophes, use two consecutive apostrophes ("'") to represent an apostrophe character in the format specification; for example:

    PRINT "("NUM can't be a real number")"

Similarly, if the expression is a character constant delimited by quotation marks (""), use two consecutive quotation marks (""") to represent a quotation mark character in the format specification.

To avoid using consecutive apostrophes or quotation marks, you can put the character constant in an I/O list instead of a format specification, as follows:

    PRINT "(A)", "NUM can't be a real number"

The following shows another character format specification:

    WRITE (6, '(I12, I4, I12)') I, J, K

In the following example, the format specification changes with each iteration of the DO loop:

```
SUBROUTINE PRINT(TABLE)
    REAL TABLE(10,5)
    CHARACTER*5 FORCHR(0:5), RPAR*1, FBIG, FMED, FSML
    DATA FORCHR(0), RPAR /'(',')/'
    DATA FBIG, FMED, FSML /'F8.2,','F9.4,','F9.6,'/
    DO I=1,10
        DO J=1,5
            IF (TABLE(I,J) .GE. 100.) THEN
                FORCHR(J) = FBIG
            ELSE IF (TABLE(I,J) .GT. 0.1) THEN
                FORCHR(J) = FMED
            ELSE
                FORCHR(J) = FSML
            END IF
        END DO
        FORCHR(5)(5:5) = RPAR
    END DO
END
```

1 These delimiters can also be quotation marks ("").
WRITE (6, FORCHR) (TABLE(I,J), J=1,5)
END DO
END

The DATA statement assigns a left parenthesis to character array element FORCHR(0), and (for later use) a right parenthesis and three F edit descriptors to character variables.

Next, the proper F edit descriptors are selected for inclusion in the format specification. The selection is based on the magnitude of the individual elements of array TABLE.

A right parenthesis is added to the format specification just before the WRITE statement uses it.

NOTE
Format specifications stored in arrays are recompiled at run time each time they are used. If a Hollerith or character run-time format is used in a READ statement to read data into the format itself, that data is not copied back into the original array, and the array is unavailable for subsequent use as a run-time format specification.

Examples

The following example shows a format specification:

```
WRITE (*, 9000) int1, real1(3), char1
9000 FORMAT (I5, 3F4.5, A16)
! I5, 3F4.5, A16 is the format list.
```

The following shows a format example using a character expression:

```
WRITE (*, '(I5, 3F5.2, A16)') iolist
! I5, 3F4.5, A16 is the format list.
```

In the following example, the format list is put into an 80-character variable called MYLIST:

```
CHARACTER(80) MYLIST
MYLIST = '(I5, 3F5.2, A16)'
WRITE (*, MYLIST) iolist
```

Consider the following two-dimensional array:

```
1 2 3
4 5 6
```

In this case, the elements are stored in memory in the order: 1, 4, 2, 5, 3, 6 as follows:

```
CHARACTER(6) array(3)
DATA array / '(I5', ',3F5.2', ',A16)' /
WRITE (*, array) iolist
```

In the following example, the WRITE statement uses the character array element array(2) as the format specifier for data transfer:

```
CHARACTER(80) array(5)
array(2) = '(I5, 3F5.2, A16)'
WRITE (*, array(2)) iolist
```

**Data Edit Descriptors**

A data edit descriptor causes the transfer or conversion of data to or from its internal representation. The part of a record that is input or output and formatted with data edit descriptors (or character string edit descriptors) is called a *field*.

**Forms for Data Edit Descriptors**

A data edit descriptor takes one of the following forms:

- \([r]\)c
- \([r]\)cw
- \([r]\)cw.m
- \([r]\)cw.d
- \([r]\)cw.d[Ee]

  - **r** Is a repeat specification. The range of **r** is 1 through 2147483647 (2**31-1). If **r** is omitted, it is assumed to be 1.
  - **c** Is one of the following format codes: I, B, O, Z, F, E, EN, ES, D, G, L, or A.
  - **w** Is the total number of digits in the field (the field width). If omitted, the system applies default values (see Default Widths for Data Edit Descriptors). The range of **w** is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. For I, B, O, Z, and F, the range can start at zero.
  - **m** Is the minimum number of digits that must be in the field (including leading zeros). The range of **m** is 0 through 32767 (2**15-1) on Intel® 64 architecture; 0 through 255 (2**8-1) on IA-32 architecture.
  - **d** Is the number of digits to the right of the decimal point (the significant digits). The range of **d** is 0 through 255. If **d** exceeds 255 at compile time, a warning is issued and the value 255 is used. If **d** exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used. The number of significant digits is affected if a scale factor is specified for the data edit descriptor.
  - **E** Identifies an exponent field.
  - **e** Is the number of digits in the exponent. The range of **e** is 0 through 255. If **e** exceeds 255 at compile time, a warning is issued and the value 255 is used. If **e** exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used.

**Description**

Standard Fortran allows the field width to be omitted only for the A descriptor. However, Intel® Fortran allows the field width to be omitted for any data edit descriptor.

The **r**, **w**, **m**, **d**, and **e** must all be positive, unsigned, integer literal constants, or the digit 0 where allowed, or variable format expressions -- no kind parameter can be specified. They must not be named constants.

Actual useful ranges for **r**, **w**, **m**, **d**, and **e** may be constrained by record sizes (RECL) and the file system.
The data edit descriptors have the following specific forms:

<table>
<thead>
<tr>
<th>Type</th>
<th>Descriptors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>$Iw.m$, $Bw.m$, $Ow.m$, and $Zw.m$</td>
</tr>
<tr>
<td>Real and complex</td>
<td>$Fw.d$, $Ew.d[Ee]$, $ENw.d[Ee]$, $ESw.d[Ee]$, $Dw.d$, and $Gw.d[Ee]$</td>
</tr>
<tr>
<td>Logical</td>
<td>$Lw$</td>
</tr>
<tr>
<td>Character</td>
<td>$A[w]$</td>
</tr>
</tbody>
</table>

The $d$ must be specified with F, E, D, and G field descriptors even if $d$ is zero. The decimal point is also required. You must specify both $w$ and $d$.

A repeat specification can simplify formatting. For example, the following two statements are equivalent:

```
20  FORMAT (E12.4,E12.4,E12.4,I5,I5,I5,I5)
20  FORMAT (3E12.4,4I5)
```

### Examples

```
! This WRITE outputs three integers, each in a five-space field
! and four reals in pairs of F7.2 and F5.2 values.
INTEGER(2) int1, int2, int3
REAL(4) r1, r2, r3, r4
DATA int1, int2, int3 /143, 62, 999/
DATA r1, r2, r3, r4 /2458.32, 43.78, 664.55, 73.8/
WRITE (*,9000) int1, int2, int3, r1, r2, r3, r4
9000  FORMAT (3I5, 2(1X, F7.2, 1X, F5.2))
```

The following output is produced from the above code:

```
143  62  999 2458.32 43.78  664.55 73.80
```

### General Rules for Numeric Editing

The following rules apply to input and output data for numeric editing (data edit descriptors I, B, O, Z, F, E, EN, ES, D, and G).

### Rules for Input Processing

Leading blanks in the external field are ignored. If BLANK='NULL' is in effect (or the BN edit descriptor has been specified) embedded and trailing blanks are ignored; otherwise, they are treated as zeros. An all-blank field is treated as a value of zero.

The following table shows how blanks are interpreted by default:

<table>
<thead>
<tr>
<th>Type of Unit or File</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>An explicitly OPENed unit</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>An internal file</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>A preconnected file¹</td>
<td>BLANK='NULL'</td>
</tr>
</tbody>
</table>
For interactive input from preconnected files, you should explicitly specify the BN or BZ edit descriptor to ensure desired behavior.

A minus sign must precede a negative value in an external field; a plus sign is optional before a positive value.

In input records, constants can include any valid kind parameter. Named constants are not permitted.

If the data field in a record contains fewer than \( w \) characters, an input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data. The comma terminates the data field, and can also be used to designate null (zero-length) fields. For more information, see Terminating Short Fields of Input Data.

Rules for Output Processing

The field width \( w \) must be large enough to include any leading plus or minus sign, and any decimal point or exponent. For example, the field width for an E data edit descriptor must be large enough to contain the following:

- For positive numbers: \( d + 5 \) or \( d + e + 3 \) characters
- For negative numbers: \( d + 6 \) or \( d + e + 4 \) characters

A positive or zero value (zero is allowed for I, B, O, Z, F, and G descriptors) can have a plus sign, depending on which sign edit descriptor is in effect. If a value is negative, the leftmost nonblank character is a minus sign.

If the value is smaller than the field width specified, leading blanks are inserted (the value is right-justified).

If the value is too large for the field width specified, the entire output field is filled with asterisks (*).

When the value of the field width is zero, the compiler selects the smallest possible positive actual field width that does not result in the field being filled with asterisks.

Forms for data edit descriptors
Format Specifications

Integer Editing

Integer editing is controlled by the I (decimal), B (binary), O (octal), and Z (hexadecimal) data edit descriptors.

I Editing

The I edit descriptor transfers decimal integer values. It takes the following form:

\[ \text{I}w[.m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item must be of type integer; logical and real items are also allowed if the compiler option check format is not specified.

The G edit descriptor can be used to edit integer data; it follows the same rules as Iw.

Rules for Input Processing

On input, the I data edit descriptor transfers \( w \) characters from an external field and assigns their integer value to the corresponding I/O list item. The external field data must be an integer constant. \( w \) must not be zero.
If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>I4</td>
<td>2788</td>
<td>2788</td>
</tr>
<tr>
<td>I3</td>
<td>-26</td>
<td>-26</td>
</tr>
<tr>
<td>I9</td>
<td>^^^^^^312</td>
<td>312</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the I data edit descriptor transfers the value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by a sign (a plus sign is optional for positive values, a minus sign is required for negative values), followed by an unsigned integer constant with no leading zeros.

If \( m \) is specified, the unsigned integer constant will have at least \( m \) digits, padded with leading zeros if necessary.

If the output list item has the value zero, and \( m \) is zero, the external field is filled with blanks; if \( w \) is also zero, the external field is one blank.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value, left justifying the value with no leading blanks. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

The following shows output using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>I3</td>

<td>242</td>
<td>0242</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors
General rules for numeric editing

**B Editing**

The B data edit descriptor transfers binary (base 2) values. It takes the following form:

\[ Bw[,m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.
Rules for Input Processing

On input, the B data edit descriptor transfers \( w \) characters from an external field and assigns their binary value to the corresponding I/O list item. The external field must contain only binary digits (0 or 1) or blanks. \( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the B edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>1001</td>
<td>9</td>
</tr>
<tr>
<td>B1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>B2</td>
<td>^0</td>
<td>0</td>
</tr>
<tr>
<td>B6</td>
<td>^^122</td>
<td>An error; the 2 is invalid in binary notation</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the B data edit descriptor transfers the binary value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of binary digits) with no leading zeros. A negative value is transferred in internal form.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the B edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>9</td>
<td>1001</td>
</tr>
<tr>
<td>B2.2</td>
<td>1</td>
<td>01</td>
</tr>
<tr>
<td>B0</td>
<td>42</td>
<td>101010</td>
</tr>
</tbody>
</table>

See Also

Forms for data edit descriptors
General rules for numeric editing

O Editing

The O data edit descriptor transfers octal (base 8) values. It takes the following form:

\[ \text{O} w[.m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing

On input, the O data edit descriptor transfers \( w \) characters from an external field and assigns their octal value to the corresponding I/O list item. The external field must contain only octal digits (0 through 7) or blanks. \( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.
The following shows input using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>05</td>
<td>77777</td>
<td>32767</td>
</tr>
<tr>
<td>04</td>
<td>77777</td>
<td>4095</td>
</tr>
<tr>
<td>03</td>
<td>97^</td>
<td>An error; the 9 is invalid in octal notation</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the O data edit descriptor transfers the octal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of octal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>06</td>
<td>32767</td>
<td>^77777</td>
</tr>
<tr>
<td>012</td>
<td>-32767</td>
<td>^37777700001</td>

<td>123</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors
General rules for numeric editing

**Z Editing**

The Z data edit descriptor transfers hexadecimal (base 16) values. It takes the following form:

\[
Zw[m]
\]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

**Rules for Input Processing**

On input, the Z data edit descriptor transfers \( w \) characters from an external field and assigns their hexadecimal value to the corresponding I/O list item. The external field must contain only hexadecimal digits (0 through 9 and A (a) through F(f)) or blanks. \( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.
Rules for Output Processing

On output, the Z data edit descriptor transfers the hexadecimal value of the corresponding I/O list item, right-justified, to an external field that is $w$ characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of hexadecimal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If $w$ is zero, the external field has the minimum number of characters necessary to represent the value. If both $w$ and $m$ are zero and the internal value is zero, the external field is one blank.

If $m$ is specified, the unsigned integer constant must have at least $m$ digits. If necessary, it is padded with leading zeros.

If $m$ is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the Z edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z4</td>

Forms for data edit descriptors
General rules for numeric editing

Real and Complex Editing

Real and complex editing is controlled by the F, E, D, EN, ES, and G data edit descriptors.

If no field width ($w$) is specified for a real data edit descriptor, the system supplies default values.

Real data edit descriptors can be affected by specified scale factors.

**NOTE**

Do not use the real data edit descriptors when attempting to parse textual input. These descriptors accept some forms that are purely textual as valid numeric input values. For example, input values T and F are treated as values -1.0 and 0.0, respectively, for .TRUE. and .FALSE.
F Editing

The F data edit descriptor transfers real values. It takes the following form:

\[ F_w.d \]

The value of \( d \) (the number of places after the decimal point) must not exceed the value of \( w \) (the field width) unless \( w \) is zero. When \( w \) is zero, the processor selects the field width. On input, \( w \) must not be zero. The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the F data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The external field data must be an integer or real constant.

An input field is one of the following:

- An IEEE exception specification
- An optional sign, followed by a string of one or more digits optionally containing a decimal symbol; any blanks are interpreted as zeros.

The basic form can be followed by an exponent in one of the following forms:

- A sign followed by one or more digits
- An E or D followed by zero or more blanks, followed by an optional sign and one or more digits

An exponent containing a D is processed in the same way as an exponent containing an E.

If the input field contains only an exponent letter or decimal point, it is treated as a zero value.

If the input field does not contain a decimal point or an exponent, it is treated as a real number of \( w \) digits, with \( d \) digits to the right of the decimal point. (Leading zeros are added, if necessary.)

If the input field contains a decimal point, the location of that decimal point overrides the location specified by the F descriptor.

If the field contains an exponent, that exponent is used to establish the magnitude of the value before it is assigned to the list element.

An input field that is an IEEE exception specification consists of optional blanks, followed by either of the following:

- An optional sign, followed by the string 'INF' or the string 'INFINITY'; this is an IEEE infinity
- An optional sign, followed by the string 'NAN', optionally followed by zero or more alphanumeric characters enclosed in parentheses, optionally followed by blanks; this is an IEEE Nan

This form can not be used if the processor does not support IEEE infinities for the input variable.

This form can not be used if the processor does not support IEEE Nans for the input variable.

The NaN value is a quiet NaN if the only nonblank characters in the field are 'NAN' or 'NAN()'.

The following shows input using the F edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>123456789</td>
<td>123.45678</td>
</tr>
<tr>
<td>F8.5</td>
<td>-1234.567</td>
<td>-1234.56</td>
</tr>
<tr>
<td>F8.5</td>
<td>24.77E+2</td>
<td>2477.0</td>
</tr>
<tr>
<td>F5.2</td>
<td>1234567.89</td>
<td>123.45</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the F data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.
For an internal value that is an IEEE infinity, the output field consists of blanks, if needed, followed by a sign (optional if the value is positive and descriptor SP is not in effect), followed by the letters 'Inf' or 'Infinity', right justified within the field.

If $w$ is less than 3, the field is filled with asterisks; otherwise, if $w$ is less than 8, 'Inf' is produced.

For an internal value that is an IEEE NaN, the output field consists of blanks, if necessary, followed by the letters 'NaN' and optionally followed by one to $w - 5$ alphanumeric characters enclosed in parentheses, right justified within the field.

If $w$ is less than 3, the field is filled with asterisks.

For an internal value that is neither an IEEE infinity nor an IEEE NaN, the $w$ must be greater than or equal to $d + 3$ to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- At least one digit to the left of the decimal point
- The decimal point
- The $d$ digits to the right of the decimal point

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.00000001 in F5.1 format will be displayed as -0.0 rather than as 0.0. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the F edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>2.3547188</td>
<td>^2.35472</td>
</tr>
<tr>
<td>F9.3</td>
<td>8789.7361</td>

Forms for data edit descriptors
General rules for numeric editing
assume compiler option

E and D Editing
The E and D data edit descriptors transfer real values in exponential form. They take the following form:
Ew.d[Ee]
Dw.d

For the E edit descriptor, the value of $d$ (the number of places after the decimal point) plus $e$ (the number of digits in the exponent) must not exceed the value of $w$ (the field width).

For the D edit descriptor, the value of $d$ must not exceed the value of $w$.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing
On input, the E and D data edit descriptors transfer $w$ characters from an external field and assigns their real value to the corresponding I/O list item. The E and D descriptors interpret and assign input data in the same way as the F data edit descriptor.
The following shows input using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>E9.3</td>
<td>734.432E3</td>
<td>73432.0</td>
</tr>
<tr>
<td>E12.4</td>
<td>1022.43E-6</td>
<td>102.243E-6</td>
</tr>
<tr>
<td>E15.3</td>
<td>52.3759663^^^^^^^</td>
<td>52.3759663</td>
</tr>
<tr>
<td>E12.5</td>
<td>210.5271D+10</td>
<td>210.5271E10</td>
</tr>
<tr>
<td>BZ,D10.2</td>
<td>12345^^^^^</td>
<td>12345000.0D0</td>
</tr>
<tr>
<td>D10.2</td>
<td>123.45D0</td>
<td>123.45D0</td>
</tr>
<tr>
<td>D15.3</td>
<td>367.4981763D+04</td>
<td>3.674981763D+06</td>
</tr>
</tbody>
</table>

If the I/O list item is single-precision real, the E edit descriptor treats the D exponent indicator as an E indicator.

**Rules for Output Processing**

On output, the E and D data edit descriptors transfer the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.

The \( w \) should be greater than or equal to \( d + 7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- An optional zero to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ew.d</td>
<td>(</td>
<td>\text{exp}</td>
<td>) 99</td>
</tr>
<tr>
<td></td>
<td>99 &lt; (</td>
<td>\text{exp}</td>
<td>) 999</td>
</tr>
<tr>
<td>Ew.dEe</td>
<td>(</td>
<td>\text{exp}</td>
<td>) 10^e - 1</td>
</tr>
<tr>
<td>Dw.d</td>
<td>(</td>
<td>\text{exp}</td>
<td>) 99</td>
</tr>
<tr>
<td></td>
<td>99 &lt; (</td>
<td>\text{exp}</td>
<td>) 999</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

The exponent field width \( (e) \) is optional for the E edit descriptor; if omitted, the default value is 2. If \( e \) is specified, the \( w \) should be greater than or equal to \( d + e + 5 \).

**NOTE**

The \( w \) can be as small as \( d + 5 \) or \( d + e + 3 \), if the optional fields for the sign and the zero are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.01 in "-5P,E20.5" format will be displayed as -0.00 rather than as 0.00. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.
The following shows output using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>

- Assume compiler option

EN Editing
The EN data edit descriptor transfers values by using engineering notation. It takes the following form:

ENw.d[Ee]

The value of d (the number of places after the decimal point) plus e (the number of digits in the exponent) must not exceed the value of w (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing
On input, the EN data edit descriptor transfers w characters from an external field and assigns their real value to the corresponding I/O list item. The EN descriptor interprets and assigns input data in the same way as the F data edit descriptor.

The following shows input using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>EN11.3</td>
<td>-600.00E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^3.150E-03</td>
<td>.00315</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

Rules for Output Processing
On output, the EN data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to d decimal positions, to an external field that is w characters long. The real value is output in engineering notation, where the decimal exponent is divisible by 3 and the absolute value of the significand is greater than or equal to 1 and less than 1000 (unless the output value is zero).

The w should be greater than or equal to d+9 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One to three digits to the left of the decimal point
- The decimal point
- The d digits to the right of the decimal point
- The exponent
The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>E(w_1).d(e_2)</td>
<td>(</td>
<td>exp</td>
<td>99) (99 &lt;</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \(w\) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

The exponent field width \(e\) is optional; if omitted, the default value is 2. If \(e\) is specified, the \(w\) should be greater than or equal to \(d + e + 5\).

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for F\(w_1\).d\(e_2\).

The following shows output using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.2</td>
<td>475867.222</td>
<td>^475.87E+03</td>
</tr>
<tr>
<td>EN11.5</td>
<td>475867.222</td>
<td>**********</td>
</tr>
<tr>
<td>EN12.3</td>
<td>0.00069</td>
<td>^690.000E-06</td>
</tr>
<tr>
<td>EN10.3</td>
<td>-0.5555</td>
<td>**********</td>
</tr>
<tr>
<td>EN11.2</td>
<td>0.0</td>
<td>^000.00E-03</td>
</tr>
</tbody>
</table>

See Also
Forms for data edit descriptors
General rules for numeric editing

ES Editing
The ES data edit descriptor transfers values by using scientific notation. It takes the following form:

\[\text{ES}w_1.d[e_2]\]

The value of \(d\) (the number of places after the decimal point) plus \(e\) (the number of digits in the exponent) must not exceed the value of \(w\) (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing
On input, the ES data edit descriptor transfers \(w\) characters from an external field and assigns their real value to the corresponding I/O list item. The ES descriptor interprets and assigns input data in the same way as the F data edit descriptor.

The following shows input using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>ES11.3</td>
<td>-6.000E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^^3.150E-03</td>
<td>.00315</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>
Rules for Output Processing

On output, the ES data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to d decimal positions, to an external field that is w characters long. The real value is output in scientific notation, where the absolute value of the significand is greater than or equal to 1 and less than 10 (unless the output value is zero).

The w should be greater than or equal to d+7 to allow for the following:
- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The d digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESw.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>99</td>
<td>E+nn</td>
<td>E-nn</td>
<td></td>
</tr>
<tr>
<td>99 &lt;</td>
<td>exp</td>
<td>999</td>
<td>+nnn</td>
</tr>
<tr>
<td>ESw.dEe</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>exp</td>
<td>10e - 1</td>
<td>E+n₁n₂...nₑ</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width w is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

The exponent field width (e) is optional; if omitted, the default value is 2. If e is specified, the w should be greater than or equal to d + e + 5.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>

Forms for data edit descriptors
General rules for numeric editing

G Editing

The G data edit descriptor for generalized editing can be used for input or output with any intrinsic type. It takes the following forms:

Gw
Gw.d
Gw.dEe

w indicates the number of positions occupied by the field. w cannot be 0 for input. For output, if w is 0, the field width is selected by the processor. If w is zero, you can only specify forms G0 or G0.d. If w is nonzero, d must be specified.
For real and complex data types, the value of \(d\) (the number of places after the decimal point) plus \(e\) (the number of digits in the exponent) must not exceed the value of \(w\) (the field width), unless \(w\) is zero. For integer, character, and logical data types \(d\) and \(e\) are ignored.

When used to specify I/O for integer data, the \(GW, GW.d\) and \(GW.dEe\) edit descriptors follow the rules for \(IW\) editing.

When used to specify I/O for logical data, the \(GW.d\) and \(GW.dEe\) edit descriptors with nonzero \(w\) follow the rules for \(LW\) editing. On output, if \(w\) is 0, the \(GW\) and \(GW.d\) edit descriptors follow the rules for \(L1\) editing.

When used to specify I/O for character data, the \(GW.d\) and \(GW.dEe\) edit descriptors with nonzero \(w\) follow the same rules as \(AW\) editing. For output, when \(w\) is zero, the \(GW\) and \(GW.d\) edit descriptors follow the rules for \(A\) editing when no \(w\) is specified.

**Rules for Real Input Processing**

On input, the \(G\) data edit descriptor transfers \(w\) characters from an external field and assigns their real value to the corresponding I/O list item. The \(G\) descriptor interprets and assigns input data in the same way as the \(F\) data edit descriptor.

**Rules for Real Output Processing**

The form in which the value is written depends on the magnitude of the internal value being edited. \(N\) is the magnitude of the internal value and \(r\) is the rounding mode value defined in the table below. If \(0 < N < 0.1 - r \times 10^{-d-1}\) or \(N \geq 10^{-d} - r\), or \(N\) is identically 0, \(w\) is nonzero, and \(d\) is 0, \(GW.d\) output editing is the same as \(k PEw.d\) output editing and \(GW.dEe\) output editing is the same as \(k PEw.d Ee\) output editing, where \(k\) is the scale factor. If \(0.1 - r \times 10^{-d-1} \leq N < 10^{-d} - r\) or \(N\) is identically 0 and \(d\) is not zero, the scale factor has no effect, and the value of \(N\) determines the editing as follows:

**Effect of Data Magnitude on G Format Conversions**

<table>
<thead>
<tr>
<th>Data Magnitude</th>
<th>Effective Conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>(N = 0)</td>
<td>(FW - n)(d -1), n('b')</td>
</tr>
<tr>
<td>(0.1 - r \times 10^{-d-1} \leq N &lt; 1 - r \times 10^{-d})</td>
<td>(FW - n).d, n('b')</td>
</tr>
<tr>
<td>(1 - r \times 10^{-d} \leq N &lt; 10 - r \times 10^{-d+1})</td>
<td>(FW - n).(d -1), n('b')</td>
</tr>
<tr>
<td>(10 - r \times 10^{-d+1} \leq N &lt; 100 - r \times 10^{-d+2})</td>
<td>(FW - n).(d -2), n('b')</td>
</tr>
<tr>
<td>(\ldots)</td>
<td>(\ldots)</td>
</tr>
<tr>
<td>(10^{d-2} - r \times 10^{-2} \leq N &lt; 10^{d-1} - r \times 10^{-1})</td>
<td>(FW - n).1, n('b')</td>
</tr>
<tr>
<td>(10^{d-1} - r \times 10^{-1} \leq N &lt; 10^{d} - r)</td>
<td>((W - n).0, n('b'))</td>
</tr>
</tbody>
</table>

The 'b' is a blank following the numeric data representation. For \(GW.d, n('b')\) is 4 blanks. For \(GW.dEe, n('b')\) is \(e+2\) blanks.

The \(r\) is defined for each I/O rounding mode as follows:

<table>
<thead>
<tr>
<th>Rounding Mode</th>
<th>(r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPATIBLE</td>
<td>0.5</td>
</tr>
<tr>
<td>NEAREST</td>
<td>0.5 if the higher value is even</td>
</tr>
<tr>
<td></td>
<td>-0.5 if the lower value is even</td>
</tr>
</tbody>
</table>
### Rounding Mode

<table>
<thead>
<tr>
<th>Rounding Mode</th>
<th>r</th>
</tr>
</thead>
<tbody>
<tr>
<td>UP</td>
<td>1</td>
</tr>
<tr>
<td>DOWN</td>
<td>0</td>
</tr>
<tr>
<td>ZERO</td>
<td>1 if the internal value is negative&lt;br&gt;0 if the internal value is positive</td>
</tr>
</tbody>
</table>

Note that the scale factor has no effect on output unless the magnitude of the datum to be edited is outside the range that permits effective use of F editing.

The \( w \) should be greater than or equal to \( d + 7 \) to allow for the following:
- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The 4-digit or \( e + 2 \)-digit exponent

If \( e \) is specified, the \( w \) should be greater than or equal to \( d + e + 5 \).

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the G edit descriptor and compares it to output using equivalent F editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>

<td>^123457.^^^^</td>
<td>F13.6</td>
<td>123456.789012</td>
</tr>
<tr>
<td>-1234567.89012345</td>
<td>G13.6</td>
<td>^-0.123457E+07</td>
<td>F13.6</td>
<td>**************</td>
</tr>
</tbody>
</table>

If \( w \) is zero, the Gw and Gw.d edit descriptors follow the rules for the G.w.dEe edit descriptors on output, but with leading and trailing blanks removed.

**See Also**
- Forms for data edit descriptors
- General rules for numeric editing
- I data edit descriptor
- L data edit descriptor
- A data edit descriptor
- Scale Factor Editing (P)

**Complex Editing**
A complex value is an ordered pair of real values. Complex editing is specified by a pair of real edit descriptors, using any combination of the forms: Fw.d, Ew.d[Ee], Dw.d, ENw.d[Ee], ESw.d[Ee], or Gw.d[Ee].
**Rules for Input Processing**

On input, the two successive fields are read and assigned to the corresponding complex I/O list item as its real and imaginary part, respectively.

The following shows input using complex editing:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5, F8.5</td>
<td>1234567812345.67</td>
<td>123.45678, 12345.67</td>
</tr>
<tr>
<td>E9.1, F9.3</td>
<td>734.432E8123456789</td>
<td>734.432E8, 123456.789</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the two parts of the complex value are transferred under the control of repeated or successive real edit descriptors. The two parts are transferred consecutively without punctuation or blanks, unless control or character string edit descriptors are specified between the pair of real edit descriptors.

The following shows output using complex editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>2F8.5</td>
<td>2.3547188, 3.456732</td>
<td>^2.35472 ^3.45673</td>
</tr>
<tr>
<td>E9.2, '^^', E5.3</td>
<td>47587.222, 56.123</td>
<td>^0.48E+06^^,*****</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors
General rules for numeric editing
General Rules for Complex Constants for details on complex constants

**Logical Editing (L)**

The L data edit descriptor transfers logical values. It takes the following form:

L\(w\)

The specified I/O list item must be of type logical or integer.

The G edit descriptor can be used to edit logical data; it follows the same rules as L\(w\).

**Rules for Input Processing**

On input, the L data edit descriptor transfers \(w\) characters from an external field and assigns their logical value to the corresponding I/O list item. The value assigned depends on the external field data, as follows:

- .TRUE. is assigned if the first nonblank character is .T, T, .t, or t. The logical constant .TRUE. is an acceptable input form.
- .FALSE. is assigned if the first nonblank character is .F, F, .f, or f, or the entire field is filled with blanks. The logical constant .FALSE. is an acceptable input form.

If an other value appears in the external field, an error occurs.

**Rules for Output Processing**

On output, the L data edit descriptor transfers the following to an external field that is \(w\) characters long: \(w - 1\) blanks, followed by a T or F (if the value is .TRUE. or .FALSE., respectively).

The following shows output using the L edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>L5</td>
<td>.TRUE.</td>
<td>^^^^T</td>
</tr>
<tr>
<td>L1</td>
<td>.FALSE.</td>
<td>F</td>
</tr>
</tbody>
</table>
See Also
Forms for data edit descriptors

Character Editing (A)
The A data edit descriptor transfers character or Hollerith values. It takes the following form:
A[w]
If the corresponding I/O list item is of type character, character data is transferred. If the list item is of any
other type, Hollerith data is transferred.
The G edit descriptor can be used to edit character data; it follows the same rules as A[w].

Rules for Input Processing
On input, the A data edit descriptor transfers \( w \) characters from an external field and assigns them to the
corresponding I/O list item.
The maximum number of characters that can be stored depends on the size of the I/O list item, as follows:

- For character data, the maximum size is the length of the corresponding I/O list item.
- For noncharacter data, the maximum size depends on the data type, as shown in the following table:

<table>
<thead>
<tr>
<th>I/O List Element</th>
<th>Maximum Number of Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(1) or LOGICAL*1</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2) or LOGICAL*2</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4) or LOGICAL*4</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8) or LOGICAL*8</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER(1) or INTEGER*1</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2) or INTEGER*2</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4) or INTEGER*4</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8) or INTEGER*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(4) or REAL*4</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8) or REAL*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16) or REAL*16</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(4) or COMPLEX*8 (^1)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX (^1)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8) or COMPLEX*16 (^1)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16) or COMPLEX*32 (^1)</td>
<td>32</td>
</tr>
</tbody>
</table>

\(^1\) Complex values are treated as pairs of real numbers, so complex editing requires a pair of edit
descriptors. (See Complex Editing.)
If \( w \) is equal to or greater than the length (\( \text{len} \)) of the input item, the rightmost characters are assigned to that item. The leftmost excess characters are ignored.

If \( w \) is less than \( \text{len} \), or less than the number of characters that can be stored, \( w \) characters are assigned to the list item, left-justified, and followed by trailing blanks.

The following shows input using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A6</td>

<td>REAL (4)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^#</td>
<td>PAGE^#^</td>
<td>REAL (8)</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the A data edit descriptor transfers the contents of the corresponding I/O list item to an external field that is \( w \) characters long.

If \( w \) is greater than the size of the list item, the data is transferred to the output field, right-justified, with leading blanks. If \( w \) is less than or equal to the size of the list item, the leftmost \( w \) characters are transferred.

The following shows output using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>

Forms for data edit descriptors

**Defined I/O Editing (DT)**

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

\[
\text{DT} \ [\text{string}] \ [(v\text{-list})]
\]

For more information on this edit descriptor, see DT Edit Descriptor in User-Defined I/O.

**Default Widths for Data Edit Descriptors**

If \( w \) (the field width) is omitted for the data edit descriptors, the system applies default values. For the real data edit descriptors, the system also applies default values for \( d \) (the number of characters to the right of the decimal point), and \( e \) (the number of characters in the exponent).

These defaults are based on the data type of the I/O list item, and are listed in the following table:

<table>
<thead>
<tr>
<th>Default Widths for Data Edit Descriptors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edit Descriptor</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>I, B, O, Z, G</td>
</tr>
<tr>
<td>Edit Descriptor</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>O, Z</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>L, G</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>F, E, ES, G, D</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>EN</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>A¹, G</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

¹ The default is the actual length of the corresponding I/O list item.

**Terminating Short Fields of Input Data**

On input, an edit descriptor such as Fw.d specifies that w characters (the field width) are to be read from the external field.

If the field contains fewer than w characters, the input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data.
Padding Short Fields
You can use the OPEN statement specifier PAD='YES' to indicate blank padding for short fields of input data. However, blanks can be interpreted as blanks or zeros, depending on which default behavior is in effect at the time. Consider the following:

```
READ (2, '(I5)') J
```

If 3 is input for J, the value of J will be 30000 or 3 depending on which default behavior is in effect (BLANK='NULL' or BLANK='ZERO'). This can give unexpected results.

To ensure that the desired behavior is in effect, explicitly specify the BN or BZ edit descriptor. For example, the following ensures that blanks are interpreted as blanks (and not as zeros):

```
READ (2, '(BN, I5)') J
```

Using Commas to Separate Input Data
You can use a comma to terminate a short data field. The comma has no effect on the d part (the number of characters to the right of the decimal point) of the specification.

The comma overrides the w specified for the I, B, O, Z, F, E, D, EN, ES, G, and L edit descriptors. For example, suppose the following statements are executed:

```
READ (5,100) I,J,A,B
100  FORMAT (2I6,2F10.2)
```

Suppose a record containing the following values is read:

```
1, -2, 1.0, 35
```

The following assignments occur:

```
I = 1
J = -2
A = 1.0
B = 0.35
```

A comma can only terminate fields less than w characters long. If a comma follows a field of w or more characters, the comma is considered part of the next field.

A null (zero-length) field is designated by two successive commas, or by a comma after a field of w characters. Depending on the field descriptor specified, the resulting value assigned is 0, 0.0, 0.0D0, 0.0Q0, or .FALSE..

General Rules for Numeric Editing

Control Edit Descriptors
A control edit descriptor either directly determines how text is displayed or affects the conversions performed by subsequent data edit descriptors.

Forms for Control Edit Descriptors
A control edit descriptor takes one of the following forms:

- c
- cn
- nc
c

Is one of the following format codes: T, TL, TR, X, S, SP, SS, BN, BZ, P, RU, RD, RZ, RN, RC, RP, DC, DP, ;, /, \, $, and Q.

n

Is a number of character positions. It must be a positive integer literal constant or a variable format expression. No kind parameter can be specified. It cannot be a named constant.

The range of n is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

Description

In general, control edit descriptors are nonrepeatable. The only exception is the slash (/) edit descriptor, which can be preceded by a repeat specification or a * indicating an unlimited repeat count.

The control edit descriptors have the following specific forms:

<table>
<thead>
<tr>
<th>Positional:</th>
<th>Tn, TLn, TRn, and nX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign:</td>
<td>S, SP, and SS</td>
</tr>
<tr>
<td>Blank interpretation:</td>
<td>BN and BZ</td>
</tr>
<tr>
<td>Rounding mode:</td>
<td>RU, RD, RZ, RN, RC, and RP</td>
</tr>
<tr>
<td>Decimal mode:</td>
<td>DC and DP</td>
</tr>
<tr>
<td>Scale factor:</td>
<td>kP</td>
</tr>
<tr>
<td>Miscellaneous:</td>
<td>;, /, , $, and Q</td>
</tr>
</tbody>
</table>

The P edit descriptor is an exception to the general control edit descriptor syntax. It is preceded by a scale factor, rather than a character position specifier.

Control edit descriptors can be grouped in parentheses and preceded by a group repeat specification.

See Also

Group repeat specifications
Format Specifications

Positional Editing

The T, TL, TR, and X edit descriptors specify the position where the next character is transferred to or from a record.

On output, these descriptors do not themselves cause characters to be transferred and do not affect the length of the record. If characters are transferred to positions at or after the position specified by one of these descriptors, positions skipped and not previously filled are filled with blanks. The result is as if the entire record was initially filled with blanks.

The TR and X edit descriptors produce the same results.

See Also

Forms for Control Edit Descriptors

T Editing

The T edit descriptor specifies a character position in an I/O record. It takes the following form:

Tn
The $n$ is a positive integer literal constant (with no kind parameter) indicating the character position of the record, relative to the left tab limit.

On input, the T descriptor positions the external record at the character position specified by $n$. On output, the T descriptor indicates that data transfer begins at the $n$th character position of the external record.

**Examples**

In the following examples, the symbol ^ represents a nonprinting blank character.

Suppose a file has a record containing the value ABC^^^XYZ, and the following statements are executed:

```fortran
READ (11,10) VALUE1, VALUE2
10 FORMAT (T7,A3,T1,A3)
```

The values read first are XYZ, then ABC.

Suppose the following statements are executed:

```fortran
PRINT 25
25 FORMAT (T51,'COLUMN 2',T21,'COLUMN 1')
```

The following line is printed at the positions indicated:

```
Position 20                  Position 50
|                           |
COLUMN 1                     COLUMN 2
```

Note that the first character of the record printed was reserved as a control character.

**See Also**

Printing of Formatted Records

**TL Editing**

The TL edit descriptor specifies a character position to the left of the current position in an I/O record. It takes the following form:

```fortran
TLn
```

The $n$ is a positive integer literal constant (with no kind parameter) indicating the $n$th character position to the left of the current character.

If $n$ is greater than or equal to the current position, the next character accessed is the first character of the record.

**TR Editing**

The TR edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

```fortran
TRn
```

The $n$ is a positive integer literal constant (with no kind parameter) indicating the $n$th character position to the right of the current character.

**X Editing**

The X edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

```fortran
nX
```

The $n$ is a positive integer literal constant (with no kind parameter) indicating the $n$th character position to the right of the current character.
On output, the X edit descriptor does not output any characters when it appears at the end of a format specification; for example:

```
WRITE (6,99) K
99 FORMAT ('^K=',I6,5X)
```

Note that the symbol ^ represents a nonprinting blank character. This example writes a record of only 9 characters. To cause $n$ trailing blanks to be output at the end of a record, specify a format of $n('^')$.

### Sign Editing

The SP, SS and S edit descriptors control the output of the optional plus (+) sign within numeric output fields. These descriptors have no effect during execution of input statements.

These specifiers correspond to the SIGN= specifier values PLUS, SUPPRESS, and PROCESSOR_DEFINED, respectively.

Within a format specification, a sign editing descriptor affects all subsequent I, F, E, EN, ES, D, and G descriptors until another sign editing descriptor occurs.

### Examples

Consider the following:

```
INTEGER i
REAL r

! The following statements write:
! 251  +251  251  +251  251
i = 251
WRITE (*, 100) i, i, i, i, i
100 FORMAT (I5, SP, I5, SS, I5, SP, I5, S, I5)

! The following statements write:
! 0.673E+4  +.673E+4 0.673E+4  +.673E+4 0.673E+4
r = 67.3E2
WRITE (*, 200) r, r, r, r, r
200 FORMAT (E8.3E1, 1X, SP, E8.3E1, SS, E8.3E1, 1X, SP, &
& E8.3E1, S, E8.3E1)
```

### See Also

Forms for Control Edit Descriptors

### SP Editing

The SP edit descriptor causes the processor to produce a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

```
SP
```

### SS Editing

The SS edit descriptor causes the processor to suppress a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

```
SS
```

### S Editing

The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the following form:
The S edit descriptor restores to the processor the discretion of producing plus characters on an optional basis.

**Blank Editing**

The BN and BZ descriptors control the interpretation of embedded and trailing blanks within numeric input fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input data transfer statement. (For more information, see the BLANK specifier in OPEN statements.)

**See Also**

Forms for Control Edit Descriptors

**BN Editing**

The BN edit descriptor causes the processor to *ignore* all embedded and trailing blanks in numeric input fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified. An all-blank field is treated as zero.

**Examples**

If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as '234'.

Consider the following code:

```fortran
READ (*, 100) n
100 FORMAT (BN, I6)
```

If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
123
123
123   456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and *iolist*. Suppose you enter 123 and press Enter in response to the following READ statement:

```fortran
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

**BZ Editing**

The BZ edit descriptor causes the processor to *interpret* all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

BZ
Examples

The input field ' 23 4 ' is interpreted as ' 23040 '. If ' 23 4 ' is entered, the formatter adds one blank to pad the input to the six-digit integer format (I6), but this extra space is ignored, and the input is interpreted as ' 2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

Round Editing

The RU, RD, RZ, RN, RC, and RP edit descriptors temporarily change the I/O rounding mode for a connection. These specifiers correspond to the ROUND= specifier values UP, DOWN, ZERO, NEAREST, COMPATIBLE, and PROCESSOR DEFINED, respectively.

The I/O rounding mode affects the conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different round editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors

RU Editing

The RU edit descriptor causes rounding to the smallest value that is greater than or equal to the original value. It takes the following form:

RU

RD Editing

The RD edit descriptor causes rounding to the largest representable value that is less than or equal to the original value. It takes the following form:

RD

RZ Editing

The RZ edit descriptor causes rounding to the value closest to the original value, but not greater in magnitude. It takes the following form:

RZ

RN Editing

The RN edit descriptor causes rounding to the closer of the two nearest representable values, if one is closer than the other. If both values are equally close then the even value is chosen. It takes the following form:

RN
**RC Editing**

The RC edit descriptor causes rounding to the closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero. It takes the following form:

RC

**RP Editing**

The RP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

RP

**Decimal Editing**

The **DC** and **DP** edit descriptors temporarily change the decimal edit mode for a connection. These specifiers correspond to the DECIMAL= specifier values COMMA and POINT, respectively. The decimal editing mode controls the representation of the decimal symbol during conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different decimal editing descriptor is encountered or until the end of the current I/O statement.

**See Also**

Forms for Control Edit Descriptors

**DC Editing**

The DC edit descriptor changes the decimal editing mode for a connection to a decimal comma. It takes the following form:

DC

Note that during list-directed I/O, a semicolon is used as a value separator in place of a comma.

**DP Editing**

The DP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

DP

**Scale-Factor Editing (P)**

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

\[ kP \]

The \( k \) is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of \( k \) is -128 to 127.

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify 0P.

Format reversion does not affect the scale factor. (For more information on format reversion, see Interaction Between Format Specifications and I/O Lists.)
**Rules for Input Processing**

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by $10^{-k}$. For example, a $2P$ scale factor multiplies an input value by .01, moving the decimal point two places to the left. A $-2P$ scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The following shows input using the $P$ edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3PE10.5</td>
<td>^^^37.614^</td>
<td>.037614</td>
</tr>
<tr>
<td>3PE10.5</td>
<td>^^37.614E2</td>
<td>3761.4</td>
</tr>
<tr>
<td>-3PE10.5</td>
<td>^^^^37.614</td>
<td>37614.0</td>
</tr>
</tbody>
</table>

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

- (3P, I6, F6.3, E8.1)
- (I6, 3P, F6.3, E8.1)
- (I6, 3PF6.3, E8.1)

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

**Rules for Output Processing**

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by $10^k$. This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by $10^k$, and $k$ is subtracted from the exponent. This changes the form of the data.

  A positive scale factor decreases the exponent; a negative scale factor increases the exponent.

  For a positive scale factor, $k$ must be less than $d + 2$ or an output conversion error occurs.
- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).

  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.
- For EN and ES editing, the scale factor has no effect.

The following shows output using the $P$ edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1PE12.3</td>
<td>-270.139</td>
<td>^^-2.701E+02</td>
</tr>
<tr>
<td>1P,E12.2</td>
<td>-270.139</td>
<td>^^^-2.70E+02</td>
</tr>
<tr>
<td>-1PE12.2</td>
<td>-270.139</td>
<td>^^^^-0.03E+04</td>
</tr>
</tbody>
</table>
Examples

The following shows a FORMAT statement containing a scale factor:

```fortran
DIMENSION A(6)
DO 10 I=1,6
  A(I) = 25.
  WRITE (6, 100) A
100  FORMAT( ' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:

```
25.00  2500.00  2500.00
2500.00  2500.00  2500.00
```

The following code uses scale-factor editing when reading:

```fortran
READ (*, 100) a, b, c, d
100   FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)
WRITE (*, 200) a, b, c, d
200   FORMAT (4F11.3)
```

If the following data is entered:

```
12340000  12340000  12340000  12340000
  12.34     12.34     12.34     12.34
  12.34e0   12.34e0   12.34e0   12.34e0
  12.34e3   12.34e3   12.34e3   12.34e3
```

The program's output is:

```
12.340  1.234  1.234  1234.000
12.340  1.234  1.234  1234.000
12340.000 12340.000 12340.000 12340.000
```

The next code shows scale-factor editing when writing:

```fortran
a = 12.34
WRITE (*, 100) a, a, a, a, a, a
100   FORMAT (1X, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
        -2P, F9.4, E11.4E2)
```

This program's output is:

```
12.3400 0.1234E+02 123.4000 1.2340E+01   0.1234 0.0012E+04
```

See Also

Forms for Control Edit Descriptors

Slash Editing (/)

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

```
[r]/
```

The $r$ is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of $r$ is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If $r$ is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:
When \( n \) consecutive slashes appear between two edit descriptors, \( n - 1 \) records are skipped on input, or \( n - 1 \) blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.

When \( n \) consecutive slashes appear at the beginning or end of a format specification, \( n \) records are skipped or \( n \) blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```
WRITE (6,99)
99 FORMAT ('1',TS1,'HEADING LINE'//TS1,'SUBHEADING LINE'//)
```

The following lines are written:

<table>
<thead>
<tr>
<th>Column 50, top of page</th>
<th>HEADING LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>(blank line)</td>
<td>SUBHEADING LINE</td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
</tbody>
</table>

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

### Examples

The following statements write spreadsheet column and row labels:

```
WRITE (*, 100)
100 FORMAT ('   A     B     C     D     E'                             &
          '/,' 1',/,' 2',/,' 3',/,' 4',/,' 5')</code`
```

The above example generates the following output:

```
A     B     C     D     E
1
2
3
4
5
```

### See Also

Forms for Control Edit Descriptors

### Colon Editing (:)

The colon edit descriptor terminates format control if there are no more items in the I/O list.

### Examples

Suppose the following statements are specified:

```
PRINT 1,3
PRINT 2,13
1 FORMAT (' I=',I2,' J=',I2)
2 FORMAT (' K=',I2,' L=',I2)
```

The above code causes the following lines to be written (the symbol ^ represents a nonprinting blank character):

```
I=^3^J=
K=13
```

The following shows another example:

```
! The following example writes a= 3.20 b= .99
REAL a, b, c, d
DATA a /3.2/, b /.9871515/
```

See Also
Forms for Control Edit Descriptors

Dollar-Sign ($) and Backslash (\) Editing

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).

For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

```
TYPE 100
100    FORMAT (' ENTER RADIUS VALUE ',',$)
ACCEPT 200, RADIUS
200    FORMAT (F6.2)
```

The following prompt is displayed:

```
ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
ENTER RADIUS VALUE    12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

```
CHARACTER(20) MYNAME
WRITE (*,9000)
9000 FORMAT ('Please type your name:','
READ (*,9001) MYNAME
9001 FORMAT (A20)
WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

The following shows the same example using Fortran standard constructs:

```
CHARACTER(20) MYNAME
WRITE (*,9000, ADVANCE='NO')
9000 FORMAT ('Please type your name:')
READ (*,9001) MYNAME
9001 FORMAT (A20)
WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

See Also
Forms for Control Edit Descriptors
Character Count Editing (Q)

The character count edit descriptor returns the remaining number of characters in the current input record.

The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```
READ (4,1000) XRAY, KK, NCHRS, (ICHR(I), I=1,NCHRS)
1000 FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)

If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

Examples

Consider the following:

```
CHARACTER ICHAR(80)
READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
1000  FORMAT (E15.7, I4, Q, 80A1)
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```

The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```
CHARACTER STR(80)
INTEGER LENGTH
REAL REAL1
OPEN (UNIT = 10, FILE = 'Q.DAT')
100  FORMAT (F8.3, Q, 80A1)
READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
 & I= 1, LENGTH)
END
```

The output on the screen is:

```
1234.567  13 Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abedefg
abcd
```
Consider it is then READ with the following statements:

```fortran
OPEN (10, FILE = "Q.DAT")
READ (10, 100) LENGTH
100 FORMAT (Q)
WRITE (*, '(I2)') LENGTH
READ (10, 100) LENGTH
WRITE (*, '(I2)') LENGTH
END
```

The output to the screen would be:

7
4

Forms for Control Edit Descriptors

Character String Edit Descriptors

Character string edit descriptors control the output of character strings. The character string edit descriptors are the character constant and H edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification or a * indicating an unlimited repeat count.

See Also
Nested and Group Repeat Specifications

Character Constant Editing

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

'\texttt{string}'

"\texttt{string}\"

The \texttt{string} is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.

To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes ("'") in the format specification; for example:

```fortran
50 FORMAT ('TODAY''S DATE IS:','I2,'/'I2,'/'I2)
```

Note that the symbol ^ represents a nonprinting blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks (""") in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.

Examples

Consider the following '(3I5)' format in the WRITE statement:

```fortran
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```fortran
WRITE (10, 100) I1, I2, I3
100 FORMAT (3I5)
```
The following shows another example:

```
! These WRITE statements both output ABC'DEF
! (The leading blank is a carriage-control character).
WRITE (*, 970)
970   FORMAT (' ABC''DEF')
WRITE (*, '('' ABC''''DEF'')')
! The following WRITE also outputs ABC'DEF. No carriage-
! control character is necessary for list-directed I/O.
WRITE (*,*) 'ABC''DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant `ABC'DEF` requires no special treatment:

```
WRITE (*,*) "ABC'DEF"
```

Format Specifications

**H Editing**

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

An H edit descriptor has the form of a Hollerith constant, as follows:

```
nHstring
```

- `n` is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in `string` (including blanks and tabs).

  The range of `n` is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

- `string` is a string of printable ASCII characters.

On input, the H edit descriptor transfers `n` characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters. If the edit descriptor appears in a FORMAT statement, the replaced characters are preserved for future uses of that FORMAT statement; otherwise, the replacement is discarded.

On output, the H edit descriptor causes `n` characters following the letter H to be output to an external record.

**Examples**

```
! These WRITE statements both print "Don't misspell 'Hollerith'"
! (The leading blanks are carriage-control characters).
! Hollerith formatting does not require you to embed additional
! single quotation marks as shown in the second example.
!
WRITE (*, 960)
960   FORMAT ('27H Don't misspell 'Hollerith')
WRITE (*, 961)
961   FORMAT (' Don''t misspell ''Hollerith'''')
```

Format Specifications

Nested and Group Repeat Specifications

Format specifications can include nested format specifications enclosed in parentheses; for example:

```fortran
15 FORMAT (E7.2, I8, I2, (A5, I6))
35 FORMAT (A6, (L8 (I2)), A)
```

A group repeat specification can precede a nested group of edit descriptors; it can be an unsigned integer literal constant, a variable format expression, or * to indicate an unlimited repeat count. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

```fortran
50 FORMAT (2I8, 3(F8.3, E15.7), 2I5)
```

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

```fortran
76 FORMAT ('MONTHLY', 3('TOTAL'))
100 FORMAT (I8, (T7), A4)
```

Each of the following can be used to read data at the end of an input record into N elements of array A:

```fortran
read (10, '<N>F8.2') A(1:N)  ! Variable format expression
read(10, '(*F8.2)') A(1:N)   ! Unlimited repeat count
```

Variable Format Expressions

A variable format expression is a numeric expression enclosed in angle brackets (< >) that can be used in a FORMAT statement or in a character format specification.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.

Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications that are not character constant expressions.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

Examples

Consider the following statement:

```fortran
FORMAT (I<J+1>)
```
When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```fortran
DIMENSION A(5)
DATA A/1.,2.,3.,4.,5./

DO 10 I=1,10
WRITE (6,100) I
100 FORMAT (I<MAX(I,5)>)
10 CONTINUE

DO 20 I=1,5
WRITE (6,101) (A(I), J=1,I)
101 FORMAT (<I>F10.<I-1>)
20 CONTINUE
END
```

On execution, these statements produce the following output:

```
1
2
3
4
5
6
7
8
9
10
2.0 2.0
3.00 3.00 3.00
4.000 4.000 4.000 4.000
5.0000 5.0000 5.0000 5.0000 5.0000
```

The following shows another example:

```fortran
WRITE(6,20) INT1
20     FORMAT(I<MAX(20,5)>)

WRITE(6,FMT=30) REAL2(10), REAL3
30     FORMAT(<J+K>X, <2*M>F8.3)
```

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

```fortran
INTEGER width, value
width=2
READ (*,10) width, value
10     FORMAT(I1, I <width>)
PRINT *, value
END
```

When given input 3123, the program will print 123 and not 12.

*Interaction Between Format Specifications and I/O Lists* for details on the synchronization of I/O lists with formats
Printing of Formatted Records

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

Printing control characters are a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following table lists the valid control characters for printing:

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Overprinting</td>
<td>Outputs the record (at the current position in the current line) and a carriage return.</td>
</tr>
<tr>
<td>-</td>
<td>One line feed</td>
<td>Outputs the record (at the beginning of the following line) and a carriage return.</td>
</tr>
<tr>
<td>0</td>
<td>Two line feeds</td>
<td>Outputs the record (after skipping a line) and a carriage return.</td>
</tr>
<tr>
<td>1</td>
<td>Next page</td>
<td>Outputs the record (at the beginning of a new page) and a carriage return.</td>
</tr>
<tr>
<td>$</td>
<td>Prompting</td>
<td>Outputs the record (at the beginning of the following line), but no carriage return.</td>
</tr>
<tr>
<td>ASCII NUL</td>
<td>Overprinting with no advance</td>
<td>Outputs the record (at the current position in the current line), but no carriage return.</td>
</tr>
</tbody>
</table>

1 Specify as CHAR( 0 ).

Any other character is interpreted as a blank and is deleted from the print line. If you do not specify a control character for printing, the first character of the record is not printed.

Interaction Between Format Specifications and I/O Lists

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, D, G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.
When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).

**Examples**

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

```plaintext
001 0101 0102 0103 0104 0105
002 0201 0202 0203 0204 0205
003 0301 0302 0303 0304 0305
004 0401 0402 0403 0404 0405
005 0501 0502 0503 0504 0505
006 0601 0602 0603 0604 0605
007 0701 0702 0703 0704 0705
008 0801 0802 0803 0804 0805
009 0901 0902 0903 0904 0905
010 1001 1002 1003 1004 1005
```

The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

```plaintext
INTEGER I, J, A(2,5), B(2)
OPEN (unit=2, access='sequential', file='FOR002.DAT')
READ (2,100) (B(I), (A(I,J), J=1,5),I=1,2) 1
100 FORMAT (2 (I3, X, 5(I4,X), /) ) 2
WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 3
999 FORMAT (' B is ', 2(I3, X), ';  A is', / 1
     (' ', 5 (I4, X)) )
READ (2,200) (B(I), (A(I,J), J=1,5),I=1,2) 4
200 FORMAT (2 (I3, X, 5(I4,X), :/) )
WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 5
```
This statement reads \( B(1) \); then \( A(1,1) \) through \( A(1,5) \); then \( B(2) \) and \( A(2,1) \) through \( A(2,5) \).

The first record read (starting with 001) starts the processing of the I/O list.

2 There are two records, each in the format \( I3, X, 5(I4, X) \). The slash (/) forces the reading of the second record after \( A(1,5) \) is processed. It also forces the reading of the third record after \( A(2,5) \) is processed; no data is taken from that record.

3 This statement produces the following output:

```
B is   1   2 ;  A is 101  102  103  104  105 201  202  203  204  205
```

4 This statement reads the record starting with 004. The slash (/) forces the reading of the next record after \( A(1,5) \) is processed. The colon (:) stops the reading after \( A(2,5) \) is processed, but before the slash (/) forces another read.

5 This statement produces the following output:

```
B is   4   5 ;  A is 401  402  403  404  405 501  502  503  504  505
```

6 This statement reads the record starting with 006. After \( A(1,5) \) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the \( I3 \).

7 This statement produces the following output:

```
B is   6   7 ;  A is 601  602  603  604  605 701  702  703  704  705
```

8 This statement reads the record starting with 008. After \( A(1,5) \) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the \( I4 \).

9 This statement produces the following output:

```
B is   8  90 ;  A is 801  802  803  804  805 9010 9020 9030 9040 100
```

The record 009 0901 0902 0903 0904 0905 is processed with \( I4 \) as "009 " for \( B(2) \), which is 90. \( X \) skips the next "0". Then "901 " is processed for \( A(2,1) \), which is 9010, "902 " for \( A(2,2) \), "903 " for \( A(2,3) \), and "904 " for \( A(2,4) \). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the \( I4 \), so "010 " is read for \( A(2,5) \), which is 100.

File Operation I/O Statements

The following are file connection, inquiry, and positioning I/O statements:

- **BACKSPACE**
  Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing.

- **CLOSE**
  Terminates the connection between a logical unit and a file or device.

- **DELETE**
  Deletes a record from a relative file.

- **ENDFILE**
  Writes an end-of-file record to a sequential file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

- **FLUSH**
  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.

- **INQUIRE**
  Requests information on the status of specified properties of a file or logical unit. For more information on specifiers you can use in INQUIRE statements, see INQUIRE Statement Specifiers.

- **OPEN**
  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations. For more information on specifiers you can use in OPEN statements, see OPEN Statement Specifiers.

- **REWIND**
  Positions a sequential or direct access file at the beginning of the file (the initial point).

- **WAIT**
  Performs a wait operation for a specified pending asynchronous data transfer operation.

The following table summarizes I/O statement specifiers:

<table>
<thead>
<tr>
<th>I/O Specifiers</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS=access</td>
<td>'SEQUENTIAL', 'DIRECT', 'STREAM', 'APPEND'</td>
<td>Specifies the method of file access.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ACTION=permission</td>
<td>'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')</td>
<td>Specifies file I/O mode.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ADVANCE=c-expr</td>
<td>'NO' or 'YES' (default is 'YES')</td>
<td>Specifies formatted sequential data input as advancing, or non-advancing.</td>
<td>READ</td>
</tr>
</tbody>
</table>
### I/O Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASSOCIATEVARIABLE=v</td>
<td>Integer variable</td>
<td>Specifies a variable to be updated to reflect the record number of the next sequential record in the file.</td>
<td>OPEN</td>
</tr>
<tr>
<td>ASYNCHRONOUS=async</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies whether or not the I/O is done asynchronously</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BINARY=bin</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file format is binary.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>BLANK=blank_control</td>
<td>'NULL' or 'ZERO' (default is 'NULL')</td>
<td>Specifies whether blanks are ignored in numeric fields or interpreted as zeros.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BLOCKSIZE=blocksize</td>
<td>Positive integer variable or expression</td>
<td>Specifies or returns the internal buffer size used in I/O.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BUFFERCOUNT=bc</td>
<td>Numeric expression</td>
<td>Specifies the number of buffers to be associated with the unit for multibuffered I/O.</td>
<td>OPEN</td>
</tr>
<tr>
<td>BUFFERED=bf</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies run-time library behavior following WRITE operations.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>CARRIAGECONTROL=control</td>
<td>'FORTRAN', 'LIST', or 'NONE'</td>
<td>Specifies carriage control processing.</td>
<td>INQUIRE, OPEN</td>

</tbody>
</table>
## I/O Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSITION=</td>
<td>'ASIS', 'REWIND' or 'APPEND' (default is 'ASIS')</td>
<td>Specifies position in a file.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>READ=rd</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file can be read.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>READONLY</td>
<td></td>
<td>Specifies that only READ statements can refer to this connection.</td>
<td>OPEN</td>
</tr>
<tr>
<td>READWRITE=rdw</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file can be both read and written to.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>REC=rec</td>
<td>Positive integer variable or expression</td>
<td>Specifies the first (or only) record of a file to be read from, or written to.</td>
<td>READ, WRITE</td>
</tr>
<tr>
<td>RECL=length</td>
<td>Positive integer variable or expression</td>
<td>Specifies the record length in direct access files, or the maximum record length in sequential files.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>RECORDTYPE=</td>
<td>'FIXED', 'VARIABLE', 'SEGMENTED', 'STREAM', 'STREAM_LF', or 'STREAM_CR'</td>
<td>Specifies the type of records in a file.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>SEQUENTIAL=</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file is connected for sequential access.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>SHARE=share</td>
<td>'COMPAT', 'DENYNONE', 'DENYWR', 'DENYRD', or 'DENYRW' (default is 'DENYNONE')</td>
<td>Controls how other processes can simultaneously access a file on networked systems.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>SHARED</td>
<td></td>
<td>Specifies that a file is connected for shared access by more than one program executing simultaneously.</td>
<td>OPEN</td>
</tr>
<tr>
<td>SIZE=size</td>
<td>Integer variable</td>
<td>Returns the number of characters read in a nonadvancing READ before an end-of-record condition occurred.</td>
<td>READ</td>
</tr>
<tr>
<td>STATUS=status</td>
<td>'OLD', 'NEW', 'UNKNOWN' or 'SCRATCH' (default is 'UNKNOWN')</td>
<td>Specifies the status of a file on opening and/or closing.</td>
<td>CLOSE, OPEN</td>
</tr>
</tbody>
</table>
### I/O Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLE=\textit{name}</td>
<td>Character expression</td>
<td>Specifies the name of a child window in a QuickWin application.</td>
<td>OPEN</td>
</tr>
<tr>
<td>UNFORMATTED=\textit{unf}</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file is connected for unformatted data transfer.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>[UNIT=\textit{unitspec}</td>
<td>Integer variable or expression</td>
<td>Specifies the unit to which a file is connected.</td>
<td>All except PRINT</td>
</tr>
<tr>
<td>USEROPEN=\textit{fname}</td>
<td>Name of a user-written function</td>
<td>Specifies an external function that controls the opening of a file.</td>
<td>OPEN</td>
</tr>
<tr>
<td>WRITE=\textit{rd}</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file can be written to.</td>
<td>INQUIRE</td>
</tr>
</tbody>
</table>

### INQUIRE Statement Specifiers

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see INQUIRE.

The following table lists the INQUIRE statement specifiers and contains links to their descriptions:

<table>
<thead>
<tr>
<th>ACCESS</th>
<th>DELIM</th>
<th>NEXTREC</th>
<th>RECL</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>DIRECT</td>
<td>NUMBER</td>
<td>RECORDTYPE</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>ENCODING</td>
<td>OPENED</td>
<td>ROUND</td>

RECL specifier in OPEN statements
FILE specifier in OPEN statements
DEFAULTFILE specifier in OPEN statements

INQUIRE: ACCESS Specifier
The ACCESS specifier asks how a file is connected. It takes the following form:
ACCESS = acc

acc

| 'SEQUENTIAL' | If the file is connected for sequential access |
| 'STREAM' | If the file is connected for stream access |
| 'DIRECT' | If the file is connected for direct access |
| 'UNDEFINED' | If the file is not connected |

INQUIRE: ACTION Specifier
The ACTION specifier asks which I/O operations are allowed for a file. It takes the following form:
ACTION = act

act

| 'READ' | If the file is connected for input only |
| 'WRITE' | If the file is connected for output only |
| 'READWRITE' | If the file is connected for both input and output |
| 'UNDEFINED' | If the file is not connected |

INQUIRE: ASYNCHRONOUS Specifier
The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:
ASYNCHRONOUS = asyn

asyn

| 'NO' | If the file or unit is connected and asynchronous input/output is not in effect. |
| 'YES' | If the file or unit is connected and asynchronous input/output is in effect. |
INQUIRE: BINARY Specifier (W*S)
The BINARY specifier asks whether a file is connected to a binary file. It takes the following form:
BINARY = bin

bin

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected to a binary file</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is connected to a nonbinary file</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

INQUIRE: BLANK Specifier
The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:
BLANK = blnk

blnk

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>If null blank control is in effect for the file</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>If zero blank control is in effect for the file</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected, or it is not connected for formatted data transfer</td>
</tr>
</tbody>
</table>

INQUIRE: BLOCKSIZE Specifier
The BLOCKSIZE specifier asks about the physical I/O transfer size. It takes the following form:
BLOCKSIZE = bks

bks

Is a scalar integer variable.
The bks is assigned the current size of the physical I/O transfer. If the unit or file is not connected, the value assigned is zero.

INQUIRE: BUFFERED Specifier
The BUFFERED specifier asks whether run-time buffering is in effect. It takes the following form:
BUFFERED = bf
**bf**

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit is connected and buffering is not in effect.</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is connected and buffering is in effect.</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected.</td>
</tr>
</tbody>
</table>

**INQUIRE: CARRIAGECONTROL Specifier**

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

```
CARRIAGECONTROL = cc
```

`cc`

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORTRAN'</td>
<td>If the file is connected with Fortran carriage control in effect</td>
</tr>
<tr>
<td>'LIST'</td>
<td>If the file is connected with implied carriage control in effect</td>
</tr>
<tr>
<td>'NONE'</td>
<td>If the file is connected with no carriage control in effect</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: CONVERT Specifier**

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

```
CONVERT = fm
```

`fm`

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'</td>
<td>If the file is connected with little endian integer and IEEE floating-point data conversion in effect</td>
</tr>
<tr>
<td>'BIG_ENDIAN'</td>
<td>If the file is connected with big endian integer and IEEE floating-point data conversion in effect</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>If the file is connected with big endian integer and CRAY floating-point data conversion in effect</td>
</tr>
</tbody>
</table>
'FDX' If the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE binary128 data conversion in effect

'FGX' If the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE binary128 data conversion in effect

'IBM' If the file is connected with big endian integer and IBM* System \370 floating-point data conversion in effect

'VAXD' If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect

'VAXG' If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect

'NATIVE' If the file is connected with no data conversion in effect

'UNKNOWN' If the file or unit is not connected for unformatted data transfer

**INQUIRE: DECIMAL Specifier**

The DECIMAL specifier asks which decimal editing mode is in effect for a file connection. It takes the following form:

DECIMAL = *dmode*

*dmode* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>dmode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'COMMA'</td>
<td>If a decimal comma is used during decimal editing mode.</td>
</tr>
<tr>
<td>'POINT'</td>
<td>If a decimal point is used during decimal editing mode.</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If there is no connection or if the connection is not for formatted I/O.</td>
</tr>
</tbody>
</table>

**INQUIRE: DELIM Specifier**

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:

DELIM = *del*
Is a scalar default character variable that is assigned one of the following values:

- **'APOSTROPHE'** If apostrophes are used to delimit character constants in list-directed and namelist output
- **'QUOTE'** If quotation marks are used to delimit character constants in list-directed and namelist output
- **'NONE'** If no delimiters are used
- **'UNDEFINED'** If the file is not connected, or is not connected for formatted data transfer

### INQUIRE: DIRECT Specifier

The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

**DIRECT = dir**

- **dir** Is a scalar default character variable that is assigned one of the following values:

  - **'YES'** If the file is connected for direct access
  - **'NO'** If the file is not connected for direct access
  - **'UNKNOWN'** If the file is not connected

### INQUIRE: ENCODING Specifier

The ENCODING specifier asks what type of encoding is in effect for a file. It takes the following form:

**ENCODING = enc**

- **enc** Is a scalar default character expression that is assigned one of the following values:

  - **'UTF-8'** If the file is connected with UTF-8 encoding in effect.
  - **'UNDEFINED'** If the file is connected for unformatted I/O.
  - **'UNKNOWN'** If the processor is unable to determine the encoding form of the file.

### INQUIRE: EXIST Specifier

The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

**EXIST = ex**
Is a scalar default logical variable that is assigned one of the following values:

| .TRUE. | If the specified file exists and can be opened, or if the specified unit exists |
| .FALSE. | If the specified file or unit does not exist or if the file exists but cannot be opened |

The unit exists if it is a number in the range allowed by the processor.

**INQUIRE: FORM Specifier**

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

```
FORM = fm
```

Is a scalar default character variable that is assigned one of the following values:

| 'FORMATTED' | If the file is connected for formatted data transfer |
| 'UNFORMATTED' | If the file is connected for unformatted data transfer |
| 'BINARY' | If the file is connected for binary data transfer |
| 'UNDEFINED' | If the file is not connected |

**INQUIRE: FORMATTED Specifier**

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

```
FORMATTED = fmt
```

Is a scalar default character variable that is assigned one of the following values:

| 'YES' | If the file is connected for formatted data transfer |
| 'NO' | If the file is not connected for formatted data transfer |
| 'UNKNOWN' | If the processor cannot determine whether the file is connected for formatted data transfer |
INQUIRE: IOFOCUS Specifier (W*S)

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. It takes the following form:

\[
\text{IOFOCUS} = \text{iof}
\]

<table>
<thead>
<tr>
<th>iof</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.TRUE.</td>
<td>If the specified unit is the active window in a QuickWin application</td>
</tr>
<tr>
<td>.FALSE.</td>
<td>If the specified unit is not the active window in a QuickWin application</td>
</tr>
</tbody>
</table>

If unit ‘*’ is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

INQUIRE: MODE Specifier

MODE is a nonstandard synonym for ACTION.

INQUIRE: NAME Specifier

The NAME specifier returns the name of a file. It takes the following form:

\[
\text{NAME} = \text{nme}
\]

<table>
<thead>
<tr>
<th>nme</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, nme is undefined. The value assigned to nme is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of nme is too small to contain the entire value.)</td>
</tr>
</tbody>
</table>

NOTE

The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

See Also

The appropriate manual in your operating system documentation set for details on the maximum size of file pathnames.

INQUIRE: NAMED Specifier

The NAMED specifier asks whether a file is named. It takes the following form:
NAMED = nmd

nmd  Is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>.TRUE.</th>
<th>If the file has a name</th>
</tr>
</thead>
<tbody>
<tr>
<td>.FALSE.</td>
<td>If the file does not have a name</td>
</tr>
</tbody>
</table>

**INQUIRE: NEXTREC Specifier**

The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:

NEXTREC = nr

nr  Is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record (r) was previously read or written, the value assigned is r + 1.
- If no record has been read or written, the value assigned is 1.
- If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.
- If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

**INQUIRE: NUMBER Specifier**

The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:

NUMBER = num

num  Is a scalar integer variable.

The num is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

**INQUIRE: OPENED Specifier**

The OPENED specifier asks whether a file is connected. It takes the following form:

OPENED = od

od  Is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>.TRUE.</th>
<th>If the specified file or unit is connected</th>
</tr>
</thead>
<tbody>
<tr>
<td>.FALSE.</td>
<td>If the specified file or unit is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: ORGANIZATION Specifier**

The ORGANIZATION specifier asks how the file is organized. It takes the following form:
ORGANIZATION = org

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SEQUENTIAL'</td>
<td>If the file is a sequential file</td>
</tr>
<tr>
<td>'RELATIVE'</td>
<td>If the file is a relative file</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine the file's organization</td>
</tr>
</tbody>
</table>

INQUIRE: PAD Specifier

The PAD specifier asks whether blank padding was specified for the file. It takes the following form:

PAD = pd

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit was connected with PAD='NO'</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is not connected, or it was connected with PAD='YES'</td>
</tr>
</tbody>
</table>

INQUIRE: PENDING Specifier

The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:

PENDING = pnd

Is a scalar default logical variable that is assigned the value .TRUE. or .FALSE..

The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable pnd is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable pnd is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.
- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable pnd is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable pnd is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.

See Also
ID Specifier
Example in INQUIRE Statement
INQUIRE: POS Specifier

The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:

\[
\text{POS} = p
\]

\(p\) is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, \(p\) is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, \(p\) is assigned the value one.

INQUIRE: POSITION Specifier

The POSITION specifier asks the position of the file. It takes the following form:

\[
\text{POSITION} = \textit{pos}
\]

\(\textit{pos}\) is a scalar default character variable that is assigned one of the following values:

- 'REWIND' if the file is connected with its position at its initial point
- 'APPEND' if the file is connected with its position at its terminal point (or before its end-of-file record, if any)
- 'ASIS' if the file is connected without changing its position
- 'UNDEFINED' if the file is not connected, or is connected for direct access data transfer and a REWIND statement has not been performed on the unit

INQUIRE: READ Specifier

The READ specifier asks whether a file can be read. It takes the following form:

\[
\text{READ} = \textit{rd}
\]

\(\textit{rd}\) is a scalar default character variable that is assigned one of the following values:

- 'YES' if the file can be read
- 'NO' if the file cannot be read
- 'UNKNOWN' if the processor cannot determine whether the file can be read
INQUIRE: READWRITE Specifier

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

READWRITE = rdwr

rdwr

Is a scalar default character variable that is assigned one of the following values:

- 'YES' If the file can be both read and written to
- 'NO' If the file cannot be both read and written to
- 'UNKNOWN' If the processor cannot determine whether the file can be both read and written to

INQUIRE: RECL Specifier

The RECL specifier asks the maximum record length for a file. It takes the following form:

RECL = rcl

rcl

Is a scalar integer variable that is assigned a value as follows:

- If the file or unit is connected, the value assigned is the maximum record length allowed.
- If the file does not exist, or is not connected, the value assigned is zero.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer and the assume byterecl compiler option is not in effect; otherwise, the value is expressed in bytes.

INQUIRE: RECORDTYPE Specifier

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:

RECORDTYPE = rtype

rtype

Is a scalar default character variable that is assigned one of the following values:

- 'FIXED' If the file is connected for fixed-length records
- 'VARIABLE' If the file is connected for variable-length records
- 'SEGMENTED' If the file is connected for unformatted sequential data transfer using segmented records
- 'STREAM' If the file's records are not terminated
'STREAM_CR' If the file's records are terminated with a carriage return

'STREAM_LF' If the file's records are terminated with a line feed

'STREAM_CRLF' If the file's records are terminated with a carriage return/line feed pair

'UNKNOWN' If the file is not connected

**INQUIRE: ROUND Specifier**

The ROUND specifier asks which rounding mode is in effect for a file connection. It takes the following form:

ROUND = rmode

**rmode**

Is a scalar default character expression that is assigned one of the following values:

- **'UP'** If the I/O rounding is set to the smallest representable value that is greater than or equal to the original value.
- **'DOWN'** If the I/O rounding is set to the largest representable value that is less than or equal to the original value.
- **'ZERO'** If the I/O rounding is set to the value closest to the original value, but no greater in magnitude than the original value.
- **'NEAREST'** If the I/O rounding is set to the closer of the two nearest representable values, if one is closer than the other.
- **'COMPATIBLE'** If the I/O rounding is set to the closer of the two nearest representable values, or the value farther from zero if halfway between them.
- **'PROCESSOR_DEFINED'** If the I/O rounding mode behaves differently than the UP, DOWN, ZERO, NEAREST, and COMPATIBLE modes.
- **'UNDEFINED'** If there is no connection or if the connection is not for formatted I/O.
INQUIRE: SEQUENTIAL Specifier

The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

```
SEQUENTIAL = seq
```

`seq` is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for sequential access</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for sequential access</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file is connected for sequential access</td>
</tr>
</tbody>
</table>

INQUIRE: SHARE Specifier

The SHARE specifier asks the current share status of a file or unit. It takes the following form:

```
SHARE = shr
```

`shr` is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for deny-read/write mode</td>
</tr>
<tr>
<td>'DENYWR'</td>
<td>If the file is connected for deny-write mode</td>
</tr>
<tr>
<td>'DENYRD'</td>
<td>If the file is connected for deny-read mode</td>
</tr>
<tr>
<td>'DENYNONE'</td>
<td>If the file is connected for deny-none mode</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected</td>
</tr>
</tbody>
</table>

On Linux* and macOS* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for exclusive access</td>
</tr>
<tr>
<td>'DENYNONE'</td>
<td>If the file is connected for shared access</td>
</tr>
<tr>
<td>'NODENY'</td>
<td>If the file is connected with default locking</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected</td>
</tr>
</tbody>
</table>
INQUIRE: SIGN Specifier

The SIGN specifier asks what treatment for plus signs is in effect during a connection. It takes the following form:

\[ \text{SIGN} = sn \]

\[ sn \]

Is a scalar default character expression that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'PLUS'</td>
<td>If the file is connected with addition of plus signs in effect.</td>
</tr>
<tr>
<td>'SUPPRESS'</td>
<td>If the file is connected with suppression of plus signs in effect.</td>
</tr>
<tr>
<td>'PROCESSOR_DEFINED'</td>
<td>If the file is connected with plus signs added at the discretion of the processor.</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If there is no connection, or if the connection is not for formatted input/output.</td>
</tr>
</tbody>
</table>

INQUIRE: SIZE Specifier

The SIZE specifier asks the size of a file in file storage units. It takes the following form:

\[ \text{SIZE} = sz \]

\[ sz \]

Is a scalar integer variable.

The sz variable is assigned the size of the file in file storage units. If the file size cannot be determined, the variable is assigned the value -1.

For a file that is connected for stream access, the file size is the number of the highest-numbered file storage unit in the file.

For a file that is connected for sequential or direct access, the file size may be different from the number of storage units implied by the data in the records; the exact relationship is processor-dependent.

INQUIRE: UNFORMATTED Specifier

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

\[ \text{UNFORMATTED} = unf \]

\[ unf \]

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for unformatted data transfer</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for unformatted data transfer</td>
</tr>
</tbody>
</table>
'UNKNOWN'  If the processor cannot determine whether the file is connected for unformatted data transfer

INQUIRE: WRITESpecifier

The WRITE specifier asks whether a file can be written to. It takes the following form:

\[
\text{WRITE} = \text{wr}
\]

\(\text{wr}\)  Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file can be written to</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file cannot be written to</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file can be written to</td>
</tr>
</tbody>
</table>

OPEN Statement Specifiers

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.

The following table summarizes the OPEN statement specifiers and contains links to their descriptions:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Function</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>'DIRECT'</td>
<td>Access mode</td>

</tr>
</tbody>
</table>

1. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.
2. If you use the compiler option specifying OpenVMS defaults, and the unit is connected to a terminal, the default is 'FORTRAN'.
3. n is the unit number.
4. If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..
5. On Linux* and macOS* systems, the default depends only on the FORM setting.
6. W*S
7. The default differs under certain conditions (see SHARE Specifier).
8. The default differs under certain conditions (see STATUS Specifier).

Key to Values

- c_expr: A scalar default character expression
- func: An external function
- label: A statement label
- n_expr: A scalar numeric expression
- var: A scalar integer variable

See Also
INQUIRE Statement for details on using the INQUIRE statement to get file attributes of existing files

OPEN: ACCESS Specifier

The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:

ACCESS = acc
**acc**

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DIRECT'</td>
<td>Indicates direct access.</td>
</tr>
<tr>
<td>'SEQUENTIAL'</td>
<td>Indicates sequential access.</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>Indicates stream access, where the file storage units of the file are accessible sequentially or by position.</td>
</tr>
<tr>
<td>'APPEND'</td>
<td>Indicates sequential access, but the file is positioned at the end-of-file record.</td>
</tr>
</tbody>
</table>

The default is 'SEQUENTIAL'.

There are limitations on record access by file organization and record type.

**OPEN: ACTION Specifier**

The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:

```
ACTION = act
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'READ'</td>
<td>Indicates that only READ statements can refer to this connection.</td>
</tr>
<tr>
<td>'WRITE'</td>
<td>Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.</td>
</tr>
<tr>
<td>'READWRITE'</td>
<td>Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.</td>
</tr>
</tbody>
</table>

The default is 'READWRITE'.

However, if compiler option fpscomp general is specified on the command line and action is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting action is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

**See Also**

fpscomp compiler option

**OPEN: ASSOCIATEVARIABLE Specifier**

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

```
ASSOCIATEVARIABLE = asv
```
asv

Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of asv.

This specifier is valid only for direct access; it is ignored for other access modes.

**OPEN: ASYNCHRONOUS Specifier**

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

**ASYNCHRONOUS = asyn**

*asyn* is a scalar expression of type default character that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>Indicates that asynchronous I/O is allowed for a unit.</td>
</tr>
<tr>
<td>'NO'</td>
<td>Indicates that asynchronous I/O is not allowed for a unit.</td>
</tr>
</tbody>
</table>

The default is 'NO'.

**OPEN: BLANK Specifier**

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

**BLANK = blnk**

*blnk* is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>Indicates all blanks (other than leading blanks) are treated as zeros.</td>
</tr>
</tbody>
</table>

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

**See Also**

Blank Editing for details on the BN and BZ edit descriptors

f66

**OPEN: BLOCKSIZE Specifier**

The BLOCKSIZE specifier indicates the physical I/O transfer size in bytes for the file. It takes the following form:

**BLOCKSIZE = bks**
**bks**

Is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for **bks**, it is rounded up to a multiple of 512 byte blocks. The maximum valid value of BLOCKSIZE is 2147467264.

If you do not specify BLOCKSIZE or you specify zero for **bks**, the default value of 128 KB (131,072 bytes) is assumed. However, if you compile with the **assume buffered_stdout** option, the default blocksize for **stdout** is 8 KB.

The default BLOCKSIZE value can be changed by using the FORT_BLOCKSIZE environment variable or by specifying the BLOCKSIZE parameter on the unit's OPEN. The BLOCKSIZE value can be changed for **stdout** by re-opening the unit corresponding to stdout with an explicit BLOCKSIZE parameter; for example:

```
OPEN(6,ACCESS='SEQUENTIAL',FORM='FORMATTED',BUFFERED='YES',BLOCKSIZE=1048576)
```

**OPEN: BUFFERCOUNT Specifier**

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

```
BUFFERCOUNT = \[bc\]
```

**bc**

Is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for **bc**, the default is 1.

**See Also**

**BLOCKSIZE specifier**

**OPEN: BUFFERED Specifier**

The BUFFERED specifier indicates run-time library behavior for READ and WRITE operations. Buffering of input records only applies to variable length, unformatted records. This specifier takes the following form:

```
BUFFERED = \[bf\]
```

**bf**

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>For WRITE operations: Requests that the run-time library send output data to the file system after each operation. For READ operations on variable length, unformatted files: Requests that the run-time library transfer input data directly from disk to user variables for each operation.</td>
</tr>
<tr>
<td>'YES'</td>
<td>Requests that the run-time library accumulate data in its internal buffer, possibly across several READ or WRITE</td>
</tr>
</tbody>
</table>
Buffering may improve run-time performance for output-intensive applications.

The default is 'NO' for buffering output. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If both BLOCKSIZE and BUFFERCOUNT for OPEN have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. Otherwise, the default size of the internal buffer is 8 KB (8192 bytes).

NOTE
On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

See Also
Rules for Unformatted Sequential READ Statements

OPEN: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

\[ \text{CARRIAGECONTROL} = \text{cc} \]

\text{cc} \quad \text{Is a scalar default character expression that evaluates to one of the following values:}

| 'FORTRAN' | Indicates normal Fortran interpretation of the first character. |
| 'LIST'    | Indicates one line feed between records. |
| 'NONE'    | Indicates no carriage control processing. |

The default for binary (W*S) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option vms or fpscomp general, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the fortpn format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.

See Also
Printing of Formatted Records for details on valid control characters for printing vms compiler option
OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

CONVERT = fm

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>fm</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'</td>
<td>Little endian integer data 2 and IEEE* floating-point data. 3</td>
</tr>
<tr>
<td>'BIG_ENDIAN'</td>
<td>Big endian integer data 2 and IEEE floating-point data. 3</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>Big endian integer data 2 and CRAY* floating-point data of size REAL(8) or COMPLEX(8).</td>
</tr>
<tr>
<td>'FDX'</td>
<td>Little endian integer data 2 and VAX* processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'FGX'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), G_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'IBM'</td>
<td>Big endian integer data 2 and IBM* System\370 floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).</td>
</tr>
<tr>
<td>'VAXD'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'VAXG'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), G_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).</td>
</tr>
</tbody>
</table>
'NATIVE' No data conversion. This is the default.

1 INTEGER(1) data is the same for little endian and big endian.
2 Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or INTEGER(8)
3 Of the appropriate size and type: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), or COMPLEX(16)

You can use CONVERT to specify multiple formats in a single program, usually one format for each specified unit number.

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a run-time message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

<table>
<thead>
<tr>
<th>Method Used</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>An environment variable</td>
<td>Highest</td>
</tr>
<tr>
<td>OPEN (CONVERT=)</td>
<td></td>
</tr>
<tr>
<td>OPTIONS/CONVERT</td>
<td></td>
</tr>
<tr>
<td>The convert compiler option</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY* numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20:

```fortran
OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
...
OPEN (FILE='graph3_native.dat', FORM='UNFORMATTED', UNIT=20)
```

See Also

Data Types, Constants, and Variables for details on supported ranges for data types

convert compiler option

OPEN: DECIMAL Specifier

The DECIMAL specifier controls the representation of the decimal symbol for a connection. It takes the following form:

```
DECIMAL = dmode
```

<table>
<thead>
<tr>
<th>dmode</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'COMMA'</td>
<td>Indicates that a decimal comma should be used for decimal editing mode.</td>
</tr>
<tr>
<td>'POINT'</td>
<td>Indicates that a decimal point should be used for decimal editing mode.</td>
</tr>
</tbody>
</table>

The default decimal editing mode is 'POINT'.
You can only use this specifier for a formatted I/O connection.

When the mode is DECIMAL='POINT', the decimal point in a numeric input or output value is a period, values are separated by commas in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a comma.

When the mode is DECIMAL='COMMA', the decimal point in a numeric input or output value is a comma, values are separated by semicolons in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a semicolon.

The decimal editing mode can be temporarily changed within a READ or WRITE statement by the DECIMAL= specifier or by the corresponding DC and DP edit descriptors.

**OPEN: DEFAULTFILE Specifier**

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

```
DEFAULTFILE = def
```

*def* Is a character expression indicating a default file pathname string.

The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE. If *def* does not end in a slash (/), a slash is added.

If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

**OPEN: DELIM Specifier**

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

```
DELIM = del
```

*del* Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'APOSTROPHE'</td>
<td>Indicates apostrophes delimit character constants. All internal apostrophes are doubled.</td>
</tr>
<tr>
<td>'QUOTE'</td>
<td>Indicates quotation marks delimit character constants. All internal quotation marks are doubled.</td>
</tr>
<tr>
<td>'NONE'</td>
<td>Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.</td>
</tr>
</tbody>
</table>

The default is 'NONE'.

The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input.

**OPEN: DISPOSE Specifier**

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:
DISPOSE = dis
DISP = dis

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'KEEP' or 'SAVE'</td>
<td>Retains the file after the unit closes.</td>
</tr>
<tr>
<td>'DELETE'</td>
<td>Deletes the file after the unit closes.</td>
</tr>
<tr>
<td>'PRINT' ¹</td>
<td>Submits the file to the line printer spooler and retains it.</td>
</tr>
<tr>
<td>'PRINT/DELETE' ¹</td>
<td>Submits the file to the line printer spooler and then deletes it.</td>
</tr>
<tr>
<td>'SUBMIT'</td>
<td>Forks a process to execute the file.</td>
</tr>
<tr>
<td>'SUBMIT/DELETE'</td>
<td>Forks a process to execute the file, and then deletes the file after the fork is completed.</td>
</tr>
</tbody>
</table>

¹ Use only on sequential files.

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

**OPEN: ENCODING Specifier**

The ENCODING specifier indicates the encoding form for a file. It takes the following form:

ENCODING = enc

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UTF-8'</td>
<td>Indicates that the encoding form of the file is UTF-8 (a unicode file). All characters therein are of ISO 10646 character type, as specified by ISO/IEC 10646-1:2000. This value must not be specified if the processor does not support the ISO 10646 character type.</td>
</tr>
<tr>
<td>'DEFAULT'</td>
<td>Indicates that the encoding form of the file is determined by the processor.</td>
</tr>
</tbody>
</table>

The default is 'DEFAULT'.

You can only use this specifier for a formatted I/O connection.

**OPEN: FILE Specifier**

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:
FILE = name

name Is a character or numeric expression.
The name can be any pathname allowed by the operating system.
Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
- The unit is not connected to a file
- STATUS='SCRATCH' is not specified
- The corresponding FORTn environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort.n, where n is the logical unit number. On Windows systems, if compiler option fpscomp general is specified, omitting FILE implies STATUS='SCRATCH'.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console.

In a Windows* QuickWin application, you can specify FILE='USER' to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the name can be blank (FILE=' ') if the compatibility compiler option fpscomp filesfromcmd is specified. If the name is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (" "), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.

2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

Assume the following command line started the program MYPROG (note that quotation marks (") are used):

myprog first.fil " " third.txt

MYPROG contains four OPEN statements with blank filenames, in the following order:

<table>
<thead>
<tr>
<th>OPEN (2, FILE = ' ')</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN (4, FILE = ' ')</td>
</tr>
<tr>
<td>OPEN (5, FILE = ' ')</td>
</tr>
<tr>
<td>OPEN (10, FILE = ' ')</td>
</tr>
</tbody>
</table>

Unit 2 is associated with the file FIRST.FIL. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

Filename missing or blank - Please enter name UNIT 4?

Unit 5 is associated with the file THIRD.TXT. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

Filename missing or blank - Please enter name UNIT 10?

fpscomp compiler option

OPEN: FORM Specifier

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

FORM = fm
fm

<table>
<thead>
<tr>
<th>fm</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORMATTED'</td>
<td>Indicates formatted data transfer</td>
</tr>
<tr>
<td>'UNFORMATTED'</td>
<td>Indicates unformatted data transfer</td>
</tr>
<tr>
<td>'BINARY'</td>
<td>Indicates binary data transfer</td>
</tr>
</tbody>
</table>

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.

The data is stored and retrieved in a file according to the file's access (set by the ACCESS specifier) and the form of the data the file contains.

A formatted file is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.

An unformatted file is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

Binary sequential files are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.

Binary direct files have very little structure. A record length is assigned by the RECL specifier in an OPEN statement. This establishes record boundaries, which are used only for repositioning and padding before and after read and write operations and during BACKSPACE operations. Record boundaries do not restrict the number of bytes that can be transferred during a read or write operation. If an I/O operation attempts to read or write more values than are contained in a record, the read or write operation is continued on the next record.

Fortran standard stream access provides similar functionality to FORM='BINARY'. This is specified using ACCESS='STREAM'.

See Also
Record Access

OPEN: IOFOCUS Specifier (W*S)

The IOFOCUS specifier indicates whether a particular unit is the active window in a QuickWin application. It takes the following form:

IOFOCUS = iof

iof

<table>
<thead>
<tr>
<th>iof</th>
<th>Is a scalar default logical expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>.TRUE.</td>
<td>Indicates the QuickWin child window is the active window</td>
</tr>
<tr>
<td>.FALSE.</td>
<td>Indicates the QuickWin child window is not the active window</td>
</tr>
</tbody>
</table>

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window. OUTTEXT, OUTGTEXT, or any other graphics routine call does not cause the focus to shift.
OPEN: MAXREC Specifier
The MAXREC specifier indicates the maximum number of records that can be transferred from or to a direct access file while the file is connected. It takes the following form:

```
MAXREC = mr
```

*mr* is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

The default is an unlimited number of records.

OPEN: MODE Specifier
MODE is a nonstandard synonym for ACTION.

OPEN: NAME Specifier
NAME is a nonstandard synonym for FILE.

OPEN: NEWUNIT Specifier
The NEWUNIT specifier opens a file on an unused unit number that is automatically chosen. It also returns the unit number that was chosen. It takes the following form:

```
NEWUNIT = u-var
```

*u-var* is a scalar integer variable that is assigned the automatically chosen unit number. It is always a negative integer.

If the OPEN is successful, *u-var* can be used in subsequent I/O statements to access the connected file.

If an error occurs during execution of the OPEN statement containing the NEWUNIT= specifier, the processor does not change the value of the variable.

OPEN: NOSHARED Specifier
The NOSHARED specifier indicates that the file is connected for exclusive access by the program. It takes the following form:

```
NOSHARED
```

OPEN: ORGANIZATION Specifier
The ORGANIZATION specifier indicates the internal organization of the file. It takes the following form:

```
ORGANIZATION = org
```

*org* is a scalar default character expression that evaluates to one of the following values:

| 'SEQUENTIAL' | Indicates a sequential file. |
| 'RELATIVE'  | Indicates a relative file.   |

The default is 'SEQUENTIAL'.
OPEN: PAD Specifier

The PAD specifier indicates whether a formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

The PAD specifier takes the following form:

\[
\text{PAD} = pd
\]

\(pd\) is a scalar default character expression that evaluates to one of the following values:

- 'YES': Indicates the record will be padded with blanks when necessary.
- 'NO': Indicates the record will not be padded with blanks. The input record must contain the data required by the input list and format specification.

The default is 'YES'.

This behavior is different from FORTRAN 77, which never pads short records with blanks. For example, consider the following:

\[
\text{READ (5,'(I5)')} J
\]

If you enter 123 followed by a carriage return, FORTRAN 77 turns the I5 into an I3 and J is assigned 123. However, Intel® Fortran pads the 123 with 2 blanks unless you explicitly open the unit with PAD='NO'.

You can override blank padding by explicitly specifying the BN edit descriptor.

The PAD specifier is ignored during output.

OPEN: POSITION Specifier

The POSITION specifier indicates the position of a file connected for sequential access. It takes the following form:

\[
\text{POSITION} = pos
\]

\(pos\) is a scalar default character expression that evaluates to one of the following values:

- 'ASIS': Indicates the file position is unchanged if the file exists and is already connected. The position is unspecified if the file exists but is not connected.
- 'REWIND': Indicates the file is positioned at its initial point.
- 'APPEND': Indicates the file is positioned at its terminal point (or before its end-of-file record, if any).

The default is 'ASIS'.

A new file (whether specified as new explicitly or by default) is always positioned at its initial point.
In addition to the POSITION specifier, you can use position statements. The BACKSPACE statement positions a file back one record. The REWIND statement positions a file at its initial point. The ENDFILE statement writes an end-of-file record at the current position and positions the file after it. Note that ENDFILE does not go the end of an existing file, but creates an end-of-file where it is.

**OPEN: READONLY Specifier**

The READONLY specifier indicates only READ statements can refer to this connection. It takes the following form:

```
READONLY
```

READONLY is similar to specifying ACTION='READ', but READONLY prevents deletion of the file if it is closed with STATUS='DELETE' in effect.

The Fortran I/O system's default privileges for file access are READWRITE. If access is denied, the I/O system automatically retries accessing the file for READ access. However, if you use compiler option vms, the I/O system does not retry accessing for READ access. So, runtime I/O errors can occur if the file protection does not permit WRITE access. To prevent such errors, if you wish to read a file for which you do not have write access, specify READONLY.

**OPEN: RECL Specifier**

The RECL specifier indicates the length of each record in a file connected for direct access, or the maximum length of a record in a file connected for sequential access.

The RECL specifier takes the following form:

```
RECL = rl
```

`rl` is a positive numeric expression indicating the length of records in the file. If necessary, the value is converted to integer data type before use.

If the file is connected for formatted data transfer, the value must be expressed in bytes (characters). Otherwise, the value is expressed in 4-byte units (longwords). If the file is connected for unformatted data transfer, the value can be expressed in bytes if compiler option assume byterecl is specified.

Except for segmented records, the `rl` is the length for record data only, it does not include space for control information. If `rl` is too large, you can exhaust your program's virtual memory resources trying to create room for the record.

The length specified is interpreted depending on the type of records in the connected file, as follows:

- For segmented records, RECL indicates the maximum length for any segment (including the four bytes of control information).
- For fixed-length records, RECL indicates the size of each record; it must be specified. If the records are unformatted, the size must be expressed as an even multiple of four.

You can use the RECL specifier in an INQUIRE statement to get the record length before opening the file.

- For variable-length records, RECL indicates the maximum length for any record.

If you read a fixed-length file with a record length different from the one used to create the file, indeterminate results can occur.

The maximum length for `rl` depends on the record type and the setting of the CARRIAGECONTROL specifier, as shown in the following table:

<table>
<thead>
<tr>
<th>Record Type</th>
<th>CARRIAGECONTROL</th>
<th>Formatted (size in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-length</td>
<td>'NONE'</td>
<td>Unlimited</td>
</tr>
</tbody>
</table>
The default value depends on the setting of the RECORDTYPE specifier, as shown in the following table:

<table>
<thead>
<tr>
<th>Default Record Lengths (RECL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECORDTYPE</td>
</tr>
<tr>
<td>'FIXED'</td>
</tr>
<tr>
<td>All other settings</td>
</tr>
</tbody>
</table>

1 To change the default record length values, you can use environment variable FORT_FMT_RECL or FORT_UFMT_RECL.

For formatted records with other than RECORDTYPE='FIXED', the default RECL is 132.

There is a property of list-directed sequential WRITE statements called the right margin. If you do not specify RECL as an OPEN statement specifier or in environmental variable FORT_FMT_RECL, the right margin value defaults to 80. When RECL is specified, the right margin is set to the value of RECL. If the length of a list-directed sequential WRITE exceeds the value of the right margin value, the remaining characters will wrap to the next line. Therefore, writing 100 characters will produce two lines of output, and writing 180 characters will produce three lines of output. You can turn off the right margin using the wrap-margin compiler option or the FORT_FMT_NO_WRAP_MARGIN environment variable.

vms compiler option
Record Transfer

OPEN: RECORDSIZE Specifier
RECORDSIZE is a nonstandard synonym for RECL.

OPEN: RECORDTYPE Specifier
The RECORDTYPE specifier indicates the type of records in a file. It takes the following form:
RECORDTYPE = typ

Is a scalar default character expression that evaluates to one of the following values:

'FIXED' Indicates fixed-length records.
A segmented record is a logical record consisting of segments that are physical records. Since the length of a segmented record can be greater than 65,535 bytes, only use segmented records for unformatted sequential access to disk or raw magnetic tape files.

Files containing segmented records can be accessed only by unformatted sequential data transfer statements.

If an output statement does not specify a full record for a file containing fixed-length records, the following occurs:

- In formatted files, the record is filled with blanks
- In unformatted files, the record is filled with zeros

**OPEN: ROUND Specifier**

The ROUND specifier indicates the I/O rounding mode for the duration of a connection. It takes the following form:

```
ROUND = rmode
```

- `rmode` is a scalar default character expression that evaluates to one of the following values:

  - `'UP'` The smallest representable value that is greater than or equal to the original value.
The largest representable value that is less than or equal to the original value.

The value closest to the original value, but no greater in magnitude than the original value.

The closer of the two nearest representable values, if one is closer than the other.

If the two nearest representable values are equidistant from the original value, the processor determines which one of them is chosen.

On processors that support IEEE rounding on conversions, NEAREST corresponds to round to nearest, as specified in the IEEE International Standard.

The closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero.

The value is determined by the default settings in the processor, which may correspond to one of the other modes.

The default I/O rounding mode is 'PROCESSOR_DEFINED'.

You can only use this specifier for a formatted I/O connection.

The rounding mode can be temporarily changed within a READ or WRITE statement by the corresponding RU, RD, RZ, RN, RC, and RP edit descriptors.

**OPEN: SHARE Specifier**

The SHARE specifier indicates whether file locking is implemented while the unit is open. It takes the following form:

```
SHARE = shr
```

*shr*

Is a scalar default character expression.

On Windows* systems, this expression evaluates to one of the following values:

- "DENYRW" Indicates deny-read/write mode. No other process can open the file.
'DENYWR' Indicates deny-write mode. No process can open the file with write access.

'DENYRD' Indicates deny-read mode. No process can open the file with read access.

'DENYNONE' Indicates deny-none mode. Any process can open the file in any mode.

On Linux* and macOS* systems, this expression evaluates to one of the following values:

'DENYRW' Indicates exclusive access for cooperating processes.

'DENYNONE' Indicates shared access for cooperating processes.

On Windows systems, the default is 'DENYWR'. However, if you specify compiler option fpscomp general or the SHARED specifier, the default is 'DENYNONE'.

On Linux and macOS* systems, no restrictions are applied to file opening if you do not use a locking mechanism.

'COMPAT' is accepted for compatibility with previous versions. It is equivalent to 'DENYNONE'.

Use the ACCESS specifier in an INQUIRE statement to determine the access permission for a file.

Be careful not to permit other users to perform operations that might cause problems. For example, if you open a file intending only to read from it, and want no other user to write to it while you have it open, you could open it with ACTION='READ' and SHARE='DENYRW'. Other users would not be able to open it with ACTION='WRITE' and change the file.

Suppose you want several users to read a file, and you want to make sure no user updates the file while anyone is reading it. First, determine what type of access to the file you want to allow the original user. Because you want the initial user to read the file only, that user should open the file with ACTION='READ'. Next, determine what type of access the initial user should allow other users; in this case, other users should be able only to read the file. The first user should open the file with SHARE='DENYWR'. Other users can also open the same file with ACTION='READ' and SHARE='DENYWR'.

See Also
fpscomp compiler option

OPEN: SHARED Specifier

The SHARED specifier indicates that the file is connected for shared access by more than one program executing simultaneously. It takes the following form:

SHARED

On Linux* and macOS* systems, shared access is the default for the Fortran I/O system. On Windows* systems, it is the default if SHARED or compiler option fpscomp general is specified.

See Also
fpscomp compiler option

OPEN: SIGN Specifier

The SIGN specifier controls the optional plus characters in formatted numeric output created during the connection. It takes the following form:
SIGN = \( sn \)

\( sn \) is a scalar default character expression that evaluates to one of the following values:

- **'PLUS'**
  - Indicates that the processor should produce a plus sign in any subsequent position where it would be otherwise optional.
  - This has the same effect as the SP edit descriptor.

- **'SUPPRESS'**
  - Indicates that the processor should suppress a plus sign in any subsequent position where it would be otherwise optional.
  - This has the same effect as the SS edit descriptor.

- **'PROCESSOR_DEFINED'**
  - Indicates that the processor determines whether a plus sign is added in any subsequent position where it would be otherwise optional.
  - This has the same effect as the S edit descriptor.

The default is **'PROCESSOR_DEFINED'**.

The setting can be overwritten by a SIGN= specifier in a WRITE statement.

**OPEN: STATUS Specifier**

The STATUS specifier indicates the status of a file when it is opened. It takes the following form:

\[ \text{STATUS} = \text{sta} \]

\( \text{sta} \) is a scalar default character expression that evaluates to one of the following values:

- **'OLD'**
  - Indicates an existing file.

- **'NEW'**
  - Indicates a new file; if the file already exists, an error occurs. Once the file is created, its status changes to 'OLD'.

- **'SCRATCH'**
  - Indicates a new file that is unnamed (called a scratch file). When the file is closed or the program terminates, the scratch file is deleted.

- **'REPLACE'**
  - Indicates the file replaces another. If the file to be replaced exists, it is deleted and a new file is created with the same name. If the file to be replaced
does not exist, a new file is created and its status changes to 'OLD'.

'UNKNOWN'

Indicates the file may or may not exist. If the file does not exist, a new file is created and its status changes to 'OLD'.

Scratch files go into a temporary directory and are visible while they are open. Scratch files are deleted when the unit is closed or when the program terminates normally, whichever occurs first.

To specify the path for scratch files, you can use one of the following environment variables:

- On Windows*: FORT_TMPDIR, TMP, or TEMP, searched in that order
- On Linux* and macOS*: FORT_TMPDIR or TMPDIR, searched in that order

If no environment variable is defined, the default is the current directory.

The default is 'UNKNOWN'. This is also the default if you implicitly open a file by using WRITE. However, if you implicitly open a file using READ, the default is 'OLD'. If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'NEW'.

**NOTE**

The STATUS specifier can also appear in CLOSE statements to indicate the file's status after it is closed. However, in CLOSE statements the STATUS values are the same as those listed for the DISPOSE specifier.

**See Also**

f66 compiler option

**OPEN: TITLE Specifier (W*S)**

The TITLE specifier indicates the name of a child window in a QuickWin application. It takes the following form:

```
TITLE = name
```

name

Is a character expression.

If TITLE is specified in a non-Quickwin application, a run-time error occurs.

**OPEN: TYPE Specifier**

TYPE is a nonstandard synonym for STATUS.

**OPEN: USEROPEN Specifier**

The USEROPEN specifier lets you pass control to a routine that directly opens a file. The file can use system calls or library routines to establish a special context that changes the effect of subsequent Fortran I/O statements.

The USEROPEN specifier takes the following form:

```
USEROPEN = function-name
```
**function-name**

Is the name of an external function of type

\[ \text{INTEGER(INT_PTR\_KIND()) on Windows and INTEGER(4) on Linux and macOS*. The external function can be written in Fortran, C, or other languages.} \]

If the function is written in Fortran, do not execute a Fortran OPEN statement to open the file named in USEROPEN.

The Intel® Fortran Run-time Library (RTL) I/O support routines call the function named in USEROPEN in place of the system calls normally used when the file is first opened for I/O.

On Windows* systems, the Fortran RTL normally calls CreateFile() to open a file. When USEROPEN is specified, the called function opens the file (or pipe, etc.) by using CreateFile() and returns the handle of the file (return value from CreateFile( )) when it returns control to the calling Fortran program.

On Linux* and macOS* systems, the Fortran RTL normally calls the open function to open a file. When USEROPEN is specified, the called function opens the file by calling open and returns the file descriptor of the file when it returns control to the calling Fortran program.

When opening the file, the called function usually specifies options different from those provided by a normal Fortran OPEN statement.

**NOTE**

You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures/USEROPEN Specifier.

**Examples**

The following shows an example on Linux and macOS* systems and an example on Windows systems.

**Example on Linux and macOS* systems:**

```fortran
PROGRAM UserOpenMain
IMPLICIT NONE
EXTERNAL UOPEN
INTEGER(4) UOPEN
CHARACTER(10) :: FileName="UOPEN.DAT"
INTEGER :: IOS
CHARACTER(255):: InqFullName
CHARACTER(100):: InqFileName
INTEGER :: InqLun
CHARACTER(30) :: WriteOutBuffer="Write_One_Record_to_the_File. 
CHARACTER(30) :: ReadInBuffer ="??????????????????????????????"

WRITE(*,'(X,"FortranMain: Test the USEROPEN Facility of Open")')
OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
IOSTAT=ios, ACTION='READWRITE')
```
When the OPEN statement is executed, the uopen_ function receives control.
The uopen_ function opens the file by calling open(), and subsequently returns control with the handle returned by open().

IF (IOS .EQ. 0) THEN
    WRITE(*,110) TRIM(FileName), IOS
    INQUIRE(10, NAME=InqFullName)
    CALL ParseForFileName(InqFullName,InqFileName)
    IF (InqFileName .NE. FileName) THEN
        WRITE(*,120) TRIM(FileName)
    END IF
ELSE
    WRITE(*,115) TRIM(FileName), IOS
    GOTO 9999
END IF

WRITE(10,*) WriteOutBuffer
REWIND(10)
READ(10,*) ReadInBuffer
IF (ReadinBuffer .NE. WriteOutBuffer) THEN
    WRITE(*,130) TRIM(FileName)
END IF
CLOSE(10)
WRITE(*,'(X,"FortranMain: Test of USEROPEN Completed")')

9999 CONTINUE
END

!---------------------------------------------------------------
! SUBROUTINE: ParseForFileName
!             Takes a full pathname and returns the filename
!             with its extension.
!---------------------------------------------------------------
SUBROUTINE ParseForFileName(FullName, FileName)
    CHARACTER(255):: FullName
    CHARACTER(255):: FileName
    INTEGER       :: P

    P = INDEX(FullName,'/',.TRUE.)
    FileName = FullName(P+1:)

END

//
// File: UserOpen_Sub.c
//
// This routine opens a file using data passed from the Intel(c) Fortran OPEN statement.
//
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <errno.h>
Example on Windows systems:

In the calling Fortran program, the function named in USEROPEN must first be declared in an EXTERNAL statement. For example, the following Fortran code might be used to call the USEROPEN procedure UOPEN:

```fortran
IMPLICIT INTEGER (A-Z)
EXTERNAL UOPEN
INTEGER(INT_PTR_KIND()) UOPEN
...
OPEN(UNIT=10, FILE='UOPEN.DAT', STATUS='NEW', USEROPEN=UOPEN)
```

When the OPEN statement is executed, the UOPEN function receives control. The function opens the file by calling CreateFile(), performs whatever operations were specified, and subsequently returns control (with the handle returned by CreateFile()) to the calling Fortran program.

Here is what the UOPEN function might look like:

```fortran
INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME, DESIRED_ACCESS, SHARE_MODE, A_NULL, CREATE_DISP, FLAGS_ATTR, B_NULL, UNIT, FLEN )
!DIR$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
!DIR$ ATTRIBUTES REFERENCE :: FILENAME
```
USE IFWIN
IMPLICIT INTEGER (A-Z)
CHARACTER*(FLEN) FILENAME
TYPE(T_SECURITY_ATTRIBUTES), POINTER :: NULL_SEC_ATTR

! Set the FILE_FLAG_WRITE_THROUGH bit in the flag attributes to CreateFile()
! (for whatever reason)
FLAGS_ATTR = FLAGS_ATTR + FILE_FLAG_WRITE_THROUGH

! Do the CreateFile() call and return the status to the Fortran rtl
STS = CreateFile( FILENAME,             
                  DESIRED_ACCESS,       
                  SHARE_MODE,           
                  NULL_SEC_ATTR,        
                  CREATE_DISP,          
                  FLAGS_ATTR,           
                  0 )

UOPEN = STS
RETURN
END

The UOPEN function is declared to use the cdecl calling convention, so it matches the Fortran rtl declaration of a useropen routine.

The following function definition and arguments are passed from the Intel Fortran Run-time Library to the function named in USEROPEN:

```
INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME, 
                  DESIRED_ACCESS, 
                  SHARE_MODE, 
                  A_NULL, 
                  CREATE_DISP, 
                  FLAGS_ATTR, 
                  B_NULL, 
                  UNIT, 
                  FLEN )

!DIR$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
!DIR$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
!DIR$ ATTRIBUTES REFERENCE :: SHARE_MODE
!DIR$ ATTRIBUTES REFERENCE :: CREATE_DISP
!DIR$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
!DIR$ ATTRIBUTES REFERENCE :: UNIT
```

The first 7 arguments correspond to the CreateFile( ) api arguments. The value of these arguments is set according the caller's OPEN( ) arguments:

FILENAME

Is the address of a null terminated character string that is the name of the file.

DESIRED_ACCESS

Is the desired access (read-write) mode passed by reference.
SHARE_MODE

Is the file sharing mode passed by reference.

A_NULL

Is always null. The Fortran runtime library always passes a NULL for the pointer to a SECURITY_ATTRIBUTES structure in its CreateFile() call.

CREATE_DISP

Is the creation disposition specifying what action to take on files that exist, and what action to take on files that do not exist. It is passed by reference.

FLAGS_ATTR

Specifies the file attributes and flags for the file. It is passed by reference.

B_NULL

Is always null. The Fortran runtime library always passes a NULL for the handle to a template file in it's CreateFile() call.

The last 2 arguments are the Fortran unit number and length of the file name:

UNIT

Is the Fortran unit number on which this OPEN is being done. It is passed by reference.

FLEN

Is the length of the file name, not counting the terminating null, and passed by value.

User-Supplied OPEN Procedures: USEROPEN Specifier

Compilation Control Lines and Statements

In addition to specifying options on the compiler command line, you can specify the following lines and statements in a program unit to influence compilation:

- The INCLUDE Line
  Incorporates external source code into programs.
- The OPTIONS Statement
  Sets options usually specified in the compiler command line. OPTIONS statement settings override command line options.

Directive Enhanced Compilation

Directive enhanced compilation is performed by using compiler directives. Compiler directives are special commands that let you perform various tasks during compilation. They are similar to compiler options, but can provide more control within your program.

Compiler directives are preceded by a special prefix that identifies them to the compiler.
Syntax Rules for Compiler Directives

The following syntax rules apply to all general and OpenMP* Fortran compiler directives. You must follow these rules precisely to compile your program properly and obtain meaningful results.

A directive prefix (tag) takes one of the following forms:

- General compiler directives: `!DIR$`
- OpenMP Fortran compiler directives: `!$OMP`

The following prefix forms can be used in place of `!DIR$`: `cDIR$`, `cDEC$, or `!MS$`, where `c` is one of the following: C (or c), !, or *.

The following prefix forms can be used in place of `$OMP`: `c$OMP`, where `c` is one of the following: C (or c), !, or *.

The following are source form rules for directive prefixes:

- In fixed and tab source forms, prefixes begin with !, C (or c), or *.
  - The prefix must appear in columns 1 through 5; column 6 must be a blank or a tab (except for prefix `!MS`). From column 7 on, blanks are insignificant, so the directive can be positioned anywhere on the line after column 6.
- In free source form, prefixes begin with !.
  - The prefix can appear in any column, but it cannot be preceded by any nonblank, nontab characters on the same line.
- In all source forms, directives spelled with two keywords can be separated by an optional space; for example, "LOOP COUNT" and "LOOPCOUNT" are both valid spellings for the same directive. However, when a directive name is preceded by the prefix "NO", this is not considered to be two keywords. For example, "NO DECLARE" is not a valid spelling; the only valid spelling for this directive is "NODECLARE".

A compiler directive ends in column 72 (or column 132, if compiler option extend-source is specified).

General compiler directives and OpenMP Fortran directives can be continued in the same way as Fortran statements can be continued:

- In fixed form, the first line of the directive {initial line} has the directive prefix in columns 1 through 5 and has a blank, a tab, or a zero in column 6; each continued line of the directive has the directive prefix in columns 1 through 5 and has a character other than a blank, a tab, or a zero in column 6.
- In free form, the initial line of the directive ends with an ampersand followed by an optional comment beginning with an exclamation point. Each continued line of the directive has the directive prefix optionally preceded by blanks or tabs, followed by an ampersand optionally preceded by blanks or tabs.

A comment beginning with an ! can follow a compiler directive on the same line.

Additional Fortran statements (or directives) cannot appear on the same line as the compiler directive.

Compiler directives cannot appear within a continued Fortran statement.

Blank common used in a compiler directive is specified by two slashes (`//`).

If the source line starts with a valid directive prefix but the directive is not recognized, the compiler displays an informational message and ignores the line.

General Compiler Directives

Compiler directives are specially formatted comments in the source file which provide information to the compiler. Some directives, such as line length or conditional compilation directives provide the compiler information which is used in interpreting the source file. Other directives, such as optimization directives provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler based on the heuristics of the optimizer and/or code generator. You do not need to specify a compiler option to enable general directives. If the directive is ignored by the compiler, no diagnostic message is issued.

The following general compiler directives are available:
• ALIAS
  Specifies an alternate external name to be used when referring to external subprograms.
• ASSUME
  Provides heuristic information to the compiler optimizer.
• ASSUME_ALIGNED
  Specifies that an entity in memory is aligned.
• ATTRIBUTES
  Specifies properties for data objects and procedures.
• BLOCK_LOOP and NOBLOCK_LOOP
  Enables or disables loop blocking for the immediately following nested DO loops.
• DECLARE and NODECLARE
  Generates or disables warnings for variables that have been used but not declared.
• DEFINE and UNDEFINE
  Defines (or undefines) a symbolic variable whose existence (or value) can be tested during conditional compilation.
• DISTRIBUT POINT
  Suggests a location at which a DO loop may be split.
• FIXEDFORM LINESIZE
  Sets the line length for fixed-form source code.
• FMA and NOFMA
  Enables (or disables) the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.
• FREEFORM and NOFREEFORM
  Specifies free-format or fixed-format source code.
• IDENT
  Specifies an identifier for an object module.
• IF and IF DEFINED
  Specifies a conditional compilation construct.
• INLINE, FORCEINLINE, NOINLINE
  Tell the compiler to perform the specified inlining on routines within statements or DO loops.
• INTEGER
  Specifies the default integer kind.
• IVDEP
  Assists the compiler’s dependence analysis of iterative DO loops.
• LOOP COUNT
  Specifies the typical trip count for a DO loop; this assists the optimizer.
• MESSAGE
  Specifies a character string to be sent to the standard output device during the first compiler pass.
• NOFUSION
  Prevents a loop from fusing with adjacent loops.
• OBJCOMMENT
  Specifies a library search path in an object file.
• OPTIMIZE and NOOPTIMIZE
  Enables or disables optimizations for the program unit.
• OPTIONS
  Affects data alignment and warnings about data alignment.
• PACK
  Specifies the memory alignment of derived-type items.
• PARALLEL and NOPARALLEL
Facilitates or prevents auto-parallelization by assisting the compiler's dependence analysis of the immediately following DO loop.

- **PREFETCH and NOPREFETCH**
  Enables or disables hint to the compiler to prefetch data from memory.

- **PSECT**
  Modifies certain characteristics of a common block.

- **REAL**
  Specifies the default real kind.

- **SIMD**
  Requires and controls SIMD vectorization of loops.

- **STRICT and NOSTRICT**
  Disables or enables language features not found in the language standard specified on the command line.

- **UNROLL and NOUNROLL**
  Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop.

- **UNROLL_AND_JAM and NOUNROLL_AND_JAM**
  Enables or disables loop unrolling and jamming.

- **VECTOR and NOVECTOR**
  Overrides default heuristics for vectorization of DO loops.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Syntax Rules for Compiler Directives  
Rules for General Directives that Affect DO Loops

---

**Rules for Placement of Directives**

Directives can have different effects depending on placement:

- Some directives affect the next statement only.
- Some directives can appear only at the beginning of a scope and affect the rest of that scope.
- Some directives affect the statements starting at that point in the source and continue until changed by another directive or until the end of the scope containing the directive.

The scope can be a contained procedure or a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. A directive does not affect modules invoked with the USE statement in the program unit that contains it, but it does affect INCLUDE statements that follow the directive.

Certain directives may appear before program units or between program units in a source file. These directives affect only the next program unit that lexically follows the directive. The effect of the directive ceases at the end of the affected program unit. For example:

```
!dir$ integer:2  
program m  
exteger k  
print *, kind(k), kind(42) ! this prints 2, 2 which means the directive took effect
```
call sub()
end

subroutine sub()
integer kk
print *, kind(kk), kind(-42)  ! this prints 4, 4 because the INTEGER:2 directive has no effect here
end

The following directives have this behavior:

- ALIAS
- ATTRIBUTES
- DECLARE and NODECLARE
- DEFINE and UDEFINE
- FIXEDFORMLINESIZE
- FREEFORM and NOFREEFORM
- IDENT
- INTEGER
- OPTIMIZE and NOOPTIMIZE
- PACK
- PREFETCH
- PSECT
- REAL
- STRICT and NOSTRICT

Other rules may apply to these directives. For more information, see the description of each directive.

### Rules for General Directives that Affect DO Loops

This table lists the general directives that affect DO loops:

<table>
<thead>
<tr>
<th>General Directive</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK_LOOP and NOBLOCK_LOOP</td>
<td></td>
</tr>
<tr>
<td>CODE_ALIGN</td>
<td>PREFETCH and NOPREFETCH</td>
</tr>
<tr>
<td>DISTRIBUTION POINT</td>
<td>SIMD</td>
</tr>
<tr>
<td>FORCESINLINE</td>
<td>UNROLL and NOUNROLL</td>
</tr>
<tr>
<td>INLINE and NOINLINE</td>
<td>UNROLL_AND_JAM</td>
</tr>
<tr>
<td>IVDEP</td>
<td>VECTOR and NOVECTOR</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td></td>
</tr>
<tr>
<td>NOFUSION</td>
<td></td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td></td>
</tr>
</tbody>
</table>

The following rules apply to all of the general directives:

- The directive must precede the DO statement for each DO loop it affects. The DO statement can be any of the following:
  - A counted DO loop
  - A DO WHILE loop
  - A DO CONCURRENT loop
- No source code lines, other than the following, can be placed between the directive statement and the DO statement:
  - One of the other general directives that affect DO loops
• An OpenMP* Fortran PARALLEL DO directive
• Comment lines
• Blank lines

Other rules may apply to these directives. For more information, see the description of each directive.

See Also
Rules for Loop Directives that Affect Array Assignment Statements

Rules for Loop Directives that Affect Array Assignment Statements
When certain loop directives precede an array assignment statement, they affect the implicit loops that are generated by the compiler.

The following loop directives can affect array assignment statements:

<table>
<thead>
<tr>
<th>General Directive</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK_LOOP and NOBLOCK_LOOP</td>
<td>NOVECTOR</td>
</tr>
<tr>
<td>CODE_ALIGN</td>
<td>PARALLEL and NOPARALLEL</td>
</tr>
<tr>
<td>DISTRIBUTION POINT</td>
<td>PREFETCH and NOPREFETCH</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>SIMD</td>
</tr>
<tr>
<td>INLINE and NOINLINE</td>
<td>UNROLL and NOUNROLL</td>
</tr>
<tr>
<td>IVDEP</td>
<td>UNROLL_AND_JAM</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>VECTOR</td>
</tr>
<tr>
<td>NOFUSION</td>
<td></td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td></td>
</tr>
</tbody>
</table>

Usually only one of the general directives can precede the array assignment statement (one-dimensional-array = expression) to affect it. The BLOCK_LOOP and NOBLOCK_LOOP directives may precede array assignment statements with any rank variable on the left-hand-side of the assignment.

Other rules may apply to the general directives. For more information, see the description of each directive.

Examples
Consider the following:

```fortran
REAL A(10), B(10)
...
!DIR$ IVDEP
A = B + 3
```

This has the same effect as writing the following explicit loop:

```fortran
!DIR$ IVDEP
DO I = 1, 10
   A (I) = B (I) + 3
END DO
```

Rules for General Directives that Affect DO Loops
OpenMP* Fortran Compiler Directives

Intel® Fortran supports OpenMP* Fortran compiler directives that comply with OpenMP Fortran Application Program Interface (API) specification Version TR4: Version 5.0.

To use these directives, you must specify compiler option `-qopenmp` (Linux* and macOS*) or `/Qopenmp` (Windows*).

OpenMP directives are specially formatted Fortran comment lines embedded in the source file which provide the compiler with hints and suggestions for parallelization, optimization, vectorization, and offloading code to accelerator hardware. The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

Options that use OpenMP* are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

This section discusses clauses used in multiple OpenMP* Fortran directives, conditional compilation rules, nesting and binding rules, and the following directives:

- **ATOMIC directive**
  Specifies that a specific memory location is to be updated atomically.

- **BARRIER directive**
  Synchronizes all the threads in a team.

- **CANCEL directive**
  Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

- **CANCELLATION POINT directive**
  Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.

- **CRITICAL directive**
  Restricts access for a block of code to only one thread at a time.

- **DECLARE REDUCTION directive**
  Declares a user-defined reduction for one or more types.

- **DECLARE SIMD directive**
  Generates a SIMD procedure.

- **DECLARE TARGET directive**
  Causes the creation of a device-specific version of a named routine that can be called from a target region. This directive only applies to Intel® MIC Architecture.

- **DISTRIBUTE directive**
  Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.

- **DISTRIBUTE PARALLEL DO directive**
  Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

- **DISTRIBUTE PARALLEL DO SIMD directive**
  Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.

- **DISTRIBUTE SIMD**
  Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.

- **DO directive**
Specifies that the iterations of the immediately following DO loop must be executed in parallel.

- **DO SIMD directive**
  Specifies a loop that can be executed concurrently using SIMD instructions.

- **FLUSH directive**
  Specifies synchronization points where the threads in a team must have a consistent view of memory.

- **MASTER directive**
  Specifies a block of code to be executed by the master thread of the team.

- **ORDERED directive**
  Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.

- **PARALLEL directive**
  Defines a parallel region.

- **PARALLEL DO directive**
  Defines a parallel region that contains a single DO directive.

- **PARALLEL DO SIMD directive**
  Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.

- **PARALLEL SECTIONS directive**
  Defines a parallel region that contains a single SECTIONS directive.

- **PARALLEL WORKSHARE directive**
  Defines a parallel region that contains a single WORKSHARE directive.

- **SECTIONS directive**
  Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team.

- **SIMD directive**
  Requires and controls SIMD vectorization of loops.

- **SINGLE directive**
  Specifies a block of code to be executed by only one thread in a team at a time.

- **TARGET directive**
  Creates a device data environment and executes the construct on the same device. This directive only applies to Intel® MIC Architecture.

- **TARGET DATA directive**
  Creates a device data environment for the extent of the region. This directive only applies to Intel® MIC Architecture.

- **TARGET ENTER DATA**
  Specifies that variables are mapped to a device data environment. This directive only applies to Intel® MIC Architecture.

- **TARGET EXIT DATA**
  Specifies that variables are unmapped from a device data environment. This directive only applies to Intel® MIC Architecture.

- **TARGET PARALLEL**
  Creates a device data environment in a parallel region and executes the construct on that device. This directive only applies to Intel® MIC Architecture.

- **TARGET PARALLEL DO**
  Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.

- **TARGET PARALLEL DO SIMD**
  Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

- **TARGET SIMD**
  Specifies a TARGET construct that contains a SIMD construct and no other statement.
• **TARGET TEAMS**
  Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE**
  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE PARALLEL DO**
  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD**
  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE SIMD**
  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

• **TARGET UPDATE directive**
  Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies to Intel® MIC Architecture.

• **TASK directive**
  Defines a task region.

• **TASKGROUP directive**
  Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

• **TASKLOOP directive**
  Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.

• **TASKLOOP SIMD directive**
  Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.

• **TASKWAIT directive**
  Specifies a wait on the completion of child tasks generated since the beginning of the current task.

• **TASKYIELD directive**
  Specifies that the current task can be suspended at this point in favor of execution of a different task.

• **TEAMS**
  Creates a group of thread teams to be used in a parallel region.

• **TEAMS DISTRIBUTE**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.

• **TEAMS DISTRIBUTE PARALLEL DO**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

• **TEAMS DISTRIBUTE PARALLEL DO SIMD**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel using multiple threads that are members of multiple teams.
Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.

- **TEAMS DISTRIBUTE SIMD**
  - Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.
- **THREADPRIVATE directive**
  - Makes named common blocks private to each thread, but global within the thread.
- **WORKSHARE directive**
  - Divides the work of executing a block of statements or constructs into separate units.

The OpenMP parallel directives can be grouped into the categories. For more information about the categories for these directives, see OpenMP* Directives Summary.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

### Clauses Used in Multiple OpenMP* Fortran Directives

This topic summarizes clauses that are used in more than one OpenMP* Fortran directive.

Other clauses (or keywords) are available for some OpenMP* Fortran directives. For more information, see each directive description.

Some of the OpenMP* Fortran directives have clauses (or options) you can specify to control the scope attributes of variables for the duration of the directive.

#### Data Scope Attribute Clauses

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Lets you specify a scope for all variables in the lexical extent of a parallel region.</td>
</tr>
<tr>
<td>FIRSTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.</td>
</tr>
<tr>
<td>IN_REDUCTION</td>
<td>Specifies that a task participates in a reduction.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LASTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.</td>
</tr>
<tr>
<td>LINEAR</td>
<td>Specifies that all variables in a list are private to a SIMD task and that they have a linear relationship within the iteration space of a loop.</td>
</tr>
<tr>
<td>PRIVATE</td>
<td>Declares one or more variables to be private to each thread in a team.</td>
</tr>
<tr>
<td>REDUCTION</td>
<td>Performs a reduction operation on the specified variables.</td>
</tr>
<tr>
<td>SHARED</td>
<td>Specifies variables that will be shared by all the threads in a team.</td>
</tr>
</tbody>
</table>

The data copying clauses let you copy data values from private or threadprivate variables in one implicit task or thread to the corresponding variables in other implicit tasks or threads in the team.

**Data Copying Clauses**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COPYIN</td>
<td>Specifies that the data in the master thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.</td>
</tr>
<tr>
<td>COPYPRIVATE</td>
<td>Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.</td>
</tr>
</tbody>
</table>

The data motion clause MAP is used in OpenMP* Fortran TARGET directives. This data motion clause does not modify the values of any of the internal control variables (ICVs).

List items that appear in this data motion clause may have corresponding new list items created in the device data environment that is associated with the construct. If a new list item is created, a new list item of the same type, kind, and rank is allocated. The initial value of the new list item is undefined.

The original list items and new list items may share storage. This means that data races can occur. Data races are caused by unintended sharing of data; for example, when WRITEs to either item by one task or device are followed by a READ of the other item by another task or device without intervening synchronization.

**Data Motion Clause**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAP</td>
<td>Maps a variable from the data environment of the current task to the data environment of the device associated with the construct.</td>
</tr>
</tbody>
</table>

The following are other clauses that can be used in more than one OpenMP* Fortran directive.

**Miscellaneous Clauses**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIGNED</td>
<td>Specifies that all variables in a list are aligned.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COLLAPSE</td>
<td>Specifies how many loops are associated with the loop construct.</td>
</tr>
<tr>
<td>DEPEND</td>
<td>Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.</td>
</tr>
<tr>
<td>DEVICE</td>
<td>Specifies the target device for certain TARGET directives.</td>
</tr>
<tr>
<td>FINAL</td>
<td>Specifies that the generated task will be a final task.</td>
</tr>
<tr>
<td>IF</td>
<td>Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.</td>
</tr>
<tr>
<td>MERGEABLE</td>
<td>Specifies that the implementation may generate a merged task.</td>
</tr>
<tr>
<td>NOWAIT</td>
<td>Specifies that threads may resume execution before the execution of the region completes.</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>Specifies that the generated tasks have the indicated priority for execution.</td>
</tr>
<tr>
<td>UNTIED</td>
<td>Specifies that the task is never tied to the thread that started its execution.</td>
</tr>
</tbody>
</table>

**Conditional Compilation Rules**

The OpenMP* Fortran API lets you conditionally compile Intel® Fortran statements if you use the appropriate directive prefix.

The prefix depends on which source form you are using, although !$ is valid in all forms.

The prefix must be followed by a valid Intel Fortran statement on the same line.

**Free Source Form**

The free source form conditional compilation prefix is !$. This prefix can appear in any column as long as it is preceded only by white space. It must appear as a single word with no intervening white space. Free-form source rules apply to the directive line.

Initial lines must have a space after the prefix. Continued lines must have an ampersand as the last nonblank character on the line. Continuation lines can have an ampersand after the prefix with optional white space before and after the ampersand.

**Fixed Source Form**

For fixed source form programs, the conditional compilation prefix is one of the following: !$, C$ (or c$), or *$.

The prefix must start in column one and appear as a single string with no intervening white space. Fixed-form source rules apply to the directive line.
After the prefix is replaced with two spaces, initial lines must have a space or zero in column six, and
continuation lines must have a character other than a space or zero in column six. For example, the following
forms for specifying conditional compilation are equivalent:

```
c23456789
!$ IAM = OMP_GET_THREAD_NUM( ) +
!$ * INDEX
IFDEF _OPENMP
IAM = OMP_GET_THREAD_NUM( ) +
* INDEX
ENDIF
```

**Nesting and Binding Rules**

This section describes the dynamic nesting and binding rules for OpenMP Fortran API directives.

**Binding Rules**

The following rules apply to dynamic binding:

- The DO, SECTIONS, SINGLE, MASTER, and BARRIER directives bind to the dynamically enclosing PARALLEL directive, if one exists.
- The ORDERED directive binds to the dynamically enclosing DO directive.
- The ATOMIC directive enforces exclusive access with respect to ATOMIC directives in all threads, not just the current team.
- The CRITICAL directive enforces exclusive access with respect to CRITICAL directives in all threads, not just the current team.
- A directive can never bind to any directive outside the closest enclosing PARALLEL directive.

**Nesting Rules**

The following rules apply to dynamic nesting:

- A PARALLEL directive dynamically inside another PARALLEL directive logically establishes a new team, which is composed of only the current thread unless nested parallelism is enabled.
- DO, SECTIONS, and SINGLE directives that bind to the same PARALLEL directive are not allowed to be nested one inside the other.
- DO, SECTIONS, and SINGLE directives are not permitted in the dynamic extent of CRITICAL and MASTER directives.
- BARRIER directives are not permitted in the dynamic extent of DO, SECTIONS, SINGLE, MASTER, and CRITICAL directives.
- MASTER directives are not permitted in the dynamic extent of DO, SECTIONS, and SINGLE directives.
- ORDERED sections are not allowed in the dynamic extent of CRITICAL sections.
- Any directive set that is legal when executed dynamically inside a PARALLEL region is also legal when executed outside a parallel region. When executed dynamically outside a user-specified parallel region, the directive is executed with respect to a team composed of only the master thread.

**Examples**

The following example shows nested PARALLEL regions:

```
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
   DO I =1, N
!$OMP PARALLEL SHARED(I,N)
!$OMP DO
   DO J =1, N
      CALL WORK(I,J)
   END DO
END DO
```
Note that the inner and outer DO directives bind to different PARALLEL regions.

The following shows a variation of the preceding example:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO 
  DO I =1, N 
    CALL SOME_WORK(I,N)
  END DO
!$OMP END PARALLEL 
...
SUBROUTINE SOME_WORK(I,N)
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO 
  DO J =1, N 
    CALL WORK(I,J)
  END DO
!$OMP END PARALLEL 
RETURN 
END
```

**OFFLOAD Compiler Directives**

Intel® Fortran provides several OFFLOAD compiler directives to perform offloading tasks during compilation. These directives are recognized by default; there is a command line option to tell the compiler to ignore them. These directives only apply when targeting Intel® Xeon Phi™ products.

Compiler directives are specially formatted comments in the source file which provide information to the compiler. Some directives, such as line length or conditional compilation directives provide the compiler information which is used in interpreting the source file. Other directives, such as optimization directives provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler based on the heuristics of the optimizer and/or code generator. If the directive is ignored by the compiler, no diagnostic message is issued.

The following OFFLOAD compiler directives are available:

- **OFFLOAD**
  Enables statements to execute on the target.

- **OFFLOAD BEGIN and END OFFLOAD**
  Enables a group of statements to execute on the target.

- **OFFLOAD_TRANSFER**
  Initiates asynchronous data transfer, or initiates and completes synchronous data transfer.

- **OFFLOAD_WAIT**
  Specifies a wait for a previously initiated asynchronous activity.

**NOTE**
These directives are deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.
## Equivalent Compiler Options

Some compiler directives and compiler options have the same effect, as shown in the table below. However, compiler directives can be turned on and off throughout a program, while compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

The following table shows compiler directives and equivalent command-line compiler options:

<table>
<thead>
<tr>
<th>Compiler Directive</th>
<th>Equivalent Command-Line Compiler Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECLARE</td>
<td>-warn declarations (Linux* and macOS*)</td>
</tr>
<tr>
<td></td>
<td>/warn:declarations (Windows*)</td>
</tr>
<tr>
<td>NODEDECLARE</td>
<td>-warn nodeclarations (Linux and macOS*)</td>
</tr>
<tr>
<td></td>
<td>/warn:nodeclarations (Windows)</td>
</tr>
<tr>
<td>DEFINE name</td>
<td>-D name (Linux and macOS*)</td>
</tr>
<tr>
<td></td>
<td>/D name (Windows)</td>
</tr>
<tr>
<td>FIXEDFORMLINESIZE:length</td>
<td>-extend-source [size] (Linux and macOS*)</td>
</tr>
<tr>
<td></td>
<td>/extend-source[:size] (Windows)</td>
</tr>
<tr>
<td>FREEFORM</td>
<td>-free or -nofixed (Linux and macOS*)</td>

Scope and Association

Program entities are identified by names, labels, input/output unit numbers, operator symbols, or assignment symbols. For example, a variable, a derived type, or a subroutine is identified by its name.

Scope refers to the area in which a name is recognized. A scoping unit is the program or part of a program in which a name is defined or known. It can be any of the following:

- An entire executable program
- A single scoping unit
- A single statement (or part of a statement)

The region of the program in which a name is known and accessible is referred to as the scope of that name. These different scopes allow the same name to be used for different things in different regions of the program.

Association is the language concept that allows different names to refer to the same entity in a particular region of a program.

Scope

Program entities have the following kinds of scope (as shown in the table below):

- Global
  Entities that are accessible throughout an executable program. The name of a global entity must be unique. It cannot be used to identify any other global entity in the same executable program.

- Scoping unit (Local scope)
  Entities that are declared within a scoping unit. These entities are local to that scoping unit. The names of local entities are divided into classes (see the table below).

A scoping unit is one of the following:

- A derived-type definition
- A procedure interface body (excluding any derived-type definitions and interface bodies contained within it)
- A program unit or subprogram (excluding any derived-type definitions, interface bodies, and subprograms contained within it)

A scoping unit that immediately surrounds another scoping unit is called the host scoping unit. Named entities within the host scoping unit are accessible to the nested scoping unit by host association, unless access is blocked by an IMPORT ONLY or IMPORT NONE statement. For information about host association, see Use and Host Association.

Once an entity is declared in a scoping unit, its name can be used throughout that scoping unit. An entity declared in another scoping unit is a different entity even if it has the same name and properties.

Within a scoping unit, a local entity name that is not generic or an OpenMP* reduction identifier must be unique within its class. However, the name of a local entity in one class can be used to identify a local entity of another class.

Within a scoping unit, a generic name can be the same as any one of the procedure names in the interface block. A generic name can be the same as the name of a derived type.

An OpenMP* reduction identifier can be the same as any local entity name.

A component name has the same scope as the derived type of which it is a component. It can appear only within a component designator of a structure of that type.

For information on interactions between local and global names, see the table below.

- Statement
  Entities that are accessible only within a statement or part of a statement; such entities cannot be referenced in subsequent statements.
The name of a statement entity can also be the name of a common block, or a local or construct variable accessible in the same scoping unit or construct; in this case, the name is interpreted within the statement as that of the statement entity.

- Construct

Construct entities are accessible during the execution of the construct in which they are declared. Entities declared in the specification part of a BLOCK construct, associate names in ASSOCIATE and SELECT TYPE constructs, and index variables in FORALL statements or constructs, or DO CONCURRENT constructs are construct entities. An index name of an inner FORALL statement or construct, or of a DO CONCURRENT construct cannot be the same as that of an index variable of an outer (containing) FORALL or DO CONCURRENT construct.

An associate name of a SELECT TYPE construct has a different scope for each block of the construct; the declared type, dynamic type, type parameters, rank or bounds may differ from block to block. An associate name for an ASSOCIATE construct has the scope of the ASSOCIATE construct.

¹ Names of common blocks can also be used to identify local entities.

² If an intrinsic procedure is not used in a scoping unit, its name can be used as a local entity within that scoping unit. For example, if intrinsic function COS is not used in a program unit, COS can be used as a local variable there.

³ The DO variable in an implied-DO list of an I/O list has local scope.

⁴ The scope of the assignment symbol (=) is global, but it can identify additional operations (see Defining Generic Assignment).

Scoping units can contain other scoping units. For example, the following shows six scoping units:

```fortran
MODULE MOD_1                   ! Scoping unit 1
  ...
  CONTAINS                      ! Scoping unit 1
  FUNCTION FIRST                ! Scoping unit 2
    TYPE NAME                   ! Scoping unit 3
      ...
    END TYPE NAME               ! Scoping unit 3
    ...
  END CONTAINS                  ! Scoping unit 2
  SUBROUTINE SUB_B             ! Scoping unit 4
    TYPE PROCESS               ! Scoping unit 5
      ...
    END TYPE PROCESS            ! Scoping unit 5
    INTERFACE                  ! Scoping unit 5
      SUBROUTINE SUB_A          ! Scoping unit 6
        ...
      END BLOCK                 ! Scoping unit 7
        ...
      END SUBROUTINE SUB_A      ! Scoping unit 6
      END INTERFACE            ! Scoping unit 5
      END SUBROUTINE SUB_B      ! Scoping unit 4
    END FUNCTION FIRST          ! Scoping unit 2
  END SUBROUTINE SUB_B          ! Scoping unit 4
END MODULE                      ! Scoping unit 1
```

Unambiguous Generic Procedure References

When a generic procedure reference is made, a specific procedure is invoked. If the following rules are used, the generic reference will be unambiguous:

- Two dummy arguments are said to be distinguishable if any of the following are true:
  - One is a procedure and the other is a data object
  - One has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN)
  - They are both data objects or both known to be functions, and they have different type and kind parameters, or different rank
  - One is a function with nonzero rank and the other is not known to be a function
- Within a scoping unit, two procedures that have the same generic name must both be subroutines or both be functions. One of the procedures must have a nonoptional dummy argument that is one of the following:
  - Not present by position or argument keyword in the other argument list
  - Is present, but is distinguishable from the dummy argument in the other argument list
- Within a scoping unit, two procedures that have the same generic operator must both have the same number of arguments or both define assignment. One of the procedures must have a dummy argument that corresponds, by position in the argument list, to a dummy argument of the other procedure that is distinguishable from the dummy argument in the other argument list.

When an interface block extends an intrinsic procedure, operator, or assignment, the rules apply as if the intrinsic consists of a collection of specific procedures, one for each allowed set of arguments.

When a generic procedure is accessed from a module, the rules apply to all the specific versions, even if some of them are inaccessible by their specific names.

Defining Generic Names for Procedures for details on generic procedure names

Resolving Procedure References

The procedure name in a procedure reference is either established to be generic or specific, or is not established. The rules for resolving a procedure reference differ depending on whether the procedure is established and how it is established.

This section discusses the following topics:

- References to Generic Names
- References to Specific Names
- References to Nonestablished Names

References to Generic Names

Within a scoping unit, a procedure name is established to be generic if any of the following is true:

- The scoping unit contains an interface block with that procedure name.
- The procedure name matches the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is established to be generic in a module, and the scoping unit contains a USE statement making that procedure name accessible.
• The scoping unit contains no declarations for that procedure name, but the procedure name is established
to be generic in a host scoping unit.

To resolve a reference to a procedure name established to be generic, the following rules are used in the
order shown:

1. If an interface block with that procedure name appears in one of the following, the reference is to the
   specific procedure providing that interface:
   a. The scoping unit that contains the reference
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with one of the specific interfaces of the interface block.

2. If the procedure name is specified with the INTRINSIC attribute in one of the following, the reference is
to that intrinsic procedure:
   a. The same scoping unit
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with the interface of that intrinsic procedure.

3. If the following is true, the reference is resolved by applying rules 1 and 2 to the host scoping unit:
   a. The procedure name is established to be generic in the host scoping unit
   b. There is agreement between the scoping unit and the host scoping unit as to whether the
      procedure is a function or subroutine name.

4. If none of the preceding rules apply, the reference must be to the generic intrinsic procedure with that
   name. The reference must be consistent with the interface of that intrinsic procedure.

Examples

The following example shows how a module can define three separate procedures and give them a generic
name DUP through an interface block. Although the main program calls all three by the generic name, there
is no ambiguity since the arguments are of different data types, and DUP is a function rather than a
subroutine. The module UN_MOD must give each procedure a different name.

```fortran
MODULE UN_MOD
  CONTAINS
    subroutine dup1(x,y)
      real x,y
      print *, ' Real arguments', x, y
    end subroutine dup1

    subroutine dup2(m,n)
      integer m,n
      print *, ' Integer arguments', m, n
    end subroutine dup2

    character function dup3 (z)
      character(len=2) z
      dup3 = 'String argument '// z
    end function dup3

END MODULE

program unclear
  !
  ! shows how to use generic procedure references
  USE UN_MOD
  INTERFACE DUP
```
MODULE PROCEDURE dup1, dup2, dup3
END INTERFACE

real a,b
integer c,d
character (len=2) state

a = 1.5
b = 2.32
c = 5
d = 47
state = 'WA'

call dup(a,b)
call dup(c,d)
print *, dup(state) !actual output is 'S' only
END

Note that the function DUP3 only prints one character, since module UN_MOD specifies no length parameter for the function result.

If the dummy arguments x and y for DUP were declared as integers instead of reals, then any calls to DUP would be ambiguous. If this is the case, a compile-time error results.

The subroutine definitions, DUP1, DUP2, and DUP3, must have different names. The generic name is specified in the first line of the interface block, and in the example is DUP.

References to Specific Names

In a scoping unit, a procedure name is established to be specific if it is not established to be generic and any of the following is true:

- The scoping unit contains an interface body with that procedure name.
- The scoping unit contains an internal procedure, module procedure, or statement function with that procedure name.
- The procedure name is the same as the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is specified with the EXTERNAL attribute in that scoping unit.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be specific in a host scoping unit.

To resolve a reference to a procedure name established to be specific, the following rules are used in the order shown:

1. If either of the following is true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram, and it contains an interface body with that procedure name.
   b. The procedure name has been declared EXTERNAL, and the procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If the scoping unit contains an interface body or the procedure name has been declared EXTERNAL, and Rule 1 does not apply, the reference is to an external procedure with that name.

3. If the scoping unit contains an internal procedure or statement function with that procedure name, the reference is to that entity.

4. If the procedure name has been declared INTRINSIC in the scoping unit, the reference is to the intrinsic procedure with that name.
5. If the scoping unit contains a USE statement that makes the name of a module procedure accessible, the reference is to that procedure. Since the USE statement allows renaming, the name referenced may differ from the name of the module procedure.

6. If none of the preceding rules apply, the reference is resolved by applying these rules to the host scoping unit.

References to Nonestablished Names

In a scoping unit, a procedure name is not established if it is not determined to be generic or specific. To resolve a reference to a procedure name that is not established, the following rules are used in the order shown:

1. If both of the following are true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram.
   b. The procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If both of the following are true, the procedure is an intrinsic procedure and the reference is to that intrinsic procedure:
   a. The procedure name matches the name of an intrinsic procedure.
   b. There is agreement between the intrinsic procedure definition and the reference of the name as a function or subroutine.

3. If neither of the preceding rules apply, the reference is to an external procedure with that name.

Association

Association allows different program units to access the same value through different names. Entities are associated when each is associated with the same storage location.

There are four kinds of association:

- Name association
- Pointer association
- Storage association
- Inheritance association

The following example shows name, pointer, and storage association between an external program unit and an external procedure.

Example of Name, Pointer, and Storage Association

```plaintext
! Scoping Unit 1: An external program unit

REAL A, B(4)
REAL, POINTER :: M(:)
REAL, TARGET :: N(12)
COMMON /COM/...
EQUIVALENCE (A, B(1)) ! Storage association between A and B(1)
M => N ! Pointer association
CALL P (actual-arg,...)
```
The following example shows inheritance association:

```fortran
TYPE POINT                  ! A base type
REAL :: X, Y
END TYPE POINT

TYPE, EXTENDS(POINT) :: COLOR_POINT   ! An extension of TYPE(POINT)
                        ! Components X and Y, and component name POINT,
                        !   are inherited from the parent type POINT
INTEGER :: COLOR
END TYPE COLOR_POINT
```

**Name Association**

Name association allows an entity to be accessed from different scoping units by the same name or by different names. There are five types of name association: argument, use, host, linkage, and construct.

**Argument Association**

Arguments are the values passed to and from functions and subroutines through calling program argument lists.

Execution of a procedure reference establishes argument association between an actual argument and its corresponding dummy argument. The name of a dummy argument can be different from the name of its associated actual argument (if any).

When the procedure completes execution, the argument association is terminated. A dummy argument of that procedure can be associated with an entirely different actual argument in a subsequent invocation of the procedure.

**Association Between Actual Arguments and Dummy Data Objects**

A scalar dummy argument of a nonelemental procedure can be associated only with a scalar actual argument.
If the actual argument is scalar, the corresponding dummy argument must be scalar unless the actual argument is of type default character, of type character with the C character kind, or is an element or substring of an element of an array that is not an assumed-shape or pointer array. If the procedure is nonelemental and is referenced by a generic name or as a defined operator or defined assignment, the ranks of the actual arguments and corresponding dummy arguments must agree.

If a scalar dummy argument is of type default character, the length of the dummy argument must be less than or equal to the length of the actual argument. The dummy argument becomes associated with the leftmost \textit{len} characters of the actual argument. If an array dummy argument is of type default character and is not assumed shape, it becomes associated with the leftmost characters of the actual argument element sequence and it must not extend beyond the end of that sequence.

If a dummy argument is not allocatable and is not a pointer, it must be type compatible with the associated actual argument. If a dummy argument is allocatable or a pointer, the associated actual argument must be polymorphic only if the dummy argument is polymorphic, and the declared type of the actual argument must be the same as the declared type of the dummy argument.

If the dummy argument has the \texttt{TARGET} attribute, does not have the \texttt{POINTER} attribute, is either a scalar or an assumed-shape array, and the corresponding actual argument has the \texttt{TARGET} attribute but is not an array section with a vector subscript, then the following is true:

- Any pointers associated with the actual argument become associated with the corresponding dummy argument on invocation of the procedure.
- When execution of the procedure completes, any pointers that do not become undefined and are associated with the dummy argument remain associated with the actual argument.

Any pointers associated with the dummy argument become undefined when execution of the procedure completes in these cases:

- If the dummy argument has the \texttt{TARGET} attribute and the corresponding actual argument does not have the \texttt{TARGET} attribute, or is an array section with a vector subscript.
• If the dummy argument has the TARGET attribute and the VALUE attribute.

If a nonpointer dummy argument has INTENT (OUT) or INTENT (INOUT), the actual argument must be definable. If a dummy argument has INTENT (OUT), the corresponding actual argument becomes undefined at the time the association is established, except for components of an object of derived type for which default initialization has been specified. If the dummy argument is not polymorphic and the type of the actual argument is an extension type of the type of the dummy argument, only the part of the actual argument that is of the same type as the dummy argument becomes undefined.

**Association Between Actual Arguments and Dummy Procedure Entities**

If a dummy argument is a procedure pointer, the associated actual argument must be a procedure pointer, a reference to a function that returns a procedure pointer, or a reference to the NULL intrinsic function.

If a dummy argument is a dummy procedure without the POINTER attribute, the associated actual argument must be the specific name of an external, module, dummy, or intrinsic procedure, an associated procedure pointer, or a reference to a function that returns an associated procedure pointer. If the specific name is also a generic name, only the specific procedure is associated with the dummy argument.

For generic declarations, a dummy argument is type, kind, and rank compatible with another dummy argument if following is true:

• The first is type compatible with the second
• The kind type parameters of the first have the same values as the corresponding kind type parameters of the second
• Both have the same rank or either is assumed-rank

If an external procedure name or a dummy procedure name is used as an actual argument, its interface must be explicit or it must be explicitly declared to have the EXTERNAL attribute.

If the interface of the dummy argument is explicit, the procedure characteristics must be the same for the associated actual argument and the corresponding dummy argument, except that a pure actual argument can be associated with a dummy argument that is not pure, and an elemental intrinsic actual procedure can be associated with a dummy procedure that is prohibited from being elemental.

If the interface of the dummy argument is implicit and either the name of the dummy argument is explicitly typed or it is referenced as a function, the dummy argument must not be referenced as a subroutine and the actual argument must be a function, function procedure pointer, or dummy procedure.

If the interface of the dummy argument is implicit and a reference to it appears as a subroutine reference, the actual argument must be a subroutine, subroutine procedure pointer, or dummy procedure.

An assumed-rank dummy argument can correspond to an actual argument of any rank. If the actual argument has rank zero (is a scalar), the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including the lack of a final extent in the case of an assumed-size array. If the actual argument is an array and the dummy argument is allocatable or a pointer, the bounds of the dummy argument are assumed from the actual argument.

An assumed-type dummy argument must not correspond to an actual argument that is of a derived type that has type parameters, type-bound procedures, or final subroutines.

**Association For C Interoperability**

When a Fortran procedure that has an INTENT(OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated upon entry to the Fortran procedure.
When a C function is invoking a Fortran procedure by means of an interface with an INTENT(OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

- Procedure Characteristics

**Use and Host Association Overview**

*Use association* allows the entities in a module to be accessible to other scoping units. *Host association* allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program.

Use association and host association remain in effect throughout the execution of the executable program.

An interface body does not access named entities by host association, but it can access entities by use association.

**Examples**

The following example shows host and use association:

```fortran
MODULE SHARE_DATA
     REAL Y, Z
END MODULE

PROGRAM DEMO
     USE SHARE_DATA ! All entities in SHARE_DATA are available
     REAL B, Q ! through use association.

     ... ! B and Q are available through host association.
     CALL CONS (Y)
     ... ! C is a local entity, explicitly declared.
CONTAINS
     SUBROUTINE CONS (Y) ! Y is a local entity (dummy argument).
     REAL C, Y

     ... ! is available through use association.
     Y = B + C + Q + Z
     ... ! C is a local entity, explicitly declared.
     END SUBROUTINE CONS

END PROGRAM DEMO
```

**See Also**
- Use Association
- Host Association
- Scope for details on entities with local scope

**Use Association**

Use association allows the entities in a module to be accessible to other scoping units. This association remains in effect throughout the execution of the program. The mechanism for use association is the *USE* statement. The *USE* statement provides access to all public entities in the module, unless ONLY is specified. In this case, only the entities named in the ONLY list can be accessed.

If an entity that is accessed by use association has the same nongeneric name as a host entity, the host entity is inaccessible. A name that appears in the scoping unit as an external name in an EXTERNAL statement is a global name, and any entity of the host that has this as its nongeneric name is inaccessible.

For more information on rules that apply to use association, see the *USE* statement.

**See Also**
- USE statement
Host Association
Scope for details on entities with local scope

Host Association
Host association allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program. This association remains in effect throughout the execution of the program.

The following also have access to entities from its host:

- A module procedure interface body
- A derived-type definition
- An interface body that is not a separate interface body has access to the named entities from its host that are made accessible by IMPORT statements in the interface body.

The accessed entities are known by the same name and have the same attributes as in the host, except that a local entity can have the ASYNCHRONOUS attribute even if the host entity does not, and a noncoarray local entity can have the VOLATILE attribute even if the host entity does not. The accessed entities can be named data objects, derived types, abstract interfaces, procedures, generic identifiers, and namelist groups.

Entities that are local to a procedure are not accessible to their hosts.

The following are considered local identifiers within a scoping unit so they are not accessible to their hosts:

- A function name in a statement function, an entity declaration in a type declaration statement, or the name of an entity declared by an interface body, unless any of these are global identifiers.
- An object name in an entity declaration in a type declaration statement or a POINTER, SAVE, ALLOCATABLE, or TARGET statement.
- A type name in a derived type statement.
- A procedure pointer that has the EXTERNAL attribute.
- The name of a variable that is wholly or partially initialized in a DATA statement.
- The name of an object that is wholly or partially initialized in an EQUIVALENCE statement.
- A namelist group name in a NAMELIST statement.
- A generic name in a generic specification in an INTERFACE statement.
- The name of a named construct.
- The name of a dummy argument in a FUNCTION, SUBROUTINE, or ENTRY statement, or a statement function.
- A named constant defined in a PARAMETER statement.
- An array name in a DIMENSION statement.
- A variable name in a common block object in a COMMON statement.
- A result name in a FUNCTION or ENTRY statement.
- An intrinsic procedure name in an INTRINSIC statement.

A name that appears in an ASYNCHRONOUS or VOLATILE statement is not necessarily the name of a local variable. In an internal or module procedure, if a variable that is accessible via host association is specified in an ASYNCHRONOUS or VOLATILE statement, that host variable is given the ASYNCHRONOUS or VOLATILE attribute in the local scope.

If an intrinsic procedure is accessed by means of host association, it must be established to be intrinsic in the host scoping unit by one of the following methods:

- It must be explicitly given the INTRINSIC attribute.
- It must be invoked as an intrinsic procedure.
- It must be accessed from a module or from its host where it is established to be intrinsic.

If a procedure gains access to a pointer by host association, the association of the pointer with a target that is current at the time the procedure is invoked remains current within the procedure. This pointer association can be changed within the procedure. After execution of the procedure, the pointer association remains current, unless the execution caused the target to become undefined. If this occurs, the host associated pointer becomes undefined.
NOTE
Implicit declarations can cause problems for host association. It is recommended that you use IMPLICIT NONE in both the host and the contained procedure, and that you explicitly declare all entities.

When all entities are explicitly declared, local declarations override host declarations, and host declarations that are not overridden are available in the contained procedure.

Examples
The following example shows how a host and an internal procedure can use host-associated entities:

```fortran
program INTERNAL
  ! shows use of internal subroutine and CONTAINS statement
  real a, b, c
  call find
  print *, c
contains
  subroutine find
    read *, a, b
    c = sqrt(a**2 + b**2)
  end subroutine find
end
```

In this case, the variables \(a\), \(b\), and \(c\) are available to the internal subroutine `find` through host association. They do not have to be passed as arguments to the internal procedure. In fact, if they are, they become local variables to the subroutine and hide the variables declared in the host program.

Conversely, the host program knows the value of \(c\), when it returns from the internal subroutine that has defined \(c\).

See Also
Use Association
Scope for details on entities with local scope

Linkage Association
Linkage association occurs between the following:
- A module variable that has the BIND attribute and the C variable with which it interoperates
- A Fortran common block and the C variable with which it interoperates

This association remains in effect throughout the execution of the program.

See Also
USE statement
Host Association
Scope for details on entities with local scope

Construct Association
Construct association establishes an association between each selector and the corresponding associate name of an ASSOCIATE or SELECT TYPE construct.

If the selector is allocatable, it must be allocated. The associate name is associated with the data object and does not have the ALLOCATABLE attribute.

If the selector has the POINTER attribute, it must be associated. The associate name is associated with the target of the pointer and does not have the POINTER attribute.
If the selector is a variable other than an array section having a vector subscript, the association is with the data object specified by the selector; otherwise, the association is with the value of the selector expression, which is evaluated before the execution of the block.

Each associate name remains associated with the corresponding selector throughout the execution of the executed block. Within the block, each selector is known by, and can be accessed by, the corresponding associate name. When the construct is terminated, the association is terminated.

USE statement
Host Association
Scope for details on entities with local scope

Pointer Association
A pointer can be associated with a target. At different times during the execution of a program, a pointer can be undefined, associated with different targets, or be disassociated. The initial association status of a pointer is undefined. A pointer can become associated by the following:

- Pointer assignment (pointer => target)
  The target must be associated, or specified with the TARGET attribute. If the target is allocatable, it must be currently allocated.
- Allocation (successful execution of an ALLOCATE statement)
  The ALLOCATE statement must reference the pointer.

A pointer becomes disassociated if any of the following occur:

- The pointer is nullified by a NULLIFY statement.
- The pointer is deallocated by a DEALLOCATE statement.
- The pointer is assigned a disassociated pointer or the NULL intrinsic function.
- The pointer is an ultimate component of an object of a type for which default initialization is specified for the component and one of the following is true:
  - A procedure is invoked with this object as an actual argument corresponding to a nonpointer, nonallocatable, dummy argument with INTENT (OUT).
  - A procedure is invoked with this object as an unsaved, nonpointer, nonallocatable local object that is not accessed by use or host association.
  - This object is allocated.

When a pointer is associated with a target, the definition status of the pointer is defined or undefined, depending on the definition status of the target. A target is undefined in the following cases:

- If it was never allocated
- If it is not deallocated through the pointer
- If a RETURN or END statement causes it to become undefined

If a pointer is associated with a definable target, the definition status of the pointer can be defined or undefined, according to the rules for a variable.

The association status of a pointer becomes undefined when a DO CONCURRENT construct is terminated and the pointer’s association status was changed in more than one iteration of the construct.

If the association status of a pointer is disassociated or undefined, the pointer must not be referenced or deallocated.

Whatever its association status, a pointer can always be nullified, allocated, or associated with a target. When a pointer is nullified, it is disassociated. When a pointer is allocated, it becomes associated, but is undefined. When a pointer is associated with a target, its association and definition status are determined by its target.

Storage Association

Storage association describes the relationships that exist among data objects. It is the association of two or more data objects that occurs when two or more storage sequences share, or are aligned with, one or more storage units. Storage sequences are used to describe relationships among variables, common blocks, and result variables.

See Also

Storage Units and Storage Sequence
Array Association

Storage Units and Storage Sequence

A storage unit is a fixed unit of physical memory allocated to certain data. A storage sequence is a sequence of storage units. The size of a storage sequence is the number of storage units in the storage sequence. A storage unit can be numeric, character, or unspecified.

A nonpointer scalar of type default real, integer, or logical occupies one numeric storage unit. A nonpointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel® Fortran, one numeric storage unit corresponds to 4 bytes of memory.

A nonpointer scalar of type default character with character length 1 occupies one character storage unit. A nonpointer scalar of type default character with character length $len$ occupies $len$ contiguous character storage units. In Intel® Fortran, one character storage unit corresponds to 1 byte of memory.

A nonpointer scalar of nondefault data type occupies a single unspecified storage unit. The number of bytes corresponding to the unspecified storage unit differs depending on the data type.

The following table lists the storage requirements (in bytes) for the intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Requirements (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>2, 4, or 8 $^1$</td>
</tr>
<tr>
<td>LOGICAL(1)</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER</td>
<td>2, 4, or 8 $^1$</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>8</td>
</tr>
<tr>
<td>REAL</td>
<td>4, 8, or 16 $^2$</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>Data Type</td>
<td>Storage Requirements (in bytes)</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>8, 16, or 32</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16)</td>
<td>32</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>1</td>
</tr>
<tr>
<td>CHARACTER*len</td>
<td>len</td>
</tr>
<tr>
<td>CHARACTER*(*)</td>
<td>assumed-length</td>
</tr>
</tbody>
</table>

1 Depending on default integer, LOGICAL and INTEGER can have 2, 4, or 8 bytes. The default allocation is four bytes.
2 Depending on default real, REAL can have 4, 8, or 16 bytes and COMPLEX can have 8, 16, or 32 bytes. The default allocations are four bytes for REAL and eight bytes for COMPLEX.
3 The value of len is the number of characters specified. The largest valid value is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture. Negative values are treated as zero.
4 The assumed-length format *(*) applies to dummy arguments, PARAMETER statements, or character functions, and indicates that the length of the actual argument or function is used. (See Assumed-Length Character Arguments.)

A nonpointer scalar of sequence derived type occupies a sequence of storage sequences corresponding to the components of the structure, in the order they occur in the derived-type definition. Note that a sequence derived type has a SEQUENCE statement.

A pointer occupies a single unspecified storage unit that is different from that of any nonpointer object and is different for each combination of type, type parameters, and rank.

The definition status and value of a data object affects the definition status and value of any storage-associated entity.

When two objects occupy the same storage sequence, they are totally storage-associated. When two objects occupy parts of the same storage sequence, they are partially associated. An EQUIVALENCE statement, a COMMON statement, or an ENTRY statement can cause total or partial storage association of storage sequences.

**See Also**

Assumed-Length Character Arguments
COMMON
ENTRY
EQUIVALENCE

**Array Association**

A nonpointer array occupies a sequence of contiguous storage sequences, one for each array element, in array element order.

Two or more arrays are associated when each one is associated with the same storage location. They are partially associated when part of the storage associated with one array is the same as part or all of the storage associated with another array.
If arrays with different data types are associated, or partially associated, with the same storage location, and the value of one array is defined (for example, by assignment), the value of the other array becomes undefined. This happens because an element of an array is considered defined only if the storage associated with it contains data of the same type as the array name.

An array element, array section, or whole array is defined by a DATA statement before program execution. Note that the array properties must be declared in a previous specification statement. During program execution, array elements and sections are defined by an assignment or input statement, and entire arrays are defined by input statements.

**See Also**
Arrays  
DATA statement  
Array Elements  
for details on array element order

**Inheritance Association**

_Inheritance association_ occurs between components of a parent component and components inherited by type extension into an extended type.

This association is not affected by the accessibility of the inherited components.

Storage Association  
Pointer Association

## Deleted and Obsolescent Language Features

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 features, and identified some Fortran 90 language features to be obsolescent.

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 obsolescent features, and identified some Fortran 90 language features to become obsolescent. Subsequent standard revisions have continued to identify some features of previous standards as obsolescent and to delete selected features that were previously deemed obsolescent.

Fortran 2008 has also identified some earlier standard language features to be obsolescent. Features considered obsolescent may be removed from future revisions of the Fortran Standard.

If you want to use features flagged with compiler messages, you can specify compiler option `stand`.

NOTE  
Intel<sup>®</sup> Fortran fully supports features identified as deleted from or obsolescent in the Fortran Standard.

**See Also**
`stand` compiler option

## Deleted Language Features in the Fortran Standard

Some language features, considered redundant in older versions of the Fortran Standard, are not included in the current Fortran Standard. _However, they are still fully supported by Intel<sup>®</sup> Fortran._
In the examples below, both forms are supported by Intel® Fortran, but the Fortran 2003 Standard only supports the second form:

- **ASSIGN and assigned GO TO statements**
  
  The ASSIGN statement, when assigning a label for use with the assigned GO TO statement, can be replaced by assigning the integer value of the label to an integer variable; the assigned GO TO statement can then be replaced by an IF statement that tests the integer variable for various values and then goes to the label that represents that value. For example, replace:

  ```fortran
  ASSIGN 10 TO J
  ...
  ASSIGN 20 TO J
  ...
  GO TO J
  ```
  
  with:

  ```fortran
  J = 10
  ...
  J = 20
  ...
  IF (J .EQ. 10) THEN
    GO TO 10
  ELSE IF (J .EQ. 20) THEN
    GO TO 20
  END IF
  ```

- **Assigned FORMAT specifier**
  
  The assigned FORMAT specifier sets an integer variable to the label of a FORMAT statement and then the integer variable is used in an I/O statement instead of the FORMAT label. You can replace the integer variable with a character variable whose value is the contents of the FORMAT statement, and then use the character variable in the I/O statement as the format. For example, replace:

  ```fortran
  ASSIGN 1000 TO IFMT
  ...
  WRITE (6, IFMT) X, Y
  ...
  1000 FORMAT (2E10.2)
  ```
  
  with:

  ```fortran
  CHARACTER(20) :: IFMT = "(2E10.2)"
  ...
  WRITE (6, IFMT) X, Y
  ```

- **Branching to an END IF statement from outside its IF block**
  
  The END IF statement can no longer be a target of a GO TO statement that is outside the IF block that ends with that END IF statement. Use a CONTINUE statement after the END IF as the target of the GO TO statement. For example, replace:

  ```fortran
  IF ...
    GO TO 100
  ELSE IF ...
  100  END IF
  ```
  
  with:

  ```fortran
  IF ...
    GO TO 100
  ELSE IF ...
  END IF
  100  CONTINUE
  ```

- **H edit descriptor**

Replace the H edit descriptor of the form \( nH \) characters with "characters". Remember to double any quotes or apostrophes in the string characters.

- **PAUSE statement**

  The PAUSE statement displays a character string on the standard output device and then suspends program execution until any character is typed on the standard input device. You can replace the PAUSE statement with a WRITE statement followed by a READ statement. For example, replace:

  ```fortran
  PAUSE " don’t forget to buy milk"
  ```

  with:

  ```fortran
  WRITE (6, *) " don’t forget to buy milk"
  READ (5, *) ! no io-list is necessary, the input is ignored
  ```

- **Real and double precision DO control variables and DO loop control expressions**

  REAL variables of any KIND can no longer be used as DO loop control variables and expressions. You can replace such DO loops with the appropriate DO WHILE loop that explicitly initializes, increments, and tests the REAL variable. For example, replace:

  ```fortran
  DO X = 0.1, 0.5, 0.01
      ...
  END DO
  ```

  with:

  ```fortran
  X = 0.1
  DO WHILE (X .LE. 0.5)
      ...
      X = X + 0.01
  END DO
  ```

- **Vertical format control**

  Formatted output to certain printing output units used to result in the first character of each record being interpreted as controlling vertical spacing on the unit. There is no standard way to detect whether output to such a unit should result in such vertical format control and no way to specify that it should be applied. The effect can be achieved by post-processing a formatted file after it is created to interpret the first character as some form of control character. This is left to the user.

Intel Fortran flags these features if you specify compiler option stand.

**See Also**

Obsolescent Language Features in the Fortran Standard

stand compiler option

---

**Obsolescent Language Features in the Fortran Standard**

Some language features, considered redundant in older versions of the Fortran Standard, are identified as obsolescent in the current Fortran Standard.

Intel® Fortran flags these features if you specify compiler option stand.

Other methods are suggested to achieve the functionality of the following obsolescent features:

- **Alternate returns (labels in an argument list)**

  To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program use a CASE construct to test the value and perform operations.

- **Arithmetic IF**

  To replace this functionality, it is recommended that you use an IF statement or construct.

- **Assumed-length character functions**

  To replace this functionality, it is recommended that you use one of the following:
• An automatic character-length function, where the length of the function result is declared in a specification expression
• A subroutine whose arguments correspond to the function result and the function arguments

Dummy arguments of a function can still have assumed character length; this feature is not obsolescent.
• CHARACTER*(*) form of CHARACTER declaration

To replace this functionality, it is recommended that you use the Fortran 90 forms of specifying a length selector in CHARACTER declarations (see Declaration Statements for Character Types).
• Computed GO TO statement

To replace this functionality, it is recommended that you use a CASE construct.
• DATA statements among executable statements

This functionality has been included since FORTRAN 66, but is considered to be a potential source of errors.
• ENTRY statement

To replace this functionality, it is recommended that you use multiple module procedures that can access shared data in the module.
• Fixed source form

Newer methods of entering data have made this source form obsolescent and error-prone.

The recommended method for coding is to use free source form.
• FORALL statement and construct

These were added to the language with the expectation they would result in very efficient and possibly parallel code. The complexity and many restrictions prevented compilers from taking advantage of them.

The DO CONCURRENT construct makes FORALL redundant. Data manipulations which can be done with FORALL can be done more effectively with pointers using rank remapping. Both the statement form and the construct became obsolescent in Fortran 2018.
• Shared DO termination and termination on a statement other than END DO or CONTINUE

To replace this functionality, it is recommended that you use an END DO statement or a CONTINUE statement.
• Statement functions

To replace this functionality, it is recommended that you use an internal function.

Additional Language Features

To facilitate compatibility with older versions of Fortran, Intel® Fortran provides the following additional language features:

• The DEFINE FILE statement
• The ENCODE and DECODE statements
• The FIND statement
• The INTERFACE TO statement
• FORTRAN 66 Interpretation of the EXTERNAL Statement
• An alternative syntax for the PARAMETER statement
• The VIRTUAL statement
• An alternative syntax for octal and hexadecimal constants
• An alternative syntax for a record specifier
• An alternate syntax for the DELETE statement
• An alternative form for namelist external records
• The integer POINTER statement
• Record structures

These language features are particularly useful in porting older Fortran programs to Standard Fortran. However, you should avoid using them in new programs on these systems, and in new programs for which portability to other Standard Fortran implementations is important.
FORTRAN-66 Interpretation of the EXTERNAL Statement

If you specify compiler option f66, the EXTERNAL statement is interpreted in the way that was specified by the FORTRAN IV (FORTRAN-66) standard. This interpretation became incompatible with FORTRAN 77 and later revisions of the Fortran standard.

The FORTRAN-66 interpretation of the EXTERNAL statement combines the functionality of the INTRINSIC statement with that of the EXTERNAL statement. This lets you use subprograms as arguments to other subprograms. The subprograms to be used as arguments can be either user-supplied procedures or Fortran intrinsic procedures.

The FORTRAN-66 EXTERNAL statement takes the following form:

EXTERNAL [*]v [, [*]v] ...

* Specifies that a user-supplied external procedure is to be used instead of a Fortran intrinsic procedure having the same name. This modifier is not standard FORTRAN-66, but was an extension in some FORTRAN-66 compilers, and provides the FORTRAN 77 meaning of EXTERNAL where required.

v Is the name of a subprogram or the name of a dummy argument associated with the name of a subprogram.

Description

The FORTRAN-66 EXTERNAL statement declares that each name in its list is an external procedure name. Such a name can then be used as an actual argument to a subprogram, which then can use the corresponding dummy argument in a function reference or CALL statement.

However, when used as an argument, a complete function reference represents a value, not a subprogram name; for example, SQRT(B) in CALL SUBR(A, SQRT(B), C). Therefore, it does not need to be defined in an EXTERNAL statement. Note that the incomplete reference SQRT would need to be defined in an EXTERNAL statement.

Examples

The following example, when compiled with compiler option f66, shows the FORTRAN-66 EXTERNAL statement:

```
Main Program                        Subprograms
EXTERNAL SIN, COS, *TAN, SINDEG     SUBROUTINE TRIG(X,F,Y)
.                                Y = F(X)
.                                RETURN
.                                END
CALL TRIG(ANGLE, SIN, SINE)       .                                FUNCTION TAN(X)
.                                TAN = SIN(X)/COS(X)
.                                RETURN
.                                END
CALL TRIG(ANGLE, COS, COSINE)     .                                FUNCTION SINDEG(X)/
.                                SINDEG = SIN(X*3.1459/180)
.                                RETURN
.                                END
CALL TRIG(ANGLED, SINDEG, SINE)   
```
The CALL statements pass the name of a function to the subroutine TRIG. The function reference F(X)
subsequently invokes the function in the second statement of TRIG. Depending on which CALL statement
invoked TRIG, the second statement is equivalent to one of the following:

\[
\begin{align*}
Y &= \text{SIN}(X) \\
Y &= \text{COS}(X) \\
Y &= \text{TAN}(X) \\
Y &= \text{SINDEG}(X)
\end{align*}
\]

The functions SIN and COS are examples of trigonometric functions supplied in the Fortran intrinsic
procedure library. The function TAN is also supplied in the library, but the asterisk (*) in the EXTERNAL
statement specifies that the user-supplied function be used, instead of the intrinsic function. The function
SINDEG is also a user-supplied function. Because no library function has the same name, no asterisk is
required.

See Also
f66 compiler option

Alternative Syntax for the PARAMETER Statement

The PARAMETER statement discussed here is similar to the one discussed in PARAMETER; they both assign a
name to a constant. However, this PARAMETER statement differs from the other one in the following ways:

- Its list is not bounded with parentheses.
- The form of the constant, rather than implicit or explicit typing of the name, determines the data type of
  the variable.

This PARAMETER statement takes the following form:

```
PARAMETER c = expr [, c = expr] ...
```

- \( c \) Is the name of the constant.
- \( expr \) Is a constant expression. It can be of any data type.

Description

Each name \( c \) becomes a constant and is defined as the value of expression \( expr \). Once a name is defined as a
constant, it can appear in any position in which a constant is allowed. The effect is the same as if the
constant were written there instead of the name.

The name of a constant cannot appear as part of another constant, except as the real or imaginary part of a
complex constant. For example:

```
PARAMETER I=3
PARAMETER M=I.25   ! Not allowed
PARAMETER N=(1.703, I)  ! Allowed
```

The name used in the PARAMETER statement identifies only the name’s corresponding constant in that
program unit. Such a name can be defined only once in PARAMETER statements within the same program
unit.

The name of a constant assumes the data type of its corresponding constant expression. The data type of a
parameter constant cannot be specified in a type declaration statement. Nor does the initial letter of the
constant’s name implicitly affect its data type.
Examples

The following are valid examples of this form of the PARAMETER statement:

```
PARAMETER PI=3.1415927, DPI=3.141592653589793238D0
PARAMETER PIOV2=PI/2, DPIOV2=DPI/2
PARAMETER FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS'
```

PARAMETER for details on compile-time constant expressions

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

In Intel® Fortran, you can use an alternative syntax for binary, octal, and hexadecimal constants. The following table shows the alternative syntax and equivalents:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Alternative Syntax</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>'0..1'B</td>
<td>B'0..1'</td>
</tr>
<tr>
<td>Octal</td>
<td>'0..7'O</td>
<td>O'0..7'</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>'0..F'X</td>
<td>X'0..F'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Z'0..F'</td>
</tr>
</tbody>
</table>

You can use a quotation mark (") in place of an apostrophe in all the above syntax forms.

For information on the # syntax for integers not in base 10, see Integer Constants.

See Also

Binary constants
Octal constants
Hexadecimal constants

Alternative Syntax for a RecordSpecifier

In Intel® Fortran, you can specify the following form for a record specifier in an I/O control list:

```
'r
r
```

Is a numeric expression with a value that represents the position of the record to be accessed using direct access I/O.

The value must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file. If necessary, a record number is converted to integer data type before being used.

If this nonkeyword form is used in an I/O control list, it must immediately follow the nonkeyword form of the io-unit specifier.

Alternative Syntax for the DELETE Statement

In Intel® Fortran, you can specify the following form of the DELETE statement when deleting records from a relative file:

```
DELETE (io-unit 'r [, ERR=label] [, IOSTAT=i-var])
```
io-unit

Is the number of the logical unit containing the record to be deleted.

r

Is the positional number of the record to be deleted.

label

Is the label of an executable statement that receives control if an error condition occurs.

i-var

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

This form deletes the direct access record specified by r.

See Also
DELETE statement

Alternative Form for Namelist External Records

In Intel® Fortran, you can use the following form for an external record:

\[\text{group-name object } = \text{ value [object } = \text{ value}] \ldots [\text{END}]\]

- **group-name**
  - Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit.

- **object**
  - Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks, but it can be preceded or followed by blanks.

- **value**
  - Is a null value, a constant (or list of constants), a repetition of constants in the form \(r^c\), or a repetition of null values in the form \(r^*\).

If more than one \(\text{object=value}\) or more than one value is specified, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks.

NAMELIST statement
Rules for Namelist Sequential READ Statements for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Record Structures

The record structure was defined in earlier versions of Intel® Fortran as a language extension. It is still supported, although its functionality has been replaced by Standard Fortran derived data types. Record structures in existing code can be easily converted to Standard Fortran derived type structures for portability, but can also be left in their old form. In most cases, an Intel Fortran record and a Standard Fortran derived type can be used interchangeably.

Intel Fortran record structures are similar to Standard Fortran derived types.

A record structure is an aggregate entity containing one or more elements. (Record elements are also called fields or components.) You can use records when you need to declare and operate on multi-field data structures in your programs.

Creating a record is a two-step process:

1. You must define the form of the record with a multistatement structure declaration.
2. You must use a RECORD statement to declare the record as an entity with a name. (More than one RECORD statement can refer to a given structure.)

Examples

Intel Fortran record structures, using only intrinsic types, easily convert to Standard Fortran derived types. The conversion can be as simple as replacing the keyword STRUCTURE with TYPE and removing slash ( / ) marks. The following shows an example conversion:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_name/</td>
<td>TYPE employee_name</td>
</tr>
<tr>
<td>CHARACTER*25  last_name</td>
<td>CHARACTER*25  last_name</td>
</tr>
<tr>
<td>CHARACTER*15  first_name</td>
<td>CHARACTER*15  first_name</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
<tr>
<td>STRUCTURE /employee_addr/</td>
<td>TYPE employee_addr</td>
</tr>
<tr>
<td>CHARACTER*20  street_name</td>
<td>CHARACTER*20  street_name</td>
</tr>
<tr>
<td>INTEGER(2)   street_number</td>
<td>INTEGER(2)   street_number</td>
</tr>
<tr>
<td>INTEGER(2)   apt_number</td>
<td>INTEGER(2)   apt_number</td>
</tr>
<tr>
<td>CHARACTER*20  city</td>
<td>CHARACTER*20  city</td>
</tr>
<tr>
<td>CHARACTER*2   state</td>
<td>CHARACTER*2   state</td>
</tr>
<tr>
<td>INTEGER(4)   zip</td>
<td>INTEGER(4)   zip</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
</tbody>
</table>

The record structures can be used as subordinate record variables within another record, such as the employee_data record. The equivalent Standard Fortran derived type would use the derived-type objects as components in a similar manner, as shown below:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_data/</td>
<td>TYPE employee_data</td>
</tr>
<tr>
<td>RECORD /employee_name/ name</td>
<td>TYPE (employee_name) name</td>
</tr>
<tr>
<td>RECORD /employee_addr/ addr</td>
<td>TYPE (employee_addr) addr</td>
</tr>
<tr>
<td>INTEGER(4)   telephone</td>
<td>INTEGER(4)   telephone</td>
</tr>
<tr>
<td>INTEGER(2)   date_of_birth</td>
<td>INTEGER(2)   date_of_birth</td>
</tr>
<tr>
<td>INTEGER(2)   date_of_hire</td>
<td>INTEGER(2)   date_of_hire</td>
</tr>
<tr>
<td>INTEGER(2)   social_security(3)</td>
<td>INTEGER(2)   social_security(3)</td>
</tr>
<tr>
<td>LOGICAL(2)   married</td>
<td>LOGICAL(2)   married</td>
</tr>
<tr>
<td>INTEGER(2)   dependents</td>
<td>INTEGER(2)   dependents</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
</tbody>
</table>

RECORD Statement

Structure Declarations

A structure declaration defines the field names, types of data within fields, and order and alignment of fields within a record. Fields and structures can be initialized, but records cannot be initialized. For more information, see STRUCTURE.

Type Declarations within Record Structures

The syntax of a type declaration within a record structure is identical to that of a normal Fortran type statement.

The following rules and behavior apply to type declarations in record structures:

• %FILL can be specified in place of a field name to leave space in a record for purposes such as alignment. This creates an unnamed field.

  %FILL can have an array specification; for example:

  ```fortran
  INTEGER %FILL (2,2)
  ```

  Unnamed fields cannot be initialized. For example, the following statement is invalid and generates an error message:

  ```fortran
  INTEGER %FILL /1980/
  ```

• Initial values can be supplied in field declaration statements. Unnamed fields cannot be initialized; they are always undefined.

• Field names must always be given explicit data types. The IMPLICIT statement does not affect field declarations.

• Any required array dimensions must be specified in the field declaration statements. DIMENSION statements cannot be used to define field names.

• Adjustable or assumed sized arrays and assumed-length CHARACTER declarations are not allowed in field declarations.

Substructure Declarations

A field within a structure can itself be a structured item composed of other fields, other structures, or both. You can declare a substructure in two ways:

• By nesting structure declarations within other structure or union declarations (with the limitation that you cannot refer to a structure inside itself at any level of nesting).

  One or more field names must be defined in the STRUCTURE statement for the substructure, because all fields in a structure must be named. In this case, the substructure is being used as a field within a structure or union.

  Field names within the same declaration nesting level must be unique, but an inner structure declaration can include field names used in an outer structure declaration without conflict.

• By using a RECORD statement that specifies another previously defined record structure, thereby including it in the structure being declared.

See the example in STRUCTURE for a sample structure declaration containing both a nested structure declaration (TIME) and an included structure (DATE).

References to Record Fields

References to record fields must correspond to the kind of field being referenced. Aggregate field references refer to composite structures (and substructures). Scalar field references refer to singular data items, such as variables.

An operation on a record can involve one or more fields.

Record field references take one of the following forms:

**Aggregate Field Reference:**

```
record-name [.aggregate-field-name] ...
```

**Scalar Field Reference:**

```
record-name [.aggregate-field-name] ... .scalar-field-name
```
record-name

Is the name used in a RECORD statement to identify a record.

aggregate-field-name

Is the name of a field that is a substructure (a record or a nested structure declaration) within the record structure identified by the record name.

scalar-field-name

Is the name of a data item (having a data type) defined within a structure declaration.

Description

Records and record fields cannot be used in DATA statements, but individual fields can be initialized in the STRUCTURE definition.

An automatic array cannot be a record field.

A scalar field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names followed by the name of a scalar field. A scalar field reference refers to a single data item (having a data type) and can be treated like a normal reference to a Fortran variable or array element.

You can use scalar field references in statement functions and in executable statements. However, they cannot be used in COMMON, SAVE, NAMELIST, or EQUIVALENCE statements, or as the control variable in an indexed DO-loop.

Type conversion rules for scalar field references are the same as those for variables and array elements.

An aggregate field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names.

You can only assign an aggregate field to another aggregate field (record = record) if the records have the same structure. Intel® Fortran supports no other operations (such as arithmetic or comparison) on aggregate fields.

Intel Fortran requires qualification on all levels. While some languages allow omission of aggregate field names when there is no ambiguity as to which field is intended, Intel Fortran requires all aggregate field names to be included in references.

You can use aggregate field references in unformatted I/O statements; one I/O record is written no matter how many aggregate and array name references appear in the I/O list. You cannot use aggregate field references in formatted, namelist, and list-directed I/O statements.

You can use aggregate field references as actual arguments and record dummy arguments. The declaration of the dummy record in the subprogram must match the form of the aggregate field reference passed by the calling program unit; each structure must have the same number and types of fields in the same order. The order of map fields within a union declaration is irrelevant.

Records are passed by reference. Aggregate field references are treated like normal variables. You can use adjustable arrays in RECORD statements that are used as dummy arguments.

Examples

The following examples show record and field references. Consider the following structure declarations:

Structure DATE:

```fortran
STRUCTURE /DATE/
    INTEGER*1 DAY, MONTH
    INTEGER*2 YEAR
STRUCTURE
```
Structure APPOINTMENT:

```fortran
STRUCTURE /APPOINTMENT/  
RECORD /DATE/    APP_DATE  
STRUCTURE /TIME/   APP_TIME(2)  
    INTEGER*1    HOUR, MINUTE  
END STRUCTURE  
CHARACTER*20       APP_MEMO(4)  
LOGICAL*1          APP_FLAG  
END STRUCTURE
```

The following RECORD statement creates a variable named NEXT_APP and a 10-element array named APP_LIST. Both the variable and each element of the array take the form of the structure APPOINTMENT.

```fortran
RECORD /APPOINTMENT/    NEXT_APP, APP_LIST(10)
```

Each of the following examples of record and field references are derived from the previous structure declarations and RECORD statement:

### Aggregate Field References

- The record NEXT_APP:
  ```fortran
  NEXT_APP
  ```
- The field APP_DATE, a 4-byte array field in the record array APP_LIST(3):
  ```fortran
  APP_LIST(3).APP_DATE
  ```

### Scalar Field References

- The field APP_FLAG, a LOGICAL field of the record NEXT_APP:
  ```fortran
  NEXT_APP.APP_FLAG
  ```
- The first character of APP_MEMO(1), a CHARACTER*20 field of the record NEXT_APP:
  ```fortran
  NEXT_APP.APP_MEMO(1)(1:1)
  ```

**NOTE**

Because periods are used in record references to separate fields, you should avoid using relational operators (.EQ., .XOR.), logical constants (.TRUE., .FALSE.), and logical expressions (.AND., .NOT., .OR.) as field names in structure declarations. Dots can also be used instead of % to separate fields of a derived type.

Consider the following example:

```fortran
module mod  
  type T1_t  
    integer :: i  
  end type T1_t  
  type T2_t  
    type (T1_t) :: eq  
    integer :: i  
  end type T2_t  
  interface operator (.eq.)  
    module procedure eq_func  
  end interface operator (.eq.)  
contains  
  function eq_func(t2, i) result (rslt)  
    type(T2_t), intent (in) :: t2  
    integer, intent (in) :: i  
    rslt = .true.
end function eq_func
end mod
```
In this case, the reference "t2.eq.i" prints 0. The reference "(t2).eq.i" will invoke eq_func and will print -10.

Aggregate Assignment

For aggregate assignment statements, the variable and expression must have the same structure as the aggregate they reference.

The aggregate assignment statement assigns the value of each field of the aggregate on the right of an equal sign to the corresponding field of the aggregate on the left. Both aggregates must be declared with the same structure.

Examples

The following example shows valid aggregate assignments:

```plaintext
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

RECORD /DATE/ TODAY, THIS_WEEK(7)
STRUCTURE /APPOINTMENT/
  ... RECORD /DATE/ APP_DATE
END STRUCTURE

RECORD /APPOINTMENT/ MEETING

DO I = 1,7
  CALL GET_DATE (TODAY)
  THIS_WEEK(I) = TODAY
  THIS_WEEK(I).DAY = TODAY.DAY + 1
END DO
MEETING.APP_DATE = TODAY
```
Additional Character Sets

This topic contains information about the additional character sets you can use in your Fortran programs.

Character Sets for details on the Standard Fortran character set

Character and Key Code Charts for Windows*

This topic contains the ASCII and ANSI character code charts, and the Key code charts that are available on Windows* OS.

ASCII Character Codes for Windows*

The ASCII character code charts contain the decimal and hexadecimal values of the extended ASCII (American Standards Committee for Information Interchange) character set. The extended character set includes the ASCII character set (Chart 1) and 128 other characters for graphics and line drawing (Chart 2), often called the "IBM* character set".

ANSI Character Codes for Windows*

The ANSI character code chart lists the extended character set of most of the programs used by Windows* operating systems. The codes of the ANSI (American National Standards Institute) character set from 32 through 126 are displayable characters from the ASCII character set. The ANSI characters displayed as solid blocks are undefined characters and may appear differently on output devices.

Key Codes for Windows*

Some keys, such as function keys, cursor keys, and ALT+KEY combinations, have no ASCII code. When a key is pressed, a microprocessor within the keyboard generates an "extended scan code" of two bytes. The first (low-order) byte contains the ASCII code, if any. The second (high-order) byte has the scan code—a unique code generated by the keyboard when a key is either pressed or released. Because the extended scan code is more extensive than the standard ASCII code, programs can use it to identify keys which do not have an ASCII code.

For more details on key codes, see:
- Key Codes Chart 1
- Key Codes Chart 2
# Key Codes Chart 1 (W*S)

1106
ASCII Character Set for Linux* and macOS*

This topic describes the ASCII character set that is available on Linux* and macOS* operating systems.

The ASCII character set contains characters with decimal values 0 through 127. The first half of each of the numbered columns identifies the character as you would enter it on a terminal or as you would see it on a printer. Except for SP and HT, the characters with names are nonprintable. In the figure, the characters with names are defined as follows:

<table>
<thead>
<tr>
<th>Key</th>
<th>Scan Code</th>
<th>ASCII (Without Control)</th>
<th>ASCII (Extended) with NUL</th>
<th>ASCII (Extended) with DC1</th>
<th>ASCII (Extended) with DC2</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUL</td>
<td>00 00</td>
<td>Null</td>
<td>DC1</td>
<td>Device Control 1 (XON)</td>
<td></td>
</tr>
<tr>
<td>SOH</td>
<td>01 01</td>
<td>Start of Heading</td>
<td>DC2</td>
<td>Device Control 2</td>
<td></td>
</tr>
<tr>
<td>STX</td>
<td>02 02</td>
<td>Start of Text</td>
<td>DC3</td>
<td>Device Control 3</td>
<td></td>
</tr>
<tr>
<td>ETX</td>
<td>03 03</td>
<td>End of Text</td>
<td>DC4</td>
<td>Device Control 4</td>
<td></td>
</tr>
</tbody>
</table>

† Extended code returns a NUL or DC2 (depending on the terminal's settings).
‡ These combinations are only recognized on extended keyboards.
§ These combinations are only recognized on extended keyboards.
− ASCII can be printed on standard or high-quality printers that can print the control characters. The control characters are not available on standard or high-quality printers that cannot print control characters. If the scan code returns an extended code and the printer is not capable of printing the extended code, it appears as a box. (†) indicates that the extended code is not supported by the printer.

10 Under Windows, if you open the SCRD.EXE file and then press Esc, you will see a screen similar to the one shown in the figure. This screen is used to display all the extended codes under Windows. To display the extended codes, press Esc and then press F1. To display the character set, press F2. To display the extended codes, press F3. To display the extended codes, press F4. To display the extended codes, press F5.

</tr>
</tbody>
</table>

The remaining half of each column identifies the character by the binary value of the byte; the value is stated in three radices—octal, decimal, and hexadecimal. For example, the uppercase letter A has, under ASCII conventions, a storage value of hexadecimal 41 (a bit configuration of 01000001), equivalent to 101 in octal notation and 65 in decimal notation.

**ASCII Character Set (L*X, M*X)**

---

### Data Representation Models

Several of the numeric intrinsic functions are defined by a model set for integers (for each intrinsic kind used) and reals (for each real kind used). The bit functions are defined by a model set for bits (binary digits).

The following intrinsic functions provide information on the data representation models:

<table>
<thead>
<tr>
<th>Intrinsic function</th>
<th>Model</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Bit</td>
<td>The number of bits (s) in the bit model</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Integer or Real</td>
<td>The number of significant digits in the model for the argument</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Real</td>
<td>The number that is almost negligible when compared to one</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>Real</td>
<td>The value of the exponent part of a real argument</td>
</tr>
<tr>
<td>FRACTION</td>
<td>Real</td>
<td>The fractional part of a real argument</td>
</tr>
</tbody>
</table>
Intrinsic function | Model             | Value returned                                                                 |
-------------------|------------------|-------------------------------------------------------------------------------|
HUGE               | Integer or Real  | The largest number in the model for the argument                              |
MAXEXPONENT        | Real             | The maximum exponent in the model for the argument                             |
MINEXPONENT        | Real             | The minimum exponent in the model for the argument                             |
NEAREST            | Real             | The nearest different machine-representable number in a given direction       |
PRECISION          | Real             | The decimal precision (real or complex) of the argument                       |
RADIX              | Integer or Real  | The base of the model for the argument                                         |
RANGE              | Integer or Real  | The decimal exponent range of the model for the argument                      |
Rspecifier         | Real             | The reciprocal of the relative spacing near the argument                      |
SCALE              | Real             | The value of the exponent part (of the model for the argument) changed by a specified value |
SET_EXPONENT       | Real             | The value of the exponent part (of the model for the argument) set to a specified value |
SPACING            | Real             | The value of the absolute spacing of model numbers near the argument          |
TINY               | Real             | The smallest positive number in the model for the argument                    |

For more information on the range of values for each data type (and kind), see Data and I/O in the Compiler Reference.

**Model for Integer Data**

In general, the model set for integers is defined as follows:

\[ i = s \times \sum_{k=1}^{q} w_k \times r^{k-1} \]

The following values apply to this model set:

- \( i \) is the integer value.
- \( s \) is the sign (either +1 or -1).
- \( q \) is the number of digits (a positive integer).
- \( r \) is the radix (an integer greater than 1).
- \( w_k \) is a nonnegative number less than \( r \).

The model for INTEGER(4) follows:
The following example shows the general integer model for \( i = -20 \) using a base \((r)\) of 2:

\[
  i = \sum_{k=1}^{21} w_k \times 2^{k-1}
\]

The following values apply to this model set:
- \( x \) is the real value.
- \( s \) is the sign (either +1 or -1).
- \( b \) is the base (real radix; an integer greater than 1; \( b = 2 \) in Intel® Fortran).
- \( p \) is the number of mantissa digits (an integer greater than 1). The number of digits differs depending on the real format, as follows:
  - REAL(4)  IEEE binary32  24
  - REAL(8)  IEEE binary64  53
  - REAL(16) IEEE binary128 113
- \( e \) is an integer in the range \( e_{\text{min}} \) to \( e_{\text{max}} \) inclusive. This range differs depending on the real format, as follows:
  - REAL(4)  IEEE binary32  \(-125\)  128
  - REAL(8)  IEEE binary64  \(-1021\)  1024
  - REAL(16) IEEE binary128 \(-16381\) 16384
- \( f_k \) is a nonnegative number less than \( b \) (\( f_1 \) is also nonzero).

For \( x = 0 \), its exponent \( e \) and digits \( f_k \) are defined to be zero.

The model set for single-precision real (REAL(4)) is defined as one of the following:

\[
  x = 0
\]
\[ x = s \times 2^e \times \left[ 1/2 + \sum_{k=2}^{24} f_k \times 2^{-k} \right], -125 \leq e \leq 128 \]

The following example shows the general real model for \( x = 20.0 \) using a base \( (b) \) of 2:

\[ x = 1 \times 2^5 \times (1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}) \]
\[ x = 1 \times 32 \times (.5 + .125) \]
\[ x = 32 \times (.625) \]
\[ x = 20.0 \]

**Model for Bit Data**

The model set for bits (binary digits) interprets a binary digit \( w \) located at position \( k \) of a nonnegative integer scalar object based on a model nonnegative integer defined by the following:

\[ j = \sum_{k=0}^{s-1} w_k \times 2^k \]

The following values apply to this model set:

- \( j \) is the integer value.
- \( s \) is the number of bits (the length of a sequence of bits).
- \( w_k \) is a bit value of 0 or 1. This defines a sequence of bits \( \text{w}_{s-1}...\text{w}_0 \), with \( \text{w}_{s-1} \) the leftmost bit and \( \text{w}_0 \) the rightmost bit. The positions of bits in the sequence are numbered from right to left, with the position of the rightmost bit being zero.

The interpretation of a negative integer as a sequence of bits is processor dependent.

The inquiry function `BIT_SIZE` provides the value of the parameter \( s \) of the model.

The following example shows the bit model for \( j = 1001 \) (integer 9) using a bit number \( (s) \) of 4:

```
 1 0 0 1
↓ ↓ ↓ ↓
\text{w}_3 \text{w}_2 \text{w}_1 \text{w}_0
```

\[ j = (\text{w}_0 \times 2^0) + (\text{w}_1 \times 2^1) + (\text{w}_2 \times 2^2) + (\text{w}_3 \times 2^3) \]
\[ j = 1 + 0 + 0 + 8 \]
\[ j = 9 \]

**See Also**

`BIT_SIZE`
Bit Sequence Comparisons

When bit sequences of unequal length are compared, the shorter sequence is padded with zero bits on the left, so that it is the same length as the longer sequence.

Bit sequences are compared from left to right, one bit at a time, until unequal bits are found, or until all bits have been compared and found to be equal.

If unequal bits are found, the sequence with zero in the unequal position is considered to be less than the sequence with one in the unequal position. Otherwise the sequences are considered to be equal.

Library Modules and Run-Time Library Routines

Intel® Fortran provides a library of modules that contain routines you can use in your programs:

<table>
<thead>
<tr>

NOTE

The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

Run-Time Library Routines

Intel® Fortran provides library modules containing the following routines:
• Routines that help you write programs for graphics, QuickWin, and other applications (in modules IFQWIN, IFLOGM, and IFCORE):
  - QuickWin routines (W*S)
  - Graphics routines (W*S)
  - Dialog routines (W*S)
  - Miscellaneous run-time routines
• Routines systems that help you write programs using Component Object Model (COM) and Automation servers (in modules IFCOM and IFAUTO):
  - COM routines (W*S)
  - AUTO routines (W*S)
• Portability routines that help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows* systems (in module IFPORT).
• National Language Support routines that help you write foreign language programs for international markets (in module IFNLS). These routines are only available on Windows* systems.
• POSIX routines that help you write Fortran programs that comply with the POSIX* Standard (in module IFPOSIX).
• ESTABLISHQQ lets you specify a routine to handle Run-Time Library (RTL) errors (in module IFESTABLISH).
• FOR__SET_FTN_ALLOC lets you specify a user-defined routine to dynamically allocate commons. The caller of FOR__SET_FTN_ALLOC must include module IFCOMMONALLOC.

When you include the statement USE module-name in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement.

Note that routines that are only available on Windows, including routines that are labeled as (W*S), are not available when targeting Intel® Xeon Phi™ products.

NOTE
The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

Overview of NLS and MCBS Routines (Windows*)
The NLS and MCBS routines are only available on Windows* systems. These library routines for handling extended and multibyte character sets are divided into three categories:
• Locale Setting and Inquiry routines to set locales (local code sets) and inquire about their current settings
  At program startup, the current language and country setting is retrieved from the operating system. The user can change this setting through the Control Panel Regional Settings icon. The current codepage is also retrieved from the system.

  There is a system default console codepage and a system default Windows codepage. Console programs retrieve the system console codepage, while Windows programs (including QuickWin applications) retrieve the system Windows codepage.
  
  The NLS Library provides routines to determine the current locale (local code set), to return parameters of the current locale, to provide a list of all the system supported locales, and to set the locale to another language, country and/or codepage. These routines are summarized in the following table. Note that the locales and codepages set with these routines affect only the program or console that calls the routine. They do not change the system defaults or affect other programs or consoles.
• NLS Formatting routines to format dates, currency, and numbers
You can set time, date, currency and number formats from the Control Panel, by clicking on the Regional Settings icon. The NLS Library also provides formatting routines for the current locale. These routines are summarized in the following table. These routines return strings in the current codepage, set by default at program start or by NLSSetLocale.

All the formatting routines return the number of bytes in the formatted string (not the number of characters, which can vary if multibyte characters are included). If the output string is longer than the formatted string, the output string is blank padded. If the output string is shorter than the formatted string, an error occurs, NLS$ErrorInsufficientBuffer is returned, and nothing is written to the output string.

- Multibyte Character Set (MBCS) routines for using multi-byte characters
  Examples of multibyte character sets are Japanese, Korean, and Chinese.
  - The MBCS inquiry routines provide information on the maximum length of multibyte characters, the length, number and position of multibyte characters in strings, and whether a multibyte character is a leading or trailing byte. These routines are summarized in the following table. The NLS library provides a parameter, MBLenMax, defined in the NLS module to be the longest length (in bytes) of any character, in any codepage. This parameter can be useful in comparisons and tests. To determine the maximum character length of the current codepage, use the MBCurMax function.
  - There are four MBCS conversion routines. Two convert Japan Industry Standard (JIS) characters to Microsoft Kanji characters or vice versa. Two convert between a codepage multibyte character string and a Unicode string.
  - There are several MBCS Fortran equivalent routines. They are the exact equivalents of Fortran intrinsic routines except that the MBCS equivalents allow character strings to contain multibyte characters.

**Examples**

The following example uses Locale Setting and Inquiry routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str ! prints Monday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints Tuesday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str ! prints Wednesday
! Change locale to Spanish, Mexico
status = NLSSetLocale("Spanish", "Mexico")
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str ! prints lunes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints martes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str ! prints miércoles
END
```

The following example uses NLS Formatting routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str
strlen = NLSFormatTime(str)
print *, str ! prints 11:42:24 AM
strlen = NLSFormatDate(str, flags= NLS$LongDate)
print *, str ! prints Friday, July 14, 2000
status = NLSSetLocale("Spanish", "Mexico")
```
The following example uses Multibyte Character Set (MBCS) inquiry routines:

```fortran
USE IFNLS
CHARACTER(4) str
INTEGER status
status = NLSSetLocale("Japan")
str = " ·, " ¿"
PRINT '(1X,"String by char = ","
DO i = 1, len(str)
   PRINT '(A2,",",str(i:i))
END DO
PRINT '(/,1X,"MBLead = ","
DO i = 1, len(str)
   PRINT '(L2,",",mblead(str(i:i)))
END DO
PRINT '(/,1X,"String as whole = ",A,,"'
PRINT '(/,1X,"MBStrLead = ","
DO i = 1, len(str)
   PRINT '(L1,",",MBStrLead(str,i))
END DO
END
```

This code produces the following output for `str = ·, " ¿`

```
String by char = · · · ·
MBLead = T T T F
String as whole = 高徳
MBStrLead = T F T F
```

The following example uses Multibyte Character Set (MBCS) Fortran equivalent routines:

```fortran
USE IFNLS
INTEGER(4) i, len(7), infotype(7)
CHARACTER(10) str(7)
LOGICAL(4) log4
data infotype / NLS$LI_SDAYNAME1, NLS$LI_SDAYNAME2, 
& NLS$LI_SDAYNAME3, NLS$LI_SDAYNAME4, 
& NLS$LI_SDAYNAME5, NLS$LI_SDAYNAME6, 
& NLS$LI_SDAYNAME7 /
WRITE(*,*) 'NLSGetLocaleInfo'
WRITE(*,*) '----------------'
WRITE(*,*) ' Getting the names of the days of the week...' 
DO i = 1, 7
   len(i) = NLSGetLocaleInfo(infotype(i), str(i))
   WRITE(*, 11) 'len/str/hex = ', len(i), str(i), str(i)
END DO
11 FORMAT (1X, A, I2, 2X, A10, 2X, '[', Z20, ']')
WRITE(*,*) ' ' 
WRITE(*,*) 'Lexically comparing the names of the days...' 
DO i = 1, 6
   log4 = MBLGE(str(i), str(i+1), NLS$IgnoreCase)
   WRITE(*, 12) 'Is day ', i, ' GT day ', i+1, '? Answer = ', log4
```

This code produces the following output when the locale is Japan:

```
NLSGetLocaleInfo

Getting the names of the days of the week...
len/str/hex = 6 月曜日 [8C8E976A93FA20202020]
len/str/hex = 6 火曜日 [89CE976A93FA20202020]
len/str/hex = 6 水曜日 [9085976A93FA20202020]
len/str/hex = 6 木曜日 [96D8976A93FA20202020]
len/str/hex = 6 金曜日 [8BE0976A93FA20202020]
len/str/hex = 6 土曜日 [9379976A93FA20202020]
len/str/hex = 6 日曜日 [93FA976A93FA20202020]

Lexically comparing the names of the days...
Is day 1 GT day 2? Answer = T
Is day 2 GT day 3? Answer = F
Is day 3 GT day 4? Answer = F
Is day 4 GT day 5? Answer = T
Is day 5 GT day 6? Answer = F
Is day 6 GT day 7? Answer = F

Done.
```

Standard Fortran Routines That Handle MBCS Characters
USE

Standard Fortran Routines That Handle MBCS Characters (Windows*)

This section describes Fortran routines that work as usual even if MBCS characters are included in strings. Because a space can never be a lead or tail byte, many routines that deal with spaces work as expected on strings containing MBCS characters. Such functions include:

- `ADJUSTL (string)`
- `ADJUSTR (string)`
- `TRIM (string)`

Some routines work with the computer collating sequence to return a character in a certain position in the sequence or the position in the sequence of a certain character. These functions are not dependent on a particular collating sequence. (You should note, however, that elsewhere in this manual the ASCII collating sequence is mentioned in reference to these functions.) Such functions use `position` and `c` values between 0 and 255 (inclusive) and include:

- `ACHAR (position)`
- `CHAR (position[,kind ])`
- `IACHAR (c)`
- `ICHAR (c)`
Because Fortran uses character lengths instead of NULLs to indicate the length of a string, some functions work solely from the length of the string, and not with the contents of the string. This function works as usual on strings containing MBCS characters, and include:

REPEAT (string, ncopies)

**Overview of Portability Routines**

This section summarizes portability routines.

**Information Retrieval Routines**

Information retrieval routines return information about system commands, command-line arguments, environment variables, and process or user information.

Group, user, and process ID are INTEGER(4) variables. Login name and host name are character variables. The functions GETGID and GETUID are provided for portability, but always return 1.

**Process Control Routines**

Process control routines control the operation of a process or subprocess. You can wait for a subprocess to complete with either SLEEP or ALARM, monitor its progress and send signals via KILL, and stop its execution with ABORT.

In spite of its name, KILL does not necessarily stop execution of a program. Rather, the routine signaled could include a handler routine that examines the signal and takes appropriate action depending on the code passed.

Note that when you use SYSTEM, commands are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The portability library does not include the FORK routine. On Linux* and macOS* systems, FORK creates a duplicate image of the parent process. Child and parent processes each have their own copies of resources, and become independent from one another.

On Windows* systems, you can create a child process (called a thread), but both parent and child processes share the same address space and share system resources. If you need to create another process, use the CreateProcessWindows API routine.

**Numeric Values and Conversion Routines**

Numeric values and conversion routines are available for calculating Bessel functions, data type conversion, and generating random numbers. Some of these functions have equivalents in Standard Fortran, in which case the standard Fortran routines should be used.

Data object conversion can be accomplished by using the INT intrinsic function instead of LONG or SHORT. The intrinsic subroutines RANDOM_NUMBER and RANDOM_SEED perform the same functions as the random number functions listed in the table showing numeric values and conversion routines.

Other bit manipulation functions such as AND, XOR, OR, LSHIFT, and RSHIFT are intrinsic functions. You do not need the IFPORT module to access them. Standard Fortran includes many bit operation routines, which are listed in the Bit Operation and Representation Routines table.

**Input and Output Routines**

The portability library contains routines that change file properties, read and write characters and buffers, and change the offset position in a file. These input and output routines can be used with standard Fortran input or output statements such as READ or WRITE on the same files, provided that you take into account the following:
• When used with direct files, after an FSEEK, GETC, or PUTC operation, the record number is the number of the next whole record. Any subsequent normal Fortran I/O to that unit occurs at the next whole record. For example, if you seek to absolute location 1 of a file whose record length is 10, the NEXTREC returned by an INQUIRE would be 2. If you seek to absolute location 10, NEXTREC would still return 2.
• On units with CARRIAGECONTROL='FORTRAN' (the default), PUTC and FPUTC characters are treated as carriage control characters if they appear in column 1.
• On sequentially formatted units, the C string "\n"'c, which represents the carriage return/line feed escape sequence, is written as CHAR(13) (carriage return) and CHAR(10) (line feed), instead of just line feed, or CHAR(10). On input, the sequence 13 followed by 10 is returned as just 10. (The length of character string "\n"'c is 1 character, whose ASCII value, indicated by ICHAR("\n"'c), is 10.)
• Reading and writing is in a raw form for direct files. Separators between records can be read and overwritten. Therefore, be careful if you continue using the file as a direct file.

I/O errors arising from the use of these routines result in an Intel® Fortran run-time error.

Some portability file I/O routines have equivalents in Standard Fortran. For example, you could use the ACCESS function to check a file specified by name for accessibility according to mode. It tests a file for read, write, or execute permission, as well as checking to see if the file exists. It works on the file attributes as they exist on disk, not as a program's OPEN statement specifies them.

Instead of ACCESS, you can use the INQUIRE statement with the ACTION specifier to check for similar information. (The ACCESS function always returns 0 for read permission on FAT files, meaning that all files have read permission.)

Date and Time Routines
Various date and time routines are available to determine system time, or convert it to local time, Greenwich Mean Time, arrays of date and time elements, or an ASCII character string.

DATE and TIME are available as either a function or subroutine. Because of the name duplication, if your programs do not include the USE IFPORT statement, each separately compiled program unit can use only one of these versions. For example, if a program calls the subroutine TIME once, it cannot also use TIME as a function.

Standard Fortran includes date and time intrinsic subroutines. For more information, see DATE_AND_TIME.

Error Handling Routines
Error handling routines detect and report errors.

IERRNO error codes are analogous to errno on Linux* and macOS* systems. The IFPORT module provides parameter definitions for many of UNIX's errno names, found typically in errno.h on UNIX systems.

IERRNO is updated only when an error occurs. For example, if a call to the GETC function results in an error, but two subsequent calls to PUTC succeed, a call to IERRNO returns the error for the GETC call. Examine IERRNO immediately after returning from one of the portability library routines. Other Standard Fortran routines might also change the value to an undefined value.

If your application uses multithreading, remember that IERRNO is set on a per-thread basis.

System, Drive, or Directory Control and Inquiry Routines
You can retrieve information about devices, directories, and files with the functions listed below. File names can be long file names or UNC file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications.

Standard Fortran provides the INQUIRE statement, which returns detailed file information either by file name or unit number. Use INQUIRE as an equivalent to FSTAT, LSTAT, or STAT. LSTAT and STAT return the same information; STAT is the preferred function.
Serial Port Routines (Windows* only)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on systems using IA-32 architecture.

Additional Routines
You can also use portability routines for program call and control, keyboards and speakers, file management, arrays, floating-point inquiry and control, IEEE* functionality, and other miscellaneous uses.

NOTE
On Windows* systems, all portability routines that take path names also accept long file names or UNC (Universal Naming Convention) file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications as well as MBCS (multiple-byte character set) characters.

Portability Routines
Overview of Serial Port I/O Routines

Overview of Serial Port I/O Routines (Windows*)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on Windows* systems.

The programming model is much the same as a normal file except the user does a connect (SPORT_CONNECT, SPORT_CONNECT_EX) and release (SPORT_RELEASE) to the port instead of an open and close of a file.

Two types of read and write operations (as determined in a mode on the connect call) are provided:

- Read and write arbitrary data from/to the port using SPORT_READ_DATA and SPORT_WRITE_DATA.
- Read and writes line-terminated data using SPORT_READ_LINE and SPORT_WRITE_LINE.

Once any I/O operation has been requested on the port, an additional thread is started that keeps a read outstanding on the port so that data will not be missed.

The SPORT_SET_STATE, SPORT_SET_STATE_EX, and SPORT_SET_TIMEOUTS (W*32 W*64) routines allow you to set basic port parameters such as baud rate, stop bits, timeouts, and so on. Additionally, you can call SPORT_GET_HANDLE to return the Windows* handle to the port so that you can call Windows* Communication Functions to implement additional needs.

Calling the Serial Port I/O Routines
The SPORT_xxx routines are functions that return an error status:

- An error status of 0 (zero) indicates success
- Other values are Windows* error values that indicate an error

As described in the calling syntax, these routines require the following USE statement:

USE IFPORT

The USE IFPORT statement includes the routine definitions in the compilation. You may also need to add a USE IFWINNTY statement to your program because some Windows* constants may be required that are typically defined in the IFWINNTY module.

Many arguments are optional. If a constant is used where an argument is both input and output, a probe for writeability is done before the output. Thus, in many cases, a constant may be used without creating a temporary variable. It should be noted, however, that doing so may not be compatible with all Fortran implementations.
Run-Time Behavior of the Serial Port I/O Routines

To help ensure that data overruns do not occur, the SPORT_xxx run-time support creates a separate thread that maintains an outstanding read to the connected port. This thread is started when any read or write operation is performed to the port using the affiliated read/write routine. As such, port parameters must not be changed after you have started reading or writing to the port. Instead, you should set up the port parameters after connecting to the port and then leave them unchanged until after the port has been released.

If the parameters of the port must be changed more dynamically, use the SPORT_CANCEL_IO routine to ensure that no I/O is in progress. Additionally, that call will kill the helper thread so that it will automatically pick up the new, correct, parameters when it restarts during the next I/O operation.

Serial Port Usage

Depending upon the application, serial port programming can be very simple or very complex. The SPORT_xxx routines are intended to provide a level of support that will help the user implement simple applications as well as providing a foundation that can be used for more complex applications. Users needing to implement full serial port protocols (such as a PPP/SLIP implementation or some other complex protocol) should use the Windows* Communication Functions directly to achieve the detailed level of control needed in those cases. Simple tasks, such as communicating with a terminal or some other data collection device are well suited for implementations using the SPORT_xxx routines.

You should first familiarize yourself with the hardware connection to the serial device. Typical connections used today involve either a 9 pin/wire connector or a 25 pin/wire connector. Many cables do not implement all 9 or 25 connections in order to save on costs. For certain applications these subset cables may work just fine but others may require the full 9 or 25 connections. All cables will implement the Receive/SendData signals as well as the SignalGround. Without these signals, there can be no data transfer. There are two other categories of important signals:

- Signals used for flow control
  Flow control signals tell the device/computer on the other end of the cable that data may be sent or that they should wait. Typically, the RequestToSend/ClearToSend signals are used for this purpose. Other signals such as DataSetReady or DataTerminalReady may also be used. Make sure that the cable used implements all the signals required by your hardware/software solution. Special characters (normally as XON/XOFF) may also be used to control the flow of data instead of or in addition to the hardware signals. Check your specific application to see what cabling is needed.

- Signals that indicate status or state of a modem or phone connection.
  These signals may not be required if the connection between the computer and the device is direct and not through a modem. This signals typically convey information such as the state of the carrier (CarrierDetect) or if the phone line is ringing (Ring). Again, make sure the cable used implements all the signals required for your application.

After the correct physical connection has been set up the programmer must become familiar with the data protocol used to communicate with the remote device/system.

Many simple devices terminate parcels of data with a "record terminator" (often a carriage return or line feed character). Other devices may simply send data in fixed length packets or packets containing some sort of count information. The two types of I/O routines provided by the SPORT_xxx support (line oriented using SPORT_READ_LINE and SPORT_WRITE_LINE or transfer raw data using SPORT_READ_DATA and SPORT_WRITE_DATA) can handle these two types of data transfer. The programmer must become familiar with the particular application to determine which type of I/O is more appropriate to use.

The SPORT_xxx routines call Windows* routines. For example, the SPORT_SET_STATE routine calls the routine SetCommState, which uses the DCB Communications Structure.

Summary of Language Extensions

This appendix summarizes the Intel® Fortran language extensions to the ANSI/ISO Fortran 2003 Standard. Most extensions are available on all supported operating systems. However, some extensions are limited to one or more platforms. If an extension is limited, it is labeled.

Language Extensions: Source Forms

The following are extensions to the methods and rules for source forms:
- Tab-formatting as a method to code lines
- The letter D as a debugging statement indicator in column 1 of fixed or tab source form
- An optional statement field width of 132 columns for fixed or tab source form
- An optional sequence number field for fixed source form
- Up to 511 continuation lines in a source program

Language Extensions: Names

As an extension, the dollar sign ($) is a valid character in names, and can be the first character.

Language Extensions: Character Sets

The following are extensions to the standard character set:
- The Tab (<Tab>) character (see Character Sets)
- ASCII Character Code Chart 2 -- IBM* Character Set
- ANSI Character Code Chart
- Key Code Charts

Language Extensions: Intrinsic Data Types

The following are data-type extensions:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Integer Type</th>
<th>Real Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>INTEGER*1</td>
<td>REAL*16</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>INTEGER*2</td>
<td>COMPLEX*8</td>
</tr>
<tr>
<td>LOGICAL*1</td>
<td>INTEGER*4</td>
<td>COMPLEX*16</td>
</tr>
<tr>
<td>LOGICAL*2</td>
<td>INTEGER*8</td>
<td>COMPLEX*32</td>
</tr>
<tr>
<td>LOGICAL*4</td>
<td>REAL*4</td>
<td></td>
</tr>
<tr>
<td>LOGICAL*8</td>
<td>REAL*8</td>
<td></td>
</tr>
</tbody>
</table>

See Also
Intrinsic Data Types

Language Extensions: Constants

Hollerith constants are allowed as an extension.
C Strings are allowed as extensions in character constants.

**Language Extensions: Expressions and Assignment**

When operands of different intrinsic data types are combined in expressions, conversions are performed as necessary (see Data Type of Numeric Expressions).

Binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

The following are extensions allowed in logical expressions:

- `.XOR.` as a synonym for `.NEQV.`
- Integers as valid logical items
- Logical operators applied to integers bit-by-bit

**Language Extensions: Specification Statements**

The following specification attributes and statements are extensions:

- `AUTOMATIC` attribute and statement
- `STATIC` attribute and statement

**Language Extensions: Execution Control**

The following control statements are extensions:

- `ASSIGN`
- `Assigned GO TO`
- `PAUSE`

These are older Fortran features that have been deleted in Fortran 2003 and Fortran 95. Intel® Fortran fully supports these features.

**Language Extensions: Compilation Control Lines and Statements**

The following line option and statement are extensions that can influence compilation:

- `[//[NO]LIST]`, which can be specified in an `INCLUDE` line
- The `OPTIONS` statement

**Language Extensions: Built-In Functions**

The following built-in functions are extensions:

- `%VAL`, `%REF`, and `%LOC`, which facilitate references to non-Fortran procedures
- `%FILL`, which can be used in record structure type definitions

**Language Extensions: I/O Statements**

The following I/O statements are extensions:
• The ACCEPT statement
• The REWRITE statement
• The TYPE statement, which is a synonym for the PRINT statement

Language Extensions: I/O Formatting

The following are extensions allowed in I/O Formatting:

• The Q edit descriptor
• The dollar sign ($) edit descriptor and carriage-control character
• The backslash (\) edit descriptor
• The ASCII NUL carriage-control character
• Variable format expressions
• The H edit descriptor
  This is an older Fortran feature that has been deleted in Fortran 95. Intel® Fortran fully supports this feature.

Language Extensions: File Operation Statements

The following statement specifiers and statements are extensions:

• CLOSE statement specifiers:
  • STATUS values: 'SAVE' (as a synonym for 'KEEP'), 'PRINT', 'PRINT/DELETE', 'SUBMIT', 'SUBMIT/DELETE'
  • DISPOSE (or DISP)
• DELETE statement
• INQUIRE statement specifiers:
  • BINARY (W*S)
  • BLOCKSIZE
  • BUFFERED
  • CARRIAGECONTROL
  • CONVERT
  • DEFAULTFILE
  • FORM values: 'UNKNOWN', 'BINARY' (W*S)
  • IFOCUS (W*S)
  • MODE as a synonym for ACTION
  • ORGANIZATION
  • RECORDTYPE
  • SHARE (W*S)
  See also INQUIRE Statement.
• OPEN statement specifiers:
  • ACCESS values: 'APPEND'
  • ASSOCIATEVARIABLE
  • BLOCKSIZE
  • BUFFERCOUNT
  • BUFFERED
  • CARRIAGECONTROL
  • CONVERT
  • DEFAULTFILE
  • DISPOSE (or DISP)
  • FORM value: 'BINARY' (W*S)
  • IFOCUS (W*S)
  • MAXREC
  • MODE as a synonym for ACTION
  • NAME as a synonym for FILE
  • NOSHARED
• ORGANIZATION
• READONLY
• RECORDSIZE as a synonym for RECL
• RECORDTYPE
• SHARE (W*S)
• SHARED
• TITLE (W*S)
• TYPE as a synonym for STATUS
• USEROPEN

See also OPEN Statement.

Language Extensions: Compiler Directives

The following General Directives are extensions:

• ALIAS
• ASSUME
• ASSUME_ALIGNED
• ATTRIBUTES
• BLOCK_LOOP and NOBLOCK_LOOP
• DECLARE and NODECLARE
• DEFINE and UNDEFINE
• DISTRIBUTE POINT
• FIXEDFORMLINESIZE
• FMA and NOFMA
• FORCEINLINE
• FREEFORM and NOFREEFORM
• IDENT
• IF and IF DEFINED
• INLINE and NOINLINE
• INTEGER
• IVDEP
• LOOP COUNT
• MESSAGE
• NOFUSION
• OBJCOMMENT
• OPTIMIZE and NOOPTIMIZE
• OPTIONS
• PACK
• PARALLEL and NOPARALLEL (loop)
• PREFETCH and NOPREFETCH
• PSECT
• REAL
• SIMD
• STRICT and NOSTRICT
• UNROLL and NOUNROLL
• UNROLL_AND_JAM and NOUNROLL_AND_JAM
• VECTOR and NOVECTOR

The following OFFLOAD Compiler Directives are extensions:

• OFFLOAD
• BEGIN OFFLOAD and END OFFLOAD
• OFFLOAD_TRANSFER
• OFFLOAD_WAIT
### Language Extensions: Intrinsic Procedures

The following intrinsic procedures are extensions available on all platforms:

#### A to D

Language Extensions: Additional Language Features

The following are language extensions that facilitate compatibility with other versions of Fortran:

- DEFINE FILE statement
- ENCODE and DECODE statements
- FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL statement
- An alternative syntax for the PARAMETER statement
- VIRTUAL statement
- AND, OR, XOR, IMAG, LSHIFT, RSHIFT intrinsics (see the A to Z Reference)
- An alternative syntax for octal and hexadecimal constants
- An alternative syntax for an I/O record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

Language Extensions: Run-Time Library Routines

The following run-time library routines are available as extensions:

- Run-Time Library Routines
- OpenMP® Run-time Library Routines for Fortran

A to Z Reference

This section contains the following:

- Language Summary Tables
  This section organizes the Fortran functions, subroutines, and statements by the operations they perform. You can use the tables to locate a particular routine for a particular task.
- The descriptions of all Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.
In the description of routines, pointers and handles are INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

The Fortran compiler understands statements and intrinsic functions in your program without any additional information, such as that provided in modules.

However, modules must be included in programs that contain the following routines:

- **Quickwin routines and graphics routines (W*S)**
  These routines require a USE IFQWIN statement to include the library and graphics modules.
- **Portability routines**
  It is recommended that you specify USE IFPORT when accessing routines in the portability library.
- **Serial port I/O routines**
  These routines require a USE IFPORT statement to access the portability library. These routines are only available on Windows* systems.
- **NLS routines (W*S)**
  These routines require a USE IFNLS statement to access the NLS library.
- **POSIX* routines**
  These routines require a USE IFPOSIX statement to access the POSIX library.
- **Dialog routines (W*S)**
  These routines require a USE IFLOGM statement to access the dialog library.
- **Component Object Module (COM) routines (W*S)**
  These routines require a USE IFCOM statement to access the COM library.
- **Automation server routines (W*S)**
  These routines require a USE IFAUTO statement to access the AUTO library.
- **Miscellaneous Run-Time Routines**
  Most of these routines require a USE IFCORE statement to obtain the proper interfaces.

Whenever required, these USE module statements are prominent in the *A to Z Reference*.

In addition to the appropriate USE statement, for some routines you must specify the types of libraries to be used when linking.

**Language Summary Tables**

**Statements for Program Unit Calls and Definitions**

The following table lists statements used for program unit definition and procedure call and return.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK DATA</td>
<td>Identifies a block-data subprogram.</td>
</tr>
<tr>
<td>CALL</td>
<td>Executes a subroutine.</td>
</tr>
<tr>
<td>COMMON</td>
<td>Delineates variables shared between program units.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Identifies the start of module procedures within a host module, contained procedures within a procedure, or bound procedures within a type.</td>
</tr>
<tr>
<td>ENTRY</td>
<td>Specifies a secondary entry point to a subroutine or external function.</td>
</tr>
<tr>
<td>EXTERNAL</td>
<td>Declares a name to be that of a user-defined subroutine or function, making it passable as an argument.</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>Identifies a program unit as a function.</td>
</tr>
</tbody>
</table>
### Statements Affecting Variables

The following table lists statements that affect variables.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>Declares a variable on the stack, rather than at a static memory location.</td>
</tr>
<tr>
<td>BYTE</td>
<td>Specifies variables as the BYTE data type; BYTE is equivalent to INTEGER(1).</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>Specifies variables as the CHARACTER data type.</td>
</tr>
<tr>
<td>CODIMENSION</td>
<td>Specifies that an entity is a coarray and specifies its corank and cobounds, if any.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Specifies variables as the COMPLEX data type.</td>
</tr>
<tr>
<td>DATA</td>
<td>Assigns initial values to variables.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>Specifies variables as the DOUBLE COMPLEX data type, equivalent to COMPLEX(8).</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>Specifies variables as the DOUBLE-PRECISION real data type, equivalent to REAL(8).</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Specifies that two or more variables or arrays share the same memory location.</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>Specifies the default types for variables and functions.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Specifies variables as the INTEGER data type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Specifies variables as the LOGICAL data type.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MAP</td>
<td>Within a UNION statement, delimits a group of variable type declarations that are to be ordered contiguously within memory.</td>
</tr>
<tr>
<td>NAMELIST</td>
<td>Declares a group name for a set of variables to be read or written in a single statement.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>Equates a constant expression with a name.</td>
</tr>
<tr>
<td>PROTECTED</td>
<td>Specifies limitations on the use of module entities.</td>
</tr>
<tr>
<td>REAL</td>
<td>Specifies variables as the REAL data type.</td>
</tr>
<tr>
<td>RECORD</td>
<td>Declares one or more variables of a user-defined structure type.</td>
</tr>
<tr>
<td>SAVE</td>
<td>Causes variables to retain their values between invocations of the procedure in which they are defined.</td>
</tr>
<tr>
<td>STATIC</td>
<td>Declares a variable is in a static memory location, rather than on the stack.</td>
</tr>
<tr>
<td>STRUCTURE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>UNION</td>
<td>Within a structure, causes two or more maps to occupy the same memory locations.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Specifies that the value of an object is totally unpredictable based on information available to the current program unit.</td>
</tr>
</tbody>
</table>

### Statements for Input and Output

The following table lists statements used for input and output.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPT</td>
<td>Statement</td>
<td>Similar to a formatted, sequential READ statement.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Statement</td>
<td>Positions a file to the beginning of the previous record.</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Statement</td>
<td>Disconnects the specified unit.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Statement</td>
<td>Deletes a record from a relative file.</td>
</tr>
<tr>
<td>ENDFILE</td>
<td>Statement</td>
<td>Writes an end-of-file record or truncates a file.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Statement</td>
<td>Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.</td>
</tr>
<tr>
<td>INQUIRE</td>
<td>Statement</td>
<td>Returns the properties of a file or unit.</td>
</tr>
<tr>
<td>OPEN</td>
<td>Statement</td>
<td>Associates a unit number with an external device or file.</td>
</tr>
<tr>
<td>PRINT(or TYPE)</td>
<td>Statement</td>
<td>Displays data on the screen.</td>
</tr>
<tr>
<td>READ</td>
<td>Statement</td>
<td>Transfers data from a file to the items in an I/O list.</td>
</tr>
<tr>
<td>REWRIND</td>
<td>Statement</td>
<td>Repositions a file to its first record.</td>
</tr>
<tr>
<td>REWRITE</td>
<td>Statement</td>
<td>Rewrites the current record.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Statement</td>
<td>Transfers data from the items in an I/O list to a file</td>
</tr>
</tbody>
</table>

**Compiler Directives**

The following tables list available compiler directives.

Each general directive name is preceded by the prefix cDIR$ (or cDEC$), where c is one of the following: !, C (or c), or *; for example, !DIR$ ALIAS).

Each OFFLOAD directive name is preceded by the prefix cDIR$, where c is one of the following: !, C (or c), or *; for example, !DIR$ OFFLOAD_TRANSFER.

Each OpenMP* Fortran directive name is preceded by the prefix c$OMP, where c is one of the following: !, C (or c), or *; for example, !$OMP ATOMIC.

Compiler directives are specially formatted comments in the source file which provide information to the compiler. Some directives, such as line length or conditional compilation directives provide the compiler information which is used in interpreting the source file. Other directives, such as optimization directives provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler based on the heuristics of the optimizer and/or code generator. If the directive is ignored by the compiler, no diagnostic message is issued.

You do not need to specify a compiler option to enable general directives.

Some directives may perform differently on Intel® microprocessors than on non-Intel microprocessors.

**General Directives**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIAS</td>
<td>Specifies an alternate external name to be used when referring to an external subprogram.</td>
</tr>
<tr>
<td>ASSUME</td>
<td>Provides heuristic information to the compiler optimizer.</td>
</tr>
<tr>
<td>ASSUME_ALIGNED</td>
<td>Specifies that an entity in memory is aligned.</td>
</tr>
<tr>
<td>ATTRIBUTES</td>
<td>Applies attributes to variables and procedures.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BLOCK_LOOP</td>
<td>Enables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>DECLARE</td>
<td>Generates warning messages for undeclared variables.</td>
</tr>
<tr>
<td>DEFINE</td>
<td>Creates a variable whose existence can be tested during conditional compilation.</td>
</tr>
<tr>
<td>DISTRIBUTED POINT</td>
<td>Suggests a location at which a DO loop may be split.</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ELSEIF</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ENDIF</td>
<td>Marks the end of a conditional-compilation block.</td>
</tr>
<tr>
<td>FIXEDFORMLINESIZE</td>
<td>Sets fixed-form line length. This directive has no effect on freeform code.</td>
</tr>
<tr>
<td>FMA</td>
<td>Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>Specifies that a routine should be inlined whenever the compiler can do so.</td>
</tr>
<tr>
<td>FREEFORM</td>
<td>Uses freeform format for source code.</td>
</tr>
<tr>
<td>IDENT</td>
<td>Specifies an identifier for an object module.</td>
</tr>
<tr>
<td>IF</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>IF DEFINED</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>INLINE</td>
<td>Specifies that the routines can be inlined.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Selects default integer size.</td>
</tr>
<tr>
<td>IVDEP</td>
<td>Assists the compiler’s dependence analysis of iterative DO loops.</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>Specifies the typical trip loop count for a DO loop; this assists the optimizer.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>Sends a character string to the standard output device.</td>
</tr>
<tr>
<td>NOBLOCK_LOOP</td>
<td>Disables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>NODECLARE</td>
<td>(Default) Turns off warning messages for undeclared variables.</td>
</tr>
<tr>
<td>NOFMA</td>
<td>Disables the generation of FMA instructions.</td>
</tr>
<tr>
<td>NOFREEFORM</td>
<td>(Default) Uses standard FORTRAN 77 code formatting column rules.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NOFUSSION</td>
<td>Prevents a loop from fusing with adjacent loops.</td>
</tr>
<tr>
<td>NOINLINE</td>
<td>Specifies that a routine should not be inlined.</td>
</tr>
<tr>
<td>NOPARALLEL</td>
<td>Disables auto-parallelization for an immediately following DO loop.</td>
</tr>
<tr>
<td>NOOPTIMIZE</td>
<td>Disables optimizations for the program unit.</td>
</tr>
<tr>
<td>NOPREFETCH</td>
<td>Disables a data prefetch from memory.</td>
</tr>
<tr>
<td>NOSTRICT</td>
<td>(Default) Disables a previous STRICT directive.</td>
</tr>
<tr>
<td>NOUNROLL</td>
<td>Disables the unrolling of a DO loop.</td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td>Disables loop unrolling and jamming.</td>
</tr>
<tr>
<td>NOVECTOR</td>
<td>Disables vectorization of a DO loop.</td>
</tr>
<tr>
<td>OBJCOMMENT</td>
<td>Specifies a library search path in an object file.</td>
</tr>
<tr>
<td>OPTIMIZE</td>
<td>Enables optimizations for the program unit.</td>
</tr>
<tr>
<td>OPTIONS</td>
<td>Controls whether fields in records and data items in common blocks are naturally aligned or packed on arbitrary byte boundaries.</td>
</tr>
<tr>
<td>PACK</td>
<td>Specifies the memory alignment of derived-type items.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Helps auto-parallelization by assisting the compiler's dependence analysis of an immediately following DO loop.</td>
</tr>
<tr>
<td>PREFETCH</td>
<td>Hints to the compiler to prefetch data from memory.</td>
</tr>
<tr>
<td>PSECT</td>
<td>Modifies certain characteristics of a common block.</td>
</tr>
<tr>
<td>REAL</td>
<td>Selects default real size.</td>
</tr>
<tr>
<td>SIMD</td>
<td>Requires and controls SIMD vectorization of loops.</td>
</tr>
<tr>
<td>STRICT</td>
<td>Disables Intel® Fortran features not in the language standard specified on the command line.</td>
</tr>
<tr>
<td>UNDEFINE</td>
<td>Removes a symbolic variable name created with the DEFINE directive.</td>
</tr>
<tr>
<td>UNROLL</td>
<td>Tells the compiler's optimizer how many times to unroll a DO loop.</td>
</tr>
<tr>
<td>UNROLL_AND_JAM</td>
<td>Enables loop unrolling and jamming.</td>
</tr>
<tr>
<td>VECTOR</td>
<td>Overrides default heuristics for vectorization of DO loops.</td>
</tr>
</tbody>
</table>

**OFFLOAD Directives**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD</td>
<td>Enables statements to execute on the target.</td>
</tr>
</tbody>
</table>
OpenMP directives are specially formatted Fortran comment lines embedded in the source file that provide the compiler with hints and suggestions for parallelization, optimization, vectorization and offloading code to accelerator hardware. The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

To use the following directives, you must specify compiler option `[q or Q]openmp`. For more information, refer to the option description in the Compiler Options reference.

### OpenMP* Fortran Directives

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC</td>
<td>Specifies that a specific memory location is to be updated atomically.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team.</td>
</tr>
<tr>
<td>CANCEL</td>
<td>Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.</td>
</tr>
<tr>
<td>CANCELLATION POINT</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>Restricts access for a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>DECLARE REDUCTION</td>
<td>Declares a user defined reduction for one or more types.</td>
</tr>
<tr>
<td>DECLARE SIMD</td>
<td>Generates a SIMD procedure.</td>
</tr>
<tr>
<td>DECLARE TARGET</td>
<td>Specifies that named variables, common blocks, functions, and subroutines are mapped to a device.</td>
</tr>
<tr>
<td>DISTRIBUTE</td>
<td>Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO SIMD</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DISTRIBUT SIMD</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DO</td>
<td>Specifies that the iterations of the immediately following DO loop must be executed in parallel.</td>
</tr>
<tr>
<td>DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Specifies synchronization points where the implementation must have a consistent view of memory.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code to be executed sequentially.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Defines a parallel region.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Defines a parallel region that contains a single DO directive.</td>
</tr>
<tr>
<td>PARALLEL DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.</td>
</tr>
<tr>
<td>PARALLEL SECTIONS</td>
<td>Defines a parallel region that contains SECTIONS directives.</td>
</tr>
<tr>
<td>PARALLEL WORKSHARE</td>
<td>Defines a parallel region that contains a single WORKSHARE directive.</td>
</tr>
<tr>
<td>SECTION</td>
<td>Appears within a SECTIONS directive construct to indicate a block (section) of code. It is optional for the first block of code within the SECTIONS directive construct.</td>
</tr>
<tr>
<td>SECTIONS</td>
<td>Specifies a block of code to be divided among threads in a team (a worksharing area).</td>
</tr>
<tr>
<td>SIMD</td>
<td>Requires and controls SIMD vectorization of loops.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>Specifies a block of code to be executed by only one thread in a team.</td>
</tr>
<tr>
<td>TARGET</td>
<td>Creates a device data environment and executes the construct on the same device.</td>
</tr>
<tr>
<td>TARGET DATA</td>
<td>Creates a device data environment for the extent of the region.</td>
</tr>
<tr>
<td>TARGET ENTER DATA</td>
<td>Specifies that variables are mapped to a device data environment.</td>
</tr>
<tr>
<td>TARGET EXIT DATA</td>
<td>Specifies that variables are unmapped from a device data environment.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TARGET PARALLEL</td>
<td>Creates a device data environment in a parallel region and executes the construct on that device. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET PARALLEL DO</td>
<td>Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.</td>
</tr>
<tr>
<td>TARGET PARALLEL DO SIMD</td>
<td>Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.</td>
</tr>
<tr>
<td>TARGET SIMD</td>
<td>Specifies a TARGET construct that contains a SIMD construct and no other statement.</td>
</tr>
<tr>
<td>TARGET TEAMS</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE SIMD</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions. This directive only applies when targeting Intel® Xeon Phi™ products.</td>
</tr>
<tr>
<td>TARGET UPDATE</td>
<td>Makes the list items in the device data environment consistent with their corresponding original list items.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TASK</td>
<td>Defines a task region.</td>
</tr>
<tr>
<td>TASKGROUP</td>
<td>Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.</td>
</tr>
<tr>
<td>TASKLOOP</td>
<td>Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.</td>
</tr>
<tr>
<td>TASKLOOP SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.</td>
</tr>
<tr>
<td>TASKWAIT</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>TASKYIELD</td>
<td>Specifies that the current task can be suspended in favor of execution of a different task.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE SIMD</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>THREADPRIVATE</td>
<td>Makes named common blocks private to a thread but global within the thread.</td>
</tr>
<tr>
<td>WORKSHARE</td>
<td>Divides the work of executing a block of statements or constructs into separate units.</td>
</tr>
</tbody>
</table>
Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Program Control Statements
The following table lists statements that affect program control.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL</td>
<td>Transfers control to a subroutine.</td>
</tr>
<tr>
<td>CASE</td>
<td>Within a SELECT CASE construct, marks a block of statements that are executed if an associated value matches the SELECT CASE expression.</td>
</tr>
<tr>
<td>CASE DEFAULT or CLASS DEFAULT</td>
<td>Identifies the block of statements to be executed in a SELECT CASE construct if the value of the expression does not match any of the CASE selectors, or in a SELECT TYPE construct if the dynamic type of the selector does not match the type of any of the TYPE IS or CLASS IS statements.</td>
</tr>
<tr>
<td>CLASS IS</td>
<td>Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the CLASS IS expression.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>Often used as the target of GOTO or as the terminal statement in a DO loop; performs no operation.</td>
</tr>
<tr>
<td>CYCLE</td>
<td>Advances control to the end statement of a DO loop; the intervening loop statements are not executed.</td>
</tr>
<tr>
<td>DO</td>
<td>Marks the beginning of a loop construct. Statements through and including the ending statement may be executed repeatedly.</td>
</tr>
<tr>
<td>DO CONCURRENT</td>
<td>Marks the beginning of a DO CONCURRENT construct. The order of executions of iterations of a DO CONCURRENT construct are indeterminate.</td>
</tr>
<tr>
<td>DO WHILE</td>
<td>Evaluates statements in the DO WHILE loop, through and including the ending statement, until a logical condition becomes .FALSE..</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>ELSEWHERE</td>
<td>Marks an optional branch in a WHERE construct.</td>
</tr>
<tr>
<td>END</td>
<td>Marks the end of a program unit. Execution of the END [PROGRAM] statement of the main program initiates normal termination for the image that executes it.</td>
</tr>
<tr>
<td>END DO</td>
<td>Marks the end of a series of statements in a DO, DO CONCURRENT, or DO WHILE construct.</td>
</tr>
<tr>
<td>END FORALL</td>
<td>Marks the end of a series of statements following a block FORALL statement.</td>
</tr>
<tr>
<td>END IF</td>
<td>Marks the end of a series of statements following a block IF statement.</td>
</tr>
<tr>
<td>END SELECT</td>
<td>Marks the end of a SELECT CASE or SELECT TYPE statement.</td>
</tr>
<tr>
<td>END WHERE</td>
<td>Marks the end of a series of statements following a block WHERE statement.</td>
</tr>
<tr>
<td>ERROR STOP</td>
<td>Initiates error termination for all images.</td>
</tr>
<tr>
<td>EXIT</td>
<td>Terminates execution of a DO loop or other construct. Execution continues with the first statement that follows the construct.</td>
</tr>
<tr>
<td>FORALL</td>
<td>Indicates a loop construct where the output from one iteration cannot change the input to another.</td>
</tr>
<tr>
<td>GOTO</td>
<td>Transfers control to a specified part of the program.</td>
</tr>
<tr>
<td>IF</td>
<td>Controls conditional execution of other statements.</td>
</tr>
<tr>
<td>PAUSE</td>
<td><strong>Suspends program execution and, optionally, executes operating-system commands.</strong></td>
</tr>
<tr>
<td>SELECT CASE</td>
<td>Transfers program control to a block of statements, determined by the value of an expression.</td>
</tr>
<tr>
<td>SELECT TYPE</td>
<td>Transfers the program to a block of statements, determined by the dynamic type of an expression.</td>
</tr>
<tr>
<td>STOP</td>
<td>Initiates normal termination for the image that executes the statement.</td>
</tr>
<tr>
<td>TYPE IS</td>
<td>Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the TYPE IS expression.</td>
</tr>
<tr>
<td>WHERE</td>
<td>Controls conditional execution of array assignments and elemental function calls.</td>
</tr>
</tbody>
</table>

**Inquiry Intrinsic Functions**

The following table lists inquiry intrinsic functions.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Determines whether an allocatable variable is allocated.</td>
</tr>
<tr>
<td>ASSOCIATED</td>
<td>Determines if a pointer is associated or if two pointers are associated with the same target.</td>
</tr>
<tr>
<td>BIT_SIZE</td>
<td>Returns the number of bits in an integer type.</td>
</tr>
<tr>
<td>CACHESIZE</td>
<td>Returns the size of a level of the memory cache.</td>
</tr>
<tr>
<td>COMMAND_ARGUMENT_COUNT</td>
<td>Returns the number of command-line arguments.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EOF</td>
<td>Determines whether a file is at or beyond the end-of-file record.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns the largest number that can be represented by numbers of the type of the argument.</td>
</tr>
<tr>
<td>IARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>INT_PTR_KIND</td>
<td>Returns the INTEGER KIND that will hold an address.</td>
</tr>
<tr>
<td>KIND</td>
<td>Returns the value of the kind parameter of the argument.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the length of a character expression.</td>
</tr>
<tr>
<td>LOC</td>
<td>Returns the address of the argument.</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NARGS</td>
<td>Returns the total number of command-line arguments, including the command.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>PRESENT</td>
<td>Determines whether an optional argument is present.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SELECTED_INT_KIND</td>
<td>Returns the value of the kind parameter of integers in range ( r ).</td>
</tr>
<tr>
<td>SELECTED_REAL_KIND</td>
<td>Returns the value of the kind parameter of reals with (optional) first argument digits and (optional) second argument exponent range. At least one optional argument is required.</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array or scalar argument.</td>
</tr>
<tr>
<td>SIZEOF</td>
<td>Returns the number of bytes of storage used by the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns the smallest positive number that can be represented by numbers of type the argument.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.</td>
</tr>
</tbody>
</table>

Random Number Intrinsic Procedures

The following table lists random number intrinsic procedures.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAN</td>
<td>Intrinsic function</td>
<td>Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1.</td>
</tr>
<tr>
<td>RANF</td>
<td>Intrinsic function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANDOM_NUMBER</td>
<td>Intrinsic subroutine</td>
<td>Returns a pseudorandom real value greater than or equal to zero and less than one.</td>
</tr>
<tr>
<td>RANDOM_SEED</td>
<td>Intrinsic subroutine</td>
<td>Changes the starting point of RANDOM_NUMBER; takes one or no arguments.</td>
</tr>
<tr>
<td>RANDU</td>
<td>Intrinsic subroutine</td>
<td>Computes a pseudorandom number as a single-precision value.</td>
</tr>
</tbody>
</table>

The portability routines RANF, RANDOM, and SEED also supply this functionality.

Date and Time Intrinsic Subroutines

The following table lists date and time intrinsic subroutines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the processor time in seconds.</td>
</tr>
</tbody>
</table>
### Intrinsic Subroutines

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current date (in dd-mmm-yy form).</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the date and time. This is the preferred procedure for date and time.</td>
</tr>
<tr>
<td>IDATE</td>
<td>Intrinsic subroutine</td>
<td>Returns three integer values representing the current month, day, and year.</td>
</tr>
<tr>
<td>SYSTEM_CLOCK</td>
<td>Intrinsic subroutine</td>
<td>Returns data from the system clock.</td>
</tr>
<tr>
<td>TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current time (in hh:mm:ss form).</td>
</tr>
</tbody>
</table>

The portability routines GETDAT, GETTIM, SETDAT, and SETTIM also supply this functionality.

### Keyboard and Speaker Library Routines

The following table lists keyboard and speaker library routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETCHARQQ</td>
<td>Run-time Function</td>
<td>Returns the next keyboard keystroke.</td>
</tr>
<tr>
<td>BEEPQQ</td>
<td>Portability subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Run-time function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Run-time function</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
</tbody>
</table>

### Statements and Intrinsic Procedures for Memory Allocation and Deallocation

The following table lists statements and intrinsic procedures that are used for memory allocation and deallocation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Statement</td>
<td>Dynamically establishes allocatable array dimensions.</td>
</tr>
<tr>
<td>ALLOCATED</td>
<td>Intrinsic Function</td>
<td>Determines whether an allocatable array is allocated.</td>
</tr>
<tr>
<td>DEALLOCATE</td>
<td>Statement</td>
<td>Frees the storage space previously reserved in an ALLOCATE statement.</td>
</tr>
</tbody>
</table>
### Intrinsic Functions for Arrays

The following table lists intrinsic functions for arrays.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td></td>
<td>Determines whether all array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>ANY</td>
<td></td>
<td>Determines whether any array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>COSHAPE</td>
<td></td>
<td>Returns the sizes of codimensions of a coarray.</td>
</tr>
<tr>
<td>COUNT</td>
<td></td>
<td>Counts the number of array elements that meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>CSHIFT</td>
<td></td>
<td>Performs a circular shift along a (optional) dimension.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td></td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOT_PRODUCT</td>
<td></td>
<td>Performs dot-product multiplication on vectors (one-dimensional arrays).</td>
</tr>
<tr>
<td>EOSHIFT</td>
<td></td>
<td>Shifts elements off one end of array along a (optional) dimension and copies (optional) boundary values in other end.</td>
</tr>
<tr>
<td>LBOUND</td>
<td></td>
<td>Returns lower dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>LCOBOUND</td>
<td></td>
<td>Returns the lower cobounds of a coarray.</td>
</tr>
<tr>
<td>MATMUL</td>
<td></td>
<td>Performs matrix multiplication on matrices (two-dimensional arrays).</td>
</tr>
<tr>
<td>MAXLOC</td>
<td></td>
<td>Returns the location of the maximum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MAXVAL</td>
<td></td>
<td>Returns the maximum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>MERGE</td>
<td></td>
<td>Merges two arrays according to conditions in a mask.</td>
</tr>
</tbody>
</table>
### Intrinsic Functions for Numeric and Type Conversion

The following table lists intrinsic functions for numeric and type conversion.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Returns the absolute value of the argument.</td>
</tr>
<tr>
<td>AIMAG</td>
<td>Returns imaginary part of complex number z.</td>
</tr>
<tr>
<td>AINT</td>
<td>Truncates the argument to a whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>AMAX0</td>
<td>Returns largest value among integer arguments as real.</td>
</tr>
<tr>
<td>AMIN0</td>
<td>Returns smallest value among integer arguments as real.</td>
</tr>
<tr>
<td>ANINT</td>
<td>Rounds to the nearest whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>CEILING</td>
<td>Returns smallest integer greater than the argument.</td>
</tr>
<tr>
<td>CMPLX</td>
<td>Converts the first argument and (optional) second argument to complex of a (optional) kind.</td>
</tr>
<tr>
<td>CONJG</td>
<td>Returns the conjugate of a complex number.</td>
</tr>
<tr>
<td>DBLE</td>
<td>Converts the argument to double precision type.</td>
</tr>
<tr>
<td>DCMPLX</td>
<td>Converts the argument to double complex type.</td>
</tr>
<tr>
<td>DFLOAT</td>
<td>Converts an integer to double precision type.</td>
</tr>
<tr>
<td>DIM</td>
<td>Returns the first argument minus the second argument if positive; else 0.</td>
</tr>
<tr>
<td>DPROD</td>
<td>Returns double-precision product of two single precision arguments.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>Converts the argument to REAL(4).</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Returns the greatest integer less than or equal to the argument.</td>
</tr>
<tr>
<td>IFIX</td>
<td>Converts a single-precision real argument to an integer argument by truncating.</td>
</tr>
<tr>
<td>IMAG</td>
<td>Same as AIMAG.</td>
</tr>
<tr>
<td>INT</td>
<td>Converts a value to integer type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Converts between logical arguments of (optional) kind.</td>
</tr>
<tr>
<td>MAX</td>
<td>Returns largest value among arguments.</td>
</tr>
<tr>
<td>MAX1</td>
<td>Returns largest value among real arguments as integer.</td>
</tr>
<tr>
<td>MIN</td>
<td>Returns smallest value among arguments.</td>
</tr>
<tr>
<td>MIN1</td>
<td>Returns smallest value among real arguments as integer.</td>
</tr>
<tr>
<td>MOD</td>
<td>Returns the remainder of the first argument divided by the second argument.</td>
</tr>
<tr>
<td>MODULO</td>
<td>Returns the first argument modulo the second argument.</td>
</tr>
<tr>
<td>NINT</td>
<td>Returns the nearest integer to the argument.</td>
</tr>
<tr>
<td>REAL</td>
<td>Converts a value to real type.</td>
</tr>
<tr>
<td>SIGN</td>
<td>Returns absolute value of the first argument times the sign of the second argument.</td>
</tr>
<tr>
<td>SNGL</td>
<td>Converts a double-precision argument to single-precision real type.</td>
</tr>
<tr>
<td>TRANSFER</td>
<td>Transforms first argument into type of second argument with (optional) size if an array.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>ZEXT</td>
<td>Extends the argument with zeros.</td>
</tr>
</tbody>
</table>

**Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures**

The following table lists intrinsic procedures for trigonometric, exponential, root, and logarithmic operations.

**NOTE**
Many routines in the LIBM library (Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOS</td>
<td>Returns the arccosine of the argument, expressed in radians between 0 and pi.</td>
</tr>
<tr>
<td>ACOSD</td>
<td>Returns the arccosine of the argument, expressed in degrees between 0 and 180.</td>
</tr>
<tr>
<td>ALOG</td>
<td>Returns natural log of the argument.</td>
</tr>
<tr>
<td>ALOG10</td>
<td>Returns common log (base 10) of the argument.</td>
</tr>
<tr>
<td>ASIN</td>
<td>Returns the arcsine of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ASIND</td>
<td>Returns the arcsine of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN</td>
<td>Returns the arctangent of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ATAND</td>
<td>Returns the arctangent of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN2</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>ATAN2D</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>CCOS</td>
<td>Returns complex cosine of the argument.</td>
</tr>
<tr>
<td>CDCOS</td>
<td>Returns the double-precision complex cosine of the argument.</td>
</tr>
<tr>
<td>CDEXP</td>
<td>Returns double-precision complex exponential value of the argument.</td>
</tr>
<tr>
<td>CDLOG</td>
<td>Returns the double-precision complex natural log of the argument.</td>
</tr>
<tr>
<td>CDSIN</td>
<td>Returns the double-precision complex sine of the argument.</td>
</tr>
<tr>
<td>CDSQRT</td>
<td>Returns the double-precision complex square root of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CEXP</td>
<td>Returns the complex exponential value of the argument.</td>
</tr>
<tr>
<td>CLOG</td>
<td>Returns the complex natural log of the argument.</td>
</tr>
<tr>
<td>COS</td>
<td>Returns the cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>COSD</td>
<td>Returns the cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>COSH</td>
<td>Returns the hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>COTAN</td>
<td>Returns the cotangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>COTAND</td>
<td>Returns the cotangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>CSIN</td>
<td>Returns the complex sine of the argument.</td>
</tr>
<tr>
<td>CSQRT</td>
<td>Returns the complex square root of the argument.</td>
</tr>
<tr>
<td>DACOS</td>
<td>Returns the double-precision arccosine of the argument radians between 0 and pi.</td>
</tr>
<tr>
<td>DACOSD</td>
<td>Returns the arccosine of the argument in degrees between 0 and 180.</td>
</tr>
<tr>
<td>DASIN</td>
<td>Returns the double-precision arcsine of the argument in radians between ±pi/2.</td>
</tr>
<tr>
<td>DASIND</td>
<td>Returns the double-precision arcsine of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN</td>
<td>Returns the double-precision arctangent of the argument radians between ±pi/2.</td>
</tr>
<tr>
<td>DATAND</td>
<td>Returns the double-precision arctangent of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN2</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>DATAN2D</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>DCOS</td>
<td>Returns the double-precision cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>DCOSD</td>
<td>Returns the double-precision cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DCOSH</td>
<td>Returns the double-precision hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>Returns the double-precision cotangent of the argument.</td>
</tr>
<tr>
<td>DEXP</td>
<td>Returns the double-precision exponential value of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DLOG</td>
<td>Returns the double-precision natural log of the argument.</td>
</tr>
<tr>
<td>DLOG10</td>
<td>Returns the double-precision common log (base 10) of the argument.</td>
</tr>
<tr>
<td>DSIN</td>
<td>Returns the double-precision sin of the argument, which is in radians.</td>
</tr>
<tr>
<td>DSIND</td>
<td>Returns the double-precision sin of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DSINH</td>
<td>Returns the double-precision hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>DSQRT</td>
<td>Returns the double-precision square root of the argument.</td>
</tr>
<tr>
<td>DTAN</td>
<td>Returns the double-precision tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>DTAND</td>
<td>Returns the double-precision tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DTANH</td>
<td>Returns the double-precision hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>EXP</td>
<td>Returns the exponential value of the argument.</td>
</tr>
<tr>
<td>EXP10</td>
<td>Returns the base 10 exponential value of the argument.</td>
</tr>
<tr>
<td>LOG</td>
<td>Returns the natural log of the argument.</td>
</tr>
<tr>
<td>LOG10</td>
<td>Returns the common log (base 10) of the argument.</td>
</tr>
<tr>
<td>SIN</td>
<td>Returns the sine of the argument, which is in radians.</td>
</tr>
<tr>
<td>SIND</td>
<td>Returns the sine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>SINH</td>
<td>Returns the hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>SQRT</td>
<td>Returns the square root of the argument.</td>
</tr>
<tr>
<td>TAN</td>
<td>Returns the tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>TAND</td>
<td>Returns the tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>TANH</td>
<td>Returns the hyperbolic tangent of the argument.</td>

**Intrinsic Functions for Floating-Point Inquiry and Control**

The following table lists intrinsic functions for floating-point inquiry and control. Certain functions (EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, and SPACING) return values related to components of the model set of real numbers. For a description of this model, see the Model for Real Data.
### Name | Description
--- | ---
DIGITS | Returns number of significant digits for data of the same type as the argument.
EPSILON | Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.
EXPONENT | Returns the exponent part of the representation of $x$.
FRACTION | Returns the fractional part of the representation of the argument.
HUGE | Returns largest number that can be represented by data of type the argument.
MAXEXPONENT | Returns the largest positive decimal exponent for data of the same type as the argument.
MINEXPONENT | Returns the largest negative decimal exponent for data of the same type as the argument.
NEAREST | Returns the nearest different machine representable number to the first argument in the direction of the sign of the second argument.
PRECISION | Returns the number of significant digits for data of the same type as the argument.
RADIX | Returns the base for data of the same type as the argument.
RANGE | Returns the decimal exponent range for data of the same type as the argument.
RRSPACING | Returns the reciprocal of the relative spacing of numbers near the argument.
SCALE | Multiplies the first argument by $2$ raised to the power of the second argument.
SET_EXPONENT | Returns a number whose fractional part is the first argument and whose exponential part is the second argument.
SPACING | Returns the absolute spacing of numbers near the argument.
TINY | Returns smallest positive number that can be represented by data of type of the argument.

The portability routines GETCONTROLFPQQ, GETSTATUSFPQQ, LCWRQQ, SCWRQQ, SETCONTROLFPQQ, and SSWRQQ also supply this functionality.

### Character Intrinsic Functions

The following table lists character intrinsic functions.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACHAR</td>
<td>Returns character in a specified position in the ASCII character set.</td>
</tr>
<tr>
<td>ADJUSTL</td>
<td>Adjusts left, removing leading blanks and inserting trailing blanks.</td>
</tr>
<tr>
<td>ADJUSTR</td>
<td>Adjusts right, removing trailing blanks and inserting leading blanks.</td>
</tr>
<tr>
<td>CHAR</td>
<td>Returns character in a specified position in the processor's character set of (optional) kind.</td>
</tr>
<tr>
<td>IACHAR</td>
<td>Returns the position of the argument in the ASCII character set.</td>
</tr>
<tr>
<td>ICHAR</td>
<td>Returns the position of the argument in the processor's character set.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Returns the starting position of a substring in a string, leftmost or (optional) rightmost occurrence.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the size of the argument.</td>
</tr>
<tr>
<td>LEN_TRIM</td>
<td>Returns the number of characters in the argument, not counting trailing blanks.</td>
</tr>
<tr>
<td>LGE</td>
<td>Tests whether the first argument is greater than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LGT</td>
<td>Tests whether the first argument is greater than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLE</td>
<td>Tests whether the first argument is less than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLT</td>
<td>Tests whether the first argument is less than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>REPEAT</td>
<td>Concatenates multiple copies of a string.</td>
</tr>
<tr>
<td>SCAN</td>
<td>Scans a string for any characters in a set and returns leftmost or (optional) rightmost position where a match is found.</td>
</tr>
<tr>
<td>TRIM</td>
<td>Removes trailing blanks from a string.</td>
</tr>
<tr>
<td>VERIFY</td>
<td>Returns the position of the leftmost or (optional) rightmost character in the argument string not in a set, or zero if all characters in the set are present.</td>
</tr>
</tbody>
</table>

**Intrinsic Procedures for Bit Operation and Representation**

The following tables list intrinsic procedures for bit operation and representation.
<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Intrinsic Function</td>
<td>Returns the number of bits in integers of the type the argument.</td>
</tr>
<tr>
<td>BTEST</td>
<td>Intrinsic Function</td>
<td>Tests a bit in a position of the argument; true if bit is 1.</td>
</tr>
<tr>
<td>IAND</td>
<td>Intrinsic Function</td>
<td>Performs a logical AND.</td>
</tr>
<tr>
<td>IBCHNG</td>
<td>Intrinsic Function</td>
<td>Reverses value of bit in a position of the argument.</td>
</tr>
<tr>
<td>IBCLR</td>
<td>Intrinsic Function</td>
<td>Clears the bit in a position of the argument to zero.</td>
</tr>
<tr>
<td>IBITS</td>
<td>Intrinsic Function</td>
<td>Extracts a sequence of bits of length from the argument starting in a position.</td>
</tr>
<tr>
<td>IBSET</td>
<td>Intrinsic Function</td>
<td>Sets the bit in a position of the argument to one.</td>
</tr>
<tr>
<td>IEOR</td>
<td>Intrinsic Function</td>
<td>Performs an exclusive OR.</td>
</tr>
<tr>
<td>IOR</td>
<td>Intrinsic Function</td>
<td>Performs an inclusive OR.</td>
</tr>
<tr>
<td>ISHA</td>
<td>Intrinsic Function</td>
<td>Shifts the argument arithmetically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from the right, ones shifted in from the left.</td>
</tr>
<tr>
<td>ISHC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the argument left or right by shift bits; left if shift positive, right if shift negative. No bits lost.</td>
</tr>
<tr>
<td>ISHFT</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>ISHFTC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the rightmost bits of (optional) size by shift bits. No bits lost.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ISHL</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>MVBITS</td>
<td>Intrinsic Subroutine</td>
<td>Copies a sequence of bits from one integer to another.</td>
</tr>
<tr>
<td>NOT</td>
<td>Intrinsic Function</td>
<td>Performs a logical complement.</td>
</tr>
</tbody>
</table>

### Bit Representation

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEADZ</td>
<td>Intrinsic Function</td>
<td>Returns leading zero bits in an integer.</td>
</tr>
<tr>
<td>POPCNT</td>
<td>Intrinsic Function</td>
<td>Returns number of 1 bits in an integer.</td>
</tr>
<tr>
<td>POPPAR</td>
<td>Intrinsic Function</td>
<td>Returns the parity of an integer.</td>
</tr>
<tr>
<td>TRAILZ</td>
<td>Intrinsic Function</td>
<td>Returns trailing zero bits in an integer.</td>
</tr>
</tbody>
</table>

### QuickWin Library Routines (W*S)

The following table lists Quickwin library routines.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABOUTBOXQQ</td>
<td>Function</td>
<td>Adds an About Box with customized text.</td>
</tr>
<tr>
<td>APPENDMENUQQ</td>
<td>Function</td>
<td>Appends a menu item.</td>
</tr>
<tr>
<td>CLICKMENUQQ</td>
<td>Function</td>
<td>Sends menu click messages to the application window.</td>
</tr>
<tr>
<td>DELETEMENUQQ</td>
<td>Function</td>
<td>Deletes a menu item.</td>
</tr>
<tr>
<td>FOCUSQQ</td>
<td>Function</td>
<td>Makes a child window active, and gives focus to the child window.</td>
</tr>
<tr>
<td>GETACTIVEQQ</td>
<td>Function</td>
<td>Gets the unit number of the active child window.</td>
</tr>
<tr>
<td>GETEXITQQ</td>
<td>Function</td>
<td>Gets the setting for a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>GETHWNDQQ</td>
<td>Function</td>
<td>Gets the true windows handle from window with the specified unit number.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETWINDOWCONFIG</td>
<td>Function</td>
<td>Returns the current window's properties.</td>
</tr>
<tr>
<td>GETWSIZEQQ</td>
<td>Function</td>
<td>Gets the size of the child or frame window.</td>
</tr>
<tr>
<td>GETUNITQQ</td>
<td>Function</td>
<td>Gets the unit number corresponding to the specified windows handle. Inverse of GETHWNDQQ.</td>
</tr>
<tr>
<td>INCHARQQ</td>
<td>Function</td>
<td>Reads a keyboard input and return its ASCII value.</td>
</tr>
<tr>
<td>INITIALSETTINGS</td>
<td>Function</td>
<td>Controls initial menu settings and initial frame window settings.</td>
</tr>
<tr>
<td>INQFOCUSQQ</td>
<td>Function</td>
<td>Determines which window is active and has the focus.</td>
</tr>
<tr>
<td>INSERTMENUQQ</td>
<td>Function</td>
<td>Inserts a menu item.</td>
</tr>
<tr>
<td>INTEGRERTORGB</td>
<td>Subroutine</td>
<td>Converts a true color value into its red, green and blue components.</td>
</tr>
<tr>
<td>MESSAGEBOXQQ</td>
<td>Function</td>
<td>Displays a message box.</td>
</tr>
<tr>
<td>MODIFYMENUFLAGSQQ</td>
<td>Function</td>
<td>Modifies a menu item state.</td>
</tr>
<tr>
<td>MODIFYMENUROUTINEQQ</td>
<td>Function</td>
<td>Modifies a menu item's callback routine.</td>
</tr>
<tr>
<td>MODIFYMENUSTRINGQQ</td>
<td>Function</td>
<td>Changes a menu item's text string.</td>
</tr>
<tr>
<td>PASSDIRKEYSQQ</td>
<td>Function</td>
<td>Determines the behavior of direction and page keys.</td>
</tr>
<tr>
<td>REGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Registers the application-defined routines to be called on mouse events.</td>
</tr>
<tr>
<td>RGBTOINTEGER</td>
<td>Function</td>
<td>Converts a trio of red, green and blue values to a true color value for use with RGB functions and subroutines.</td>
</tr>
<tr>
<td>SETACTIVEQQ</td>
<td>Function</td>
<td>Makes the specified window the current active window without giving it the focus.</td>
</tr>
<tr>
<td>SETEXITQQ</td>
<td>Function</td>
<td>Sets a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>SETMESSAGEQQ</td>
<td>Subroutine</td>
<td>Changes any QuickWin message, including status bar messages, state messages and dialog box messages.</td>
</tr>
<tr>
<td>SETMOUSECURSOR</td>
<td>Function</td>
<td>Sets the mouse cursor for the window in focus.</td>
</tr>
</tbody>
</table>
### Graphics Library Routines (W*S)

The following table lists library routines for graphics.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETWINDOWCONFIG</td>
<td>Function</td>
<td>Configures the current window's properties.</td>
</tr>
<tr>
<td>SETWINDOWMENUQQ</td>
<td>Function</td>
<td>Sets the Window menu to which current child window names will be appended.</td>
</tr>
<tr>
<td>SETWSIZEQQ</td>
<td>Function</td>
<td>Sets the size of the child or frame window.</td>
</tr>
<tr>
<td>UNREGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Removes the callback routine registered by REGISTERMOUSEEVENT.</td>
</tr>
<tr>
<td>WAITONMOUSEEVENT</td>
<td>Function</td>
<td>Blocks return until a mouse event occurs.</td>
</tr>
</tbody>
</table>

### Graphics Library Routines (W*S)

The following table lists library routines for graphics.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC, ARC_W</td>
<td>Functions</td>
<td>Draws an arc.</td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>Subroutine</td>
<td>Clears the screen, viewport, or text window.</td>
</tr>
<tr>
<td>DISPLAYCURSOR</td>
<td>Function</td>
<td>Turns the cursor off and on.</td>
</tr>
<tr>
<td>ELLIPSE, ELLIPSE_W</td>
<td>Functions</td>
<td>Draws an ellipse or circle.</td>
</tr>
<tr>
<td>FLOODFILL, FLOODFILL_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current color index, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB, FLOODFILLRGB_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current RGB color, using the current fill mask.</td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>Function</td>
<td>Determines the end points of the most recently drawn arc or pie.</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>Function</td>
<td>Returns the current background color index.</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>Function</td>
<td>Returns the current background RGB color.</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>Function</td>
<td>Returns the current color index.</td>
</tr>
<tr>
<td>GETCOLORRGB</td>
<td>Function</td>
<td>Returns the current RGB color.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION, GETCURRENTPOSITION_W</td>
<td>Subroutines</td>
<td>Returns the coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GETFILLMASK</td>
<td>Subroutine</td>
<td>Returns the current fill mask.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETFONTINFO</td>
<td>Function</td>
<td>Returns the current font characteristics.</td>
</tr>
<tr>
<td>GETGTEXTEXTENT</td>
<td>Function</td>
<td>Determines the width of the specified text in the current font.</td>
</tr>
<tr>
<td>GETGTEXTROTATION</td>
<td>Function</td>
<td>Get the current text rotation angle.</td>
</tr>
<tr>
<td>GETIMAGE, GETIMAGE_W</td>
<td>Subroutines</td>
<td>Stores a screen image in memory.</td>
</tr>
<tr>
<td>GETLINSTYLE</td>
<td>Function</td>
<td>Returns the current line style.</td>
</tr>
<tr>
<td>GETLINEWIDTHQQ</td>
<td>Function</td>
<td>Returns the current line width or the line width set by the last call to SETLINEWIDTHQQ.</td>
</tr>
<tr>
<td>GETPHYSCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to physical coordinates.</td>
</tr>
<tr>
<td>GETPIXEL, GETPIXEL_W</td>
<td>Functions</td>
<td>Returns a pixel's color index.</td>
</tr>
<tr>
<td>GETPIXELRGB, GETPIXELRGB_W</td>
<td>Functions</td>
<td>Returns a pixel's RGB color.</td>
</tr>
<tr>
<td>GETPIXELS</td>
<td>Function</td>
<td>Returns the color indices of multiple pixels.</td>
</tr>
<tr>
<td>GETPIXELSRGB</td>
<td>Function</td>
<td>Returns the RGB colors of multiple pixels.</td>
</tr>
<tr>
<td>GETTEXTCOLOR</td>
<td>Function</td>
<td>Returns the current text color index.</td>
</tr>
<tr>
<td>GETTEXTCOLORRGB</td>
<td>Function</td>
<td>Returns the current text RGB color.</td>
</tr>
<tr>
<td>GETTEXTPOSITION</td>
<td>Subroutine</td>
<td>Returns the current text-output position.</td>
</tr>
<tr>
<td>GETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Returns the boundaries of the current text window.</td>
</tr>
<tr>
<td>GETVIEWCOORD, GETVIEWCOORD_W</td>
<td>Subroutines</td>
<td>Converts physical or window coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETWINDOWCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to window coordinates.</td>
</tr>
<tr>
<td>GETWRITEMODE</td>
<td>Function</td>
<td>Returns the logical write mode for lines.</td>
</tr>
<tr>
<td>GRSTATUS</td>
<td>Function</td>
<td>Returns the status (success or failure) of the most recently called graphics routine.</td>
</tr>
<tr>
<td>IMAGESIZE, IMAGESIZE_W</td>
<td>Functions</td>
<td>Returns image size in bytes.</td>
</tr>
<tr>
<td>INITIALIZEFONTS</td>
<td>Function</td>
<td>Initializes the font library.</td>
</tr>
<tr>
<td>LINETO, LINETO_W</td>
<td>Functions</td>
<td>Draws a line from the current position to a specified point.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LINETOAR</td>
<td>Function</td>
<td>Draws a line between points in one array and corresponding points in another array.</td>
</tr>
<tr>
<td>LINETOAREX</td>
<td>Function</td>
<td>Similar to LINETOAR, but also lets you specify color and line style.</td>
</tr>
<tr>
<td>LOADIMAGE, LOADIMAGE_W</td>
<td>Functions</td>
<td>Reads a Windows bitmap file (.BMP) and displays it at the specified location.</td>
</tr>
<tr>
<td>MOVETO, MOVETO_W</td>
<td>Subroutines</td>
<td>Moves the current position to the specified point.</td>
</tr>
<tr>
<td>OUTGTEXT</td>
<td>Subroutine</td>
<td>Sends text in the current font to the screen at the current position.</td>
</tr>
<tr>
<td>OUTTEXT</td>
<td>Subroutine</td>
<td>Sends text to the screen at the current position.</td>
</tr>
<tr>
<td>PIE, PIE_W</td>
<td>Functions</td>
<td>Draws a pie slice.</td>
</tr>
<tr>
<td>POLYBEZIER, POLYBEZIER_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYBEZIERTO, POLYBEZIERTO_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYGON, POLYGON_W</td>
<td>Functions</td>
<td>Draws a polygon.</td>
</tr>
<tr>
<td>POLYLINEQQ</td>
<td>Function</td>
<td>Draws a line between successive points in an array.</td>
</tr>
<tr>
<td>PUTIMAGE, PUTIMAGE_W</td>
<td>Subroutines</td>
<td>Retrieves an image from memory and displays it.</td>
</tr>
<tr>
<td>RECTANGLE, RECTANGLE_W</td>
<td>Functions</td>
<td>Draws a rectangle.</td>
</tr>
<tr>
<td>REMAPALLPALETTERGB</td>
<td>Function</td>
<td>Remaps a set of RGB color values to indices recognized by the current video configuration.</td>
</tr>
<tr>
<td>REMAPPALETTERGB</td>
<td>Function</td>
<td>Remaps a single RGB color value to a color index.</td>
</tr>
<tr>
<td>SAVEIMAGE, SAVEIMAGE_W</td>
<td>Functions</td>
<td>Captures a screen image and saves it as a Windows bitmap file.</td>
</tr>
<tr>
<td>SCROLLTEXTWINDOW</td>
<td>Subroutine</td>
<td>Scrolls the contents of a text window.</td>
</tr>
<tr>
<td>SETBKCOLOR</td>
<td>Function</td>
<td>Sets the current background color.</td>
</tr>
<tr>
<td>SETBKCOLORRRGB</td>
<td>Function</td>
<td>Sets the current background color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETCLIPRGN</td>
<td>Subroutine</td>
<td>Limits graphics output to a part of the screen.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SETCOLOR</td>
<td>Function</td>
<td>Sets the current color to a new color index.</td>
</tr>
<tr>
<td>SETCOLORRGB</td>
<td>Function</td>
<td>Sets the current color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETFILLMASK</td>
<td>Subroutine</td>
<td>Changes the current fill mask to a new pattern.</td>
</tr>
<tr>
<td>SETFONT</td>
<td>Function</td>
<td>Finds a single font matching the specified characteristics and assigns it to OUTGTEXT.</td>
</tr>
<tr>
<td>SETGTEXTROTATION</td>
<td>Subroutine</td>
<td>Sets the direction in which text is written to the specified angle.</td>
</tr>
<tr>
<td>SETLINESTYLE</td>
<td>Subroutine</td>
<td>Changes the current line style.</td>
</tr>
<tr>
<td>SETLINEWIDTHQQ</td>
<td>Subroutine</td>
<td>Sets the width of a solid line drawn using any of the supported graphics functions.</td>
</tr>
<tr>
<td>SETPIXEL, SETPIXEL_W</td>
<td>Functions</td>
<td>Sets color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELRGB, SETPIXELRGB_W</td>
<td>Functions</td>
<td>Sets RGB color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELS</td>
<td>Subroutine</td>
<td>Sets the color indices of multiple pixels.</td>
</tr>
<tr>
<td>SETPIXELSRGB</td>
<td>Subroutine</td>
<td>Sets the RGB color of multiple pixels.</td>
</tr>
<tr>
<td>SETTEXTCOLOR</td>
<td>Function</td>
<td>Sets the current text color to a new color index.</td>
</tr>
<tr>
<td>SETTEXTCOLORRGB</td>
<td>Function</td>
<td>Sets the current text color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETTEXTCURSOR</td>
<td>Function</td>
<td>Sets the height and width of the text cursor for the window in focus.</td>
</tr>
<tr>
<td>SETTEXTPosition</td>
<td>Subroutine</td>
<td>Changes the current text position.</td>
</tr>
<tr>
<td>SETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Sets the current text display window.</td>
</tr>
<tr>
<td>SETVIEWORIGIN</td>
<td>Subroutine</td>
<td>Positions the viewport coordinate origin.</td>
</tr>
<tr>
<td>SETVIEWPORT</td>
<td>Subroutine</td>
<td>Defines the size and screen position of the viewport.</td>
</tr>
<tr>
<td>SETWINDOW</td>
<td>Function</td>
<td>Defines the window coordinate system.</td>
</tr>
</tbody>
</table>
### Portability Library Routines

The following tables list library routines for portability.

If you have programs that use these routines, it is recommended that they access the portability library with `USE IFPORT`.

Some routines in this library can be called with different sets of arguments, and some can be used as a function or a subroutine. In these cases, the arguments and calling mechanism determine the meaning of the routine. The `IFPORT` module contains generic interface blocks that give procedure definitions for these routines.

### Information Retrieval

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR_IFCORE_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran run-time library (ifcore).</td>
</tr>
<tr>
<td>FOR_IFPORT_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran portability library (ifport).</td>
</tr>
<tr>
<td>FSTAT</td>
<td>Function</td>
<td>Returns information about a logical file unit.</td>
</tr>
<tr>
<td>GETCWD</td>
<td>Function</td>
<td>Returns the pathname of the current working directory.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Subroutine</td>
<td>Searches the environment for a given string and returns its value if found.</td>
</tr>
<tr>
<td>GETGID</td>
<td>Function</td>
<td>Returns the group ID of the user.</td>
</tr>
<tr>
<td>GETLOG</td>
<td>Subroutine</td>
<td>Returns the user's login name.</td>
</tr>
<tr>
<td>getpid</td>
<td>Function</td>
<td>Returns the process ID of the process.</td>
</tr>
<tr>
<td>getuid</td>
<td>Function</td>
<td>Returns the user ID of the user of the process.</td>
</tr>
<tr>
<td>HOSTNAM(^1)</td>
<td>Function</td>
<td>Returns the name of the user's host.</td>
</tr>
<tr>
<td>isatty</td>
<td>Function</td>
<td>Checks whether a logical unit number is a terminal.</td>
</tr>
<tr>
<td>lstat</td>
<td>Function</td>
<td>Returns information about a named file. STAT is the preferred form of this function.</td>
</tr>
<tr>
<td>rename</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>STAT</td>
<td>Function</td>
<td>Returns information about a named file.</td>
</tr>
<tr>
<td>UNLINK</td>
<td>Function</td>
<td>Deletes the file given by path.</td>
</tr>
</tbody>
</table>

**Process Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT</td>
<td>Subroutine</td>
<td>Stops execution of the current process, clears I/O buffers, and writes a string to external unit 0.</td>
</tr>
<tr>
<td>ALARM</td>
<td>Function</td>
<td>Executes an external subroutine after waiting a specified number of seconds.</td>
</tr>
<tr>
<td>KILL</td>
<td>Function</td>
<td>Sends a signal code to the process given by ID.</td>
</tr>
<tr>
<td>SIGNAL</td>
<td>Function</td>
<td>Changes the action for signal.</td>
</tr>
<tr>
<td>SLEEP</td>
<td>Subroutine</td>
<td>Suspends program execution for a specified number of seconds.</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Function</td>
<td>Executes a command in a separate shell.</td>
</tr>
</tbody>
</table>

**Numeric Values and Conversion**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN</td>
<td>Functions</td>
<td>Return single-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>BIC, BIS</td>
<td>Subroutines</td>
<td>Perform bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>BIT</td>
<td>Function</td>
<td>Performs bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>CDFLOAT</td>
<td>Function</td>
<td>Converts a COMPLEX(4) argument to DOUBLE PRECISION type.</td>
</tr>
<tr>
<td>COMPLINT, COMPLREAL, COMPLLOG</td>
<td>Functions</td>
<td>Return a BIT-WISE complement or logical .NOT. of the argument.</td>
</tr>
<tr>
<td>CSMG</td>
<td>Function</td>
<td>Performs an effective BIT-WISE store under mask.</td>
</tr>
<tr>
<td>DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN</td>
<td>Functions</td>
<td>Return double-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>DFLOATI, DFLOATJ, DFLOATK</td>
<td>Functions</td>
<td>Convert an integer to double-precision real type.</td>
</tr>

<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>IDFLOAT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to double-precision real type.</td>
</tr>
<tr>
<td>IFLOATI, IFLOATJ</td>
<td>Functions</td>
<td>Convert an integer to single-precision real type.</td>
</tr>
<tr>
<td>INMAX</td>
<td>Function</td>
<td>Returns the maximum positive value for an integer.</td>
</tr>
<tr>
<td>INTC</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>IRAND, IRANDM</td>
<td>Functions</td>
<td>Return a positive integer in the range 0 through 2<strong>31-1 or 2</strong>15-1 if called without an argument.</td>
</tr>
<tr>
<td>IRANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>IRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>JABS</td>
<td>Function</td>
<td>Computes an absolute value.</td>
</tr>
<tr>
<td>LONG</td>
<td>Function</td>
<td>Converts an INTEGER(2) argument to INTEGER(4) type.</td>
</tr>
<tr>
<td>QRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for a sequence of pseudo-random numbers.</td>
</tr>
<tr>
<td>RAND, RANDOM2</td>
<td>Functions</td>
<td>Return random values in the range 0 through 1.0.</td>
</tr>
<tr>
<td>RANF</td>
<td>Function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>RANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>SEED</td>
<td>Subroutine</td>
<td>Changes the starting point of RANDOM.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>SRAND</td>
<td>Subroutine</td>
<td>Seeds the random number generator used with IRAND and RAND.</td>
</tr>

</thead>
<tbody>
<tr>
<td>IDATE3</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>IDATE4</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>ITIME</td>
<td>Subroutine</td>
<td>Returns current time as a 3-element array (hour, minute, second).</td>
</tr>
<tr>
<td>JDATE3</td>
<td>Function</td>
<td>Returns current date as an 8-character string with the Julian date.</td>
</tr>
<tr>
<td>JDATE4</td>
<td>Function</td>
<td>Returns current date as a 10-character string with the Julian date.</td>
</tr>
<tr>
<td>LTIME</td>
<td>Subroutine</td>
<td>Returns local time as a 9-element integer array.</td>
</tr>
<tr>
<td>RTC</td>
<td>Function</td>
<td>Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>SECONDS</td>
<td>Function</td>
<td>Returns number of seconds since midnight, less the value of its argument.</td>
</tr>
<tr>
<td>SETDAT</td>
<td>Function</td>
<td>Sets the date.</td>
</tr>
<tr>
<td>SETTIM</td>
<td>Function</td>
<td>Sets the time.</td>
</tr>
<tr>
<td>TIME</td>
<td>Subroutine or Function</td>
<td>As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>TIMEF</td>
<td>Function</td>
<td>Returns the number of seconds since the first time this function was called (or zero).</td>
</tr>
</tbody>
</table>

### Error Handling

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>

<tr>
<td>GETLASTERRORQQ</td>
<td>Function</td>
<td>Returns the last error set by a run-time function or subroutine.</td>
</tr>
<tr>
<td>IERRNO</td>
<td>Function</td>
<td>Returns the last code error.</td>
</tr>
<tr>
<td>SETERRORMODEQQ</td>
<td>Subroutine</td>
<td>Sets the mode for handling critical errors.</td>
</tr>
</tbody>
</table>
### Program Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISEQQ</td>
<td>Function</td>
<td>Sends an interrupt to the executing program, simulating an interrupt from the operating system.</td>
</tr>
<tr>
<td>RUNQQ</td>
<td>Function</td>
<td>Calls another program and waits for it to execute.</td>
</tr>
<tr>
<td>SIGNALQQ</td>
<td>Function</td>
<td>Controls signal handling.</td>
</tr>
<tr>
<td>SLEEPQQ</td>
<td>Subroutine</td>
<td>Delays execution of the program for the specified time.</td>
</tr>
</tbody>
</table>

### System, Drive, and Directory

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHDIR</td>
<td>Function</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>CHANGEDIRQQ</td>
<td>Function</td>
<td>Makes the specified directory the current (default) directory.</td>
</tr>
<tr>
<td>CHANGEDRIVEQQ</td>
<td>Function</td>
<td>Makes the specified drive the current drive.</td>
</tr>
<tr>
<td>DELDIRQQ</td>
<td>Function</td>
<td>Deletes a specified directory.</td>
</tr>
<tr>
<td>GETDRIVEDIRQQ</td>
<td>Function</td>
<td>Returns the current drive and directory path.</td>
</tr>
<tr>
<td>GETDRIVESIZEQQ</td>
<td>Function</td>
<td>Gets the size of the specified drive.</td>
</tr>
<tr>
<td>GETDRIVESQQ</td>
<td>Function</td>
<td>Reports the drives available to the system.</td>
</tr>
<tr>
<td>GETENVQQ</td>
<td>Function</td>
<td>Gets a value from the current environment.</td>
</tr>
<tr>
<td>MAKEDIRQQ</td>
<td>Function</td>
<td>Makes a directory with the specified directory name.</td>
</tr>
<tr>
<td>SETENVQQ</td>
<td>Function</td>
<td>Adds a new environment variable, or sets the value of an existing one.</td>
</tr>
<tr>
<td>SYSTEMQQ</td>
<td>Function</td>
<td>Executes a command by passing a command string to the operating system's command interpreter.</td>
</tr>
</tbody>
</table>

### Speaker

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>Subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
</tbody>
</table>
# File Management

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELFILESQQ</td>
<td>Function</td>
<td>Deletes the specified files in a specified directory.</td>
</tr>
<tr>
<td>FINDFILEQQ</td>
<td>Function</td>
<td>Searches for a file in the directories specified in the PATH environment variable.</td>
</tr>
<tr>
<td>FULLPATHQQ</td>
<td>Function</td>
<td>Returns the full path for a specified file or directory.</td>
</tr>
<tr>
<td>GETFILEINFOQQ</td>
<td>Function</td>
<td>Returns information about files with names that match a request string.</td>
</tr>
<tr>
<td>PACKTIMEQQ</td>
<td>Subroutine</td>
<td>Packs time values for use by SETFILETIMEQQ.</td>
</tr>
<tr>
<td>RENAMEFILEQQ</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>SETFILEACCESSQQ</td>
<td>Function</td>
<td>Sets file-access mode for the specified file.</td>
</tr>
<tr>
<td>SETFILETIMEQQ</td>
<td>Function</td>
<td>Sets modification time for a given file.</td>
</tr>
<tr>
<td>SPLITPATHQQ</td>
<td>Function</td>
<td>Breaks a full path into four components.</td>
</tr>
<tr>
<td>UNPACKTIMEQQ</td>
<td>Subroutine</td>
<td>Unpacks a file’s packed time and date value into its component parts.</td>
</tr>
</tbody>
</table>

# Arrays

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSEARCHQQ</td>
<td>Function</td>
<td>Performs a binary search for a specified element on a sorted one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
<tr>
<td>SORTQQ</td>
<td>Subroutine</td>
<td>Sorts a one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
</tbody>
</table>

# Floating-Point Inquiry and Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEARSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Clears the exception flags in the floating-point processor status word.</td>
</tr>
<tr>
<td>GETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>GETSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor status word.</td>
</tr>
<tr>
<td>LCWRQQ</td>
<td>Subroutine</td>
<td>Same as SETCONTROLFPQQ.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>SCWRQQ</td>
<td>Subroutine</td>
<td>Same as GETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Sets the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>SSWRQQ</td>
<td>Subroutine</td>
<td>Same as GETSTATUSFPQQ.</td>
</tr>
</tbody>
</table>

**IEEE Functionality**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_FLAGS</td>
<td>Function</td>
<td>Sets, gets, or clears IEEE flags.</td>
</tr>
<tr>
<td>IEEE_HANDLER</td>
<td>Function</td>
<td>Establishes a handler for IEEE exceptions.</td>
</tr>
</tbody>
</table>

**Serial Port I/O**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPORT_CANCEL_IO</td>
<td>Function</td>
<td>Cancels any I/O in progress to the specified port.</td>
</tr>
<tr>
<td>SPORT_CONNECT</td>
<td>Function</td>
<td>Establishes the connection to a serial port and defines certain usage parameters.</td>
</tr>
<tr>
<td>SPORT_CONNECT_EX</td>
<td>Function</td>
<td>Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.</td>
</tr>
<tr>
<td>SPORT_GET_HANDLE</td>
<td>Function</td>
<td>Returns the Windows* handle associated with the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits, and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE_EX</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_TIMEOUTS</td>
<td>Function</td>
<td>Returns the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_PEEK_DATA</td>
<td>Function</td>
<td>Returns information about the availability of input data.</td>
</tr>
<tr>
<td>SPORT_PEEK_LINE</td>
<td>Function</td>
<td>Returns information about the availability of input records.</td>
</tr>
<tr>
<td>SPORT_PURGE</td>
<td>Function</td>
<td>Executes a purge function on the specified port.</td>
</tr>
<tr>
<td>SPORT_READ_DATA</td>
<td>Function</td>
<td>Reads available data from the port specified.</td>
</tr>
<tr>
<td>SPORT_READ_LINE</td>
<td>Function</td>
<td>Reads a record from the port specified.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SPORT_RELEASE</td>
<td>Function</td>
<td>Releases a serial port that has previously been connected.</td>
</tr>
<tr>
<td>SPORT_SET_STATE</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_STATE_EX</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_TIMEOUTS</td>
<td>Function</td>
<td>Sets the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_SHOW_STATE</td>
<td>Function</td>
<td>Displays the state of a port.</td>
</tr>
<tr>
<td>SPORT_SPECIAL_FUNC</td>
<td>Function</td>
<td>Executes a communications function on a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_DATA</td>
<td>Function</td>
<td>Outputs data to a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_LINE</td>
<td>Function</td>
<td>Outputs data to a specified port and follows it with a record terminator.</td>
</tr>
</tbody>
</table>

**Miscellaneous**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNBLNK</td>
<td>Function</td>
<td>Returns the index of the last non-blank character in a string.</td>
</tr>
<tr>
<td>QSORT</td>
<td>Subroutine</td>
<td>Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.</td>
</tr>
<tr>
<td>RINDEX</td>
<td>Function</td>
<td>Returns the index of the last occurrence of a substring in a string.</td>
</tr>
<tr>
<td>SCANENV</td>
<td>Subroutine</td>
<td>Scans the environment for the value of an environment variable.</td>
</tr>
<tr>
<td>TTYNAM</td>
<td>Subroutine</td>
<td>Checks whether a logical unit is a terminal.</td>
</tr>
</tbody>
</table>

1 This routine can also be specified as HOSTNM.
2 There is also a RANDOM subroutine in the portability library.
3 The two-digit year return value of DATE, IDATE, and JDATE may cause problems with the year 2000. Use the intrinsic subroutine DATE_AND_TIME instead.
4 W*S

**National Language Support Library Routines (W*S)**

The following table lists library routines for National Language Support (NLS).

Programs that use these routines must access the NLS library with USE IFNLS. These routines are restricted to Windows* systems.
Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBCharLen</td>
<td>Function</td>
<td>Returns the length of the first multibyte character in a string.</td>
</tr>
<tr>
<td>MBConvertMBToUnicode</td>
<td>Function</td>
<td>Converts a character string from a multibyte codepage to a Unicode string.</td>
</tr>
<tr>
<td>MBConvertUnicodeToMB</td>
<td>Function</td>
<td>Converts a Unicode string to a multibyte character string of the current codepage.</td>
</tr>
<tr>
<td>MBCurMax</td>
<td>Function</td>
<td>Returns the longest possible multibyte character for the current codepage.</td>
</tr>
<tr>
<td>MBINCHARQQ</td>
<td>Function</td>
<td>Same as INCHARQQ, but can read a single multibyte character at once.</td>
</tr>
<tr>
<td>MBINDEX</td>
<td>Function</td>
<td>Same as INDEX, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBJISToJMS</td>
<td>Function</td>
<td>Converts a Japan Industry Standard (JIS) character to a Kanji (Shift JIS or JMS) character.</td>
</tr>
<tr>
<td>MBJMSToJIS</td>
<td>Function</td>
<td>Converts a Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.</td>
</tr>
<tr>
<td>MBLLead</td>
<td>Function</td>
<td>Determines whether a given character is the first byte of a multibyte character.</td>
</tr>
<tr>
<td>MBLen</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, including trailing spaces.</td>
</tr>
<tr>
<td>MBLen_Trim</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, not including trailing spaces.</td>
</tr>
<tr>
<td>MBLGE, MBLGT, MBLLE, MBLLT,MBLEQ, MBLNE</td>
<td>Function</td>
<td>Same as LGE, LGT, LLE, and LLT, and the logical operators .EQ. and .NE., except that multibyte characters can be included in their arguments.</td>
</tr>
<tr>
<td>MBNext</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately after the given string position.</td>
</tr>
<tr>
<td>MBPrev</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately before the given string position.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MBSCAN</td>
<td>Function</td>
<td>Same as SCAN, except that multibyte characters can be included in its arguments</td>
</tr>
<tr>
<td>MBStrLead</td>
<td>Function</td>
<td>Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.</td>
</tr>
<tr>
<td>MBVERIFY</td>
<td>Function</td>
<td>Same as VERIFY, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>NLSEnumCodepages</td>
<td>Function</td>
<td>Returns an array of valid codepages for the current console.</td>
</tr>
<tr>
<td>NLSEnumLocales</td>
<td>Function</td>
<td>Returns an array of locales (language/country combinations) installed on the system.</td>
</tr>
<tr>
<td>NLSFormatCurrency</td>
<td>Function</td>
<td>Formats a currency number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatDate</td>
<td>Function</td>
<td>Formats a date according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatNumber</td>
<td>Function</td>
<td>Formats a number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatTime</td>
<td>Function</td>
<td>Formats a time according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSGetEnvironmentCodepage</td>
<td>Function</td>
<td>Returns the current codepage for the system Window or console.</td>
</tr>
<tr>
<td>NLSGetLocale</td>
<td>Subroutine</td>
<td>Returns the current language, country, and/or codepage.</td>
</tr>
<tr>
<td>NLSGetLocaleInfo</td>
<td>Function</td>
<td>Returns information about the current locale.</td>
</tr>
<tr>
<td>NLSSetEnvironmentCodepage</td>
<td>Function</td>
<td>Sets the codepage for the console.</td>
</tr>
<tr>
<td>NLSSetLocale</td>
<td>Function</td>
<td>Sets the current language, country, and codepage.</td>
</tr>
</tbody>
</table>

**POSIX* Library Procedures**

The following table lists library procedures for POSIX*.

Programs that use POSIX procedures must access the appropriate libraries with USE IFPOSIX. The IPX nnnn routines are functions; the PXF nnnn routines are subroutines, except for the routines named PXFIS nnnn and PXFWIF nnnn.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPXFARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>IPXFCONST</td>
<td>Returns the value associated with a constant defined in the C POSIX standard.</td>
</tr>
<tr>
<td>IPXFLENTTRIM</td>
<td>Returns the index of the last non-blank character in an input string.</td>
</tr>
<tr>
<td>IPXFWEXITSTATUS1</td>
<td>Returns the exit code of a child process.</td>
</tr>
<tr>
<td>IPXFWSTOPSIG1</td>
<td>Returns the number of the signal that caused a child process to stop.</td>
</tr>
<tr>
<td>IPXFWTERMSIG1</td>
<td>Returns the number of the signal that caused a child process to terminate.</td>
</tr>
<tr>
<td>PXF(type)GET</td>
<td>Gets the value stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXF(type)SET</td>
<td>Sets the value of a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)GET</td>
<td>Gets the array values stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)SET</td>
<td>Sets the value of an array component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFACCESS</td>
<td>Determines the accessibility of a file.</td>
</tr>
<tr>
<td>PXFALARM</td>
<td>Schedules an alarm.</td>
</tr>
<tr>
<td>PXFCALLSUBHANDLE</td>
<td>Calls the associated subroutine.</td>
</tr>
<tr>
<td>PXFCFGETISPEED1</td>
<td>Returns the input baud rate from a <code>termios</code> structure.</td>
</tr>
<tr>
<td>PXFCFGETOSPEED1</td>
<td>Returns the output baud rate from a <code>termios</code> structure.</td>
</tr>
<tr>
<td>PXFCFSETISPEED1</td>
<td>Sets the input baud rate in a <code>termios</code> structure.</td>
</tr>
<tr>
<td>PXFCFSETOSPEED1</td>
<td>Sets the output baud rate in a <code>termios</code> structure.</td>
</tr>
<tr>
<td>PXFCHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>PXFCHMOD</td>
<td>Changes the ownership mode of the file.</td>
</tr>
<tr>
<td>PXFCHOWN1</td>
<td>Changes the owner and group of the file.</td>
</tr>
<tr>
<td>PXFCLEARENV</td>
<td>Clears the process environment.</td>
</tr>
<tr>
<td>PXFCLOSE</td>
<td>Closes the file associated with the descriptor.</td>
</tr>
<tr>
<td>PXFCLOSEDIR</td>
<td>Closes the directory stream.</td>
</tr>
<tr>
<td>PXFCNTL1</td>
<td>Generates a terminal pathname.</td>
</tr>
<tr>
<td>PXFCREAT</td>
<td>Creates a new file or rewrites an existing file.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFDUP, PXFDUP2</td>
<td>Duplicates an existing file descriptor.</td>
</tr>
<tr>
<td>PXFE(type)GET</td>
<td>Gets the value stored in an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFE(type)SET</td>
<td>Sets the value of an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFEXEV, PXFEXECVE, PXFEXECVP</td>
<td>Executes a new process by passing command-line arguments.</td>
</tr>
<tr>
<td>PXFEXIT, PXFFASTEXIT</td>
<td>Exits from a process.</td>
</tr>
<tr>
<td>PXFFDOPEN</td>
<td>Opens an external unit.</td>
</tr>
<tr>
<td>PXFFFLUSH</td>
<td>Flushes a file directly to disk.</td>
</tr>
<tr>
<td>PXFFGETC</td>
<td>Reads a character from a file.</td>
</tr>
<tr>
<td>PXFFILENO</td>
<td>Returns the file descriptor associated with a specified unit.</td>
</tr>
<tr>
<td>PXFFORK¹</td>
<td>Creates a child process that differs from the parent process only in its PID.</td>
</tr>
<tr>
<td>PXFFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFFPUTC</td>
<td>Writes a character to a file.</td>
</tr>
<tr>
<td>PXFFSEEK</td>
<td>Modifies a file position.</td>
</tr>
<tr>
<td>PXFFSTAT</td>
<td>Gets a file's status information.</td>
</tr>
<tr>
<td>PXFFTELL</td>
<td>Returns the relative position in bytes from the beginning of the file.</td>
</tr>
<tr>
<td>PXFGETARG</td>
<td>Gets the specified command-line argument.</td>
</tr>
<tr>
<td>PXFGETC</td>
<td>Reads a character from standard input unit 5.</td>
</tr>
<tr>
<td>PXFGETCWD</td>
<td>Returns the path of the current working directory.</td>
</tr>
<tr>
<td>PXFGETEgid¹</td>
<td>Gets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETENV</td>
<td>Gets the setting of an environment variable.</td>
</tr>
<tr>
<td>PXFGETEUID¹</td>
<td>Gets the effective user ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGID¹</td>
<td>Gets the real group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGRGID¹</td>
<td>Gets group information for the specified GID.</td>
</tr>
<tr>
<td>PXFGETGRNAM¹</td>
<td>Gets group information for the named group.</td>
</tr>
<tr>
<td>PXFGETGROUPS¹</td>
<td>Gets supplementary group IDs.</td>
</tr>
<tr>
<td>PXFGETLOGIN</td>
<td>Gets the name of the user.</td>
</tr>
<tr>
<td>PXFGETPGRP¹</td>
<td>Gets the process group ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPID</td>
<td>Gets the process ID of the calling process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFGETPPID</td>
<td>Gets the process ID of the parent of the calling process.</td>
</tr>
<tr>
<td>PXFGETPWNUM</td>
<td>Gets password information for a specified name.</td>
</tr>
<tr>
<td>PXFGETPWUID</td>
<td>Gets password information for a specified UID.</td>
</tr>
<tr>
<td>PXFGETSUBHANDLE</td>
<td>Returns a subroutine handle for a subroutine.</td>
</tr>
<tr>
<td>PXFGETUID</td>
<td>Gets the real user ID of the current process.</td>
</tr>
<tr>
<td>PXFISATTY</td>
<td>Tests whether a file descriptor is connected to a terminal.</td>
</tr>
<tr>
<td>PXFISBLK</td>
<td>Tests for a block special file.</td>
</tr>
<tr>
<td>PXFISCHR</td>
<td>Tests for a character file.</td>
</tr>
<tr>
<td>PXFISCONST</td>
<td>Tests whether a string is a valid constant name.</td>
</tr>
<tr>
<td>PXFISDIR</td>
<td>Tests whether a file is a directory.</td>
</tr>
<tr>
<td>PXFISFIFO</td>
<td>Tests whether a file is a special FIFO file.</td>
</tr>
<tr>
<td>PXFISREG</td>
<td>Tests whether a file is a regular file.</td>
</tr>
<tr>
<td>PXFKILL</td>
<td>Sends a signal to a specified process.</td>
</tr>
<tr>
<td>PXFLINK</td>
<td>Creates a link to a file or directory.</td>
</tr>
<tr>
<td>PXFLOCALTIME</td>
<td>Converts a given elapsed time in seconds to local time.</td>
</tr>
<tr>
<td>PXFLSEEK</td>
<td>Positions a file a specified distance in bytes.</td>
</tr>
<tr>
<td>PXFMKDIR</td>
<td>Creates a new directory.</td>
</tr>
<tr>
<td>PXFMKFIFO</td>
<td>Creates a new FIFO.</td>
</tr>
<tr>
<td>PXFOPEN</td>
<td>Opens or creates a file.</td>
</tr>
<tr>
<td>PXFOPENDIR</td>
<td>Opens a directory and associates a stream with it.</td>
</tr>
<tr>
<td>PXFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFPAUSE</td>
<td>Suspends process execution.</td>
</tr>
<tr>
<td>PXFPIPE</td>
<td>Creates a communications pipe between two processes.</td>
</tr>
<tr>
<td>PXFPOSIXIO</td>
<td>Sets the current value of the POSIX I/O flag.</td>
</tr>
<tr>
<td>PXFPUTC</td>
<td>Outputs a character to logical unit 6 (stdout).</td>
</tr>
<tr>
<td>PXFREAD</td>
<td>Reads from a file.</td>
</tr>
<tr>
<td>PXFREADDIR</td>
<td>Reads the current directory entry.</td>
</tr>
<tr>
<td>PXFRENAME</td>
<td>Changes the name of a file.</td>
</tr>
<tr>
<td>PXFREGINNDDIR</td>
<td>Resets the position of the stream to the beginning of the directory.</td>
</tr>
<tr>
<td>PXFRMDIR</td>
<td>Removes a directory.</td>
</tr>
</tbody>
</table>

1. Indicates that the function is 1 argument.
<table>

COM and Automation Library Routines (W*S)
The following tables list COM and Automation library routines.

Programs that use COM routines must access the appropriate libraries with USE IFCOM. Programs that use automation routines must access the appropriate libraries with USE IFAUTO. Some procedures also require the USE IFWINTY module.

The COM and Automation routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.
## Component Object Model (COM) Procedures (USE IFCOM)

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMAddObjectReference</td>
<td>Function</td>
<td>Adds a reference to an object's interface.</td>
</tr>
<tr>
<td>COMCLSIDFromProgID</td>
<td>Subroutine</td>
<td>Passes a programmatic identifier and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCLSIDFromString</td>
<td>Subroutine</td>
<td>Passes a class identifier string and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCreateObject</td>
<td>Subroutine</td>
<td>A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.</td>
</tr>
<tr>
<td>COMCreateObjectByGUID</td>
<td>Subroutine</td>
<td>Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.</td>
</tr>
<tr>
<td>COMCreateObjectByProgID</td>
<td>Subroutine</td>
<td>Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object's IDispatch interface.</td>
</tr>
<tr>
<td>COMGetActiveObjectByGUID</td>
<td>Subroutine</td>
<td>Passes a class identifier and returns a pointer to the interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetActiveObjectByProgID</td>
<td>Subroutine</td>
<td>Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetFileObject</td>
<td>Subroutine</td>
<td>Passes a file name and returns a pointer to the IDispatch interface of an Automation object that can manipulate the file.</td>
</tr>
<tr>
<td>COMInitialize</td>
<td>Subroutine</td>
<td>Initializes the COM library.</td>
</tr>
<tr>
<td>COMIsEqualGUID</td>
<td>Function</td>
<td>Determines whether two GUIDs are the same.</td>
</tr>
<tr>
<td>COMQueryInterface</td>
<td>Subroutine</td>
<td>Passes an interface identifier and returns a pointer to an object's interface.</td>
</tr>
<tr>
<td>COMReleaseObject</td>
<td>Function</td>
<td>Indicates that the program is done with a reference to an object's interface.</td>
</tr>
<tr>
<td>COMStringFromGUID</td>
<td>Subroutine</td>
<td>Passes a GUID and returns a string of printable characters.</td>
</tr>
<tr>
<td>COMUninitialize</td>
<td>Subroutine</td>
<td>Uninitializes the COM library.</td>
</tr>
</tbody>
</table>
### Automation Server Procedures (USE IFAUTO)

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOAddArg</td>
<td>Subroutine</td>
<td>Passes an argument name and value and adds the argument to the argument list data structure.</td>
</tr>
<tr>
<td>AUTOAllocateInvokeArgs</td>
<td>Function</td>
<td>Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.</td>
</tr>
<tr>
<td>AUTODeallocateInvokeArgs</td>
<td>Subroutine</td>
<td>Deallocates an argument list data structure.</td>
</tr>
<tr>
<td>AUTOGetExceptInfo</td>
<td>Subroutine</td>
<td>Retrieves the exception information when a method has returned an exception status.</td>
</tr>
<tr>
<td>AUTOGetProperty</td>
<td>Function</td>
<td>Passes the name or identifier of the property and gets the value of the Automation object’s property.</td>
</tr>
<tr>
<td>AUTOGetPropertyByID</td>
<td>Function</td>
<td>Passes the member ID of the property and gets the value of the Automation object’s property into the argument list’s first argument.</td>
</tr>
<tr>
<td>AUTOGetPropertyInvokeArgs</td>
<td>Function</td>
<td>Passes an argument list data structure and gets the value of the Automation object’s property specified in the argument list’s first argument.</td>
</tr>
<tr>
<td>AUTOInvoke</td>
<td>Function</td>
<td>Passes the name or identifier of an object’s method and an argument list data structure and invokes the method with the passed arguments.</td>
</tr>
<tr>
<td>AUTOSetProperty</td>
<td>Function</td>
<td>Passes the name or identifier of the property and a value, and sets the value of the Automation object’s property.</td>
</tr>
<tr>
<td>AUTOSetPropertyByID</td>
<td>Function</td>
<td>Passes the member ID of the property and sets the value of the Automation object’s property, using the argument list’s first argument.</td>
</tr>
<tr>
<td>AUTOSetPropertyInvokeArgs</td>
<td>Function</td>
<td>Passes an argument list data structure and sets the value of the Automation object’s property specified in the argument list’s first argument.</td>
</tr>
</tbody>
</table>

1These routines also require USE IFWINTY.
## Miscellaneous Run-Time Library Routines

The following table lists miscellaneous run-time library routines. Programs that use most of these routines should contain a USE IFCORE statement to obtain the proper interfaces to these routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMITQQ</td>
<td>Function</td>
<td>Forces the operating system to execute any pending write operations for a file.</td>
</tr>
<tr>
<td>FOR_DESCRIPTOR_ASSIGN(^1)</td>
<td>Subroutine</td>
<td>Creates an array descriptor in memory.</td>
</tr>
<tr>
<td>FOR_GET_FPE</td>
<td>Function</td>
<td>Returns the current settings of floating-point exception flags.</td>
</tr>
<tr>
<td>FOR_GET_HBW_AVAILABILITY</td>
<td>Function</td>
<td>Returns the availability of High Bandwidth (HBW) memory for a program.</td>
</tr>
<tr>
<td>FOR_GET_HBW_SIZE</td>
<td>Function</td>
<td>Returns the available free high-bandwidth memory and the total high-bandwidth memory that is available on a node of the High Bandwidth Memory partition.</td>
</tr>
<tr>
<td>FOR_LFENCE</td>
<td>Subroutine</td>
<td>Inserts a memory load fence instruction that ensures completion of preceding load instructions.</td>
</tr>
<tr>
<td>FOR_MFENCE</td>
<td>Subroutine</td>
<td>Inserts a memory access fence instruction that ensures completion of preceding memory access instructions.</td>
</tr>
<tr>
<td>for_rtl_finish_(^2)</td>
<td>Function</td>
<td>Cleans up the Fortran run-time environment.</td>
</tr>
<tr>
<td>for_rtl_init_(^2)</td>
<td>Function</td>
<td>Initializes the Fortran run-time environment.</td>
</tr>
<tr>
<td>FOR_SET_FASTMEM_POLICY</td>
<td>Function</td>
<td>Sets or gets the value of the Fortran Run-Time Library (RTL) FASTMEM policy mode, which is the desired action to occur when an ALLOCATE statement requests FASTMEM/HBW memory, but it is not available to the program or node.</td>
</tr>
<tr>
<td>FOR_SET_FPE</td>
<td>Function</td>
<td>Sets the floating-point exception flags.</td>
</tr>
<tr>
<td>FOR_SET_FTN_ALLOC</td>
<td>Function</td>
<td>Tells the Fortran Run-Time Library (RTL) to use a user-defined routine to dynamically allocate commons.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FOR_SET_REENTRANCY</td>
<td>Function</td>
<td>Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits.</td>
</tr>
<tr>
<td>FOR_SFENCE</td>
<td>Subroutine</td>
<td>Inserts a memory store fence instruction that ensures completion of preceding store instructions.</td>
</tr>
<tr>
<td>GERROR</td>
<td>Subroutine</td>
<td>Returns a message for the last error detected by a Fortran runtime routine.</td>
</tr>
<tr>
<td>GETCHARQQ</td>
<td>Function</td>
<td>Returns the next keystroke.</td>
</tr>
<tr>
<td>GETEXCEPTIONPTRSQL</td>
<td>Function</td>
<td>Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Function</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
<tr>
<td>PERROR</td>
<td>Subroutine</td>
<td>Sends a message to the standard error stream, preceded by a specified string, for the last detected error.</td>
</tr>
<tr>
<td>TRACEBACKQQ</td>
<td>Subroutine</td>
<td>Provides traceback information.</td>
</tr>
</tbody>
</table>

1 W*S
2 You do not need a USE IFCORE statement for this routine.

### A to B

#### ABORT

*Portability Subroutine:* Flushes and closes I/O buffers, and terminates program execution.

**Module**

USE IFPORT

**Syntax**

CALL ABORT[string]
string (Input; optional) Character(*). Allows you to specify an abort message at program termination. When ABORT is called, "abort:" is written to external unit 0, followed by string. If omitted, the default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the program that launched it.

Example

USE IFPORT
!The following prints "abort: Fortran Abort Called"
CALL ABORT
!The following prints "abort: Out of here!"
Call ABORT ("Out of here!")

See Also
EXIT
STOP

ABOUTBOXQQ (W*S)
QuickWin Function: Specifies the information displayed in the message box that appears when the user selects the About command from a QuickWin application’s Help menu.

Module
USE IFQWIN

Syntax
result=ABOUTBOXQQ(cstring)

cstring (Input; output) Character(*). Null-terminated C string.

Results
The value of the result is INTEGER(4). It is zero if successful; otherwise, nonzero.
If your program does not call ABOUTBOXQQ, the QuickWin run-time library supplies a default string.

Example

USE IFQWIN
  INTEGER(4) dummy
! Set the About box message
dummy = ABOUTBOXQQ ('Matrix Multiplier\r      Version 1.0'C)

ABS
Elemental Intrinsic Function (Generic): Computes an absolute value.

Syntax
result=ABS(a)
a

(Input) Must be of type integer, real, or complex.

Results

The result has the same type and kind type parameter as a except if a is complex value, the result type is real. If a is an integer or real value, the value of the result is | a |; if a is a complex value (X, Y), the result is the real value SQRT (X**2 + Y**2).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CABS 3</td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>CDABS^4</td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>CQABS</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

^1 Or HABS.

^2 Or JIABS. For compatibility with older versions of Fortran, IABS can also be specified as a generic function, which allows integer arguments of any kind and produces a result of type default INTEGER.

^3 The setting of compiler options specifying real size can affect CABS, making CABS generic, which allows a complex argument of any kind to produce a result of default REAL.

^4 This function can also be specified as ZABS.

Example

ABS (-7.4) has the value 7.4.

ABS ((6.0, 8.0)) has the value 10.0.

The following ABS.F90 program calculates two square roots, retaining the sign:

```
REAL mag(2), sgn(2), result(2)
WRITE (*, '(A)') ' Enter two signed magnitudes: '
READ (*, *) mag
sgn = SIGN((/1.0, 1.0/), mag) ! transfer the signs to 1.0s
result = SQRT (ABS (mag))
! Restore the sign by multiplying by -1 or +1:
result = result * sgn
WRITE (*, '*') result
END
```

ABSTRACT INTERFACE

Statement: Defines an abstract interface.
### Syntax

**ABSTRACT INTERFACE**

```
[interface-body]...
```

**END INTERFACE**

**interface-body**

Is one or more function or subroutine subprograms or a procedure pointer. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

The subprogram must not contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

The subprogram can contain a USE statement.

### Description

An abstract interface block defines an interface whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics.

An abstract interface block cannot contain a PROCEDURE statement or a MODULE PROCEDURE statement.

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

### Example

Previously, within an interface block, you needed to individually declare subroutines and functions that had the same argument keywords and characteristics. For example:

```fortran
INTERFACE
  SUBROUTINE SUB_ONE (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE SUB_ONE
  SUBROUTINE SUB_TWO (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE SUB_TWO
  ...
END INTERFACE
```

Now you can use an abstract interface to specify a subprogram name for these identical arguments and characteristics. For example:

```fortran
ABSTRACT INTERFACE
  SUBROUTINE TEMPLATE (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE TEMPLATE
END INTERFACE
```
You can then use the subprogram in the abstract interface as a template in a PROCEDURE statement to declare procedures. For example:

```
PROCEDURE (TEMPLATE) :: SUB_ONE, SUB_TWO, ...
```

**See Also**
- INTERFACE
- PROCEDURE
- FUNCTION
- SUBROUTINE
- Procedure Interfaces
- Use and Host Association

**ACCEPT**

**Statement:** Transfers input data.

**Syntax**

**Formatted:**

```
ACCEPT form[,io-list]
```

**Formatted - List-Directed:**

```
ACCEPT *[,io-list]
```

**Formatted - Namelist:**

```
ACCEPT nml
```

- `form` Is the nonkeyword form of a format specifier (no FMT=).
- `io-list` Is an I/O list.
- `*` Is the format specifier indicating list-directed formatting.
- `nml` Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

The ACCEPT statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using environment variable FOR_ACCEPT.

**Example**

In the following example, character data is read from the implicit unit and binary values are assigned to each of the five elements of array CHARAR:

```
CHARACTER*10 CHARAR(5)
ACCEPT 200, CHARAR
200 FORMAT (5A10)
```

**ACCESS Function**

**Portability Function:** Determines if a file exists and how it can be accessed.

**Module**

```
USE IFPORT
```
Syntax

\[
\text{result} = \text{ACCESS}(\text{name, mode})
\]

\text{name} (Input) Character*(*). Name of the file whose accessibility is to be determined.

\text{mode} (Input) Character*(*). Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Tests for read permission</td>
</tr>
<tr>
<td>w</td>
<td>Tests for write permission</td>
</tr>
<tr>
<td>x</td>
<td>Tests for execute permission. On Windows* systems, the extension of \text{name} must be .COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.</td>
</tr>
<tr>
<td>(blank)</td>
<td>Tests for existence</td>
</tr>
</tbody>
</table>

The characters within \text{mode} can appear in any order or combination. For example, \text{wrx} and \text{r} are legal forms of \text{mode} and represent the same set of inquiries.

Results

The value of the result is INTEGER(4). It is zero if all inquiries specified by \text{mode} are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:

- EACCESS: Access denied; the file’s permission setting does not allow the specified access
- EINVAL: The mode argument is invalid
- ENOENT: File or path not found

For a list of error codes, see IERRNO.

The \text{name} argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

Example

use ifport

! checks for read and write permission on the file "DATAFILE.TXT"
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J

! checks whether "DATAFILE.TXT" is executable. It is not, since
! it does not end in .COM, .EXE, .BAT, or .CMD
J = ACCESS ("DATAFILE.TXT","x")
PRINT *, J

See Also

INQUIRE
GETFILEINFOQQ
**ACHAR**

**Elemental Intrinsic Function (Generic):** Returns the character in a specified position of the ASCII character set, even if the processor's default character set is different. It is the inverse of the IACHAR function. In Intel® Fortran, ACHAR is equivalent to the CHAR function.

**Syntax**

\[
\text{result} = \text{ACHAR} \left( i [\text{, kind}] \right)
\]

- \(i\) (Input) Is of type integer.
- \(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is character with length 1. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \(i\) has a value within the range 0 to 127, the result is the character in position \(i\) of the ASCII character set; otherwise, it is processor defined. ACHAR (IACHAR(C)) has the value C for any character C capable of representation in the default character set. For a complete list of ASCII character codes, see Character and Key Code Charts.

**Example**

ACHAR (71) has the value 'G'.

ACHAR (63) has the value '?'.

**See Also**

CHAR
IACHAR
ICHAR

**ACOS**

**Elemental Intrinsic Function (Generic):** Produces the arccosine of \(x\).

**Syntax**

\[
\text{result} = \text{ACOS} \left( x \right)
\]

- \(x\) (Input) Must be of type real, where \(|x| \leq 1\), or of type complex.

**Results**

The result type and kind are the same as \(x\) and is expressed in radians.

If the result is real, the value is expressed in radians and lies in the range \(0 \leq \text{ACOS}(X) \leq \pi\).

If the result is complex, the real part is expressed in radians and lies in the range \(0 \leq \text{REAL(ACOS (x))} \leq \pi\).
<table>

¹The setting of compiler options specifying real size can affect ACOS and DACOS.
²Or QARCOS.

**Example**

ACOS (0.68032123) has the value .8225955.

**ACOSD**

*Elemental Intrinsic Function (Generic): Produces the arccosine of x.*

**Syntax**

\[ \text{result} = \text{ACOSD} (x) \]

\( x \) (Input) Must be of type real. The \( |x| \) must be less than or equal to 1.

**Results**

The result type and kind are the same as \( x \) and are expressed in degrees. The value lies in the range \(-90\) to \(90\) degrees.

<table>

</tbody>
</table>

¹The setting of compiler options specifying real size can affect ACOSD and DACOSD.

**Example**

ACOSD (0.886579) has the value 27.55354.

**ACOSH**

*Elemental Intrinsic Function (Generic): Produces the hyperbolic arccosine of x.*

**Syntax**

\[ \text{result} = \text{ACOSH} (x) \]

\( x \) (Input) Must be of type real, where \( x \) must be greater than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as \( x \).
If the result is complex, the imaginary part is expressed in radians and lies in the range \(0 \leq \text{AIMAG \ (ACOSH} (x)) \leq \pi\).

<table>
<thead>
<tr>
<th>Specific Name</th>

</tr>
<tr>
<td>QACOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ACOSH and DACOSH.

**Example**

ACOSH (1.0) has the value 0.0.

ACOSH (180.0) has the value 5.8861.

**ADJUSTL**

**Elemental Intrinsic Function (Generic):** Adjusts a character string to the left, removing leading blanks and inserting trailing blanks.

**Syntax**

\[\text{result} = \text{ADJUSTL} (\text{string})\]

\[\text{string} \quad \text{(Input) Must be of type character.}\]

**Results**

The result type is character with the same length and kind parameter as \text{string}. The value of the result is the same as \text{string}, except that any leading blanks have been removed and inserted as trailing blanks.

**Example**

```
CHARACTER(16) STRING
STRING= ADJUSTL('    Fortran 90    ') ! returns 'Fortran 90    '
ADJUSTL ('    SUMMERTIME') ! has the value 'SUMMERTIME    '
```

**See Also**

ADJUSTR

**ADJUSTR**

**Elemental Intrinsic Function (Generic):** Adjusts a character string to the right, removing trailing blanks and inserting leading blanks.

**Syntax**

\[\text{result} = \text{ADJUSTR} (\text{string})\]

\[\text{string} \quad \text{(Input) Must be of type character.}\]

**Results**

The result type is character with the same length and kind parameter as \text{string}.
The value of the result is the same as string, except that any trailing blanks have been removed and inserted as leading blanks.

**Example**

```fortran
CHARACTER(16) STRING
STRING= ADJUSTR('   Fortran 90   ') ! returns '     Fortran 90'
ADJUSTR ('SUMMERTIME    ')     ! has the value '    SUMMERTIME'
```

**See Also**

ADJUSTL

**AIMAG**

*Elemental Intrinsic Function (Generic):* Returns the imaginary part of a complex number. *This function can also be specified as IMAG.*

**Syntax**

```fortran
result = AIMAG (z)
```

z (Input) Must be of type complex.

**Results**

The result type is real with the same kind parameter as z. If z has the value (x, y), the result has the value y.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIMAG ¹</td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DIMAG</td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QIMAG</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying real size can affect AIMAG.

To return the real part of complex numbers, use REAL.

**Example**

AIMAG ((4.0, 5.0)) has the value 5.0.

If C is complex, C%IM is the same as AIMAG (C).

The program AIMAG.F90 applies the quadratic formula to a polynomial and allows for complex results:

```fortran
REAL a, b, c
COMPLEX ans1, ans2, d
WRITE ( *, 100)
100 FORMAT (' Enter A, b, and c of the ', &
             'polynomial ax**2 + bx + c: ')
READ (*, *) a, b, c
d = CSQRT (CMPLX (b**2 - 4.0*a*c))  ! d is either:
   ! 0.0 + i root, or
   ! root + i 0.0
ans1 = (-b + d) / (2.0 * a)
ans2 = (-b + d) / (2.0 * a)
WRITE (*, 200)
200 FORMAT (' The roots are:' )
```
WRITE (*, 300) REAL(ans1), AIMAG(ans1), &
     REAL(ans2), AIMAG(ans2)
300 FORMAT (' X = ', F10.5, ' + i', F10.5)
END

CONJG
DBLE

AINT
Elemental Intrinsic Function (Generic): Truncates
a value to a whole number.

Syntax
result = AINT (a [,kind])

a  (Input) Must be of type real.

kind (Input; optional) Must be a scalar integer constant expression.

Results
The result type is real. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter is that of a.

The result is defined as the largest integer whose magnitude does not exceed the magnitude of a and whose sign is the same as that of a. If | a | is less than 1, AINT( a ) has the value zero.

Specific Name | Argument Type | Result Type
--- | --- | ---
AINT ¹ | REAL(4) | REAL(4)
DINT ¹ | REAL(8) | REAL(8)
QINT | REAL(16) | REAL(16)

¹The setting of compiler options specifying real size can affect AINT and DINT.

To round rather than truncate, use **ANINT**.

Example
AINT (3.678) has the value 3.0.

AINT (-1.375) has the value -1.0.

REAL r1, r2
REAL(8) r3(2)
r1 = AINT(2.6)  ! returns the value 2.0
r2 = AINT(-2.6) ! returns the value -2.0
r3 = AINT((/1.3, 1.9/), KIND = 8) ! returns the values (1.0D0, 1.0D0)

See Also
ANINT
**ALARM**

*Portability Function:* Causes a subroutine to begin execution after a specified amount of time has elapsed.

---

**Module**

USE IFPORT

**Syntax**

```
result = ALARM (time, proc)
```

- **time** (Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when proc is to begin execution. If time is 0, the alarm is turned off and no routine is called.

- **proc** (Input) Name of the procedure to call. The procedure takes no arguments and must be declared EXTERNAL.

**Results**

The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After ALARM is called and the timer starts, the calling program continues for time seconds. The calling program then suspends and calls proc, which runs in another thread. When proc finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If proc performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries.

The thread that proc runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until proc terminates, or is blocked on some other event, such as I/O.

No alarms can occur after the main process ends. If the main program finishes or any thread executes an EXIT call, than any pending alarm is deactivated before it has a chance to run.

**Example**

```
USE IFPORT
INTEGER(4) numsec, istat
EXTERNAL subprog
numsec = 4
write *, 'subprog will begin in ', numsec, ' seconds'
ISTAT = ALARM (numsec, subprog)
```

**See Also**

RUNQQ

---

**ALIAS Directive**

*General Compiler Directive:* Declares alternate external names for external subprograms.

**Syntax**

```
!DIR$ ALIAS internal-name,external-name
```
**internal-name**

The name of the entity as used in the current program unit. It can be a procedure name, a COMMON block name, a module variable that is initialized, or a PARAMETER in a module. It may not be the name of an internal procedure.

**external-name**

A name or a character constant, delimited by apostrophes or quotation marks.

If a name is specified, the name (in uppercase) is used as the external name for the specified internal-name. If a character constant is specified, it is used as is; the string is not changed to uppercase, nor are blanks removed.

The ALIAS directive affects only the external name used for references to the specified internal-name.

Names that are not acceptable to the linker will cause link-time errors.

**See Also**

ATTRIBUTES ALIAS
ATTRIBUTES DECORATE
ATTRIBUTES DEFAULT
General Compiler Directives
Syntax Rules for Compiler Directives

**ALIGNED Clause**

**Parallel Directive Clause:** Specifies that all variables in a list are aligned.

**Syntax**

ALIGNED (list [:n])

- **list**
  
  Is the name of one or more variables. Each name must be separated by a comma. Any variable that appears in list cannot appear in more than one ALIGNED clause.

- **n**
  
  Must be a constant positive integer expression; it indicates the number of bytes for the alignment. If n is not specified, the compiler uses the default alignment specified for SIMD instructions on the target platform.

The ALIGNED clause declares that the location of each list item is aligned to the number of bytes expressed in the optional alignment parameter n of the ALIGNED clause. If a list item has the ALLOCATABLE attribute, its allocation status must be allocated. If it has the POINTER attribute, its association status must be associated. If the type of a list item is type(C_PTR) or a Cray pointer, the item must be defined.

**NOTE**

Be careful when using the ALIGNED clause. Instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

**ALL**

**Transformational Intrinsic Function (Generic):**

Determines if all values are true in an entire array or in a specified dimension of an array.
Syntax

result = ALL (mask [,dim])

mask          (Input) Must be a logical array.
dim           (Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( mask \).

Results

The result is an array or a scalar of type logical.

The result is a scalar if \( dim \) is omitted or \( mask \) has rank one. A scalar result is true only if all elements of \( mask \) are true, or \( mask \) has size zero. The result has the value false if any element of \( mask \) is false.

An array result has the same type and kind parameters as \( mask \), and a rank that is one less than \( mask \). Its shape is \((d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of \( mask \).

Each element in an array result is true only if all elements in the one dimensional array defined by \( mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) \) are true.

Example

```plaintext
LOGICAL mask( 2, 3), AR1(3), AR2(2)
mask = RESHAPE((/ .TRUE., .TRUE., .FALSE., .TRUE., .FALSE., &
               .FALSE./),(/2,3/))
! mask is true false false
! true true false
   AR1 = ALL(mask,DIM = 1) ! evaluates the elements column by
   ! column yielding [true false false]
   AR2 = ALL(mask,DIM = 2) ! evaluates the elements row by row
   ! yielding [false false].
```

ALL ((/ .TRUE., .FALSE., .TRUE./)) has the value false because some elements of MASK are not true.
ALL ((/ .TRUE., .TRUE., .TRUE./)) has the value true because all elements of MASK are true.

A is the array

```
[ 1  5  7 ]
[ 3  6  8 ]
```

and B is the array

```
[ 0  5  7 ]
[ 2  6  9 ].
```

ALL (A .EQ. B, DIM=1) tests to see if all elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, false) because only the second column has elements that are all equal.

ALL (A .EQ. B, DIM=2) tests to see if all elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (false, false) because each row has some elements that are not equal.

ANY
COUNT
ALLOCATABLE

**Statement and Attribute:** Specifies that an object is allocatable. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array. A character object may have a deferred length that is determined when the object is allocated with an ALLOCATE statement. A allocatable scalar object of any type may be allocated with an ALLOCATE statement.

**Syntax**

The ALLOCATABLE attribute can be specified in a type declaration statement or an ALLOCATE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls,] ALLOCATABLE [, att-ls] :: a[(d-spec)] [[coarray-spec]][, a[(d-spec)]] [[coarray-spec]]...
```

**Statement:**

```
ALLOCATABLE [:] a[(d-spec)] [[coarray-spec]][, a[(d-spec)]] [[coarray-spec]]...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `a` Is the name of the allocatable object.
- `d-spec` Is a deferred-shape specification (: [: :] ...) where each colon represents a dimension of the array or a deferred-coshape specification.
- `coarray-spec` Is a deferred-coshape specification. The left bracket and right bracket are required.

**Description**

A character object declaration uses LEN=: to indicate it is deferred length.

If the array is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

When the allocatable object is no longer needed, it can be deallocated by execution of a DEALLOCATE statement.

An allocatable object cannot be specified in a COMMON, EQUIVALENCE, DATA, or NAMELIST statement.

Allocatable objects are not saved by default. If you want to retain the values of an allocatable object across procedure calls, you must specify the SAVE attribute for the object.

**Example**

```
! Method for declaring and allocating objects.

INTEGER, ALLOCATABLE :: matrix(:, :)       ! deferred shape
REAL, ALLOCATABLE    :: vector(:)
CHARACTER, ALLOCATABLE :: c1                 ! char scalar, len=1
INTEGER, ALLOCATABLE :: k                   ! numeric scalar
CHARACTER(LEN=::), ALLOCATABLE :: c2, c3(:)   ! deferred length, shape
```
ALLOCATE(matrix(3,5),vector(-2:N+2))       ! specifies shapes
ALLOCATE(c1)                               ! specifies scalar, len=1
ALLOCATE(k)                                ! specifies scalar
ALLOCATE(character(len=5) :: c2)           ! specifies scalar, len=5
ALLOCATE(character(len=3) :: c3(2:4))      ! specifies length, shape

The following example shows a type declaration statement specifying the ALLOCATABLE attribute:

REAL, ALLOCATABLE :: Z(:, :, :)

The following is an example of the ALLOCATABLE statement:

REAL A, B(:)
ALLOCATE :: A(:,:), B

Compatible attributes
ALLOCATE
DEALLOCATE
Arrays
Allocation of Allocatable Arrays
SAVE

ALLOCATE
**Statement:** Dynamically creates storage for allocatable variables and pointer targets.

**Syntax**

ALLOCATE ([type::] object[(s-spec[, s-spec]...)] [, object[(s-spec[, s-spec]...)]] ... [[coarray-spec]]...[, alloc-opt[, alloc-opt]...])

**type**

Is a data type specifier. If specified, the kind type parameters of each object must be the same as the corresponding type parameter values and each object must be type compatible with the specified type. The type must not have an ultimate subcomponent that is a coarray.

You cannot specify type if you specify SOURCE= or MOLD=.

**object**

Is the object to be allocated. It is a variable name or structure component, and must be a pointer or an allocatable object. The object can be of type character with zero length. If the object is a coarray and type is specified, type may not be C_PTR or C_FUNPTR. The object may not be coindexed.

**s-spec**

Is an array shape specification in the form [lower-bound:]upper-bound. Each bound must be a scalar integer expression. The number of shape specifications must be the same as the rank of the object.

You can specify an s-spec list for each array object in an ALLOCATE statement.

**coarray-spec**

Is a coarray shape specification in the form:
The brackets around `coarray-spec` are required. A coarray shape specification can only appear if the object is a coarray. The number of coarray specifications must be one less than the corank of the coarray object.

Can be any of the following keywords:

- **STAT=stat-var** (Output) The `stat-var` is a scalar integer variable in which the status of the allocation is stored.
- **ERRMSG=err-var** (Output) The `err-var` is a scalar default character variable in which an error condition is stored if such a condition occurs.
- **SOURCE=source-expr** (Input) The `source-expr` is an expression that is scalar or has the same rank as `object`.
  - If `MOLD=` or `SOURCE=` is specified, `type` cannot be specified and each `object` must have the same rank as `source-expr` unless `source-expr` is scalar.
  - Only one of `MOLD=` or `SOURCE=` can appear in the same `ALLOCATE` statement.
  - If `source-expr` appears and its declared type is `C_PTR` or `C_FUNPTR`, `object` cannot be a coarray.
  - The declared type of `source-expr` cannot be `EVENT_TYPE` or `LOCK_TYPE`, or have a subcomponent of either type, or have a subcomponent that is a coarray.

You can specify `STAT=`, `ERRMSG=`, and one of `MOLD=` or `SOURCE=` in the same `ALLOCATE` statement. The keywords can appear in any order.

**Description**

The storage space allocated is uninitialized unless `SOURCE=` is specified or the type of the object is default initialized.

A bound in `s-spec` must not be an expression containing an array inquiry function whose argument is any allocatable object in the same `ALLOCATE` statement; for example, the following is not permitted:

```fortran
INTEGER ERR
INTEGER, ALLOCATABLE :: A(:), B(:)
...
ALLOCATE(A(10:25), B(SIZE(A)), STAT=ERR)  ! A is invalid as an argument to function SIZE
```

If `object` is an array, `s-spec` must appear and the number of `s-specs` must equal the rank of `object`, or `source-expr` must appear and have the same rank as `object` and the shape of `object` is that of `source-expr`. If both `s-spec` and `SOURCE=source-expr` appear, `source-expr` must be scalar. If `object` is scalar, no `s-spec` should appear. If `SOURCE=source-expr` appears, `object` is initialized with the value of `source-expr`.

A type parameter value in `type` can be an asterisk if and only if each `object` is a dummy argument for which the corresponding type parameter is assumed.
If a STAT= variable, ERRMSG= variable, or source-expr is specified, it must not be allocated in the ALLOCATE statement in which it appears; nor can they depend on the value, bounds, length type parameters, allocation status, or association status of any object in the same ALLOCATE statement.

If the allocation is successful for STAT= or ERRMSG=, the variable is set to zero. If the allocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the ERRMSG= variable contains the error condition.

If no STAT= variable is specified and an error condition occurs, program execution terminates.

If the allocation is successful and source-expr is specified, the dynamic type and value of the allocated object becomes that of the source expression. If the value of a non-deferred length type parameter of object is different from the value of the corresponding type parameter of source-expr, an error condition occurs.

If any object has a deferred type parameter, is unlimited polymorphic, or is of ABSTRACT type, either type or source-expr must appear.

If object is a coarray, source-expr must not have a dynamic type of C_PTR, C_FUNPTR, EVENT_TYPE, or LOCK_TYPE, or have a subcomponent whose dynamic type is EVENT_TYPE or LOCK_TYPE. The object cannot be a coindexed object.

When an ALLOCATE statement is executed for an object that is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the statement the same number of times.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images has initiated termination of execution, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT= variable becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE.

If MOLD= appears and source-expr is a variable, its value does not have to be defined.

To release the storage for an object, use DEALLOCATE.

To determine whether an allocatable object is currently allocated, use the ALLOCATED intrinsic function.

To determine whether a pointer is currently associated with a target, use the ASSOCIATED intrinsic function.

Example

```fortran
!Method for creating and allocating deferred shape arrays.
INTEGER,ALLOCATABLE::matrix(:,:,)
REAL, ALLOCATABLE:: vector(:)
...
ALLOCATE (matrix(3,5),vector(-2:N+2))
...
```

The following shows another example of the ALLOCATE statement:

```fortran
INTEGER J, N, ALLOC_ERR
REAL, ALLOCATABLE :: A(:,:), B(:,:,)
...
ALLOCATE(A(0:80), B(-3:J+1, N), STAT = ALLOC_ERR)
```

The above example allocates the scalar objects s and t to be 15 by 25 matrices with the value of r.
Consider the following:

```fortran
REAL(KIND=8) :: r(15, 25)
REAL(KIND=8), ALLOCATABLE :: s(:,,:), t(:,:)
...
ALLOCATE(s,SOURCE=r)
ALLOCATE(t,SOURCE=r)
```

The above example allocates \( s \) and \( t \) to be 15 by 25 arrays with the values of \( r \).

- `POINTER`
- Dynamic Allocation
- Pointer Assignments

### ALLOCATED

**Inquiry Intrinsic Function (Generic):** Indicates whether an allocatable array or allocatable scalar is currently allocated.

**Syntax**

```fortran
result = ALLOCATED ([ARRAY=]array)
result = ALLOCATED ([SCALAR=]scalar)
```

- `array` (Input) Must be an allocatable array.
- `scalar` (Input) Must be an allocatable scalar.

**Results**

The result is a scalar of type default logical.

The result has the value true if argument `array` or `scalar` is currently allocated; it has the value false if the argument is not currently allocated.

**NOTE**

When the argument keyword ARRAY is used, `array` must be an allocatable array. When the argument keyword SCALAR is used, `scalar` must be an allocatable scalar.

**Example**

```fortran
REAL, ALLOCATABLE :: A(:)
...
IF (.NOT. ALLOCATED(A)) ALLOCATE (A (5))
```

Consider the following:

```fortran
REAL, ALLOCATABLE, DIMENSION (:,:) :: E
PRINT *, ALLOCATED (E)  ! Returns the value false
ALLOCATE (E (12, 15, 20))
PRINT *, ALLOCATED (E)  ! Returns the value true
```

ANINT
Elemental Intrinsic Function (Generic): Calculates the nearest whole number.

Syntax

\[
\text{result} = \text{ANINT} \ (a[, \text{kind}])
\]

- \(a\) (Input) Must be of type real.
- \(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

Results

The result type is real. If \(\text{kind}\) is present, the kind parameter is that specified by \(\text{kind}\); otherwise, the kind parameter is that of \(a\). If \(a\) is greater than zero, ANINT \((a)\) has the value AINT \((a + 0.5)\); if \(a\) is less than or equal to zero, ANINT \((a)\) has the value AINT \((a - 0.5)\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<tr>
<td>DNINT (^1)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QNINT</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ANINT and DNINT.

To truncate rather than round, use AINT.

Example

ANINT (3.456) has the value 3.0.
ANINT (-2.798) has the value -3.0.

Consider the following:

```plaintext
REAL r1, r2
r1 = ANINT(2.6)    ! returns the value 3.0
r2 = ANINT(-2.6)   ! returns the value -3.0

! Calculates and adds tax to a purchase amount.
REAL amount, taxrate, tax, total
taxrate = 0.081
amount = 12.99
tax = ANINT(amount * taxrate * 100.0) / 100.0
total = amount + tax
WRITE (*, 100) amount, tax, total
100 FORMAT (1X, 'AMOUNT', F7.2 /
```
ANY

Transformational Intrinsic Function (Generic):
Determines if any value is true in an entire array or in a specified dimension of an array.

Syntax

\[
\text{result} = \text{ANY} \left( \text{mask} \ [\text{, dim}] \right)
\]

*mask*  
(Input) Must be a logical array.

*dim*  
(Input; optional) Must be a scalar integer expression with a value in the range 1 to *n*, where *n* is the rank of *mask*.

Results

The result is an array or a scalar of type logical.

The result is a scalar if *dim* is omitted or *mask* has rank one. A scalar result is true if any elements of *mask* are true. The result has the value false if no element of *mask* is true, or *mask* has size zero.

An array result has the same type and kind parameters as *mask*, and a rank that is one less than *mask*. Its shape is \((d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of *mask*.

Each element in an array result is true if any elements in the one dimensional array defined by *mask* \((s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)\) are true.

Example

LOGICAL mask(2, 3), AR1(3), AR2(2)

logical, parameter :: T = .true.
logical, parameter :: F = .false.
DATA mask /T, T, F, T, F, F/

! mask is     true false false
!             true true false
AR1 = ANY(mask,DIM = 1)  ! evaluates the elements column by column yielding [true true false]
AR2 = ANY(mask,DIM = 2)  ! evaluates the elements row by row yielding [true true]

ANY ((/.FALSE., .FALSE., .TRUE./)) has the value true because one element is true.

A is the array

\[
\begin{bmatrix}
1 & 5 & 7 \\
3 & 6 & 8
\end{bmatrix}
\]

and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9
\end{bmatrix}
\]

ANY (A .EQ. B, DIM=1) tests to see if any elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, true) because the second and third columns have at least one element that is equal.
ANY (A .EQ. B, DIM=2) tests to see if any elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (true, true) because each row has at least one element that is equal.

APPENDMENUQQ (W*S)

QuickWin Function: Appends a menu item to the end of a menu and registers its callback subroutine.

Module
USE IFQWIN

Syntax
result = APPENDMENUQQ (menuID, flags, text, routine)

menuID (Input) INTEGER(4). Identifies the menu to which the item is appended, starting with 1 as the leftmost menu.

flags (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:
- $MENUGRAYED - Disables and grays out the menu item.
- $MENUDISABLED - Disables but does not gray out the menu item.
- $MENUENABLED - Enables the menu item.
- $MENUSEPARATOR - Draws a separator bar.
- $MENUCHECKED - Puts a check by the menu item.
- $MENUUNCHECKED - Removes the check by the menu item.

text (Input) Character*(*). Menu item name. Must be a null-terminated C string, for example, 'WORDS OF TEXT'.

routine (Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:
- WINPRINT - Prints the program.
- WINSAVE - Saves the program.
- WINEXIT - Terminates the program.
- WINSELECTTEXT - Selects text from the current window.
- WINSELECTGRAPHICS - Selects graphics from the current window.
- WINSELECTALL - Selects the entire contents of the current window.
- WININPUT - Brings to the top the child window requesting input and makes it the current window.
- WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
- WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WINCLEARPASTE - Clears the paste buffer.
- WINSIZETO FIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results

The result type is logical. It is .TRUE. if successful; otherwise, .FALSE..

You do not need to specify a menu item number, because APPENDMENUQQ always adds the new item to the bottom of the menu list. If there is no item yet for a menu, your appended item is treated as the top-level menu item (shown on the menu bar), and text becomes the menu title. APPENDMENUQQ ignores the callback routine for a top-level menu item if there are any other menu items in the menu. In this case, you can set routine to NUL.

If you want to insert a menu item into a menu rather than append to the bottom of the menu list, use INSERTMENUQQ.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUNCHECKED .OR. $MENUNABLED. Some combinations do not make sense, such as $MENUNABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to APPENDMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY (ALT+R in the example) as an alternative to selecting the item with the mouse.

Example

```fortran
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
...
! Append two items to the bottom of the first (FILE) menu
str = 'Add to File Menu' ! 'A' is a quick-access key
result = APPENDMENUQQ(1, $MENUNABLED, str, WINSTATUS)
str = 'Menu Item &2b' ! '2' is a quick-access key
result = APPENDMENUQQ(1, $MENUNABLED, str, WINTILE)
! Append an item to the bottom of the second (EDIT) menu
str = 'Add to Second &Menu' ! 'M' is a quick-access key
result = APPENDMENUQQ(2, $MENUNABLED, str, WINTILE)
```

**ARC, ARC_W (W*S)**

*Graphics Functions:* Draw elliptical arcs using the current graphics color.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{ARC} (x_1, y_1, x_2, y_2, x_3, y_3, x_4, y_4) \\
\text{result} = \text{ARC}_W (w_{x1}, w_{y1}, w_{x2}, w_{y2}, w_{x3}, w_{y3}, w_{x4}, w_{y4})
\]

- **x1, y1** (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
- **x2, y2** (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
- **x3, y3** (Input) INTEGER(2). Viewport coordinates of start vector.
- **x4, y4** (Input) INTEGER(2). Viewport coordinates of end vector.
- **wx1, wy1** (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
- **wx2, wy2** (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
- **wx3, wy3** (Input) REAL(8). Window coordinates of start vector.
- **wx4, wy4** (Input) REAL(8). Window coordinates of end vector.

**Results**

The result type is INTEGER(2). It is nonzero if successful; otherwise, 0. If the arc is clipped or partially out of bounds, the arc is considered successfully drawn and the return is 1. If the arc is drawn completely out of bounds, the return is 0.

The center of the arc is the center of the bounding rectangle defined by the points \((x_1, y_1)\) and \((x_2, y_2)\) for ARC and \((w_{x1}, w_{y1})\) and \((w_{x2}, w_{y2})\) for ARC_W.

The arc starts where it intersects an imaginary line extending from the center of the arc through \((x_3, y_3)\) for ARC and \((w_{x3}, w_{y3})\) for ARC_W. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through \((x_4, y_4)\) for ARC and \((w_{x4}, w_{y4})\) for ARC_W.

ARC uses the view-coordinate system. ARC_W uses the window-coordinate system. In each case, the arc is drawn using the current color.

**NOTE**

The ARC routine described here is a QuickWin graphics routine. If you are trying to use the Microsoft* Platform SDK version of the Arc routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Arc.
Example

This program draws the arc shown below.

```fortran
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 75
x4 = 90; y4 = 180
status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
END
```

ASIN

**Elemental Intrinsic Function (Generic):** Produces the arcsine of an argument.

**Syntax**

```
result = ASIN(x)
```

*x* (Input) Must be of type real, where |x| must be less than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as x.

If the result is real, it is expressed in radians and lies in the range - pi/2 <= ASIN(x) <= pi/2.

If the result is complex, the real part is expressed in radians and lies in the range pi/2 <= REAL(ASIN(x)) <= pi/2.

</tbody>
</table>

**Example**

ASIN (0.79345021) has the value 0.9164571.
ASIND

*Elemental Intrinsic Function (Generic)*: Produces the arcsine of *x*.

**Syntax**

```
result = ASIND (x)
```

*Input* Must be of type real. The | *x* | must be less than or equal to 1.

**Results**

The result type and kind are the same as *x* and are expressed in degrees. The value lies in the range −90 to 90 degrees.

</tbody>
</table>

**Example**

ASIND (0.2467590) has the value 14.28581.

ASINH

*Elemental Intrinsic Function (Generic)*: Produces the hyperbolic arcsine of *x*.

**Syntax**

```
result = ASINH (x)
```

*Input* Must be of type real or complex.

**Results**

The result type and kind are the same as *x*.

If the result is complex, the imaginary part is expressed in radians and lies in the range - π/ 2 <= AIMAG (ASINH (x)) <= π / 2.

<table>
<thead>

</tbody>
</table>

**Example**

ASINH (1.0) has the value -0.88137.

ASINH (180.0) has the value 5.88611.
ASSIGN - Label Assignment

**Statement:** Assigns a statement label value to an integer variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

ASSIGN label TO var

- **label**
  - Is the label of a branch target or FORMAT statement in the same scoping unit as the ASSIGN statement.

- **var**
  - Is a scalar integer variable.

When an ASSIGN statement is executed, the statement label is assigned to the integer variable. The variable is then undefined as an integer variable and can only be used as a label (unless it is later redefined with an integer value).

The ASSIGN statement must be executed before the statements in which the assigned variable is used.

Indirect branching through integer variables makes program flow difficult to read, especially if the integer variable is also used in arithmetic operations. Using these statements permits inconsistent usage of the integer variable, and can be an obscure source of error. The ASSIGN statement was used to simulate internal procedures, which now can be coded directly.

**Example**

The value of a label is not the same as its number; instead, the label is identified by a number assigned by the compiler. In the following example, 400 is the label number (not the value) of IVBL:

```
ASSIGN 400 TO IVBL
```

Variables used in ASSIGN statements are not defined as integers. If you want to use a variable defined by an ASSIGN statement in an arithmetic expression, you must first define the variable by a computational assignment statement or by a READ statement, as in the following example:

```
IVBL = 400
```

The following example shows ASSIGN statements:

```
INTEGER ERROR
...
ASSIGN 10 TO NSTART
ASSIGN 99999 TO KSTOP
ASSIGN 250 TO ERROR
```

Note that NSTART and KSTOP are integer variables implicitly, but ERROR must be previously declared as an integer variable.

The following statement associates the variable NUMBER with the statement label 100:

```
ASSIGN 100 TO NUMBER
```

If an arithmetic operation is subsequently performed on variable NUMBER (such as follows), the run-time behavior is unpredictable:

```
NUMBER = NUMBER + 1
```

To return NUMBER to the status of an integer variable, you can use the following statement:

```
NUMBER = 10
```
This statement dissociates NUMBER from statement 100 and assigns it an integer value of 10. Once NUMBER is returned to its integer variable status, it can no longer be used in an assigned GO TO statement.

**See Also**
Assignment: intrinsic
Obsolescent Language Features in the Fortran Standard

**Assignment(=) - Defined Assignment**

**Statement:** An interface block that defines generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

**Syntax**
The initial line for such an interface block takes the following form:

```fortran
INTERFACE ASSIGNMENT (=)
```

**Description**
The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN and/or attribute VALUE.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

**Example**
The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN) :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC
  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE                    ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR     ! A variable-length string
    CHARACTER(*) , INTENT(IN) :: CHAR   ! A variable-length string
  END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```
The following is an example of a declaration and reference to a defined assignment:

```fortran
!Converting circle data to interval data.
module mod1
  TYPE CIRCLE
    REAL radius, center_point(2)
  END TYPE CIRCLE
  TYPE INTERVAL
    REAL lower_bound, upper_bound
  END TYPE INTERVAL
  CONTAINS
    SUBROUTINE circle_to_interval(I,C)
      type (interval),INTENT(OUT)::I
      type (circle),INTENT(IN)::C
      !Project circle center onto the x=-axis
      !Note: the length of the interval is the diameter of the circle
      I%lower_bound = C%center_point(1) - C%radius
      I%upper_bound = C%center_point(1) + C%radius
    END SUBROUTINE circle_to_interval
  end module mod1

PROGRAM assign
  use mod1
  TYPE(CIRCLE) circle1
  TYPE(INTERVAL) interval1
  INTERFACE ASSIGNMENT(=)
    module procedure circle_to_interval
  END INTERFACE
  !Begin executable part of program
  circle1%radius = 2.5
  circle1%center_point = (/3.0,5.0/)
  interval1 = circle1
  . . .
END PROGRAM
```

INTERFACE
Assignment Statements

Assignment - Intrinsic Computational

**Statement:** Assigns a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

**Syntax**

```
variable=expression
```

variable

Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.
expression  Is of intrinsic type or the same derived type as variable. Its shape must conform with variable. If necessary, it is converted to the same type and kind as variable.

Description
Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

NOTE
When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

If the !DIR$ NOSTRICT compiler directive (the default) is in effect, then you can assign a character expression to a noncharacter variable, and a noncharacter variable or array element (but not an expression) to a character variable.

Example

```fortran
REAL a, b, c
LOGICAL abigger
CHARACTER(16) assertion
  c = .01
  a = SQRT (c)
  b = c**2
  assertion = 'a > b'
  abigger = (a .GT. b)
  WRITE (*, 100) a, b
100 FORMAT (' a=', F7.4, ' b=', F7.4)
  IF (abigger) THEN
    WRITE (*, *) assertion, ' is true.'
  ELSE
    WRITE (*, *) assertion, ' is false.'
  END IF
END

The program above has the following output:
! a =    .1000     b =   .0001         a > b is true.
! The following code shows legal and illegal assignment statements:

INTEGER i, j
REAL rone(4), rtwo(4), x, y
COMPLEX z
CHARACTER name6(6), name8(8)
  i = 4
  x = 2.0
  z = (3.0, 4.0)
  rone(1) = 4.0
  rone(2) = 3.0
```
rone(3) = 2.0
rone(4) = 1.0
name8  = 'Hello,'

! The following assignment statements are legal:
i     = rone(2); j = rone(i); j = x
y     = x; y = z; y = rone(3); rtwo = rone; rtwo = 4.7
name6 = name8

! The following assignment statements are illegal:
name6 = x + 1.0; int = name8//'test'; y = rone
END

See Also
Assignment: defined
NOSTRICT directive

ASSOCIATE

Statement: Marks the beginning of an ASSOCIATE construct. The ASSOCIATE construct creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.

Syntax

```
[<name>] ASSOCIATE (<assoc-entity>[, <assoc-entity>...] )

   block

END ASSOCIATE [<name>]
```

- **name** (Optional) is the name of the ASSOCIATE construct.
- **assoc-entity** is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct.
- **selector** is an expression or variable. It becomes the associated entity.
- **block** is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an ASSOCIATE statement, the same name must appear in the corresponding END ASSOCIATE statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of an ASSOCIATE statement, you cannot specify one following the END ASSOCIATE statement.

During execution of the block within the construct, each **associate-name** identifies an entity, which is associated with the corresponding **selector**. The associating entity assumes the declared type and type parameters of the selector.

You can only branch to an END ASSOCIATE statement from within its ASSOCIATE construct.
Within an ASSOCIATE construct, each associating entity has the same rank as its associated selector. The lower bound of each dimension is the result of the intrinsic function LBOUND applied to the corresponding dimension of selector. The upper bound of each dimension is one less than the sum of the lower bound and the extent.

If the selector has the ALLOCATABLE attribute, it must be allocated. The associating entity is associated with the associated entity and does not have the ALLOCATABLE attribute. If the selector has the POINTER attribute, it must be associated. The associating entity is associated with the target of the pointer and does not have the POINTER attribute. If the selector has the TARGET, VOLATILE, or ASYNCHRONOUS attribute, an associating entity that is a variable has those attributes.

This construct is useful when you want to simplify multiple accesses to a variable that has a lengthy description; for example, if the variable contains multiple subscripts and component names.

**Example**

The following shows an expression as a selector:

```fortran
ASSOCIATE (O => (A-F)**2 + (B+G)**2)
   PRINT *, SQRT (O)
END ASSOCIATE
```

The following shows association with an array section:

```fortran
ASSOCIATE (ARRAY => AB % D (I, :) % X)
   ARRAY (3) = ARRAY (1) + ARRAY (2)
END ASSOCIATE
```

Without the ASSOCIATE construct, this is what you would need to write:

```fortran
AB % D (I, 3) % X = AB % D (I, 1) % X + AB % D (I, 2) % X
```

**ASSOCIATED**

*Inquiry Intrinsic Function (Generic):* Returns the association status of its pointer argument or indicates whether the pointer is associated with the target.

**Syntax**

```fortran
result = ASSOCIATED (pointer [, target])
```

- `pointer` *(Input)* Must be a pointer. It can be of any data type. The pointer association status must be defined.

- `target` *(Input; optional)* Must be a pointer or target. If it is a pointer, the pointer association status must be defined.

**Results**

The result is a scalar of type default logical. The setting of compiler options specifying integer size can affect this function.

If only `pointer` appears, the result is true if it is currently associated with a target; otherwise, the result is false.

If `target` also appears and is a target, the result is true if `pointer` is currently associated with `target`; otherwise, the result is false.

If `target` is a pointer, the result is true if both `pointer` and `target` are currently associated with the same target; otherwise, the result is false. (If either `pointer` or `target` is disassociated, the result is false.)
Example

REAL C (:), D(:), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
C => E                           ! pointer assignment
D => E                           ! pointer assignment
STATUS = ASSOCIATED(C)           ! returns TRUE; C is associated
STATUS = ASSOCIATED(C, E)        ! returns TRUE; C is associated with E
STATUS = ASSOCIATED(C, D)        ! returns TRUE; C and D are associated
                               ! with the same target

Consider the following:

REAL, TARGET, DIMENSION (0:50) :: TAR
REAL, POINTER, DIMENSION (: ) :: PTR
PTR => TAR
PRINT *, ASSOCIATED (PTR, TAR)   ! Returns the value true

The subscript range for PTR is 0:50. Consider the following pointer assignment statements:

(1) PTR => TAR (:)
(2) PTR => TAR (0:50)
(3) PTR => TAR (0:49)

For statements 1 and 2, ASSOCIATED (PTR, TAR) is true because TAR has not changed (the subscript range for PTR in both cases is 1:51, following the rules for deferred-shape arrays). For statement 3, ASSOCIATED (PTR, TAR) is false because the upper bound of TAR has changed.

Consider the following:

REAL, POINTER, DIMENSION (: ) :: PTR2, PTR3
ALLOCATE (PTR2 (0:15))
PTR3 => PTR2
PRINT *, ASSOCIATED (PTR2, PTR3)  ! Returns the value true
...                             
NULLIFY (PTR2)
NULLIFY (PTR3)
PRINT *, ASSOCIATED (PTR2, PTR3)  ! Returns the value false

ASSUME

**General Compiler Directive:** Provides heuristic information to the compiler optimizer.

**Syntax**

!DIR$ ASSUME (scalar-Boolean-expression)

*scalar-Boolean-expression* is any expression that evaluates to .TRUE. or .FALSE. at run-time.

The *scalar-Boolean-expression* is presumed to be true and may be used by the optimizer to generate better code.
If the `check assume` option is specified and `scalar-Boolean-expression` does not evaluate to `.TRUE.` at runtime, an error message is displayed and execution is aborted.

**Example**

In the example below, the compiler is told that `A` is aligned on a 32-byte boundary using the `ASSUME_ALIGNED` directive. The `ASSUME` directive says that the length of the first dimension of `A` is a multiple of 8. Therefore the optimizer knows that `A(I,J+1)` and `A(I,J-1)` are 0 mod 64 bytes away from `A(I,J)` and are therefore also aligned on 32-byte boundaries. This information helps the optimizer in generating efficiently vectorized code for these loops.

```fortran
SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ ASSUME (MOD(NX,8) .EQ. 0)
! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
DO J=J1,J2
   DO I=I1,I2
      A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
   ENDDO
ENDDO
END SUBROUTINE F
```

**See Also**

General Compiler Directives

Syntax Rules for Compiler Directives

ASSUME_ALIGNED directive

check compiler option (setting assume)

**ASSUME_ALIGNED**

*General Compiler Directive:* Specifies that an entity in memory is aligned.

**Syntax**

```
!DIR$ ASSUME_ALIGNED address1:n1 [, address2:n2]...
```

- `address`: An array variable. It can be of any data type, kind, or rank > 0. It can be an array component of a variable of derived type or a record field reference, host or use associated, or have the ALLOCATABLE or POINTER attribute.

  It cannot be any of the following:
  - An entity in COMMON (or an entity EQUIVALENCEd to something in COMMON)
  - A component of a variable of derived type or a record field reference
  - An entity accessed by use or host association

  If it is a module variable, that address is silently ignored.

- `n`: A positive integer constant expression. Its value must be a power of 2 between 1 and 256, that is, 1, 2, 4, 8, 16, 32, 64, 128, 256. It specifies the memory alignment in bytes of `address`. 
The ASSUME_ALIGNED directive must appear after the specification statements section or inside the executable statements section.

If you specify more than one address item, they must be separated by a comma.

If address is a Cray POINTER or it has the POINTER attribute, it is the POINTER and not the pointee or the TARGET that is assumed aligned.

If the check assume option is specified and address is not aligned on an n-byte boundary at run-time, an error message is displayed and execution is aborted.

For more information, see the example in the description of the ASSUME directive.

Example
The following example shows the correct placement and usage of the ASSUME_ALIGNED directive:

```fortran
SUBROUTINE F(A, N)
  TYPE NODE
    REAL(KIND=8), POINTER :: A(:, :)
  END TYPE NODE

  TYPE(NODE), POINTER :: NODES

  ALLOCATE(NODES)
  ALLOCATE(NODES%A(1000,1000))

  !DIR$ ASSUME_ALIGNED NODES%A(1,1) : 16
  DO I=1,N
    NODES%A(1,I) = NODES%A(1,I)+1
  ENDDO

END
```

It is illegal to place ASSUME_ALIGNED inside a type definition; for example:

```fortran
TYPE S
  !DIR$ ASSUME_ALIGNED T : 16
  REAL(8), ALLOCATABLE :: T(:)
END TYPE S
```

ASYNCHRONOUS
Statement and Attribute: Specifies that a variable can be used for asynchronous input and output.

Syntax
The ASYNCHRONOUS attribute can be specified in a type declaration statement or an ASYNCHRONOUS statement, and takes one of the following forms:

Type Declaration Statement:

```
type, [att-ls] ASYNCHRONOUS [, att-ls] :: var [, var] ...
```
Statement:

ASYNCHRONOUS [:] var [, var] ...

- **type**
  - Is a data type specifier.
- **att-ls**
  - Is an optional list of attribute specifiers.
- **var**
  - Is the name of a variable.

Description

Asynchronous I/O, or non-blocking I/O, allows a program to continue processing data while the I/O operation is performed in the background.

A variable can have the ASYNCHRONOUS attribute in a particular scoping unit without necessarily having it in other scoping units. If an object has the ASYNCHRONOUS attribute, then all of its subobjects also have the ASYNCHRONOUS attribute.

The ASYNCHRONOUS attribute can also be implied by use of a variable in an asynchronous READ or WRITE statement.

You can specify variables that are used for asynchronous communication, such as with Message Passing Interface Standard (MPI). Asynchronous communication has the following restrictions:

- For input, a pending communication affector must not be referenced, become defined, become undefined, become associated with a dummy argument that has the VALUE attribute, or have its pointer association status changed.
- For output, a pending communication affector must not be redefined, become undefined, or have its pointer association status changed.

Examples

The following example shows how the ASYNCHRONOUS attribute can be applied in an OPEN and READ statement.

```fortran
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1, file='asynch.dat', asynchronous='YES',
    form='unformatted')
  write (1) (i, i=1, 100)
  rewind (1)
  read (1, asynchronous='YES') array
  wait (1)
  write (*,*) array(1:10)
end
```

ATAN

**Elemental Intrinsic Function (Generic):** Produces the arctangent of an argument.

Syntax

- `result = ATAN (x)`
- `result = ATAN (y, x)`
(Input) Must be of type real.

(Input) If y appears, x must be of type real with the same kind type parameter as y.
If y has the value zero, x must not have the value zero.
If y does not appear, x must be of type real or complex.

Results

The result type and kind are the same as x.

If y appears, the result is the same as the result of ATAN2 (y, x).

If y does not appear, the real part of the result is expressed in radians and lies in the range -pi/2 <= ATAN(x) <= pi/2.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ATAN (1.5874993) has the value 1.008666.

ATAN (2.679676, 1.0) has the value 1.213623.

ATAN2

Elemental Intrinsic Function (Generic): Produces an arctangent (inverse tangent). The result is the principal value of the argument of the nonzero complex number (x, y).

Syntax

result = ATAN2 (y, x)

(Input) Must be of type real.

(Input) Must have the same type and kind parameters as y. If y has the value zero, x cannot have the value zero.

Results

The result type and kind are the same as x and are expressed in radians. The value lies in the range -pi <= ATAN2 (y, x) <= pi.

If x is not zero, the result is approximately equal to the value of arctan (y/ x).

If y > zero, the result is positive.

If y < zero, the result is negative.

If y is zero and x > zero, the result is y (so for x>0, ATAN2 ((+0.0), x) is +0.0 and ATAN2 ((-0.0), x) is -0.0).

If y is a positive real zero and x < zero, the result is pi.

If y is a negative real zero and x < zero, the result is -pi.
If \( x \) is a positive real zero, the result is \( \pi/2 \).
If \( y \) is a negative real zero, the result is \(-\pi/2\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN2</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN2</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATAN2 (2.679676, 1.0) has the value 1.213623.

If \( Y \) is an array that has the value

\[
\begin{bmatrix}
  1 & 1 \\
  -1 & -1
\end{bmatrix}
\]

and \( X \) is an array that has the value

\[
\begin{bmatrix}
  -1 & 1 \\
  -1 & 1
\end{bmatrix}
\]

then ATAN2 (\( Y, X \)) is

\[
\begin{bmatrix}
  \frac{3\pi}{4} & \frac{\pi}{4} \\
  -\frac{3\pi}{4} & -\frac{\pi}{4}
\end{bmatrix}
\]

**ATAN2D**

*Elemental Intrinsic Function (Generic):* Produces an arctangent. The result is the principal value of the argument of the nonzero complex number \((x, y)\).

**Syntax**

\[
\text{result} = \text{ATAN2D} (y, x)
\]

\( y \)  
(Input) Must be of type real.

\( x \)  
(Input) Must have the same type and kind parameters as \( y \). If \( y \) has the value zero, \( x \) cannot have the value zero.

**Results**

The result type and kind are the same as \( x \) and are expressed in degrees. The value lies in the range -180 degrees to 180 degrees. If \( x \) zero, the result is approximately equal to the value of arctan \((y/ x)\).

If \( y \) > zero, the result is positive.
If \( y \) < zero, the result is negative.
If \( y = \) zero, the result is zero (if \( x \) > zero) or 180 degrees (if \( x < \) zero).
If \( x = \) zero, the absolute value of the result is 90 degrees.
Specific Name | Argument Type | Result Type
--- | --- | ---
ATAN2D | REAL(4) | REAL(4)
DATAN2D | REAL(8) | REAL(8)
QATAN2D | REAL(16) | REAL(16)

Example

ATAN2D (2.679676, 1.0) has the value 69.53546.

ATAND

Elemental Intrinsic Function (Generic): Produces the arctangent of x.

Syntax

```fortran
result = ATAND (x)
```

x

(Input) Must be of type real and must be greater than or equal to zero.

Results

The result type and kind are the same as x and are expressed in degrees.

Specific Name | Argument Type | Result Type
--- | --- | ---
ATAND | REAL(4) | REAL(4)
DATAND | REAL(8) | REAL(8)
QATAND | REAL(16) | REAL(16)

Example

ATAND (0.0874679) has the value 4.998819.

ATANH

Elemental Intrinsic Function (Generic): Produces the hyperbolic arctangent of x.

Syntax

```fortran
result = ATANH (x)
```

x

(Input) Must be of type real, where \(|x|\) is less than or equal to 1, or of type complex.

Results

The result type and kind are the same as x.

If the result is real, it lies in the range -1.0 < ATANH (x) < 1.0.

If the result is complex, the imaginary part is expressed in radians and lies in the range -\(\pi/2\) <= AIMAG (ATANH (x)) <= \(\pi/2\).
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATANH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATANH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATANH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATANH (-0.77) has the value -1.02033.
ATANH (0.5) has the value 0.549306.

**ATOMIC**

*OpenMP* **Fortran Compiler Directive**: Ensures that a specific memory location is updated atomically; this prevents the possibility of multiple threads simultaneously reading and writing the specific memory location.

**Syntax**

```
!$OMP ATOMIC [type-clause[[, clause]]]
-or- !$OMP ATOMIC [clause[[, type-clause]]]
    block
!$OMP END ATOMIC
```

*type-clause* (Optional) Is one of the following:

- **CAPTURE**
  
  If !$OMP ATOMIC CAPTURE is specified, block is either one update-statement and one capture-statement in either order, or one capture-statement followed by one write-statement in that order.

- **READ**
  
  If !$OMP ATOMIC READ is specified, block is a capture-statement.

- **WRITE**
  
  If !$OMP ATOMIC WRITE is specified, block is a write-statement.

- **UPDATE**
  
  If !$OMP ATOMIC UPDATE is specified, block is an update-statement.

For details on the effects of these clauses, see the table in the Description section.

*clause* (Optional) Is the following:

- **SEQ_CST**
  
  Forces the atomically performed operation to include an implicit flush operation without a list. For details on the effects of this clause, see the table in the Description section.
**capture-statement**
Is an expression in the form $v = x$.

**write-statement**
Is an expression in the form $x = \text{expr}$.

**update-statement**
Is an expression with one of the following forms:

```
  x = x \text{ operator} \text{ expr}
  x = \text{ expr} \text{ operator} x
  x = \text{ intrinsic (} x, \text{ expr-list})
  x = \text{ intrinsic (} \text{ expr-list,} x)
```

The following rules apply:

- Operators in \( \text{expr} \) must have precedence equal to or greater than the precedence of operator.
- \( x \text{operator} \text{expr} \) must be mathematically equivalent to \( x \text{ operator} (\text{expr}) \). This requirement is satisfied if the \( \text{operators} \) in \( \text{expr} \) have precedence greater than \( \text{operator} \), or by using parentheses around \( \text{expr} \) or subexpressions of \( \text{expr} \).
- \( \text{expr} \text{operator} x \) must be mathematically equivalent to \( (\text{expr}) \text{ operator} x \). This requirement is satisfied if the \( \text{operators} \) in \( \text{expr} \) have precedence equal to or greater than \( \text{operator} \), or by using parentheses around \( \text{expr} \) or subexpressions of \( \text{expr} \).
- All assignments must be intrinsic assignments.

\( x, v \)
Are scalar variables of intrinsic type. During execution of an atomic region, all references to storage location \( x \) must specify the same storage location. \( v \) must not access the same storage location as \( x \).

\( \text{expr, expr-list} \)
The \( \text{expr} \) is a scalar expression. The \( \text{expr-list} \) is a comma-separated, non-empty list of scalar expressions. They must not access the same storage location as \( x \).

If \( \text{intrinsic} \) is IAND, IOR, or IEOR, only one expression can appear in \( \text{expr-list} \).

\( \text{operator} \)
Is one of the following intrinsic operators: +, *, -, /, ,AND., ,OR., .EQV., or .NEQV..

\( \text{intrinsic} \)
Is one of the following intrinsic procedures: MAX, MIN, IAND, IOR, or IEOR.

The binding thread set for an ATOMIC construct is all threads. Atomic regions enforce exclusive access with respect to other atomic regions that access the same storage location \( x \) among all the threads in the program without regard to the teams to which the threads belong.

If \$OMP ATOMIC is specified with no \text{type-clause} or no \text{clause}, it is the same as specifying \$OMP ATOMIC UPDATE.

If \$OMP ATOMIC CAPTURE is specified, you must include an \$OMP END ATOMIC directive following the block. Otherwise, the \$OMP END ATOMIC directive is optional.

Note that the following restriction applies to the ATOMIC directive:

- All atomic accesses to the storage locations designated by \( x \) throughout the program must have the same type and type parameters.

The following table describes what happens when you specify one of the clauses in an ATOMIC construct.
<table>
<thead>
<tr>
<th>Clause</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAPTURE</td>
<td>Causes an atomic update of the location designated by $x$ using the designated operator or intrinsic while also capturing the original or final value of the location designated by $x$ in $v$. The following rules also apply:</td>
</tr>
</tbody>
</table>
|              | • The original or final value of the location designated by $x$ is written in the location designated by $v$, depending on the form of the ATOMIC construct, structured block, or statements, following the usual language semantics.  
|              | • Only the read and write of the location designated by $x$ are performed mutually atomically.  
|              | • The evaluation of $expr$ or $expr$-list, and the write to the location designated by $v$ do not need to be atomic with respect to the read or write of the location designated by $x$.                                                                                                                                                                                                                     |
|              | No task scheduling points are allowed between the read and the write of the location designated by $x$.                                                                                                                                                                                                                                                                                                                                                           |
| READ         | Causes an atomic read of the location designated by $x$ regardless of the native machine word size.                                                                                                                                                                                                                                                                                                                                                                 |
| SEQ_CST      | Causes the atomically performed operation to include an implicit flush operation without a list.                                                                                                                                                                                                                                                                                                                                                                         |
|              | If this clause is specified, the construct is a sequentially consistent atomic construct.                                                                                                                                                                                                                                                                                                                                                                          |
|              | Unlike non-sequentially consistent atomic constructs, sequentially consistent atomic constructs preserve the interleaving (sequentially consistent) behavior of correct, data-race-free programs.                                                                                                                                                                                                                                           |
|              | However, they are not designed to replace the FLUSH directive as a mechanism to enforce ordering for non-sequentially consistent atomic constructs, and attempts to do so require extreme caution.                                                                                                                                                                                                                                                                 |
|              | For example, a sequentially consistent atomic write construct may appear to be reordered with a subsequent non-sequentially consistent atomic write construct, since such reordering would not be observable by a correct program if the second write were outside an ATOMIC directive.                                                                                                                                                                          |
| UPDATE       | Causes an atomic update of the location designated by $x$ using the designated operator or intrinsic. The following rules also apply:                                                                                                                                                                                                                                                                                                                                 |
|              |
The evaluation of expr or expr-list need not be atomic with respect to the read or write of the location designated by x.

No task scheduling points are allowed between the read and the write of the location designated by x.

Causes an atomic write of the location designated by x regardless of the native machine word size.

Any combination of two or more of these atomic constructs enforces mutually exclusive access to the locations designated by x.

A race condition exists when two unsynchronized threads access the same shared variable with at least one thread modifying the variable; this can cause unpredictable results. To avoid race conditions, all accesses of the locations designated by x that could potentially occur in parallel must be protected with an ATOMIC construct.

Atomic regions do not guarantee exclusive access with respect to any accesses outside of atomic regions to the same storage location x even if those accesses occur during a CRITICAL or ORDERED region, while an OpenMP lock is owned by the executing task, or during the execution of a REDUCTION clause.

However, other OpenMP* synchronization can ensure the desired exclusive access. For example, a BARRIER directive following a series of atomic updates to x guarantees that subsequent accesses do not form a race condition with the atomic accesses.

**Example**

The following example shows a way to avoid race conditions by using ATOMIC to protect all simultaneous updates of the location by multiple threads.

Since the ATOMIC directive below applies only to the statement immediately following it, elements of Y are not updated atomically.

```fortran
REAL FUNCTION FOO1(I)
  INTEGER I
  FOO1 = 1.0 * I
RETURN
END FUNCTION FOO1

REAL FUNCTION FOO2(I)
  INTEGER I
  FOO2 = 2.0 * I
RETURN
END FUNCTION FOO2

SUBROUTINE SUB(X, Y, INDEX, N)
  REAL X(*), Y(*)
  INTEGER INDEX(*), N
  INTEGER I
  !$OMP PARALLEL DO SHARED(X, Y, INDEX, N)
  DO I=1,N
    !$OMP ATOMIC UPDATE
    X(INDEX(I)) = X(INDEX(I)) + FOO1(I)
    Y(I) = Y(I) + FOO2(I)
  ENDDO
END SUBROUTINE SUB
```
PROGRAM ATOMIC_DEMO
   REAL X(1000), Y(10000)
   INTEGER INDEX(10000)
   INTEGER I
   DO I=1,10000
      INDEX(I) = MOD(I, 1000) + 1
      Y(I) = 0.0
   ENDDO
   DO I = 1,1000
      X(I) = 0.0
   ENDDO
   CALL SUB(X, Y, INDEX, 10000)
END PROGRAM ATOMIC_DEMO

The following non-conforming example demonstrates the restriction on the ATOMIC construct:

SUBROUTINE ATOMIC_INCORRECT()
   INTEGER:: I
   REAL:: R
   EQUIVALENCE(I,R)
   !$OMP PARALLEL
   !$OMP ATOMIC UPDATE
      I = I + 1
   !$OMP ATOMIC UPDATE
      R = R + 1.0
   !$OMP END PARALLEL
END SUBROUTINE ATOMIC_INCORRECT

ATOMIC_DEFINE

Intrinsic Subroutine (Generic): Defines a variable atomically.

Syntax
CALL ATOMIC_DEFINE (atom, value)

atom (Output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND. If its kind is the same as that of value or its type is logical, it becomes defined with the value of value. Otherwise, it becomes defined with the value of INT (VALUE, ATOMIC_INT_KIND).
ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.

_value_

(Input) Must be a scalar and of the same type as _atom_.

**Example**
Consider the following:

CALL ATOMIC_DEFINE (N [9], 7)

This causes N on image 9 to become defined with the value 7.

**See Also**
ISO_FORTRAN_ENV Module

---

**ATOMIC_REF**

*Intrinsic Subroutine (Generic):* Lets you reference a variable atomically.

**Syntax**

CALL ATOMIC_REF (value, atom)

_value_

(Output) Must be a scalar and of the same type as _atom_. If its kind is the same as that of _atom_ or its type is logical, it becomes defined with the value of _atom_. Otherwise, it is defined with the value of INT(ATOM, KIND (VALUE)).

_atom_

(Input) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND.

ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.

**Example**
Consider the following:

CALL ATOMIC_REF (SOL, I [9])

This causes SOL to become defined with the value of I on image 9.

**See Also**
ISO_FORTRAN_ENV Module

---

**ATTRIBUTES**

*General Compiler Directive:* Declares properties for specified variables.

**Syntax**

!DIR$ ATTRIBUTES att[att]...:: object[object]...

_att_

Is one of the following options (or properties):

<table>
<thead>
<tr>
<th>ALIAS</th>
<th>DLLEXPORT</th>
<th>NOCLONE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option</td>
<td>Variable and Array Declarations</td>

<td>No</td>
<td>No</td>
<td>Yes ⁵</td>
</tr>
</tbody>
</table>

¹ A common block name is specified as [/]common-block-name[/]

² This option can only be applied to arrays.

³ Module-level variables and arrays only.

⁴ This option can only be applied to INTERFACE blocks.

⁵ This option cannot be applied to EXTERNAL statements.

⁶ This option can be applied to named main programs.

These options can be used in function and subroutine definitions, in type declarations, and with the INTERFACE and ENTRY statements.

Options applied to entities available through use or host association are in effect during the association. For example, consider the following:

```fortran
MODULE MOD1
  INTERFACE
    SUBROUTINE NEW_SUB
      !DIR$ ATTRIBUTES C, ALIAS:"othername" :: NEW_SUB
      END SUBROUTINE
  END INTERFACE
  CONTAINS
    SUBROUTINE SUB2
      CALL NEW_SUB
      END SUBROUTINE
  END MODULE
```
In this case, the call to NEW_SUB within SUB2 uses the C and ALIAS options specified in the interface block. Options C, STDCALL, REFERENCE, VALUE, and VARYING affect the calling conventions of routines:

- You can specify C, STDCALL, REFERENCE, and VARYING for an entire routine.
- You can specify VALUE and REFERENCE for individual arguments.

Examples

INTERFACE
  SUBROUTINE For_Sub (I)
    !DIR$ ATTRIBUTES C, ALIAS:'_For_Sub' :: For_Sub
    INTEGER I
  END SUBROUTINE For_Sub
END INTERFACE

You can assign more than one option to multiple variables with the same compiler directive. All assigned options apply to all specified variables. For example:

!DIR$ ATTRIBUTES REFERENCE, VARYING, C :: A, B, C

In this case, the variables A, B, and C are assigned the REFERENCE, VARYING, and C options. The only restriction on the number of options and variables is that the entire compiler directive must fit on one line.

The identifier of the variable or procedure that is assigned one or more options must be a simple name. It cannot include initialization or array dimensions. For example, the following is not allowed:

!DIR$ ATTRIBUTES C :: A(10)  ! This is illegal.

The following shows another example:

SUBROUTINE ARRAYTEST(arr)
  !DIR$ ATTRIBUTES DLLEXPORT :: ARRAYTEST
  REAL(4) arr(3, 7)
  INTEGER i, j
  DO i = 1, 3
    DO j = 1, 7
      arr (i, j) = 11.0 * i + j
    END DO
  END DO
END SUBROUTINE

See Also
General Compiler Directives
Syntax Rules for Compiler Directives
Programming with Mixed Languages Overview

ATTRIBUTES ALIAS

The ATTRIBUTES directive option ALIAS specifies an alternate external name to be used when referring to external subprograms.

Syntax

!DIR$ ATTRIBUTES ALIAS: external-name: subprogram

external-name

Is a character constant delimited by apostrophes or quotation marks. The character constant is used as is; the string is not changed to uppercase, nor are blanks removed.

subprogram

Is an external subprogram.
The ALIAS option overrides the C (and STDCALL) option. If both C and ALIAS are specified for a subprogram, the subprogram is given the C calling convention, but not the C naming convention. It instead receives the name given for ALIAS, with no modifications.

ALIAS cannot be used with internal procedures, and it cannot be applied to dummy arguments.

The following example gives the subroutine happy the name "OtherName@4" outside this scoping unit:

```fortran
INTERFACE
  SUBROUTINE happy(i)
    !DIR$ ATTRIBUTES STDCALL, DECORATE, ALIAS:'OtherName' :: happy
    INTEGER i
  END SUBROUTINE
END INTERFACE
```

!DIR$ ATTRIBUTES ALIAS has the same effect as the !DIR$ ALIAS directive.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES DECORATE

ATTRIBUTES ALIGN
The ATTRIBUTES directive option ALIGN specifies the byte alignment for variables and for allocatable or pointer components of derived types.

Syntax
!DIR$ ATTRIBUTES ALIGN: n:: object

$n$
Is the number of bytes for the minimum alignment boundary.

For allocatable $object$s, the boundary value must be a power of 2, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. $n$ must have a value between 1 and 2097152 == 2**21 == 2MB on Linux* and macOS* systems, and between 1 and 8192 == 2**13 == 8KB on Windows* systems.

For non-allocatable $object$s, the boundary value must be a power of 2 between 1 and 64 on Windows systems, between 1 and 65536 == 2**16 == 64KB on Linux systems, or between 1 and 4096 == 2**12 == 4KB on macOS* systems.

$object$
Is the variable or the allocatable or pointer component of a derived type to be aligned.

Objects that can be aligned by this directive include static local variables, automatic variables, module variables, dynamically allocated arrays, allocatable array components of derived types, and the start of common blocks. This directive cannot be used to align variables within common blocks.

If you specify directive !DIR$ ATTRIBUTES ALIGN on an object with the ALLOCATABLE or POINTER attribute, an ALLOCATE statement will attempt to use that alignment when the memory is allocated.

For allocatable or pointer components of derived types, the directive must appear within the derived-type TYPE...END TYPE block.

If the TYPE is an extended type, the directive cannot reference a component in the parent type.
Example

Consider the following:

```fortran
TYPE EXAMPLE
  !DIR$ ATTRIBUTES ALIGN : 64 :: R_alloc
  REAL, ALLOCATABLE :: R_alloc (:)
  REAL :: R_scalar
  INTEGER :: I_nonalloc(25)
END TYPE EXAMPLE

TYPE (EXAMPLE) :: MyVar

ALLOCATE (MyVar%R_alloc(1000)) ! Memory is allocated aligned at a 64-byte boundary
```

Note that it is valid to give the ALIGN:64 attribute to component R_alloc, but not to component R_scalar or to component I_nonalloc.

The following example shows that the name of a common block may optionally be enclosed in slashes:

```fortran
!DIR$ ATTRIBUTES ALIGN: n :: /common_name/
```

See Also

ATTRIBUTES
ASSUME_ALIGNED directive
align compiler option (see setting arraynbyte)

Syntax Rules for Compiler Directives

ATTRIBUTES ALLOCATABLE

The ATTRIBUTES directive option ALLOCATABLE is provided for compatibility with older programs. It lets you delay allocation of storage for a particular declared entity until some point at run time when you explicitly call a routine that dynamically allocates storage for the entity.

Syntax

```fortran
!DIR$ ATTRIBUTES ALLOCATABLE :: entity
```

entity
Is the name of the entity that should have allocation delayed.

The recommended method for dynamically allocating storage is to use the ALLOCATABLE statement or attribute.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES ALLOW_NULL

The ATTRIBUTES directive option ALLOW_NULL enables a corresponding dummy argument to pass a NULL pointer (defined by a zero or the NULL intrinsic) by value for the argument.

Syntax

```fortran
!DIR$ ATTRIBUTES ALLOW_NULL :: arg
```
arg

Is the name of the argument.

ALLOW_NULL is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES C and STDCALL
The ATTRIBUTES directive options C and STDCALL specify procedure calling, naming, and argument passing conventions.

Syntax
!DIR$ ATTRIBUTES C :: object[, object] ...
!DIR$ ATTRIBUTES STDCALL :: object[, object] ...

object

Is the name of a data object or procedure.

On Windows* systems on IA-32 architecture, C and STDCALL have slightly different meanings; on all other platforms, STDCALL is treated as C.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions. The effects depend on whether or not the subprogram is interoperable (has the BIND attribute).

For interoperable subprograms with the BIND attribute, ATTRIBUTES STDCALL has the following effects for subprograms in applications targeting Windows systems on IA-32 architecture:

• The STDCALL calling convention is used where the called subprogram cleans up the stack at exit.
• The external name has @n appended, where n is the number of bytes of arguments pushed on the stack.

No other effects of ATTRIBUTES STDCALL are applied for interoperable subprograms. If pass-by-value is desired for a dummy argument to an interoperable subprogram, the Fortran standard VALUE attribute should be specified for that argument.

For platforms other than Windows systems on IA-32 architecture, ATTRIBUTES STDCALL has no effect on interoperable subprograms. You should not specify ATTRIBUTES C for interoperable subprograms.

The following table and subsequent text summarizes the differences between the calling conventions for subprograms that are not interoperable:

<table>
<thead>
<tr>
<th>Convention</th>
<th>C 1</th>
<th>STDCALL 1</th>
<th>Default 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments passed by value</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Case of external subprogram names</td>
<td>L<em>X, M</em>X: Lowercase</td>
<td>L<em>X, M</em>X: Lowercase</td>
<td>L<em>X, M</em>X: Lowercase</td>
</tr>
<tr>
<td></td>
<td>W*S: Lowercase</td>
<td>W*S: Lowercase</td>
<td>W*S: Uppercase</td>
</tr>
<tr>
<td><strong>L</strong>X, <strong>M</strong>X only:</td>
<td>No</td>
<td>No</td>
<td>Yes 3</td>
</tr>
<tr>
<td>Trailing underscore added</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>M</strong>X only:</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>
If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore ( _ ) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:

- By default, hidden lengths are put at the end of the argument list.
  
  On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.

- If C or STDCALL (only) is specified:
  
    On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).

- If C or STDCALL is specified, and REFERENCE is specified for the argument:
  
    On all systems, the string is passed with no length.

- If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is not specified for the argument, if any):
  
    On all systems, the string is passed with the length.

Syntax Rules for Compiler Directives
iface compiler option

Compiler Reference section: Mixed Language Programming
ATTRIBUTES CODE_ALIGN

The ATTRIBUTES directive option CODE_ALIGN
specifies the byte alignment for a procedure.

Syntax

!DIR$ ATTRIBUTES CODE_ALIGN: n:: procedure-name

n
Is the number of bytes for the minimum alignment boundary. It must
be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64,
128, and so on.

If you specify 1 for n, no alignment is performed. If you do not specify
n, the default alignment is 16 bytes.

procedure-name
Is the name of a procedure.

This directive can be affected by compiler option -falign-loops (Linux* and macOS*) or /Qalign-loops
(Windows*), the CODE_ALIGN directive, and the CODE_ALIGN attribute.

If code is compiled with the -falign-loops=m (Linux and macOS*) or /Qalign-loops:m (Windows) option
and a procedure has the CODE_ALIGN:k attribute, the procedure is aligned on a MAX (m, k) byte boundary.
If a procedure has the CODE_ALIGN:k attribute and a CODE_ALIGN:n directive precedes a loop, then both
the procedure and the loop are aligned on a MAX (k, n) byte boundary.

Example

Consider the following code fragment in file test_align.f90:

```fortran
FUNCTION F ()
  !DIR$ ATTRIBUTES CODE_ALIGN:32 :: F
  ...
  !DIR$ CODE_ALIGN:16
  DO J = 1, N
    ...
  END DO
  ...
END FUNCTION F
```

Compiling test_align.f90 with option -falign-loops=64 (Linux and macOS*) or /Qalign-loops:64
(Windows) aligns the function F and the DO J loop on 64-byte boundaries.

CODE_ALIGN directive
falign-loops, Qalign-loops compiler option
Syntax Rules for Compiler Directives

ATTRIBUTES CONCURRENCY_SAFE

The ATTRIBUTES directive option
CONCURRENCY_SAFE specifies that there are no
unacceptable side effects and no illegal (or improperly
synchronized) memory access interferences among
multiple invocations of a routine or between an
invocation of the specified routine and other
statements in the program if they were executed
concurrently.
Syntax

!DIR$ ATTRIBUTES CONCURRENCY_SAFE [:: clause] :: routine-name-list

clause

Is one of the following:

• profitable
• cost (int-cycle-count)

int-cycle-count

Is an integer scalar constant expression.

routine-name-list

Is a comma-separated list of function and subroutine names.

When a CONCURRENCY_SAFE routine is called from parallelized code, you can ignore assumed cross-block or cross-iteration dependencies and side effects of calling the specified routine from parallelized code.

The profitable clause indicates that the loops or blocks that contain calls to the routine can be safely executed in parallel if the loop or blocks are legal to be parallelized; that is, if it is profitable to parallelize them.

The cost clause indicates the execution cycles of the routine where the compiler can perform parallelization profitability analysis while compiling its enclosing loops or blocks.

The attribute can appear in the declaration of the routine; for example:

```fortran
function f(x)
!DIR$ attributes concurrency_safe :: f
```

The attribute can also appear in the code of the caller; for example:

```fortran
main m
integer f
external f
!dir$ attributes concurrency_safe :: f ! or it could be in an interface block describing f...
Print *, f(x)
```

NOTE
For every routine named in routine-name-list, you should ensure that any possible side effects are acceptable or expected, and the memory access interferences are properly synchronized.

See Also

ATTRIBUTES Syntax Rules for Compiler Directives

ATTRIBUTES CVF

The ATTRIBUTES direction option CVF tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation.

Syntax

!DIR$ ATTRIBUTES CVF :: object[, object] ...

object

Is the name of a data object or procedure.

The conventions that are used are as follows:

• The calling mechanism: STDCALL on Windows* systems using IA-32 architecture
• The argument passing mechanism: by reference
• Character-length argument passing: following the argument address
• The external name case: uppercase
• The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows® systems using IA-32 architecture, @n suffix where n is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.

See Also
ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES DECORATE
The ATTRIBUTES directive option DECORATE specifies that the external name used in !DIR$ ALIAS or !DIR$ ATTRIBUTES ALIAS should have the prefix and postfix decorations performed on it that are associated with the platform and calling mechanism that is in effect. These are the same decorations performed on the procedure name when ALIAS is not specified, except that, on Linux® and macOS® systems, DECORATE does not add a trailing underscore signifying a Fortran procedure.

Syntax
!DIR$ ATTRIBUTES DECORATE :: exname

exname Is an external name. It may not be the name of an internal procedure.

The case of the ALIAS external name is not modified.

If ALIAS is not specified, this option has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES ALIAS
The summary of prefix and postfix decorations in the description of the ATTRIBUTES options C and STDCALL

ATTRIBUTES DEFAULT
The ATTRIBUTES directive option DEFAULT overrides certain compiler options that can affect external routine and COMMON block declarations.

Syntax
c!DIR$ ATTRIBUTES DEFAULT :: entity

entity Is an external procedure, a COMMON block, a module variable that is initialized, or a PARAMETER in a module.

It specifies that the compiler should ignore compiler options that change the default conventions for external symbol naming and argument passing for routines and COMMON blocks (such as names, assume underscore, assume 2underscores on Linux systems, and iface on Windows® systems).

This option can be combined with other ATTRIBUTES options, such as STDCALL, C, REFERENCE, ALIAS, etc. to specify properties different from the compiler defaults.
This option is useful when declaring INTERFACE blocks for external routines, since it prevents compiler options from changing calling or naming conventions.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
iface compiler option
names compiler option
assume compiler option

ATTRIBUTES DLLEXPORT and DLLIMPORT
The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library's interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. These directive options are available on Windows* and macOS* systems.

Syntax
!DIR$ ATTRIBUTES DLLEXPORT :: object[, object] ...
!DIR$ ATTRIBUTES DLLIMPORT :: object[, object] ...

object Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.

DLLEXPORT and DLLIMPORT define the interface for the following dynamic-link libraries:
• DLL on Windows*
• DYLIB on macOS*

DLLEXPORT specifies that procedures or data are being exported to other applications or dynamic libraries. This causes the compiler to produce efficient code; for example, eliminating the need on Windows systems for a module definition (.def) file to export symbols.

DLLEXPORT should be specified in the routine to which it applies. If the routine's implementation is in a submodule, specify DLLEXPORT in the parent module's INTERFACE block for the routine. If MODULE PROCEDURE is used in the submodule, the DLLEXPORT attribute will be inherited; otherwise you must also specify DLLEXPORT in the submodule routine.

Symbols defined in a DLL are imported by programs that use them. On Windows*, the program must link with the DLL import library (.lib).

The DLLIMPORT option is used inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES EXTERN
The ATTRIBUTES directive option EXTERN specifies that a variable is allocated in another source file. EXTERN can be used in global variable declarations, but it must not be applied to dummy arguments.

Syntax
!DIR$ ATTRIBUTES EXTERN :: var
var 

Is the variable to be allocated.

This option must be used when accessing variables declared in other languages.

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives

**ATTRIBUTES MEMKIND**

The ATTRIBUTES directive option MEMKIND enables High Band Width (HBW) memory or non-HBW memory (DDR) allocation for an allocated object. This directive option only applies to Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) and it is only available for Linux® systems.

**Syntax**

```
!DIR$ ATTRIBUTES MEMKIND : memory :: object [, object]...
```

- **memory**
  
  Specifies the requested memory kind. It must be one of the following:

  - **HBW**
    
    Enables High Band Width memory allocation for a non-scalar, allocated object at run time.

  - **DDR**
    
    Enables non-HBW memory (Double Data Rate Random Access Memory) allocation for a non-scalar, allocated object at run time.

- **object**

  Is an array with the ALLOCATABLE attribute. It can be of any data type, kind, or rank > 0. It can be an array component of a variable of derived type. It cannot be a local variable, a common block, an array that will be allocated on the stack, or have the POINTER attribute. It can be a dummy argument.

**NOTE**

!DIR ATTRIBUTES FASTMEM has the same meaning as !DIR ATTRIBUTES MEMKIND:HBW, but the preferred directive is !DIR ATTRIBUTES MEMKIND:HBW.

When the specified object is allocated using the ALLOCATE statement at runtime, the Fortran Run-Time Library (RTL) allocates the memory in the specified memory (HBW or DDR). When the specified object is deallocated using the DEALLOCATE statement at runtime, the Fortran RTL deallocates the memory in the specified memory.

If the hardware is not available to allocate the object to High Band Width (HBW) memory, or if the libraries required for HBW memory support are not linked into the executable then either a 183 or 184 error will be issued by the ALLOCATE statement.

If enough HBW memory is not available to satisfy the allocation, then allocation is performed using non-HBW memory.

You can determine if the HBW memory hardware is available and if the libraries required for HBW memory support are linked into the executable by calling the FOR_GET_HBW_AVAILABILITY() function. You can change the behavior of the ALLOCATE statement when HBW memory hardware is not available or if the required libraries are not linked into the executable by calling the FOR_SET_FASTMEM_POLICY() function. Alternatively, you can set environment variables FOR_FASTMEM_RETRY or FOR_FASTMEM_RETRY_WARN.
When you use `ATTRIBUTES MEMKIND:HBW` in a program, you must specify the following on the compiler or linker command line:

```
-lmemkind
```

The following example shows a way to use this directive option to allocate High Band Width (HBW) memory:

```fortran
REAL, ALLOCATABLE :: X (:,:)
!DIR$ ATTRIBUTES MEMKIND:HBW :: X
...
ALLOCATE (X(100,100))
```

You can use `ATTRIBUTES MEMKIND` on a field of a derived type; for example:

```fortran
TYPE EXAMPLE
!DIR$ ATTRIBUTES MEMKIND:HBW :: R_ALLOC
REAL, ALLOCATABLE :: R_ALLOC ( : )
END TYPE EXAMPLE

TYPE (EXAMPLE) :: MYVAR
ALLOCATE (MYVAR%R_ALLOC(1000))
```

You can use `ATTRIBUTES option ALIGN with MEMKIND`; for example:

```fortran
!DIR$ ATTRIBUTES MEMKIND:HBW, ALIGN:64 :: A
ALLOCATE ( A(1000), STAT= integer-variable )
...
DEALLOCATE ( A )
```

`ATTRIBUTES MEMKIND` on an object interacts with a `MEMKIND` directive on the `ALLOCATE` for that object. For more information, see the `MEMKIND` directive.

**NOTE**

`ATTRIBUTES MEMKIND` cannot be used with an array with the `POINTER` attribute but the `MEMKIND` directive can be used to request a specific memory allocation space before the `ALLOCATE` statement for an array with the `POINTER` attribute.

- Using HBW Memory
ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE
The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

Syntax
The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.
!
!DIR$ ATTRIBUTES INLINE :: procedure
procedure
Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function.
!
!DIR$ ATTRIBUTES NOINLINE :: procedure
procedure
Is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors.
!
!DIR$ ATTRIBUTES FORCEINLINE :: procedure
procedure
Is the function or subroutine that must be inlined.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES IGNORE_LOC
The ATTRIBUTES directive option IGNORE_LOC enables %LOC to be stripped from an argument.

Syntax
!
!DIR$ ATTRIBUTES IGNORE_LOC :: arg
arg
Is the name of an argument.

IGNORE_LOC is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG
These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed.

MIXED_STR_LEN_ARG specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list.
NOMIXED_STR_LEN_ARG specifies that these hidden lengths should be placed in sequential order at the end of the argument list.

Syntax

!DIR$ ATTRIBUTES MIXED_STR_LEN_ARG :: args

!DIR$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: args

args

Is a list of arguments.

The default is NOMIXED_STR_LEN_ARG. However, if you specify compiler option /iface:CVF
or /iface:mixed_str_len_arg (Windows*), or compiler option -mixed-str-len-arg (Linux* and macOS*), the default is MIXED_STR_LEN_ARG.

See Also

ATTRIBUTES directive
Syntax Rules for Compiler Directives
iface compiler option

ATTRIBUTES NO_ARG_CHECK

The ATTRIBUTES directive option NO_ARG_CHECK specifies that type and shape matching rules related to explicit interfaces are to be ignored. This permits the construction of an INTERFACE block for an external procedure or a module procedure that accepts an argument of any type or shape; for example, a memory copying routine.

Syntax

!DIR$ ATTRIBUTES NO_ARG_CHECK :: object

object

Is the name of an argument or procedure.

NO_ARG_CHECK can appear only in an INTERFACE block for a non-generic procedure or in a module procedure. It can be applied to an individual dummy argument name or to the routine name, in which case the option is applied to all dummy arguments in that interface.

NO_ARG_CHECK cannot be used for procedures with the PURE or ELEMENTAL prefix.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES NOCLONE

The ATTRIBUTES directive option NOCLONE can be used to prevent a procedure from being considered for cloning, which is a mechanism performed by interprocedural constant propagation that produces specialized copies of the procedure.

Syntax

!DIR$ ATTRIBUTES NOCLONE :: procedure

procedure

Is a function or subroutine that can be inlined.

Note that if you specify ATTRIBUTES NOINLINE, it does not prevent this cloning.
The ATTRIBUTES directive option OFFLOAD ensures that variables, COMMON blocks, and procedures are available on the target. This directive option only applies when targeting Intel® Xeon Phi™ products. This directive is deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.

### Syntax

```fortran
!DIR$ ATTRIBUTES OFFLOAD: target-name:: object-name
```

- `target-name` is a specific target. The only supported value for this argument is MIC.
- `object-name` is the name of a procedure, or a variable, or a COMMON block name (enclosed in slashes).

The statement following an OFFLOAD directive is converted into an outlined function that runs on the processor. This code is permitted to call other procedures. To ensure that these called procedures are also available on the processor, they should also include the ATTRIBUTES OFFLOAD:MIC directive.

All procedures in the program are always compiled for the CPU and are available to be called on the CPU. However, only procedures that include the ATTRIBUTES OFFLOAD:MIC directive are available to be called by offloaded code, and only these procedures can be called on the processor.

Global variables and COMMON blocks are treated in a similar fashion. All global variables are always present in the CPU code. But only global variables and COMMON blocks declared with the ATTRIBUTES OFFLOAD:MIC directive are compiled into the code offloaded to the processor. If an data object in a named COMMON block is given the OFFLOAD:MIC attribute, the entire named COMMON block is given the OFFLOAD:MIC attribute.

Compiling only procedures and data explicitly marked with the ATTRIBUTES OFFLOAD:MIC directive into the Intel® MIC Architecture binary ensures that the code on the processor is as small as possible.

The compiler issues warnings for procedures and data referenced within offloaded code that do not include the ATTRIBUTES OFFLOAD:MIC directive.

### NOTE

The definition and all declarations of a variable or procedure with the ATTRIBUTES OFFLOAD:MIC directive must be consistent with each other across all compilation units.

### Example

```fortran
module m
  !dir$ attributes offload:mic :: global
  integer :: global = 55
end module m

!dir$ attributes offload:mic :: foo
function foo ()
  use m
  integer :: foo
  global = global + 1
  foo = global
end function foo
```
end function foo

program main
  use m
  integer :: i
  !dir$ attributes offload:mic :: foo
  integer :: foo
  !dir$ offload target(mic) in(global) out(i, global)
  i = foo()
  write(*, '( " global = ", i0, " I = ", i0)' ) global, i
end program main

Calling function foo() within an offloaded construct requires adding the ATTRIBUTES OFFLOAD:MIC directive within both the calling routine's scope and the function definition/scope for foo() itself.

OFFLOAD

ATTRIBUTES OPTIMIZATION_PARAMETER
The ATTRIBUTES directive option
OPTIMIZATION_PARAMETER passes certain
information about a procedure or main program to the
optimizer.

Syntax
!DIR$ ATTRIBUTES OPTIMIZATION_PARAMETER: string::( procedure-name | named-main-program)

string

Is a character constant that is passed to the optimizer. The constant
must be delimited by apostrophes or quotation marks, and it may
have one of the following values:

- **TARGET_ARCH= cpu**
  Tells the compiler to generate code specialized for a particular processor. For the list of cpus you can specify, see option [Q] x.

- **G2S = {ON | OFF}**
  Disables or enables the use of gather/scatter instructions in the specified program unit.
  ON tells the optimizer to disable the generation of gather/scatter and to transform gather/scatter into unit-strided loads/stores plus a set of shuffles wherever possible.
  OFF tells the optimizer to enable the generation of gather/scatter instructions and not to transform gather/scatter into unit-strided loads/stores.

- **INLINE_MAX_PER_ROUTINE= n**
Specifies the maximum number of times the inliner may inline into the procedure. The n is one of the following:

- A non-negative scalar integer constant (>=0) that specifies the maximum number of times the the inliner may inline into the procedure. If you specify zero, no inlining is done into the routine.
- The keyword UNLIMITED, which means that there is no limit to the number of times the inliner may inline into the procedure.

For more information, see option [Q]inline-max-per-routine.

- INLINE_MAX_TOTAL_SIZE=n

Specifies how much larger a routine can normally grow when inline expansion is performed. The n is one of the following:

- A non-negative scalar integer constant (>=0) that specifies the permitted increase in the routine's size when inline expansion is performed. If you specify zero, no inlining is done into the routine.
- The keyword UNLIMITED, which means that there is no limit to the size a routine may grow when inline expansion is performed.

For more information, see option [Q]inline-max-total-size.

procedure-name

Is the name of a procedure.

named-main-program

Is the name of a main program

Description

The characters in string can appear in any combination of uppercase and lowercase. The following rules also apply to string:

- If string does not contain an equal sign (=), then the entire value of string is converted to lowercase before being passed to the optimizer.
- If string contains an equal sign, then all characters to the left of the equal sign are converted to lowercase before all of string is passed to the optimizer.

Characters to the right of the equal sign are not converted to lowercase since their value may be case sensitive to the optimizer, for example “target_arch=AVX”.

You can specify multiple ATTRIBUTES OPTIMIZATION_PARAMETER directives for one procedure or one main program.

For the named procedure or main program, the values specified for ATTRIBUTES OPTIMIZATION_PARAMETER override any settings specified for the following compiler options:

- [Q]x, -m, and /arch
- [Q]inline-max-per-routine
- [Q]inline-max-total-size
Example

Consider the two attributes optimization_parameter directives in the following code:

```fortran
function f (x)
!dir$ attributes optimization_parameter: "inline_max_per_routine=10" :: f
!dir$ attributes optimization_parameter: "inline_max_total_size=2000" :: f
real :: f, x
...
```

The two directives have the same effect as if the function F had been compiled with
"/Qinline-max-per-routine:10 /Qinline-max-total-size:2000" on Windows* or with
"-inline-max-per-routine=10 -inline-max-total-size=2000" on Linux* or macOS*, that is, inlining
will not increase the size of F by more than 2000 and the inliner will not inline routines into F more than 10
times.

inline-max-per-routine, Qinline-max-per-routine compiler option
inline-max-total-size, Qinline-max-total-size compiler option

ATTRIBUTES REFERENCE and VALUE

The ATTRIBUTES directive options REFERENCE and
VALUE specify how a dummy argument is to be passed.

Syntax

```
!DIR$ ATTRIBUTES REFERENCE :: arg
!DIR$ ATTRIBUTES VALUE :: arg
```

arg Is the name of a dummy argument.

REFERENCE specifies a dummy argument's memory location is to be passed instead of the argument's value.

VALUE specifies a dummy argument's value is to be passed instead of the argument's memory location.

When VALUE is specified for a dummy argument, the actual argument passed to it can be of a different type.
If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, two floating-point arguments (one containing the real part, the other containing the imaginary part) are passed by immediate value.

Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by value.
If REFERENCE (only) is specified for a character argument, the string is passed with no length.

If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified for the routine, the string is passed with no length. This is true even if REFERENCE is also specified for the routine.

If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has not been specified for the argument, the string is passed with the length.

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.

In the following example integer x is passed by value:

```fortran
SUBROUTINE Subr (x)
INTEGER x
!DIR$ ATTRIBUTES VALUE :: x
```
ATTRIBUTES VARYING
The ATTRIBUTES directive option VARYING allows a Fortran routine to call a C/C++ routine with a variable number of arguments.

Syntax
!DIR$ ATTRIBUTES VARYING :: var[, var] ...

var Is a variable representing a C/C++ routine that takes a variable number of arguments.

This attribute can be used in an interface block to create an explicit interface for a C/C++ routine or it can be used on a variable declared EXTERN that represents a C/C++ routine. When the routine is called from the Fortran code, a variable number of arguments can be specified.

This attribute cannot be used with a Fortran routine declaration.

If ATTRIBUTES VARYING is specified, the C calling convention must also be used, either implicitly or explicitly.

All actual arguments in the routine call are passed to the called routine, regardless of the number of dummy arguments specified in the interface. If the called routine tries to access a dummy argument that has no matching actual argument, it causes a user error and the program may fail unpredictably.

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES VECTOR
The ATTRIBUTES directive option VECTOR tells the compiler to vectorize the specified function or subroutine.

Syntax
!DIR$ ATTRIBUTES [att] VECTOR [:clause] [, att]... :: routine-name
!DIR$ ATTRIBUTES [att] VECTOR :(clause [, clause]...) [, att] :: routine-name

att Is an ATTRIBUTES directive option. For a list of possible directive options, see the description of argument att in ATTRIBUTES.

clause Is one or more of the following optional clauses:

• LINEAR (var1:step1 [, var2:step2]... )

var Is a scalar variable that is a dummy argument in the specified routine.

step Is a compile-time positive, integer constant expression.
Tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of var1 is incremented by step1, var2 is incremented by step2, and so on.

If more than one step is specified for a particular var, a compile-time error occurs.

Multiple LINEAR clauses are merged as a union.

- [NO]MASK
  Determines whether the compiler generates a masked vector version of the routine.

- PROCESSOR (cpuid)

- UNIFORM (arg [, arg]...)

  arg Is a scalar variable that is a dummy argument in the specified routine.

  Tells the compiler that the values of the specified arguments can be broadcasted to all iterations as a performance optimization.

  Multiple UNIFORM clauses are merged as a union.

- VECTORLENGTH (n[, n]...)

  n Is a vector length (VL). It must be an integer, scalar constant expression that is a power of 2; the value must be 2, 4, 8, or 16. If you specify more than one n, the compiler will choose the VL from the values specified.

  Tells the compiler that each routine invocation at the call site should execute the computation equivalent to n times the scalar function execution.

  The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

  Multiple VECTORLENGTH clauses cause a syntax error.

- VECTORLENGTHFOR (data-type)

  data-type Is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
</tbody>
</table>
Causes each iteration in the vector loop to execute the computation equivalent to \( n \) iterations of scalar loop execution where \( n \) is computed from \( \frac{\text{size of vector register}}{\text{sizeof(data type)}} \).

For example, \texttt{VECTORLENGTHFOR (REAL (KIND=4))} results in \( n=4 \) for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and \( n=8 \) for AVX target (packed float operations available on 256-bit YMM registers). \texttt{VECTORLENGTHFOR(INTEGER (KIND=4))} results in \( n=4 \) for SSE2 to AVX targets.

The \texttt{VECTORLENGTHFOR} and \texttt{VECTORLENGTH} clauses are mutually exclusive. You cannot use the \texttt{VECTORLENGTHFOR} clause with the \texttt{VECTORLENGTH} clause, and vice versa.

Multiple \texttt{VECTORLENGTHFOR} clauses cause a syntax error.

Without explicit \texttt{VECTORLENGTH} and \texttt{VECTORLENGTHFOR} clauses, the compiler will choose a \texttt{VECTORLENGTH} using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

\texttt{routine-name} Is the name of a routine (a function or subroutine). It must be the enclosing routine or the routine immediately following the directive.

If you specify more than one clause, they must be separated by commas and enclosed in parentheses.

When you specify the \texttt{ATTRIBUTES VECTOR} directive, the compiler provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. If you specify one or more clauses, they affect the data parallel semantics provided by the compiler.

If you specify the \texttt{ATTRIBUTES VECTOR} directive with no \texttt{VECTORLENGTH} clause, a default \texttt{VECTORLENGTH} is computed based on efficiency heuristics of the vectorizer and the following:

- The return type of the function, if the function has a return type.
- The data type of the first non-scalar argument (that is, the first argument that is specified in the scalar clause), if any.
- Default integer type, if neither of the above is supplied.
If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model.

If you specify the ATTRIBUTES VECTOR directive with no clause, the compiler will generate vector code based on compiler efficiency heuristics and whatever processor compiler options are specified.

The VECTOR attribute implies the C attribute, so that when you specify the VECTOR attribute on a routine, the C attribute is automatically also set on the same routine. This changes how the routine name is decorated and how arguments are passed.

NOTE
You should ensure that any possible side effects for the specified routine-name are acceptable or expected, and the memory access interferences are properly synchronized.

The Fortran Standard keyword ELEMENTAL specifies that a procedure written with scalar arguments can be extended to conforming array arguments by processing the array elements one at a time in any order. The ATTRIBUTES VECTOR directive tells the optimizer to produce versions of the procedure routine-name that execute with contiguous slices of the array arguments as defined by the VECTORLENGTH clause in an "elemental" fashion. routine-name does not need to be defined as ELEMENTAL to be given the VECTOR attribute.

The VECTOR attribute causes the compiler to generate a short vector form of the procedure, which can perform the procedure's operation on multiple elements of its array arguments in a single invocation. The short vector version may be able to perform multiple operations as fast as the regular implementation performs a single operation by using the vector instruction set in the CPU.

In addition, when invoked from an OMP construct, the compiler may assign different copies of the elemental procedures to different threads, executing them concurrently. The end result is that your data parallel operation executes on the CPU using both the parallelism available in the multiple cores and the parallelism available in the vector instruction set. If the short vector procedure is called inside a parallel loop or an auto-parallelized loop that is vectorized, you can achieve both vector-level and thread-level parallelism.

The INTENT(OUT) or INTENT(INOUT) attribute is not allowed for arguments of a procedure with the VECTOR attribute since the VECTOR attribute forces the procedure to receive its arguments by value.

The Intel C/C++ compiler built-in function __intel_simd_lane() may be helpful in removing certain performance penalties caused by non-unit stride vector access. Consider the following:

interface
  ! returns a number between 0 and vectorlength - 1 that reflects the current "lane id" within the SIMD vector
  ! __intel_simd_lane() will return zero if the loop is not vectorized
  function for_simd_lane () bind (C, name = "__intel_simd_lane")
    integer (kind=4) :: for_simd_lane
  !DEC$ attributes known_intrinsic, default :: for_simd_lane
  end function for_simd_lane
end interface

For more details, see the Intel C++ documentation.
Example

The ATTRIBUTES VECTOR directive must be accessible in the caller, either via an INTERFACE block or by USE association.

The following shows an example of an external function with an INTERFACE block:

```
!... function definition

    function f(x)
    !dir$ attributes vector :: f
    real :: f, x
    ...
    ! attribute vector explicit in calling procedure using an INTERFACE

    interface
        function f(x)
        !dir$ attributes vector :: f
        real :: f, x
    end function
    end interface
    ...
    do i=1,n
        z(i) = f( x(i) )
    end do
```

The ATTRIBUTES VECTOR directive can be brought into the caller by USE association if the vector function is a module procedure; for example:

```
! attribute vector in definition of module procedure

module use_vect
    contains
        function f(x)
        !dir$ attributes vector :: f
        real :: f, x
        ...
        end function
    end module use_vect

! USE and call of f(x) from another procedure with a module USE statement

    USE use_vect !brings in ATTRIBUTE VECTOR for f(x)
    ...

! now simply call f(x)
```
do i=1,n
  z(i) = f( x(i) )
end do

You can specify more than one SCALAR or LINEAR clause in an ATTRIBUTES VECTOR directive. For example, all of the following are valid:

```
!DIR$ ATTRIBUTES VECTOR:PROCESSOR(atom) :: f
!DIR$ ATTRIBUTES VECTOR:(SCALAR(a), SCALAR(b)) :: f
!DIR$ ATTRIBUTES VECTOR:(LINEAR(x:1), LINEAR(y:1)) :: f
```

The three directives above are equivalent to specifying a single, continued, directive in fixed-form source, as follows:

```
!DIR$ ATTRIBUTES VECTOR: ( PROCESSOR(atom),
!DIR$& SCALAR(a, b),
!DIR$& LINEAR(x:1, y:1) ) :: f
```

The following example for Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) tells the compiler to generate vector functions for that processor:

```
integer function f(a, b)
  integer :: a, b
  f = a + b
end function f
```

ATTRIBUTES
Syntax Rules for Compiler Directives

AUTOAddArg (W*S)

**AUTO Subroutine:** Passes an argument name and value and adds the argument to the argument list data structure.

**Module**

USE IFAUTO
USE IFWINTY

**Syntax**

```
CALL AUTOAddArg (invoke_args, name, value[, intent_arg][, type])
```

- `invoke_args`:
  The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

- `name`:
  The argument's name of type CHARACTER*(*).

- `value`:
  The argument's value. Must be of type INTEGER(1), INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), CHARACTER*(*), or a single dimension array of one of these types. Can also be of type VARIANT, which is defined in the IFWINTY module.

- `intent_arg`:
  Indicates the intended use of the argument by the called method. Must be one of the following constants defined in the IFAUTO module:
• AUTO_ARG_IN: The argument's value is read by the called method, but not written. This is the default value if `intent_arg` is not specified.
• AUTO_ARG_OUT: The argument's value is written by the called method, but not read.
• AUTO_ARG_INOUT: The argument's value is read and written by the called method.

When the value of `intent_arg` is AUTO_ARG_OUT or AUTO_ARG_INOUT, the variable used in the `value` argument should be declared using the VOLATILE attribute. This is because the value of the variable will be changed by the subsequent call to AUTOInvoke. The compiler's global optimizations need to know that the value can change unexpectedly.

The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_VARIANT</td>
<td>TYPE(VARIANT)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Example**

See the example in COMInitialize.

**AUTOAllocateInvokeArgs (W*S)**

**AUTO Function:** Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.

**Module**

USE IFAUTO
**Syntax**

```plaintext
result = AUTOAllocateInvokeArgs()
```

**Results**

The value returned is an argument list data structure of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.

**AUTODeallocateInvokeArgs (W*S)**

**AUTO Subroutine**: Deallocates an argument list data structure.

**Module**

USE IFAUTO

**Syntax**

```plaintext
CALL AUTODeallocateInvokeArgs (invoke_args)
```

`invoke_args` The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.

**AUTOGetExceptInfo (W*S)**

**AUTO Subroutine**: Retrieves the exception information when a method has returned an exception status.

**Module**

USE IFAUTO

**Syntax**

```plaintext
CALL AUTOGetExceptInfo (invoke_args, code, source, description, h_file, h_context, scode)
```

`invoke_args` The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

`code` An output argument that returns the error code. Must be of type INTEGER(2).

`source` An output argument that returns a human-readable name of the source of the exception. Must be of type CHARACTER(*)

`description` An output argument that returns a human-readable description of the error. Must be of type CHARACTER(*).
**h_file**

An output argument that returns the fully qualified path of a Help file with more information about the error. Must be of type CHARACTER(*).

**h_context**

An output argument that returns the Help context of the topic within the Help file. Must be of type INTEGER(4).

**scode**

An output argument that returns an SCODE describing the error. Must be of type INTEGER(4).

---

**AUTOGetProperty (W*S)**

**AUTO Function**: Passes the name or identifier of the property and gets the value of the automation object's property.

**Module**

USE IFAUTO

USE IFWINTY

**Syntax**

```
result = AUTOGetProperty (idispatch, id, value[, type])
```

**idispatch**

The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**id**

The argument’s name of type CHARACTER(*), or its member ID of type INTEGER(4).

**value**

An output argument that returns the argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER(*), or a single dimension array of one of these types.

**type**

The variant type of the requested argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(*)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VARIANT Type</td>
<td>Value Type</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOGetPropertyByID (W*S)**

*AUTO Function:* Passes the member ID of the property and gets the value of the automation object's property into the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOGetPropertyByID}(\text{idispatch, memid, invoke_args})
\]

- **idispatch**: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **memid**: Member ID of the property. Must be of type INTEGER(4).
- **invoke_args**: The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOGetPropertyInvokeArgs (W*S)**

*AUTO Function:* Passes an argument list data structure and gets the value of the automation object's property specified in the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOGetPropertyInvokeArgs}(\text{idispatch, invoke_args})
\]

- **idispatch**: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **invoke_args**: The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(INT_PTR_KIND()).
**AUTOInvoke (W*S)**

**AUTO Function:** Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOInvoke}(\text{idispatch}, \text{id}, \text{invoke_args})
\]

- \text{idispatch}: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- \text{id}: The argument's name of type CHARACTER*(*) or its member ID of type INTEGER(4).
- \text{invoke_args}: The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**Example**

See the example in COMInitialize.

---

**AUTOMATIC**

**Statement and Attribute:** Controls the storage allocation of variables in subprograms (as does STATIC). Variables declared as AUTOMATIC and allocated in memory reside in the stack storage area, rather than at a static memory location.

**Syntax**

The AUTOMATIC attribute can be specified in a type declaration statement or an AUTOMATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

\[
type, [\text{att-\text{-ls}},] \text{AUTOMATIC}[, \text{att-\text{-ls}}] : : v[, v] ... 
\]

**Statement:**

\[
\text{AUTOMATIC}[::] v[, v] ... 
\]

- \text{type}: Is a data type specifier.
- \text{att-\text{-ls}}: Is an optional list of attribute specifiers.
- \text{v}: Is the name of a variable or an array specification. It can be of any type.

AUTOMATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.
Automatic variables can reduce memory use because only the variables currently being used are allocated to memory.

Automatic variables allow possible recursion. With recursion, a subprogram can call itself (directly or indirectly), and resulting values are available upon a subsequent call or return to the subprogram. For recursion to occur, RECURSIVE must be specified in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

By default, the compiler allocates local scalar variables on the stack. Other non-allocatable variables of non-recursive subprograms are allocated in static storage by default. This default can be changed through compiler options. Appropriate use of the SAVE attribute may be required if your program assumes that local variables retain their definition across subprogram calls.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE (in one of the ways mentioned above).

To override any compiler option that may affect variables, explicitly specify the variables as AUTOMATIC.

**NOTE**

Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as AUTOMATIC more than once in the same scoping unit.

If the variable is a pointer, AUTOMATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as AUTOMATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>AUTOMATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>No</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

If a variable is in a module's outer scope, it cannot be specified as AUTOMATIC.

Use the heap-arrays compiler option to avoid stack overflows at run-time by placing large automatic arrays in the heap instead of on the stack.

**Example**

The following example shows a type declaration statement specifying the AUTOMATIC attribute:

```fortran
REAL, AUTOMATIC :: A, B, C
```

The following example uses an AUTOMATIC statement:

```fortran
... CONTAINS
INTEGER FUNCTION REDO_FUNC
INTEGER I, J(10), K
```
REAL C, D, E(30)
AUTOMATIC I, J, K(20)
STATIC C, D, E
...
END FUNCTION

In this example, all variables within the program unit are saved, except for "var1" and "var3". These are explicitly declared in an AUTOMATIC statement, and thus have memory locations on the stack:

SUBROUTINE DoIt (arg1, arg2)
INTEGER(4) arg1, arg2
INTEGER(4) var1, var2, var3, var4
SAVE
AUTOMATIC var1, var3

var2 and var4 are saved

Modules and Module Procedures

**AUTOSetProperty (W*S)**

Auto Function: Passes the name or identifier of the property and a value, and sets the value of the automation object's property.

Syntax

```fortran
result = AUTOSetProperty (idispatch, id, value[, type])
```

**idispatch**

The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**id**

The argument's name of type CHARACTER(*), or its member ID of type INTEGER(4).

**value**

The argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER(*), or a single dimension array of one of these types.
**type**

The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

---

**AUTOSetPropertyByID (W*S)**

**AUTO Function**: Passes the member ID of the property and sets the value of the automation object's property into the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

```plaintext
result = AUTOSetPropertyByID (idispatch, memid, invoke_args)
```

- `idispatch` : The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- `memid` : Member ID of the property. Must be of type INTEGER(4).
- `invoke_args` : The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).
AUTOSetPropertyInvokeArgs (W*S)

**AUTO Function:** Passes an argument list data structure and sets the value of the automation object's property specified in the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOSetPropertyInvokeArgs} \left( \text{idispatch}, \text{invoke\_args} \right)
\]

- **idispatch**
  - The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

- **invoke\_args**
  - The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**BACKSPACE**

**Statement:** Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing. It takes one of the following forms:

**Syntax**

\[
\text{BACKSPACE} \left( \left[ \text{UNIT=} \text{io-unit[, ERR=label]} \right] \left[, \text{IOMSG=msg-var} \right] \left[, \text{IOSTAT=i-var} \right] \right)
\]

- **io-unit**
  - (Input) Is an external unit specifier.

- **label**
  - Is the label of the branch target statement that receives control if an error occurs.

- **msg-var**
  - (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

- **i-var**
  - (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

The I/O unit number must specify an open file on disk or magnetic tape.

Backspacing from the current record \( n \) is performed by rewinding to the start of the file and then performing \( n - 1 \) successive READs to reach the previous record.

A BACKSPACE statement must not be specified for a file that is open for direct or append access, because \( n \) is not available to the Fortran I/O system.

BACKSPACE cannot be used to skip over records that have been written using list-directed or namelist formatting.
If a file is already positioned at the beginning of a file, a BACKSPACE statement has no effect.
If the file is positioned between the last record and the end-of-file record, BACKSPACE positions the file at
the start of the last record.

Example

BACKSPACE 5
BACKSPACE (5)
BACKSPACE lunit
BACKSPACE (UNIT = lunit, ERR = 30, IOSTAT = ios)

The following statement repositions the file connected to I/O unit 4 back to the preceding record:

BACKSPACE 4

Consider the following statement:

BACKSPACE (UNIT=9, IOSTAT=IOS, ERR=10)

This statement positions the file connected to unit 9 back to the preceding record. If an error occurs, control
is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

Branch Specifiers

BADDRESS

Inquiry Intrinsic Function (Generic): Returns the address of an argument. This function cannot be
passed as an actual argument. This function can also be specified as IADDR.

Syntax

result = BADDRESS (x)

x

Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a
statement function. If it is a pointer, it must be defined and associated with a target.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the
result represents the address of the data object or, in the case of pointers, the address of its associated
target. If the argument is not valid, the result is undefined.

Example

PROGRAM batest
  INTEGER X(5), I
  DO I=1, 5
    PRINT *, BADDRESS(X(I))
  END DO
END
**BARRIER**

*OpenMP* Fortran Compiler Directive:

Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.

**Syntax**

```fortran
!$OMP BARRIER
```

The binding thread set for a BARRIER construct is the current team. A barrier region binds to the innermost enclosing parallel region.

Each barrier region must be encountered by all threads in a team or by none at all, unless cancellation has been requested for the innermost enclosing parallel region.

The barrier region must also be encountered in the same order by all threads in a team.

**Example**

```fortran
INTEGER K
K = 17

!$OMP PARALLEL SHARED (K) NUM_THREADS (2)
IF (OMP_GET_THREAD_NUM() == 0) THEN
    X = 5
ELSE
    ! The following read access of K creates a race condition
    PRINT *,"1: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ENDIF

! This barrier contains implicit flushes on all threads, as well as a thread
! synchronization: this guarantees that the value 5 will be printed by
! both PRINT 2 and PRINT 3 below.

!$OMP BARRIER

IF (OMP_GET_THREAD_NUM() == 0) THEN
    PRINT *,"2: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ELSE
    PRINT *,"3: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ENDIF

!$OMP END PARALLEL
```

**BEEPQQ**

*Portability Subroutine:* Sounds the speaker at the specified frequency for the specified duration in milliseconds.
Module
USE IFPORT

Syntax
CALL BEEPQQ (frequency, duration)

frequency (Input) INTEGER(4). Frequency of the tone in Hz.
duration (Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Example
USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration = 1000
CALL BEEPQQ(frequency, duration)

See Also
SLEEPQQ

BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

Portability Functions: Compute the single-precision values of Bessel functions of the first and second kinds.

Module
USE IFPORT

Syntax
result = BESJ0 (value)
result = BESJ1 (value)
result = BESJN (n, value)
result = BESY0 (posvalue)
result = BESY1 (posvalue)
result = BESYN (n, value)

value (Input) REAL(4). Independent variable for a Bessel function.

n (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.

posvalue (Input) REAL(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results
BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and n, respectively, with the independent variable posvalue.
BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and \( n \), respectively, with the independent variable `posvalue`.

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the `BESSEL_*` functions, if you need to use quad-precision (REAL(16)).

### See Also

DBESJ0, DBESJ1, DBESJN

### BESSEL_J0

**Elemental Intrinsic Function (Generic):** Computes a Bessel function of the first kind, order 0.

**Syntax**

```fortran
result = BESSEL_J0 (x)
```

\( x \) (Input) Must be of type real.

**Results**

The result type and kind are the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order zero of \( x \).

**Example**

BESSEL_J0 (1.0) has the approximate value 0.765.

### BESSEL_J1

**Elemental Intrinsic Function (Generic):** Computes a Bessel function of the first kind, order 1.

**Syntax**

```fortran
result = BESSEL_J1 (x)
```

\( x \) (Input) Must be of type real.

**Results**

The result type and kind are the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order 1 of \( x \).

**Example**

BESSEL_J1 (1.0) has the approximate value 0.440.
BESSEL_JN
Elemental and Transformational Intrinsic Functions (Generic): Compute Bessel functions of the first kind.

Syntax
Elemental function: result = BESSEL_JN (n, x)
Transformational function: result = BESSEL_JN (n1, n2, x)

n, n1, n2  (Input) Must be of type integer and nonnegative.
x  (Input) Must be of type real.

Results
The result type and kind are the same as x.
The result of BESSEL_JN (n, x) is scalar. The result value of BESSEL_JN (n, x) is a processor-dependent approximation to the Bessel function of the first kind and order n of x.
The result of BESSEL_JN (n1, n2, x) is a rank-one array with extent MAX (n2 - n1 + 1, 0). Element i of the result value of BESSEL_JN (n1, n2, x) is a processor-dependent approximation to the Bessel function of the first kind and order n1 + i - 1 of x.

Example
BESSEL_JN (2, 1.0) has the approximate value 0.115.

Consider the following program Bessel.f90:

```fortran
real :: z (6) = [0:5]/5.          ! 0.0 through 1.0 by 0.2
print *, z
print *, bessel_jn (2, 1.0)      ! scalar argument, answer about 0.115
print *, bessel_jn (1, z)          ! elemental
print *, bessel_jn (1, 4, 1.0)  ! orders 1 thru 4 on a scalar
end
```

Compile bessel.f90 and execute the result:

```bash
> ifort Bessel.f90 -o Bessel
> bessel
```

The above commands produce the following result:

```
0.0000000E+00  0.2000000  0.4000000  0.6000000  0.8000000  1.000000
0.1149035
0.0000000E+00  9.9500835E-02  0.1960266  0.2867010  0.3688421  0.4400506
0.4400506  0.1149035  1.9563355E-02  2.4766389E-03
```

BESSEL_Y0
Elemental Intrinsic Function (Generic): Computes a Bessel function of the second kind, order 0.

Syntax
result = BESSEL_Y0 (x)

x  (Input) Must be of type real with a value greater than zero.
Results
The result type and kind are the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order zero of \( x \).

Example
BESSEL_Y0 (1.0) has the approximate value 0.088.

**BESSEL_Y1**

*Elemental Intrinsic Function (Generic): Computes a Bessel function of the second kind, order 1.*

Syntax
```
result = BESSEL_Y1 (x)
```

\( x \)  
(Input) Must be of type real with a value greater than zero.

Results
The result type and kind are the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order 1 of \( x \).

Example
BESSEL_Y1 (1.0) has the approximate value -0.781.

**BESSEL_YN**

*Elemental and Transformational Intrinsic Functions (Generic): Compute Bessel functions of the second kind.*

Syntax
Elemental function: 
```
result = BESSEL_YN (n, x)
```

Transformational function: 
```
result = BESSEL_YN (n1, n2, x)
```

\( n, n1, n2 \)  
(Input) Must be of type integer and nonnegative.

\( x \)  
(Input) Must be of type real with a value greater than zero.

Results
The result type and kind are the same as \( x \).

The result of BESSEL_YN \((n, x)\) is scalar. The result value of BESSEL_YN \((n, x)\) is a processor-dependent approximation to the Bessel function of the second kind and order \( n \) of \( x \).

The result of BESSEL_YN \((n1, n2, x)\) is a rank-one array with extent MAX \((n2 - n1 + 1, 0)\). Element \( i \) of the result value of BESSEL_YN \((n1, n2, x)\) is a processor-dependent approximation to the Bessel function of the second kind and order \( n1 + i - 1 \) of \( x \).

Example
BESSEL_YN (2, 1.0) has the approximate value -1.651.
**BGE**

**Elemental Intrinsic Function (Generic):** Performs a bitwise greater than or equal to on its arguments.

**Syntax**

```plaintext
result = BGE (i, j)
```

- `i` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
- `j` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of `i` and `j` do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by `i` is greater than or equal to the sequence of bits represented by `j`, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

If `BIT_SIZE (J)` has the value 8, `BGE (Z'FF', J)` has the value true for any value of `J`. `BGE (0, -1)` has the value false.

**See Also**

BIT_SIZE

---

**BGT**

**Elemental Intrinsic Function (Generic):** Performs a bitwise greater than on its arguments.

**Syntax**

```plaintext
result = BGT (i, j)
```

- `i` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
- `j` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of `i` and `j` do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by `i` is greater than the sequence of bits represented by `j`, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.
The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in *Binary, Octal, Hexadecimal, and Hollerith Constants*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**Example**

BGT (Z'FF', Z'FC') has the value true. BGT (0, -2) has the value false.

### BIC, BIS

*Portability Subroutines: Perform a bit-level set and clear for integers.*

#### Module

USE IFPORT

#### Syntax

CALL BIC (bitnum, target)

CALL BIS (bitnum, target)

- **bitnum** *(Input) INTEGER(4). Bit number to set. Must be in the range 0 (least significant bit) to 31 (most significant bit) if target is INTEGER(4). If target is INTEGER(8), bitnum must be in range 0 to 63.*

- **target** *(Input) INTEGER(4) or INTEGER(8). Variable whose bit is to be set.*

BIC sets bit *bitnum* of *target* to 0; BIS sets bit *bitnum* to 1.

#### Example

Consider the following:

```fortran
USE IFPORT
integer(4) bitnum, target_i4
integer(8) target_i8

target_i4 = Z'AAAA'
bitnum = 1
call BIC(bitnum, target_i4)
target_i8 = Z'FFFFFFFF00000000'
bitnum = 40
call BIC(bitnum, target_i8)
bitnum = 0
call BIS(bitnum, target_i4)
bitnum = 1
call BIS(bitnum, target_i8)
print '('integer*4 result ',Z)', target_i4
print '('integer*8 result ',Z)', target_i8
end
```

**See Also**

BIT

### BIND

*Statement and Attribute: Specifies that an object is interoperable with C and has external linkage.*
**Syntax**

The BIND attribute can be specified in a type declaration statement or a BIND statement, and takes one of the following forms:

**Type Declaration Statement:**

type, [attr-ls, ] BIND (C [, NAME=ext-name]) [, attr-ls] :: object

**Statement:**

BIND (C [, NAME=ext-name]) [:] object

- `type` is a data type specifier.
- `attr-ls` is an optional list of attribute specifiers.
- `ext-name` is a character scalar constant expression that can be used to construct the external name.
- `object` is the name of a variable or common block. It can also be the name of an internal procedure if NAME= is not specified.

**Description**

If a common block is specified in a BIND statement, it must be specified with the same binding label in each scoping unit in which it is declared.

For variables and common blocks, BIND also implies the SAVE attribute, which may be explicitly confirmed with SAVE.

A variable given the BIND attribute (or declared in a BIND statement) must appear in the specification part of a module. You cannot specify BIND for a subroutine local variable or a variable in a main program.

The BIND attribute is similar to directive !DIR$ ATTRIBUTES C as follows:

- The compiler applies the same naming rules, that is, names are lowercase (unless NAME= specifies otherwise).
- The compiler applies the appropriate platform decoration, such as a leading underscore.

However, procedure argument passing differs. When BIND is specified, procedure arguments are passed by reference unless the VALUE attribute is also specified.

The BIND attribute can optionally be used in a PROCEDURE, SUBROUTINE, or FUNCTION declaration. It must be used in an ENUM declaration.

**Example**

The following example shows the BIND attribute used in a type declaration statement, a statement, and a SUBROUTINE statement.

```plaintext
INTEGER, BIND(C) :: SOMEVAR

BIND(C,NAME='SharedCommon') :: /SHAREDCOMMON/

! you need empty parens after the subroutine name if BIND is present
SUBROUTINE FOOBAR() BIND(C, NAME='FooBar')
... 
END SUBROUTINE
```

FUNCTION

SUBROUTINE

PROCEDURE

Enumerations and Enumerators (ENUM)

BIND(C)

in mixed language programming

BIT

Portability Function: Performs a bit-level test for integers.

Module

USE IFPORT

Syntax

result = BIT (bitnum, source)

bitnum (Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).

source (Input) INTEGER(4) or INTEGER(8). Variable being tested.

Results

The result type is logical. It is .TRUE. if bit bitnum of source is 1; otherwise, .FALSE..

See Also

BIC, BIS

BIT_SIZE

Inquiry Intrinsic Function (Generic): Returns the number of bits in an integer type.

Syntax

result = BIT_SIZE (i)

i (Input) Must be of type integer or of type logical (which is treated as an integer).

Results

The result is a scalar integer with the same kind parameter as i. The result value is the number of bits (s) defined by the bit model for integers with the kind parameter of the argument. For information on the bit model, see Model for Bit Data.
Example
BIT_SIZE (1_2) has the value 16 because the KIND=2 integer type contains 16 bits.

See Also
BTEST
IBCLR
IBITS
IBSET

BLE
Elemental Intrinsic Function (Generic): Performs a bitwise less than or equal to on its arguments.

Syntax
result = BLE (i, j)

i (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

j (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results
The result is true if the sequence of bits represented by i is less than or equal to the sequence of bits represented by j, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
BLE (0, J) has the value true for any value of J. BLE (-2, 0) has the value false.

BLOCK
Statement: Marks the beginning of a BLOCK construct. The BLOCK construct executes a block of statements or constructs that can contain declarations.

Syntax
[name:] BLOCK
   [specification-part]
   block
END BLOCK [name]
name

(Optional) Is the name of the BLOCK construct.

specification-part

(Optional) Is one or more specification statements, except for the following:

- COMMON
- FUNCTION (outside of an INTERFACE block)
- EQUIVALENCE
- IMPLICIT
- INTENT (or its equivalent attribute)
- MODULE
- NAMELIST
- OPTIONAL (or its equivalent attribute)
- SUBROUTINE (outside of an INTERFACE block)
- VALUE (or its equivalent attribute)
- Statement functions

block

Is a sequence of zero or more statements or constructs, except for the following:

- CONTAINS (outside of a TYPE definition)
- ENTRY
- IMPORT (outside of a TYPE definition)
- Statement functions

Description

A BLOCK construct is itself a scoping unit. Entities declared in a BLOCK construct are local to the BLOCK construct and are accessible only in that construct and in any contained constructs. A local entity in a block construct hides any entity with the same name in its host scope. No transfer of control into a block from outside the block is allowed, except for the return from a procedure call. Transfers within a block or out of the block are allowed.

If a construct name is specified at the beginning of a BLOCK statement, the same name must appear in the corresponding END BLOCK statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a BLOCK statement, you cannot specify one following the END BLOCK statement.

You can only branch to an END BLOCK statement from within its BLOCK construct.

The SAVE attribute specifies that a local variable of a BLOCK construct retains its association status, allocation status, definition status, and value after termination of the construct unless it is a pointer and its target becomes undefined. If the BLOCK construct contains a SAVE statement, the SAVE statement cannot specify the name of a common block. A SAVE statement outside a BLOCK construct does not affect variables local to the BLOCK construct, because a SAVE statement affects variables in its scoping unit which excludes nested scoping units in it.

The statements specified within the specification-part are evaluated in a processor-dependent order, followed by execution of block. When execution exits block, all non-SAVEEd automatic and allocatable local variables are deallocated.

Example

The following shows a BLOCK construct:

```
block
  integer :: i
  real :: a(n)
  do i = 1,n
    a(i) = i
```

When control exits the bottom of the BLOCK, local variables $i$ and $a$ revert to their meaning outside the block.

The following example shows two nested BLOCK constructs where the inner BLOCK construct has the construct name INNER and the outer one does not have a name:

```
BLOCK
  ...
  INNER: BLOCK
    ...
  END BLOCK INNER
  ...
END BLOCK
```

In the following example, the appearance and the reference of the FORMAT statement are legal:

```
PROGRAM MAIN
  WRITE(6, FMT=10)
  ...
  BLOCK
    10 FORMAT("Hello")
    END BLOCK
END
```

Implicit typing is not affected by BLOCK constructs. In the following example, even if $\text{NSQP}$ only appears in the two BLOCK constructs, the scope of $\text{NSQP}$ is the whole subroutine $\text{S}$:

```
SUBROUTINE $\text{S}(\text{N})$
  ...
  IF (N>0) THEN
    BLOCK
      $\text{NSQP} = \text{CEILING(DBLE(N))}$
    END BLOCK
  END IF
  ...
  IF (N>0) THEN
    BLOCK
      PRINT *,$\text{NSQP}$
    END BLOCK
  END IF
END SUBROUTINE $\text{S}$
```

**BLOCK DATA**

**Statement:** Identifies a block-data program unit, which provides initial values for variables in named common blocks.

**Syntax**

```
BLOCK DATA [name]
  [specification-part]
END [BLOCK DATA[name]]
```
**name**

Is the name of the block data program unit.

**specification-part**

Is one or more of the following statements:

<table>
<thead>
<tr>
<th>COMMON</th>
<th>INTRINSIC</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>PARAMETER</td>
<td>TARGET</td>
</tr>
<tr>
<td>Derived-type</td>
<td>POINTER</td>
<td>Type declaration</td>
</tr>
<tr>
<td>definition</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DIMENSION</td>
<td>RECORD(^1)</td>
<td>USE(^3)</td>
</tr>
<tr>
<td>EQUVALENCE</td>
<td>Record structure</td>
<td>declaration(^1)</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>SAVE</td>
<td></td>
</tr>
</tbody>
</table>

\(^1\) For more information, see RECORD statement and record structure declarations.

\(^2\) Can only contain attributes: DIMENSION, INTRINSIC, PARAMETER, POINTER, SAVE, STATIC, or TARGET.

\(^3\) Allows access to only named constants.

---

**Description**

A block data program unit need not be named, but there can only be one unnamed block data program unit in an executable program.

If a name follows the END statement, it must be the same as the name specified in the BLOCK DATA statement.

An interface block must not appear in a block data program unit and a block data program unit must not contain any executable statements.

If a DATA statement initializes any variable in a named common block, the block data program unit must have a complete set of specification statements establishing the common block. However, all of the variables in the block do not have to be initialized.

A block data program unit can establish and define initial values for more than one common block, but a given common block can appear in only one block data program unit in an executable program.

The name of a block data program unit can appear in the EXTERNAL statement of a different program unit to force a search of object libraries for the block data program unit at link time.

**Example**

The following shows a block data program unit:

```fortran
BLOCK DATA BLKDAT
  INTEGER S,X
  LOGICAL T,W
  DOUBLE PRECISION U
  DIMENSION R(3)
  COMMON /AREA1/R,S,U,T /AREA2/W,X,Y
  DATA R/1.0,2*2.0/, T/.FALSE./, U/0.214537D-7/, W/.TRUE./, Y/3.5/
END
```
The following shows another example:

```c
C Main Program
CHARACTER(LEN=10) family
INTEGER a, b, c, d, e
REAL X(10), Y(4)
COMMON/Lakes/a,b,c,d,e,family/Blk2/x,y
...
C The following block-data subprogram initializes
C the named common block /Lakes/:
C
BLOCK DATA InitLakes
COMMON /Lakes/ erie, huron, michigan, ontario,
+        superior, fname
DATA erie, huron, michigan, ontario, superior /1, 2, 3, 4, 5/
CHARACTER(LEN=10) fname/'GreatLakes'/
INTEGER erie, huron, michigan, ontario, superior
END
```

Program Units and Procedures

BLOCK LOOP and NOBLOCK LOOP

**General Compiler Directives:** Enables or disables loop blocking for the immediately following nested DO loops. BLOCK LOOP enables loop blocking for the nested loops. NOBLOCK LOOP disables loop blocking for the nested loops.

**Syntax**

```c
!DIR$ BLOCK_LOOP [clause[,,] clause]...
!DIR$ NOBLOCK LOOP
```

**clause**

Is one or more of the following:

- **FACTOR(expr)**
  
  expr Is a positive scalar constant integer expression representing the blocking factor for the specified loops.

  This clause is optional. If the FACTOR clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the directive.

  At most only one FACTOR clause can appear in a BLOCK_LOOP directive.

- **LEVEL(level [, level]...)**

  level Is specified in the form:

  `const1` or `const1:const2`
where \( const1 \) is a positive integer constant \( m \leq 8 \) representing the loop at level \( m \), where the immediate following loop is level 1.

The \( const2 \) is a positive integer constant \( n \leq 8 \) representing the loop at level \( n \), where \( n > m: const1:const2 \) represents the nested loops from level \( const1 \) through \( const2 \).

This clause is optional. If the LEVEL clause is not present, the specified blocking factor is applied to all levels of the immediately following nested loops.

At most only one LEVEL clause can appear in a BLOCK_LOOP directive.

The clauses can be specified in any order. If you do not specify any clause, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.

The BLOCK_LOOP directive lets you exert greater control over optimizations on a specific DO loop inside a nested DO loop.

Using a technique called loop blocking, the BLOCK_LOOP directive separates large iteration counted DO loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no LEVEL and FACTOR clause, the blocking factor will be determined based on the processor's type and memory access patterns and it will apply to all the levels in the nested loops following this directive.

You can use the NOBLOCK_LOOP directive to tune the performance by disabling loop blocking for nested loops.

---

**NOTE**

The loop-carried dependence is ignored during the processing of BLOCK_LOOP directives.

---

**Example**

```fortran
!dir$ block_loop factor(256) level(1)       ! applies blocking factor 256 to
!dir$ block_loop factor(512) level(2)       ! the top level loop in the following
!           ! nested loop and blocking factor 512 to
!           ! the 2nd level (1st nested) loop

!dir$ block_loop factor(256) level(2)       ! levels can be specified in any order
!dir$ block_loop factor(512) level(1)       ! adjacent loops can be specified as a range

!dir$ block_loop factor(256) ! the blocking factor applies to all levels of loop nest

!dir$ block_loop (256)       ! the blocking factor will be determined based on
!                           ! processor type and memory access patterns and will
!                           ! be applied to all the levels in the nested loop
!                           ! following the directive
```
Consider the following:

```
!dir$ block_loop factor(256) level(1:2)
do  j = 1,n
   f = 0
   do  i =1,n
       f = f + a (i) * b (i)
   enddo
   c(j) = c(j) + f
enddo
```

The above code produces the following result after loop blocking:

```
do jj=1,n/256+1
   do ii = 1,n/256+1
       do j = (jj-1)*256+1, min(jj*256, n)
           f = 0
           do i = (ii-1)*256+1, min(ii*256,n)
               f = f + a(i) * b(i)
           enddo
           c(j) = c(j) + f
       enddo
   enddo
endo
do jj=1,n/256+1
   do ii = 1,n/256+1
       do j = (jj-1)*256+1, min(jj*256, n)
           f = 0
           do i = (ii-1)*256+1, min(ii*256,n)
               f = f + a(i) * b(i)
           enddo
           c(j) = c(j) + f
       enddo
   enddo
endo
```

**BLT**

*Elemental Intrinsic Function (Generic): Performs a bitwise less than on its arguments.*

**Syntax**

```
result = BLT (i,j)
```

- `i` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
- `j` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of `i` and `j` do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by `i` is less than the sequence of bits represented by `j`, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.
The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

BLT (0, 2) has the value true. BLT (Z'FF', Z'FC') has the value false.

**BSEARCHQQ**

*Portability Function:* Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.

**Module**

USE IFPORT

**Syntax**

```fortran
result = BSEARCHQQ (adrkey, adrray, length, size)
```

- **adrkey**
  
  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the variable containing the element to be found (returned by LOC).

- **adrray**
  
  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

- **length**
  
  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in the array.

- **size**
  
  (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**Results**

The result type is INTEGER(4). It is an array index of the matched entry, or 0 if the entry is not found.

The array must be sorted in ascending order before being searched.
Caution
The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the length and size arguments are correct, and that size is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

Example
USE IFORT
INTEGER(4) array(10), length
INTEGER(4) result, target
length = SIZE(array)
...
result = BSEARCHQQ(LOC(target),LOC(array),length,SRT$INTEGER4)

See Also
SORTQQ
LOC

BTEST
Elemental Intrinsic Function (Generic): Tests a bit of an integer argument.

Syntax
result = BTEST (i,pos)

i
(Input) Must be of type integer or of type logical (which is treated as an integer).

pos
(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(i).

The rightmost (least significant) bit of i is in position 0.

Results
The result type is default logical.

The result is true if bit pos of i has the value 1. The result is false if pos has the value zero. For more information, see Bit Functions.

For information on the model for the interpretation of an integer value as a sequence of bits, see Model for Bit Data.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBTEST</td>
<td>INTEGER(1)</td>
<td>LOGICAL(1)</td>
</tr>
<tr>
<td>BITEST ¹</td>
<td>INTEGER(2)</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>BTEST ²</td>
<td>INTEGER(4)</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>
Specific Name | Argument Type | Result Type |
---|---|---|
BKTEST | INTEGER(8) | LOGICAL(8) |

1 Or HTEST
2 Or BJTEST

**Example**

BTEST (9, 3) has the value true.

If A has the value

```
[ 1  2 ]
[ 3  4 ],
```

the value of BTEST (A, 2) is

```
[ false false ]
[ false true ]
```

and the value of BTEST (2, A) is

```
[ true false ]
[ false false ].
```

The following shows more examples:

<table>
<thead>
<tr>
<th>Function reference</th>
<th>Value of i</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTEST (i,2)</td>
<td>00011100 01111000</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>BTEST (i,3)</td>
<td>00011100 01111000</td>
<td>.TRUE.</td>
</tr>
</tbody>
</table>

The following shows another example:

```fortran
INTEGER(1) i(2)
LOGICAL  result(2)
i(1) = 2#10101010
i(2) = 2#01010101
result = BTEST(i, (/3,2/))  ! returns (.TRUE.,.TRUE.)
write(*,*) result
```

**BYTE**

*Statement:* Specifies the BYTE data type, which is equivalent to INTEGER(1).

**Example**

```
BYTE count, matrix(4, 4) / 4*1, 4*2, 4*4, 4*8 /
BYTE num   / 10 /
```
C to D

**C_ASSOCIATED**

*Intrinsic Module Inquiry function (Generic):*

Indicates the association status of one argument, or whether two arguments are associated with the same entity.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

\[
\text{result} = \text{C\_ASSOCIATED}(c\_ptr\_1[, c\_ptr\_2])
\]

- **c_ptr_1** (Input) Is a scalar of derived type C_PTR or C_FUNPTR.
- **c_ptr_2** (Optional; input) Is a scalar of the same type as c_ptr_1.

**Results**

The result is a scalar of type default logical. The result value is one of the following:

- If only \(c\_ptr\_1\) is specified, the result is false if \(c\_ptr\_1\) is a C null pointer; otherwise, the result is true.
- If \(c\_ptr\_2\) is specified, the result is false if \(c\_ptr\_1\) is a C null pointer. The result is true if \(c\_ptr\_1\) is equal to \(c\_ptr\_2\); otherwise, the result is false.

Intrinsic Modules

ISO_C_BINDING Module

---

**C_F_POINTER**

*Intrinsic Module Subroutine:*

Associates a data pointer with the target of a C pointer and specifies its shape.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

\[
\text{CALL C\_F\_POINTER}(cptr, fptr [,shape])
\]
(Input) Is a scalar of derived type C_PTR. Its value is the C address of an interoperable data entity, or the result of a reference to function C_LOC with a noninteroperable argument. If the value of \texttt{cptr} is the C address of a Fortran variable, it must have the TARGET attribute.

\texttt{fptr} (Output) Is a data pointer. If it is an array, \texttt{shape} must be specified.

\texttt{shape} (Optional, input) Must be of type integer and rank one. Its size equals the rank of \texttt{fptr}.

If the value of \texttt{cptr} is the C address of an interoperable data entity, \texttt{fptr} must be a data pointer with type and type parameters interoperable with the type of the entity. In this case, \texttt{fptr} becomes pointer-associated with the target of \texttt{cptr}.

If \texttt{fptr} is an array, it has the shape specified by \texttt{shape} and each lower bound is 1.

If the value of \texttt{cptr} is the result of a reference to C_LOC with a noninteroperable argument \(x\), the following rules apply:

- C_LOC argument \(x\) (or its target) must not have been deallocated or have become undefined due to the execution of a RETURN or END statement since the reference to C_LOC.
- \texttt{fptr} is a scalar pointer with the same type and type parameters as \(x\). \texttt{fptr} becomes pointer-associated with \(x\), or it becomes pointer-associated with its target if \(x\) is a pointer.

Since the resulting data pointer \texttt{fptr} could point to a target that was not allocated with an ALLOCATE statement, \texttt{fptr} cannot be freed with a DEALLOCATE statement.

Intrinsic Modules

ISO_C_BINDING Module

C_LOC

\textbf{C_F_PROCPOINTER}

\textit{Intrinsic Module Subroutine:} Associates a Fortran procedure pointer with the target of a C function pointer.

\textbf{Module}

USE, INTRINSIC :: ISO_C_BINDING

\textbf{Syntax}

CALL C_F_POINTER(cptr, fptr)

\texttt{cptr} (Input) Is a scalar of derived type C_FUNPTR. Its value is the C address of a procedure.

\texttt{fptr} (Output) Is a Fortran procedure pointer. It becomes pointer-associated with the target of \texttt{cptr}. 

Intel® Fortran Compiler 19.0 Developer Guide and Reference
Example
The following Fortran subroutine can be called from a C program that passes a pointer to a C function to be called:

```fortran
SUBROUTINE CallIt (cp) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
TYPE(C_FUNPTR), INTENT(IN) :: cp
ABSTRACT INTERFACE
  SUBROUTINE Add_Int (i) BIND(C)
    IMPORT
    INTEGER(C_INT), INTENT(INOUT) :: i
  END SUBROUTINE Add_Int
END INTERFACE
PROCEDURE(Add_Int), POINTER :: fp
INTEGER(C_INT) :: j
CALL C_F_PROCPOINTER (cp, fp)
j = 1
CALL fp(j)
...
```

ISO_C_BINDING Module
Procedure Pointers

C_FUNLOC

*Intrinsic Module Inquiry function (Generic):*  
Returns the C address of a function pointer.

Module
USE, INTRINSIC :: ISO_C_BINDING

Syntax
result = C_FUNLOC(x)

*(Input)* Is a procedure or a Fortran pointer of type INTEGER associated with a procedure. If `x` is a procedure pointer, it must be associated. `x` cannot be a coindexed object.

Results
The result is a scalar of derived type C_FUNPTR. The result value represents the C address of the argument.

See Also
Intrinsic Modules
ISO_C_BINDING Module
**C_LOC**

**Intrinsic Module Inquiry function (Generic):**

Returns the C address of an argument.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

\[
\text{result} = \text{C_LOC}(x)
\]

(Input) Is one of the following:

- An interoperable variable that has the TARGET attribute; if the variable is an array, it does not have to be interoperable
- An interoperable, allocatable, variable that is allocated, has the TARGET attribute, and is not an array of size zero; if the variable is an array, it does not have to be interoperable
- An associated, interoperable scalar pointer
- A scalar that has no length type parameters and is one of the following:
  - A nonallocatable, nonpointer variable that has the TARGET attribute
  - An allocatable variable that is allocated and has the TARGET attribute
  - An associated pointer

**Results**

The result is a scalar of derived type C_PTR. The result value represents the C address of the argument.

The result is a value that can be used as an actual CPTR argument in a call to procedure C_F_POINTER where \( fptr \) has attributes that allow the pointer assignment \( fptr=>x \). Such a call to C_F_POINTER has the effect of the pointer assignment \( fptr=>x \).

If \( x \) is a scalar, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of \( x \) and the pointer assignment CPTR%PX=>x were executed.

If \( x \) is an array, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of \( x \) and the pointer assignment CPTR%PX to the first element of \( x \) were executed.

**See Also**

Intrinsic Modules

ISO_C_BINDING Module

C_F_POINTER
**C_SIZEOF**

**Intrinsic Module Inquiry function (Generic):**
Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.

**Module**

```
USE, INTRINSIC :: ISO_C_BINDING
```

**Syntax**

```
result = C_SIZEOF(x)
```

*x* (Input) Is an interoperable data entity of any type and any rank. It must not be an assumed-size array or an assumed-rank array associated with an assumed-size array.

**Results**

The result is a scalar of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. If *x* is scalar, the result value is the size of *x* in bytes. If *x* is an array, the result value is the size of a single element of *x* multiplied by the number of elements in *x*.

**Example**

Consider the following:

```plaintext
INTEGER(4) :: S
INTEGER(4) :: T(3)
C_SIZEOF(S) ! has the value 4
C_SIZEOF(T) ! has the value 12
```

**See Also**

Intrinsic Modules

ISO_C_BINDING Module

SIZEOF

---

**CACHESIZE**

**Inquiry Intrinsic Function (Generic):** Returns the size of a level of the memory cache.

**Syntax**

```
result = CACHESIZE(n)
```

*n* (Input) Must be scalar and of type integer.

**Results**

The result type and kind are the same as *n*. The result value is the number of kilobytes in the level *n* memory cache.

*n* = 1 specifies the first level cache; *n* = 2 specifies the second level cache; etc. If cache level *n* does not exist, the result value is 0.
Example

CACHESIZE(1) returns 16 for a processor with a 16KB first level memory cache.

CALL

**Statement:** Transfers control to a subroutine subprogram.

**Syntax**

```
CALL sub(( [a-arg[,a-arg]...])
```

*sub* is the name of the subroutine subprogram or other external procedure, or a dummy argument associated with a subroutine subprogram or other external procedure.

*a-arg* is an actual argument optionally preceded by [keyword=], where *keyword* is the name of a dummy argument in the explicit interface for the subroutine. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, the name of a procedure, or an alternate return specifier. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)

An alternate return specifier is an asterisk (*), or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement. (An alternate return is an obsolescent feature in Standard Fortran.)

**Description**

When the CALL statement is executed, any expressions in the actual argument list are evaluated, then control is passed to the first executable statement or construct in the subroutine. When the subroutine finishes executing, control returns to the next executable statement following the CALL statement, or to a statement identified by an alternate return label (if any).

If an argument list appears, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures).

The procedure invoked by the CALL statement must be a subroutine subprogram and not a function. Calling a function as if it were a subroutine can cause unpredictable results.
Example

The following example shows valid CALL statements:

```
CALL CURVE(BASE,3.14159+X,Y,LIMIT,R(LT+2))
CALL PNTOUT(A,N,'ABCD')
CALL EXIT
CALL MULT(A,B,*10,*20,C)       ! The asterisks and ampersands denote
CALL SUBA(X,&30,&50,Y)         !     alternate returns
```

The following example shows a subroutine with argument keywords:

```
PROGRAM KEYWORD_EXAMPLE
  INTERFACE
    SUBROUTINE TEST_C(I, L, J, KYWD2, D, F, KYWD1)
      INTEGER I, L(20), J, KYWD1
      REAL, OPTIONAL :: D, F
      COMPLEX KYWD2
      ...
    END SUBROUTINE TEST_C
  END INTERFACE
  INTEGER I, J, K
  INTEGER L(20)
  COMPLEX Z1
  CALL TEST_C(I, L, J, KYWD1 = K, KYWD2 = Z1)
  ...
```

The first three actual arguments are associated with their corresponding dummy arguments by position. The argument keywords are associated by keyword name, so they can appear in any order.

Note that the interface to subroutine TEST has two optional arguments that have been omitted in the CALL statement.

The following shows another example of a subroutine call with argument keywords:

```
CALL TEST(X, Y, N, EQUALITIES = Q, XSTART = X0)
```

The first three arguments are associated by position.

The following shows another example:

```
! Variations on a subroutine call
REAL S,T,X
INTRINSIC NINT
S=1.5
T=2.5
X=14.7
!This calls SUB1 using keywords. NINT is an intrinsic function.
CALL SUB1(B=X,C=S*T,FUNC=NINT,A=4.0)
!Here is the same call using an implicit reference
CALL SUB1(4.0,X,S*T,NINT)
CONTAINS
    SUBROUTINE sub1(a,b,c,func)
      INTEGER func
      REAL a,b,c
      PRINT *, a,b,c, func(b)
    END SUBROUTINE
END
```

See Also

SUBROUTINE
CONTAINS
CANCEL
OpenMP* Fortran Compiler Directive: Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

Syntax

```fortran
$OMP CANCEL construct-clause [!] if-clause
```

- **construct-clause**
  - Is one of the following:
    - DO
    - PARALLEL
    - SECTIONS
    - TASKGROUP

- **if-clause**
  - (Optional) IF (scalar-logical-expression)

The binding thread set of a CANCEL construct is the current team. The cancel region binds to the innermost enclosing construct of the type corresponding to the *construct-clause* specified in the directive specifying the innermost DO, PARALLEL, SECTIONS, or TASKGROUP construct.

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

If *construct-clause* is TASKGROUP, the CANCEL construct must be closely nested inside a TASK construct. Otherwise, the CANCEL construct must be closely nested inside an OpenMP construct that matches the type specified in *construct-clause*.

The CANCEL construct requests cancellation of the innermost enclosing region of the type specified. The request is checked at a cancellation point. When a cancellation is observed, execution jumps to the end of the canceled region.

Cancellation points are implied at certain locations, as follows:

- Implicit barriers
- BARRIER regions
- CANCEL regions
- CANCELLATION POINT regions

When cancellation of tasks occurs with a CANCEL TASKGROUP construct, the encountering task jumps to the end of its task region and is considered complete. Any task that belongs to the innermost enclosing taskgroup and has already begun execution, must run to completion or run until a cancellation point is reached. Any task that belongs to the innermost enclosing taskgroup and has not begun execution may be discarded and considered completed.

When cancellation occurs for a PARALLEL region, each thread of the binding thread set resumes execution at the end of the canceled region and any tasks that have been created by a TASK construct and their descendants are canceled according to the above taskgroup cancellation semantics.

When cancellation occurs for a DO or SECTIONS region, each thread of the binding thread set resumes execution at the end of the canceled region but no task cancellation occurs.
A DO construct that is being canceled must not have a NOWAIT or an ORDERED clause. A SECTIONS construct that is being canceled must not have a NOWAIT clause.

The behavior for concurrent cancellation of a region and a region nested within it is unspecified.

**NOTE**
You must release locks and similar data structures that can cause a deadlock when a CANCEL construct is encountered; blocked threads cannot be canceled.

If the canceled construct contains a REDUCTION or LASTPRIVATE clause, the final value of the REDUCTION or LASTPRIVATE variable is undefined.

All private objects or subobjects with the ALLOCATABLE attribute that are allocated inside the canceled construct are deallocated.

Parallel Processing Model for information about Binding Sets

**CANCELLATION POINT**

*OpenMP* Fortran Compiler Directive: Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.

**Syntax**

```fortran
!$OMP CANCELLATION POINT construct-clause
```

*construct-clause* is one of the following:

- **DO**
- **PARALLEL**
- **SECTIONS**
- **TASKGROUP**

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

A CANCELLATION POINT region binds to the current task region.

If *construct-clause* is TASKGROUP, the CANCELLATION POINT construct must be closely nested inside a TASK construct. Otherwise, the CANCELLATION POINT construct must be closely nested inside an OpenMP construct that matches the type specified by the *construct-clause*.

When an implicit or explicit task reaches a user-defined cancellation point, the task immediately checks for cancellation of the region specified in the clause and performs cancellation of this region if cancellation is observed. If the clause specified is TASKGROUP then the current task region is canceled.

An OpenMP program with orphaned CANCELLATION POINT constructs is non-conforming.
CASE

**Statement:** Marks the beginning of a CASE construct. A CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.

**Syntax**

```fortran
[name:] SELECT CASE (expr)
[CASE (case-value [, case-value] ...) [name]
   block]...
[CASE DEFAULT [name]
   block]
END SELECT [name]
```

- **name**
  - Is the name of the CASE construct.

- **expr**
  - Is a scalar expression of type integer, logical, or character (enclosed in parentheses). Evaluation of this expression results in a value called the case index.

- **case-value**
  - Is one or more scalar integer, logical, or character initialization expressions enclosed in parentheses. Each case-value must be of the same type and kind parameter as expr. If the type is character, case-value and expr can be of different lengths, but their kind parameter must be the same.

  Integer and character expressions can be expressed as a range of case values, taking one of the following forms:

  ```fortran
  low:high
  low:
  :high
  ```

  Case values must not overlap.

- **block**
  - Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified in a SELECT CASE statement, the same name must appear in the corresponding END SELECT statement. The same construct name can optionally appear in any CASE statement in the construct. The same construct name must not be used for different named constructs in the same scoping unit.

The case expression (expr) is evaluated first. The resulting case index is compared to the case values to find a matching value (there can only be one). When a match occurs, the block following the matching case value is executed and the construct terminates.

The following rules determine whether a match occurs:

- When the case value is a single value (no colon appears), a match occurs as follows:
Data Type | A Match Occurs If:
---|---
Logical | case-index .EQV. case-value
Integer or Character | case-index = = = case-value

- When the case value is a range of values (a colon appears), a match depends on the range specified, as follows:

<table>
<thead>
<tr>
<th>Range</th>
<th>A Match Occurs If:</th>
</tr>
</thead>
<tbody>
<tr>
<td>low : high</td>
<td>case-index &gt;= low &lt;= high</td>
</tr>
</tbody>
</table>

The following are all valid case values:

- `CASE (1, 4, 7, 11:14, 22)` — Individual values as specified: 1, 4, 7, 11, 12, 13, 14, 22
- `CASE (: -1)` — All values less than zero
- `CASE (0)` — Only zero
- `CASE (1:)` — All values above zero

If no match occurs but a CASE DEFAULT statement is present, the block following that statement is executed and the construct terminates.

If no match occurs and no CASE DEFAULT statement is present, no block is executed, the construct terminates, and control passes to the next executable statement or construct following the END SELECT statement.

The following figure shows the flow of control in a CASE construct:

**Flow of Control in CASE Constructs**

You cannot use branching statements to transfer control to a CASE statement. However, branching to a SELECT CASE statement is allowed. Branching to the END SELECT statement is allowed only from within the CASE construct.

**Example**

The following are examples of CASE constructs:

```fortran
INTEGER FUNCTION STATUS_CODE (I)
  INTEGER I
  CHECK_STATUS: SELECT CASE (I)
  CASE (: -1)
    STATUS_CODE = -1
  CASE (0)
    STATUS_CODE = 0
  CASE (1:)
    STATUS_CODE = 1
  END SELECT CHECK_STATUS
END FUNCTION STATUS_CODE

SELECT CASE (J)
  CASE (1, 3:7, 9) ! Values: 1, 3, 4, 5, 6, 7, 9
    CALL SUB_A
```
CASE DEFAULT
   CALL SUB_B
END SELECT

The following three examples are equivalent:

1. SELECT CASE (ITEST .EQ. 1)
   CASE (.TRUE.)
     CALL SUB1 ()
   CASE (.FALSE.)
     CALL SUB2 ()
   END SELECT

2. SELECT CASE (ITEST)
   CASE DEFAULT
     CALL SUB2 ()
   CASE (1)
     CALL SUB1 ()
   END SELECT

3. IF (ITEST .EQ. 1) THEN
   CALL SUB1 ()
ELSE
   CALL SUB2 ()
END IF

The following shows another example:

CHARACTER*1 cmdchar
GET_ANSWER: SELECT CASE (cmdchar)
CASE ('0')
   WRITE (*, *) "Must retrieve one to nine files"
CASE ('1':'9')
   CALL RetrieveNumFiles (cmdchar)
CASE ('A', 'a')
   CALL AddEntry
CASE ('D', 'd')
   CALL DeleteEntry
CASE ('H', 'h')
   CALL Help
CASE DEFAULT
   WRITE (*, *) "Command not recognized; please use H for help"
END SELECT GET_ANSWER

Execution Control

CDFLOAT

Portability Function: Converts a COMPLEX(4) argument to double-precision real type.

Module
USE IFPORT

Syntax

result = CDFLOAT (input)
(Input) COMPLEX(4). The value to be converted.

Results
The result type is REAL(8).

CEILING
Elemental Intrinsic Function (Generic): Returns the smallest integer greater than or equal to its argument.

Syntax
result = CEILING (a[,kind])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>(Input) Must be of type real.</td>
</tr>
<tr>
<td>kind</td>
<td>(Input; optional) Must be a scalar integer constant expression.</td>
</tr>
</tbody>
</table>

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.
The value of the result is equal to the smallest integer greater than or equal to a.
The setting of compiler options specifying integer size can affect this function.

Example
CEILING (4.8) has the value 5.
CEILING (-2.55) has the value -2.0.
The following shows another example:

```fortran
INTEGER I, IARRAY(2)
I = CEILING(8.01) ! returns 9
I = CEILING(-8.01) ! returns -8
IARRAY = CEILING((/8.01,-5.6/)) ! returns (9, -5)
```

FLOOR

CFI_address
C function prototype: Returns the C address of an object described by a C descriptor.

Syntax
void *CFI_address (const CFI_cdesc_t *dv,
                        const CFI_index_t subscripts[]);
The address of a C descriptor describing the object. The object must not be an unallocated allocatable variable or a pointer that is not associated.

subscripts

A null pointer or the address of an array of type CFI_index_t. If the object is an array, subscripts must be the address of an array of type CFI_index_t with at least \( n \) elements, where \( n \) is the rank of the object. The value of subscripts \([i]\) must be within the bounds of dimension \( i \) specified by the \( \text{dim} \) member of the C descriptor.

**Result Value**

If the object is an array of rank \( n \), the result is the C address of the element of the object that the first \( n \) elements of the subscripts argument would specify if used as subscripts. If the object is scalar, the result is its C address.

**Example**

If \( dv \) is the address of a C descriptor for the Fortran array A declared as follows:

```fortran
REAL(C_FLOAT) :: A(100, 100)
```

then the following code calculates the C address of A(5, 10):

```c
CFI_index_t subscripts[2];
float *address;
subscripts[0] = 4;
subscripts[1] = 9;
address = (float *) CFI_address(dv, subscripts);
```

**See Also**

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_allocate**

*C function prototype:* Allocates memory for an object described by a C descriptor.

**Syntax**

```c
int CFI_allocate (CFI_cdesc_t *dv,
    const CFI_index_t lower_bounds[]),
    const CFI_index_t upper_bounds[],
    size_t elem_len);
```

**Formal Parameters:**

- **dv**
  
  The address of a C descriptor specifying the rank and type of the object. The base_addr member of the C descriptor is a null pointer. If the type is not a character type, the elem_len member must specify the element length. The attribute member must have a value of CFI_attribute Allocatable or CFI_attribute Pointer.

- **lower_bounds**
  
  The address of an array with at least \( dv->\text{rank} \) elements. The first \( dv->\text{rank} \) elements of \( lower\_bounds \) provide the lower Fortran bounds for each corresponding dimension of the object.
upper_bounds

The address of an array with at least dv->rank elements. The first dv->rank elements of upper_bounds provide the upper Fortran bounds for each corresponding dimension of the object.

elem_len

If the type specified in the C descriptor type is a Fortran character type, the value of elem_len is the storage size in bytes of an element of the object; otherwise, elem_len is ignored.

Description

Successful execution of CFI_allocate allocates memory for the object described by the C descriptor with the address dv using the same mechanism as the Fortran ALLOCATE statement, and assigns the address of that memory to dv->base_addr.

The first dv->rank elements of the lower_bounds and upper_bounds arguments provide the lower and upper Fortran bounds, respectively, for each corresponding dimension of the object. The supplied lower and upper bounds override any current dimension information in the C descriptor. If the rank is zero, the lower_bounds and upper_bounds arguments are ignored.

If the type specified in the C descriptor is a character type, the supplied element length overrides the current element-length information in the descriptor.

If an error is detected, the C descriptor is not modified.

Result Value

The result is an error indicator.

Example

If dv is the address of a C descriptor for the Fortran array A declared as follows:

```c
REAL, ALLOCATABLE :: A(:, :)
```

and the array is not allocated, the following code allocates it to be of shape [100, 500]:

```c
CFI_index_t lower[2], upper[2];
int ind;
lower[0] = 1; lower[1] = 1;
upper[0] = 100; upper[1] = 500;
ind = CFI_allocate(dv, lower, upper, 0);
```

See Also

ALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_deallocate

C function prototype: Deallocates memory for an object described by a C descriptor.

Syntax

```c
int CFI_deallocate (CFI_cdesc_t *dv);
```

Formal Parameters:
The address of a C descriptor describing the object. It must have been allocated using the same mechanism as the Fortran ALLOCATE statement. If the object is a pointer, it must be associated with a target satisfying the conditions for successful deallocation by the Fortran DEALLOCATE statement.

**Description**

Successful execution of `CFI_deallocate` deallocates memory for the object using the same mechanism as the Fortran DEALLOCATE statement, and the `base_addr` member of the C descriptor becomes a null pointer.

If an error is detected, the C descriptor is not modified.

**Result Value**

The result is an error indicator.

**Example**

If `dv` is the address of a C descriptor for the Fortran array `A` declared as follows:

```fortran
REAL, ALLOCATABLE :: A(:, :)
```

and the array is allocated, the following code deallocates it:

```c
int ind;
ind = CFI_deallocate(dv);
```

**See Also**

ALLOCATE
DEALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_establish**

*C function prototype:* Establishes a C descriptor.

**Syntax**

```c
int CFI_establish(CFI_cdesc_t *dv, void *base_addr,
                  CFI_attribute_t attribute,
                  CFI_type_t type, size_t elem_len,
                  CFI_rank_t rank,
                  const CFI_index_t extents[]);
```

**Formal Parameters:**

- `dv` The address of a data object large enough to hold a C descriptor of the rank specified by `rank`. It must not have the same value as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument. It must not be the address of a C descriptor that describes an allocated allocatable object.
**base_addr**

A null pointer or the base address of the object to be described. If it is not a null pointer, it must be the address of a contiguous storage sequence that is appropriately aligned for an object of the type specified by `type`.

**attribute**

One of the attribute codes in Table "Macros for attribute codes" in C Typedefs and Macros for interoperability. If it is `CFI_attribute Allocatable`, `base_addr` must be a null pointer.

**type**

One of the type codes in Table "Macros for type codes" in C Typedefs and Macros for interoperability.

**elem_len**

If the type is `CFI_type struct`, `CFI_type other`, or a Fortran character type code, `elem_len` must be greater than zero and equal to the storage size in bytes of an element of the object. Otherwise, `type` is ignored.

**rank**

A value in the range $0 \leq rank \leq CFI_MAX_RANK$. It specifies the rank of the object.

**extents**

This is ignored if rank is equal to zero or if `base_addr` is a null pointer. Otherwise, it must be the address of an array with rank elements; the value of each element must be nonnegative, and `extents[i]` specifies the extent of dimension `i` of the object.

**Description**

Successful execution of `CFI_establish` updates the object with the address `dv` to be an established C descriptor for a nonallocatable nonpointer data object of known shape, an unallocated allocatable object, or a data pointer.

If `base_addr` is not a null pointer, it is the address for a nonallocatable entity that is a scalar or a contiguous array. If the attribute argument has the value `CFI_attribute_pointer`, the lower bounds of the object described by `dv` are set to zero. If `base_addr` is a null pointer, the established C descriptor is for an unallocated allocatable, a disassociated pointer, or is a C descriptor that has the attribute `CFI_attribute Other` but does not describe a data object. If `base_addr` is the C address of a Fortran data object, the `type` and `elem_len` arguments must be consistent with the type and type parameters of the Fortran data object.

The remaining properties of the object are given by the other arguments.

`CFI_establish` is used to initialize a C descriptor declared in C with `CFI_CDESC_T` before passing it to any other functions as an actual argument, in order to set the rank, attribute, type and element length.

A C descriptor with attribute `CFI_attribute Other` and a `base_addr` that is a null pointer can be used as the argument result in calls to `CFI_section` or `CFI_select_part`, which will produce a C descriptor for a nonallocatable nonpointer data object.

If an error is detected, the object with the address `dv` is not modified.

**Result Value**

The result is an error indicator.
Example
The following code fragment establishes a C descriptor for an unallocated rank-one allocatable array that can be passed to Fortran for allocation there:

```c
CFI_rank_t rank;
CFI_CDESC_T(1) field;
int ind;
rank = 1;
ind = CFI_establish((CFI_cdesc_t *)&field, NULL,
CFI_attribute_allocatable,
CFI_type_double, 0, rank, NULL);
```

If the following Fortran type definition is specified:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
```

and a Fortran subprogram that has an assumed-shape dummy argument of type T, the following code fragment creates a descriptor `a_fortran` for an array of size 100 that can be used as the actual argument in an invocation of the subprogram from C:

```c
typedef struct {double x; double _Complex y;} t;
t a_c[100];
CFI_CDESC_T(1) a_fortran;
int ind;
CFI_index_t extent[1];
extent[0] = 100;
ind = CFI_establish((CFI_cdesc_t *)&a_fortran, a_c,
CFI_attribute_other,
CFI_type_struct, sizeof(t), 1, extent);
```

See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_is_contiguous**

*C function prototype:* Tests contiguity of an array.

**Syntax**

```c
int CFI_is_contiguous(const CFI_cdesc_t *dv);
```

**Formal Parameters:**

`dv`  
The address of a C descriptor describing an array. The `base_addr` member of the C descriptor must not be a null pointer.

**Result Value**

The value of the result is 1 if the array described by `dv` is contiguous; otherwise, 0.

Since assumed-size and allocatable arrays are always contiguous, the result of `CFI_is_contiguous` on a C descriptor for such an array is 1.
See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_section

C function prototype: Updates a C descriptor for an array section for which each element is an element of a given array.

Syntax

```c
int CFI_section(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                const CFI_index_t lower_bounds[],
                const CFI_index_t upper_bounds[],
                const CFI_index_t strides[]);
```

Formal Parameters:

- **result**: The address of a C descriptor with rank equal to the rank of `source` minus the number of zero `strides`. The attribute member must have the value `CFI_attribute_other` or `CFI_attribute_pointer`. If the value of `result` is the same as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument, the attribute member must have the value `CFI_attribute_pointer`. Successful execution of `CFI_section` updates the `base_addr` and `dim` members of the C descriptor with the address result to describe the array section determined by `source`, `lower_bounds`, `upper_bounds`, and `strides`, as follows:
  - The array section is equivalent to the Fortran array section `SOURCE(sectsub1, sectsub2, ... sectsubn)`, where `SOURCE` is the array described by `source`, `n` is the rank of that array, and `sectsubi` is the subscript `loweri` if `stridesi` is zero, and the section subscript `loweri : upperi : stridesi` otherwise.
  - The value of `loweri` is the lower bound of dimension `i` of `SOURCE` if `lower_bounds` is a null pointer and `lower_bounds[i]` otherwise.
  - The value of `upperi` is the upper bound of dimension `i` of `SOURCE` if `upper_bounds` is a null pointer and `upper_bounds[i]` otherwise.
  - The value of `stridesi` is 1 if `strides` is a null pointer and `strides[i]` otherwise. If `stridesi` has the value zero, `loweri` must have the same value as `upperi`.

- **source**: The address of a C descriptor that describes a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer. The `elem_len` and `type` members of source must have the same values as the corresponding members of result.

- **lower_bounds**: A null pointer or the address of an array with at least `source->rank` elements. If it is not a null pointer, and `stridesi` is zero or `(upperi - lower_bounds[i] + stridesi)/stridesi > 0`, the value of `lower_bounds[i]` must be within the bounds of dimension `i` of `SOURCE`.

- **upper_bounds**: A null pointer or the address of an array with at least `source->rank` elements. If `source` describes an assumed-size array, `upper_bounds` must not be a null pointer. If it is not a null pointer and `stridesi` is zero...
or 

\[(upper\_bounds[i] - loweri + stridei)/stridei > 0\]

, the value of 

\[upper\_bounds[i]\]

must be within the bounds of dimension \(i\) of \(SOURCE\).

\[strides\]

A null pointer or the address of an array with at least \(source->rank\) elements.

If an error is detected, the C descriptor with the address result is not modified.

**Result Value**

The result is an error indicator.

**Example**

If source is already the address of a C descriptor for the rank-one Fortran array \(A\), the lower bounds of \(A\) are equal to 1, and the lower bounds in the C descriptor are equal to 0, the following code fragment establishes a new C descriptor section and updates it to describe the array section \(A(3:5)\):

```
CFI_index_t lower[1], strides[1];
CFI_CDESC_T(1) section;
int ind;
lower[0] = 2;
strides[0] = 5;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, NULL, strides);
```

If source is already the address of a C descriptor for a rank-two Fortran assumed-shape array \(A\) with lower bounds equal to 1, the following code fragment establishes a C descriptor and updates it to describe the rank-one array section \(A(:, 42)\):

```
CFI_index_t lower[2], upper[2], strides[2];
CFI_CDESC_T(1) section;
int ind;
lower[0] = source->dim[0].lower_bound;
upper[0] = source->dim[0].lower_bound + source->dim[0].extent - 1;
strides[0] = 1;
strides[1] = 0;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, upper, strides);
```

**See Also**

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_select_part**

*Function prototype:*

Updates a C descriptor for an array section for which each element is a part of the corresponding element of an array.
Syntax

```c
int CFI_select_part(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                        size_t displacement, size_t elem_len);
```

**Formal Parameters:**

- **result**
  The address of a C descriptor; result->rank must have the same value as source->rank and result->attribute must have the value CFI_attribute_other or CFI_attribute_pointer. If the address specified by result is the value of a C formal parameter that corresponds to a Fortran actual argument or of a C actual argument that corresponds to a Fortran dummy argument, result->attribute must have the value CFI_attribute_pointer. The value of result->type specifies the type of the array section.

- **source**
  The address of a C descriptor for a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer.

- **displacement**
  A value 0 ≤ displacement ≤ source->elem_len − 1, and the sum of the displacement and the size in bytes of an element of the array section must be less than or equal to source->elem_len. The address displacement bytes greater than the value of source->base_addr is the base of the array section and must be appropriately aligned for an object of the type of the array section.

- **elem_len**
  A value equal to the storage size in bytes of an element of the array section if result->type specifies a Fortran character type; otherwise, **elem_len** is ignored.

**Description**

Successful execution of CFI_select_part updates the base_addr, dim, and elem_len members of the C descriptor with the address result for an array section for which each element is a part of the corresponding element of the array described by the C descriptor with the address source. The part must be a component of a structure, a substring, or the real or imaginary part of a complex value.

If an error is detected, the C descriptor with the address result is not modified.

**Result Value**

The result is an error indicator.

**Example**

If source is already the address of a C descriptor for the Fortran array A declared as follows:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
TYPE(T) A(100)
```

then the following code fragment establishes a C descriptor for the array A%Y:

```c
typedef struct {
    double x; double _Complex y;
} t;
CFI_CDESC_T(1) component;
CFI_cdesc_t * comp_cdesc = (CFI_cdesc_t *)&component;
```
See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_setpointer

C function prototype: Updates a C descriptor for a Fortran pointer to be associated with the whole of a given object or to be disassociated.

Syntax

```c
int CFI_setpointer(CFI_cdesc_t *result, CFI_cdesc_t *source,
                   const CFI_index_t lower_bounds[]);
```

Formal Parameters:

- **result**: The address of a C descriptor for a Fortran pointer. It is updated using information from the `source` and `lower_bounds` arguments.

- **source**: A null pointer or the address of a C descriptor for a nonallocatable nonpointer data object, an allocated allocatable object, or a data pointer object. If `source` is not a null pointer, the corresponding values of the `elem_len`, `rank`, and `type` members must be the same in the C descriptors with the addresses `source` and `result`.

- **lower_bounds**: If `source` is not a null pointer and `source->rank` is nonzero, `lower_bounds` must be a null pointer or the address of an array with at least `source->rank` elements.

Description

Successful execution of `CFI_setpointer` updates the `base_addr` and `dim` members of the C descriptor with the address result as follows:

- If `source` is a null pointer or the address of a C descriptor for a disassociated pointer, the updated C descriptor describes a disassociated pointer.
- Otherwise, the C descriptor with the address result becomes a C descriptor for the object described by the C descriptor with the address source, except that if `source->rank` is nonzero and `lower_bounds` is not a null pointer, the lower bounds are replaced by the values of the first `source->rank` elements of the `lower_bounds` array.

Result Value

The result is an error indicator.
Example
If \( \text{ptr} \) is already the address of a C descriptor for an array pointer of rank 1, the following code updates it to be a C descriptor for a pointer to the same array with lower bound 0:

```c
CFI_index_t lower_bounds[1];
int ind;
lower_bounds[0] = 0;
ind = CFI_setpointer(ptr, ptr, lower_bounds);
```

Interoperating with arguments using C descriptors

CHANGEDIRQQ

**Portability Function:** Makes the specified directory the current, default directory.

**Module**
USE IFPORT

**Syntax**
`result = CHANGEDIRQQ (dir)`

*dir* (Input) Character*(*). Directory to be made the current directory.

**Results**
The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..

If you do not specify a drive in the *dir* string, the named directory on the current drive becomes the current directory. If you specify a drive in *dir*, the named directory on the specified drive becomes the current directory.

**Example**

```fortran
USE IFPORT
LOGICAL(4) status
status = CHANGEDIRQQ('d:\fps90\bin'))
! We are now CCed to 'd:\fps90\bin'
status = CHANGEDIRQQ('bessel')
! We are now CCed to 'd:\fps90\bin\bessel'
```

Syntax

\[
\text{result} = \text{CHANGEDRIVEQQ} \ (\text{drive})
\]

*drive* (Input) Character*(*). String beginning with the drive letter.

**Results**

The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE. On Linux* and macOS* systems, the result is always .FALSE.. Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of *drive*. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.

**Example**

```
USE IFPORT
LOGICAL(4) status
status = CHANGEDRIVEQQ('d')
```

CHANGEDIRQQ

**CHAR**

*Elemental Intrinsic Function (Generic): Returns the character in the specified position of the processor’s character set. It is the inverse of the function ICHAR.*

**Syntax**

\[
\text{result} = \text{CHAR} \ (i[,kind])
\]

*i* (Input) Must be of type integer with a value in the range 0 to \( n - 1 \), where \( n \) is the number of characters in the processor’s character set.

*kind* (Input; optional) Must be a scalar integer constant expression.

**Results**

The result is of type character with length 1. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is the character in position *i* of the processor’s character set. ICHAR(CHAR( i, kind( c))) has the value 1 for 0 to \( n - 1 \) and CHAR(ICHCAR( c), kind( c)) has the value *c* for any character *c* capable of representation in the processor.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTGER(1)</td>

CHARACTER
Statement: Specifies the CHARACTER data type.

Syntax
CHARACTER ([LEN=len [, [KIND=n]])
CHARACTER (KIND=n [, [LEN=len])
CHARACTER* len

n
len

Is kind 1.

Is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

Example
C
C   Length of wt and vs is 10, city is 80, and ch is 1
C
C   CHARACTER wt*10, city*80, ch
C   CHARACTER (LEN = 10), PRIVATE :: vs
C   CHARACTER*(*) arg !declares a dummy argument
C
C   name and plume are ten-element character arrays
C   of length 20
C   CHARACTER name(10)*20
C   CHARACTER(len=20), dimension(10):: plume
C
C   Length of susan, patty, and dotty are 2, alice is 12,
C   jane is a 79-member array of length 2
C
C   CHARACTER(2) susan, patty, alice*12, dotty, jane(79)
CHDIR

**Portability Function:** Changes the default directory.

**Module**

USE IFPORT

**Syntax**

```
result = CHDIR(dir_name)
```

*dir_name* (Input) Character*(*). Name of a directory to become the default directory.

**Results**

The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The named directory does not exist.
- ENOTDIR: The *dir_name* parameter is not a directory.

**Example**

```fortran
use ifport
integer(4) istatus, enoent, enotdir
character(255) newdir
character(300) prompt, errmsg

prompt = 'Please enter directory name: '
10   write(*,*) TRIM(prompt)
read *, newdir
ISTATUS = CHDIR(newdir)
select case (istatus)
  case (2)  ! ENOENT
    errmsg = 'The directory '/TRIM(newdir)//' does not exist'
  case (20) ! ENOTDIR
    errmsg = TRIM(newdir)//' is not a directory'
  case (0) ! NO error
  goto 40
  case default
    write (errmsg,*) 'Error with code ', istatus
end select

write(*,*) TRIM(errmsg)  goto 10
40    write(*,*) 'Default directory successfully changed.'
end
```
CHMOD

**Portability Function:** Changes the access mode of a file.

**Module**

USE IFPORT

**Syntax**

```
result = CHMOD (name, mode)
```

*name* (Input) Character*(*). Name of the file whose access mode is to be changed. Must have a single path.

*mode* (Input) Character*(*). File permission: either Read, Write, or Execute. The *mode* parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

<table>
<thead>
<tr>
<th>Permission bit</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>4000</td>
<td>Set user ID on execution</td>
<td>W*S: Ignored; never true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>2000</td>
<td>Set group ID on execution</td>
<td>W*S: Ignored; never true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>1000</td>
<td>Sticky bit</td>
<td>W*S: Ignored; never true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0400</td>
<td>Read by owner</td>
<td>W*S: Ignored; always true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0200</td>
<td>Write by owner</td>
<td>Settable</td>
</tr>
<tr>
<td>0100</td>
<td>Execute by owner</td>
<td>W*S: Ignored; based on file name extension</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0040, 0020, 0010</td>
<td>Read, Write, Execute by group</td>
<td>W*S: Ignored; assumes owner permissions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
</tbody>
</table>
The following regular expression represents a symbolic mode:

\[\text{ugo}\ast[+\text{-}=] \text{[rwxXst]}\ast\]

On Windows* systems, "[ugo]\ast" is ignored. On Linux* and macOS* systems, a combination of the letters "ugo" control which users' access to the file will be changed:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>u</td>
<td>The user who owns the file</td>
</tr>
<tr>
<td>g</td>
<td>Other users in the group that owns the file</td>
</tr>
<tr>
<td>o</td>
<td>Other users not in the group that owns the file</td>
</tr>
<tr>
<td>a</td>
<td>All users</td>
</tr>
</tbody>
</table>

"[+ - =]" indicates the operation to carry out:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Add the permission</td>
</tr>
<tr>
<td>-</td>
<td>Remove the permission</td>
</tr>
<tr>
<td>=</td>
<td>Absolutely set the permission</td>
</tr>
</tbody>
</table>

"[rwxXst]\ast" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux and macOS* systems, all letters are significant.

**Results**

The result type is INTEGER(4). It is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:

- **ENOENT**: The specified file was not found.
- **EINVAL**: The mode argument is invalid.
- **EPERM**: Permission denied; the file's mode cannot be changed.

**Example**

```
USE IFPORT
integer(4) I,Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (i) then
   ISTATUS = CHMOD ("datafile.txt", "[+w]")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, i
```

**See Also**

SETFILEACCESSQQ
**CLASS**

**Statement:** Declares a polymorphic object. It takes one of the following forms:

**Syntax**

CLASS (name) att-list :: v-list

CLASS (*) att-list :: v-list

*name*  
Is the name of the extensible derived data type.

*att-list*  
Is one or more attribute specifiers. These are the same attribute specifiers allowed for a derived-type TYPE statement.

*v-list*  
Is the name of one or more data objects or functions. The name can optionally be followed by any of the following:

- An array specification, if the object is an array.
  
  In a function declaration, an array must be a deferred-shape array if it has the POINTER attribute; otherwise, it must be an explicit-shape array.

- A character length, if the object is of type character.

- A coarray specification, if the object is a coarray.

- A constant expression preceded by an = or, for pointer objects, => NULL( ).

**Description**

A polymorphic object can have differing types during program execution.

The type of the object at a particular point during execution of a program is its dynamic type.

The declared type of a data entity is the type that it is declared to have, either explicitly or implicitly.

If CLASS (*) is specified, it denotes an unlimited polymorphic object. An unlimited polymorphic entity is not declared to have a type. It is not considered to have the same declared type as any other entity, including another unlimited polymorphic entity.

An entity declared with the CLASS keyword must be a dummy argument or have the ALLOCATABLE or POINTER attribute.

A polymorphic entity that is not an unlimited polymorphic entity is type compatible with entities of the same declared type or any of its extensions. Even though an unlimited polymorphic entity is not considered to have a declared type, it is type compatible with all entities. An entity is said to be type compatible with a type if it is type compatible with entities of that type.

A polymorphic allocatable object can be allocated to be of any type with which it is type compatible.

During program execution, a polymorphic pointer or dummy argument can be associated with objects with which it is type compatible.

TYPE Statement (Derived Types)
**CLEARSCREEN (W*S)**

*Graphics Subroutine:* Erases the target area and fills it with the current background color.

**Module**

USE IFQWIN

**Syntax**

CALL CLEARSCREEN (area)

(area) (Input) INTEGER(4). Identifies the target area. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- $GCLEARSCREEN - Clears the entire screen.
- $GVIEWPORT - Clears only the current viewport.
- $GWINDOW - Clears only the current text window (set with SETTEXTWINDOW).

All pixels in the target area are set to the color specified with SETBKCOLORRGB. The default color is black.

**Example**

USE IFQWIN
CALL CLEARSCREEN($GCLEARSCREEN)

**See Also**

GETBKCOLORRGB
SETBKCOLORRGB
SETTEXTWINDOW
SETVIEWPORT

**CLEARSTATUSFPQQ**

*Portability Subroutine:* Clears the exception flags in the floating-point processor status word.

**Module**

USE IFPORT

**Syntax**

CALL CLEARSTATUSFPQQ()

**Description**

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see *Floating-Point Operations: Floating-Point Environment.*
Example

! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a
! floating-point exception has occurred.
! So, build this console application with the default
! floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows)
! or -O0 (Linux) to get the correct results.
!
! PROGRAM CLEARFP

USE IFPORT

REAL*4 A,B,C
INTEGER*2 STS

A = 2.0E0
B = 0.0E0

! Poll and display initial floating point status
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS

! Cause a divide-by-zero exception
! Poll and display the new floating-point status
C = A/B
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS

! If a divide by zero error occurred, clear the floating-point
! status register so future exceptions can be detected.
IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
    CALL CLEARSTATUSFPQQ()
    CALL GETSTATUSFPQQ(STS)
    WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
ENDIF

END

This program is available in the online samples.

SIGNALQQ

CLICKMENUQQ (W*S)
QuickWin Function: Simulates the effect of clicking
or selecting a menu command. The QuickWin
application responds as though the user had clicked or
selected the command.

Module
USE IFQWIN
Syntax
result = CLICKMENUQQ (item)

*item* (Input) INTEGER(4). Constant that represents the command selected from the Window menu. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- QWIN$STATUS - Status command
- QWIN$TILE - Tile command
- QWIN$CASCADE - Cascade command
- QWIN$ARRANGE - Arrange Icons command

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

REGISTERMOUSEEVENT
UNREGISTERMOUSEEVENT
WAITONMOUSEEVENT

CLOCK
*Portability Function: Converts a system time into an 8-character ASCII string.*

Module
USE IFPORT

Syntax
result = CLOCK ( )

Results
The result type is character with a length of 8. The result is the current time in the form hh:mm:ss, using a 24-hour clock.

Example
```
USE IFPORT
character(8) whatimeisit
whatimeisit = CLOCK ( )
print *, 'The current time is ',whatimeisit
```

See Also
DATE_AND_TIME

CLOCKX
*Portability Subroutine: Returns the processor clock in units of microseconds.*

Module
USE IFPORT
Syntax

CALL CLOCKX (clock)

clock       (Input) REAL(8). The current time.

On Windows systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

CLOSE

Statement: Disconnects a file from a unit.

Syntax

io-unit     (Input) an external unit specifier.

p           (Input) a scalar default character expression indicating the status of the file after it is closed. It has one of the following values:

• 'KEEP' or 'SAVE' - Retains the file after the unit closes.
• 'DELETE' - Deletes the file after the unit closes (unless OPEN(READONLY) is in effect).
• 'PRINT' - Submits the file to the line print spooler, then retains it (sequential files only).
• 'PRINT/DELETE' - Submits the file to the line print spooler, then deletes it (sequential files only).
• 'SUBMIT' - Forks a process to execute the file.
• 'SUBMIT/DELETE' - Forks a process to execute the file, then deletes the file after the fork is completed.

The default is 'DELETE' for user windows in Windows* QuickWin applications and for scratch files. For all other files, the default is 'KEEP'.

Scratch files are temporary and are always deleted upon normal program termination; specifying STATUS='KEEP' for scratch files causes a run-time error.

For user windows in Windows* QuickWin applications, STATUS='KEEP' causes the child window to remain on the screen even after the unit closes. The default status is 'DELETE', which removes the child window from the screen.

label      Is the label of the branch target statement that receives control if an error occurs.

msg-var    (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var      (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The CLOSE statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.
The status specified in the CLOSE statement supersedes the status specified in the OPEN statement, except that a file opened as a scratch file cannot be saved, printed, or submitted, and a file opened for read-only access cannot be deleted.

If a CLOSE statement is specified for a unit that is not open, it has no effect.

You do not need to explicitly close open files. Normal program termination closes each file according to its default status. The CLOSE statement does not have to appear in the same program unit that opened the file.

Closing unit 0 automatically reconnects unit 0 to the keyboard and screen. Closing units 5 and 6 automatically reconnects those units to the keyboard or screen, respectively. Closing the asterisk (*) unit causes a compile-time error. In Windows QuickWin applications, use CLOSE with unit 0, 5, or 6 to close the default window. If all of these units have been detached from the console (through an explicit OPEN), you must close one of these units beforehand to reestablish its connection with the console. You can then close the reconnect unit to close the default window.

If a parameter of the CLOSE statement is an expression that calls a function, that function must not cause an I/O operation or the EOF intrinsic function to be executed, because the results are unpredictable.

**NOTE**
You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures: USEROPEN Specifier.

**Example**

```
! Close and discard file:
CLOSE (7, STATUS = 'DELETE')
```

Consider the following statement:

```
CLOSE (UNIT=J, STATUS='DELETE', ERR=99)
```

This statement closes the file connected to unit J and deletes it. If an error occurs, control is transferred to the statement labeled 99.

Data Transfer I/O Statements
Branch Specifiers

**CMPLX**

_Elemental Intrinsic Function (Specific):_ Converts the argument to complex type. This function cannot be passed as an actual argument.

**Syntax**

```
result = CMPLX (x[,y] [,kind])
```

- **x** (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
$y$  
(Input; optional) Must be of type integer or real, or a binary, octal, or hexadecimal literal constant. It must not be present if $x$ is of type complex.

$kind$  
(Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is complex. If $kind$ is present, the kind parameter is that specified by $kind$; otherwise, the kind parameter is that of default real type.

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If $y$ is not specified and $x$ is complex, the result value is `CMPLX(REAL($x$), AIMAG($x$)).`

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

`CMPLX($x$, $y$, $kind$)` has the complex value whose real part is `REAL($x$, $kind$)` and whose imaginary part is `REAL($y$, $kind$)`.

The setting of compiler options specifying real size can affect this function.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

**NOTE**

The result values of `CMPLX` are defined by references to the intrinsic function `REAL` with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to `CMPLX` is the same as for the intrinsic function `REAL`.

**Example**

`CMPLX (-3)` has the value (-3.0, 0.0).

`CMPLX (4.1, 2.3)` has the value (4.1, 2.3).

The following shows another example:

```
COMPLEX z1, z2
COMPLEX(8) z3
z1 = CMPLX(3)   ! returns the value 3.0 + i 0.0
z2 = CMPLX(3,4) ! returns the value 3.0 + i 4.0
z3 = CMPLX(3,4,8) ! returns a COMPLEX(8) value 3.0D0 + i 4.0D0
```

**CODE_ALIGN**

*General Compiler Directive:* Specifies the byte alignment for a loop.

**Syntax**

```fortran
!DIR$ CODE_ALIGN [:n]
```

- **n** (Optional) A positive integer constant expression indicating the number of bytes for the minimum alignment boundary. Its value must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.
- If you specify 1 for `n`, no alignment is performed. If you do not specify `n`, the default alignment is 16 bytes.

This directive must precede the loop or block of code to be aligned.

If code is compiled with the `-falign-loops=m` (Linux* and macOS*) or `/Qalign-loops:m` (Windows*) option and a “CODE_ALIGN:n” directive precedes a loop, the loop is aligned on a MAX (m, n) byte boundary.

If a procedure has the “CODE_ALIGN:k” attribute and a “CODE_ALIGN:n” directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

**Example**

Consider the following code fragment in file `test_code_align.f90`:

```fortran
!DIR$ CODE_ALIGN
DO J = 1, N
...
END DO
```

Compiling `test_code_align.f90` aligns the code that begins the DO J loop on a (default) 16-byte boundary. If you do not specify the CODE_ALIGN directive, the alignment of the loop is implementation-dependent and may change from compilation to compilation.

**See Also**

- General Compiler Directives
- Syntax Rules for Compiler Directives
- `falign-loops`, `Qalign-loops` compiler option
- `ATTRIBUTES CODE_ALIGN` directive

**CODIMENSION**

*Statement and Attribute:* Specifies that an entity is a coarray, and specifies its corank and cobounds, if any.

**Syntax**

The CODIMENSION attribute can be specified in a type declaration statement or a CODIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
  type, [att-ls,] CODIMENSION [coarray-spec] :: var-list [(array-spec)]...
  type, [att-ls,] var-list [(array-spec)] [coarray-spec]...
```
Statement:
CODIMENSION [::] var-list [coarray-spec]...

\textbf{type} \hspace{1cm} \text{Is a data type specifier.}

\textbf{att-ls} \hspace{1cm} \text{Is an optional list of attribute specifiers.}

\textbf{coarray-spec} \hspace{1cm} \text{Is an allocatable (deferred-coshape) coarray or an explicit-coshape coarray.}

\textbf{var-list} \hspace{1cm} \text{Is a list of variable names, separated by commas.}

\textbf{Description}
In Intel\textsuperscript{®} Fortran, the sum of the rank and corank of an entity must not exceed 31. The Fortran 2008 Standard allows a combined rank of up to 15.

A coarray must be a component or a variable that is not a function result.

A coarray must not be of type C\_PTR or C\_FUNPTR.

An entity whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar, must not be a coarray, and must not be a function result.

A coarray or an object with a coarray ultimate component must be an associate name, a dummy argument, or have the ALLOCATABLE or SAVE attribute.

A coarray must not be a dummy argument of a procedure that has a BIND attribute.

A coarray can be a derived type with pointer or allocatable components. The target of such a pointer component is always on the same image as the pointer.

\textbf{Examples}
Explicit-shape coarrays that are not dummy arguments must have the SAVE attribute. Because of this, automatic coarrays are not allowed. For example, coarray \texttt{TASK} in the following code is not valid:

\begin{verbatim}
SUBROUTINE \texttt{SUBA(I,C,D)}
INTEGER :: I
REAL :: C(I)[*], D(I)
REAL :: TASK(I)[*] ! Not permitted
\end{verbatim}

The following lines show valid examples of CODIMENSION attribute specifications:

\begin{verbatim}
REAL, CODIMENSION[3,*] :: B(:) ! Assumed-shape coarray
REAL R(50,50)[0:5,*] ! Explicit-shape coarray
REAL, CODIMENSION[*] :: A ! Scalar coarray
REAL, CODIMENSION[:],ALLOCATABLE :: C(:,:) ! Allocatable coarray
\end{verbatim}

\textbf{COLLAPSE Clause}
\textbf{Parallel Directive Clause:} Specifies how many loops are associated with a loop construct.

\textbf{Syntax}
COLLAPSE \((n)\)

\begin{itemize}
  \item \texttt{n} \hspace{1cm} \text{Must be a constant positive scalar integer expression.}
\end{itemize}
If \( n \) is greater than one, the iterations of all associated loops are collapsed into one larger iteration, which is then divided according to the SCHEDULE clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration. The associated loops must be perfectly nested, that is, there must be no intervening code or any OpenMP* directive between any two loops.

The iteration count for each associated loop is computed before entry to the outermost loop. If execution of any associated loop changes any of the values used to compute any of the iteration counts, then the behavior is unspecified. The integer kind used to compute the iteration count for the collapsed loop is implementation defined.

If COLLAPSE is not specified, the only loop that is associated with the loop construct is the one that immediately follows the construct.

At most one COLLAPSE clause can appear in a directive that allows the clause.

See Nested DO Constructs for restrictions on perfectly nested loops using COLLAPSE.

If more than one loop is associated with a TASKLOOP construct, then the iterations of all associated loops are collapsed into one larger iteration space that is then divided according to the specifications in the GRAIN_SIZE and NUM_TASKS clauses. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

**COMAddObjectReference (W*S)**

**COM Function**: Adds a reference to an object's interface.

**Syntax**

\[
\text{result} = \text{COMAddObjectReference}\ (iunknown)
\]

\( iunknown \) An IUnknown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

The result type is INTEGER(4). It is the object's current reference count.

**See Also**

IUnknown::AddRef in the Microsoft* Platform SDK

**COMCLSIDFromProgID (W*S)**

**COM Subroutine**: Passes a programmatic identifier and returns the corresponding class identifier.

**Module**

USE IFCOM

USE IFWINTY
Syntax
CALL COMCLSIDFromProgID (prog_id, clsid, status)

prog_id The programmatic identifier of type CHARACTER*(*).
clsid The class identifier corresponding to the programmatic identifier. Must be of type GUID, which is defined in the IFWINTY module.
status The status of the operation. It can be any status returned by CLSIDFromProgID. Must be of type INTEGER(4).

See Also
CLSIDFromProgID in the Microsoft* Platform SDK

COMCLSIDFromString (W*S)
COM Subroutine: Passes a class identifier string and returns the corresponding class identifier.

Module
USE IFCOM
USE IFWINTY

Syntax
CALL COMCLSIDFromString (string, clsid, status)

string The class identifier string of type CHARACTER*(*).
clsid The class identifier corresponding to the identifier string. Must be of type GUID, which is defined in the IFWINTY module.
status The status of the operation. It can be any status returned by CLSIDFromString. Must be of type INTEGER(4).

See Also
CLSIDFromString in the Microsoft* Platform SDK

COMCreateObject (W*S)
COM Subroutine: A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.

Module
USE IFCOM
USE IFWINTY

Description
Your application obtains its first pointer to an object's interface by calling COMCreateObject. It creates a new instance of an object class and returns a pointer to it.

COMCreateObjectByGUID
COMCreateObjectByProgID
COMCreateObjectByGUID (W*S)

**COM Subroutine**: Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.

**Module**
USE IFCOM
USE IFWINTY

**Syntax**
CALL COMCreateObjectByGUID (clsid, clsctx, iid, interface, status)

- **clsid**: The class identifier of the class of object to be created. Must be of type GUID, which is defined in the IFWINTY module.
- **clsctx**: Lets you restrict the types of servers used for the object. Must be of type INTEGER(4). Must be one of the CLSCTX_* constants defined in the IFWINTY module.
- **iid**: The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
- **interface**: An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **status**: The status of the operation. It can be any status returned by CoCreateInstance. Must be of type INTEGER(4).

**See Also**
CoCreateInstance in the Microsoft* Platform SDK
Using the Intel(R) Fortran Module Wizard (COM Client) in Key Features: Fortran Language Extensions

COMCreateObjectByProgID (W*S)

**COM Subroutine**: Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object's IDispatch interface.

**Module**
USE IFCOM

**Syntax**
CALL COMCreateObjectByProgID (prog_id, idispatch, status)

- **prog_id**: The programmatic identifier of type CHARACTER*(*)
- **idispatch**: An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **status**: The status of the operation. It can be any status returned by CLSIDFromProgID or CoCreateInstance. Must be of type INTEGER(4).

**See Also**
COMCLSIDFromProgID
COMGetActiveObjectByGUID (W*S)

**COM Subroutine**: Passes a class identifier and returns a pointer to the interface of a currently active object.

Module

USE IFCOM
USE IFWINTY

Syntax

CALL COMGetActiveObjectByGUID (clsid, iid, interface, status)

**clsid**
The class identifier of the class of object to be found. Must be of type GUID, which is defined in the IFWINTY module.

**iid**
The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

**interface**
An output argument that returns the object’s interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**status**
The status of the operation. It can be any status returned by GetActiveObject. Must be of type INTEGER(4).

See Also

GetActiveObject in the Microsoft* Platform SDK

COMGetActiveObjectByProgID (W*S)

**COM Subroutine**: Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.

Module

USE IFCOM

Syntax

CALL COMGetActiveObjectByProgID (prog_id, idispatch, status)

**prog_id**
The programmatic identifier of type CHARACTER*(*).

**idispatch**
An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**status**
The status of the operation. It can be any status returned by CLSIDFromProgID or GetActiveObject. Must be of type INTEGER(4).

Example

See the example in COMInitialize.
See Also
CLSIDFromProgID and GetActiveObject in the Microsoft® Platform SDK

**COMGetFileObject (W*S)**

**COM Subroutine**: Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file.

**Module**
USE IFCOM

**Syntax**
CALL COMGetFileObject (filename, idispatch, status)

**filename**
The path of the file of type CHARACTER*(*)

**idispatch**
An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**status**
The status of the operation. It can be any status returned by the CreateBindCtx or MkParseDisplayName routines, or the IMoniker::BindToObject method. Must be of type INTEGER(4).

See Also
CreateBindCtx, MkParseDisplayName, and IMoniker::BindToObject in the Microsoft® Platform SDK

**COMInitialize (W*S)**

**COM Subroutine**: Initializes the COM library.

**Module**
USE IFCOM

**Syntax**
CALL COMInitialize (status)

**status**
The status of the operation. It can be any status returned by OleInitialize. Must be of type INTEGER(4).

You must use this routine to initialize the COM library before calling any other COM or AUTO routine.

**Example**
Consider the following:

```fortran
program COMInitExample
    use ifwin
    use ifcom
    use ifauto
    implicit none

    integer(4) word_app
    integer(4) status
```

1318
integer(INT_PTR_KIND()) invoke_args

call COMInitialize(status)

! Call GetActiveObject to get a reference to a running MS WORD application
call COMGetActiveObjectByProgID("Word.Application", word_app, status)
if (status >= 0) then

  ! Print the active document
  invoke_args = AutoAllocateInvokeArgs()
  call AutoAddArg(invoke_args, "Copies", 2)
  status = AutoInvoke(word_app, "PrintOut", invoke_args)
  call AutoDeallocateInvokeArgs(invoke_args)

  ! Release the reference
  status = COMReleaseObject(word_app)
end if

call COMUninitialize()

end program

See Also
OleInitialize in the Microsoft* Platform SDK

COMIsEqualGUID (W*S)

COM Function: Determines whether two globally unique identifiers (GUIDs) are the same.

Module
USE IFCOM
USE IFWINTY

Syntax
result = COMIsEqualGUID (guid1, guid2)

%guid1% The first GUID. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

%guid2% The second GUID, which will be compared to %guid1%. It must be the same type of GUID as %guid1%. For example, if %guid1% is a CLSID, %guid2% must also be a CLSID.

Results
The result type is LOGICAL(4). The result is .TRUE. if the two GUIDs are the same; otherwise, .FALSE.

See Also
IsEqualGUID in the Microsoft* Platform SDK

COMMAND_ARGUMENT_COUNT

Inquiry Intrinsic Function (Generic): Returns the number of command arguments.
Syntax

\[
\text{result} = \text{COMMAND\_ARGUMENT\_COUNT}() 
\]

Results

The result is a scalar of type default integer. The result value is equal to the number of command arguments available. If there are no command arguments available, the result is 0. The command name does not count as one of the command arguments.

Example

Consider the following:

```fortran
program echo_command_line
    integer i, cnt, len, status
    character c*30, b*100
    
call get_command (b, len, status)
    if (status .ne. 0) then
        write (*,*) 'get_command failed with status = ', status
        stop
    end if
    write (*,*) 'command line = ', b (1:len)
    
call get_command_argument (0, c, len, status)
    if (status .ne. 0) then
        write (*,*) 'Getting command name failed with status = ', status
        stop
    end if
    write (*,*) 'command name = ', c (1:len)
    cnt = command_argument_count ()
    write (*,*) 'number of command arguments = ', cnt
    do i = 1, cnt
        call get_command_argument (i, c, len, status)
        if (status .ne. 0) then
            write (*,*) 'get_command_argument failed: status = ', status, ' arg = ', i
            stop
        end if
        write (*,*) 'command arg ', i, ' = ', c (1:len)
    end do
    write (*,*) 'command line processed'
end
```

If the above program is invoked with the command line "echo_command_line.exe -o 42 -a hello b", the following is displayed:

```
command line = echo_command_line.exe -o 42 -a hello b
command name = echo_command_line.exe
number of command arguments = 5
command arg 1 = -o
command arg 2 = 42
command arg 3 = -a
command arg 4 = hello
command arg 5 = b
command line processed
```

**COMMITQQ**

*Run-Time Function:* Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file's physical device.

**Module**
USE IFCORE

**Syntax**

result = COMMITQQ (unit)

*unit* (Input) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

**Results**

The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initially written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.

COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

**Example**

```
USE IFCORE
INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff
OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')
DO WHILE (.TRUE.)
    WRITE (*, '(A, \)') 'Enter some data (Hit RETURN to &
    exit): '
    len = GETSTRQQ (stuff)
    IF (len .EQ. 0) EXIT
    WRITE (unit, *) stuff
    IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
```
COMMON Statement: Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items.

Syntax

COMMON [ /cname]/ [var-list][,] /cname]/ var-list]...

cname (Optional) Is the name of the common block. The name can be omitted for blank common (/).

var-list Is a list of variable names, separated by commas.

The variable must not be a dummy argument, allocatable array, automatic object, function, function result, a variable with the BIND attribute, or entry to a procedure. It must not have the PARAMETER attribute. If an object of derived type is specified, it must be a sequence type or a type with the BIND attribute.

Description

Common blocks can be named or unnamed (a blank common).

A common block is a global entity, and must not have the same name as any other global entity in the program, such as a subroutine or function.

Any common block name (or blank common) can appear more than once in one or more COMMON statements in a program unit. The list following each successive appearance of the same common block name is treated as a continuation of the list for the block associated with that name. Consider the following COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin
COMMON /     / shepard, grissom, carpenter
COMMON /glenn/ borman, anders
COMMON /young/ mcdiivitt, white, conrad
COMMON schirra, cooper
```

They are equivalent to these COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin, borman, anders
COMMON shepard, grissom, carpenter, schirra, cooper
COMMON /young/ mcdiivitt, white, conrad
```

A variable can appear in only one common block within a scoping unit.

A common block object must not be one of the following:
- A dummy argument
- A result variable
- An allocatable variable
- A derived-type object with an ultimate component that is allocatable
- A procedure pointer
- An automatic object
- A variable with the BIND attribute
- An unlimited polymorphic pointer
- A coarray

If an array is specified, it can be followed by an explicit-shape array specification, each bound of which must be a constant specification expression. Such an array must not have the POINTER attribute.

A pointer can only be associated with pointers of the same type and kind parameters, and rank.

An object with the TARGET attribute can only be associated with another object with the TARGET attribute and the same type and kind parameters.

A nonpointer can only be associated with another nonpointer, but association depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Variable</th>
<th>Type of Associated Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric or numeric sequence</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence</td>
<td>Can be of either of these types</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

\(^1\text{Default integer, default real, double precision real, default complex, double complex, or default logical.}\n
\(^2\text{If an object of numeric sequence or character sequence type appears in a common block, it is as if the individual components were enumerated directly in the common list.}\n
So, variables can be associated if they are of different numeric type. For example, the following is valid:

```fortran
INTEGER A(20)
REAL Y(20)
COMMON /QUANTA/ A, Y
```

When common blocks from different program units have the same name, they share the same storage area when the units are combined into an executable program.

Entities are assigned storage in common blocks on a one-for-one basis. So, the data type of entities assigned by a COMMON statement in one program unit should agree with the data type of entities placed in a common block by another program unit. For example:

<table>
<thead>
<tr>
<th>Program Unit A</th>
<th>Program Unit B</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON CENTS</td>
<td>INTEGER(2) MONEY</td>
</tr>
<tr>
<td>…</td>
<td>COMMON MONEY</td>
</tr>
<tr>
<td>…</td>
<td>…</td>
</tr>
</tbody>
</table>

When these program units are combined into an executable program, incorrect results can occur if the 2-byte integer variable MONEY is made to correspond to the lower-addressed two bytes of the real variable CENTS.

Named common blocks must be declared to have the same size in each program unit. Blank common can have different lengths in different program units.
NOTE
If a common block is initialized by a DATA statement, the module containing the initialization
must declare the common block to be its maximum defined length.
This limitation does not apply if you compile all source modules together.

Example

PROGRAM MyProg
COMMON i, j, x, k(10)
COMMON /mycom/ a(3)
...
END
SUBROUTINE MySub
COMMON pe, mn, z, idum(10)
COMMON /mycom/ a(3)
...
END

In the following example, the COMMON statement in the main program puts HEAT and X in blank common,
and KILO and Q in a named common block, BLK1:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON HEAT, X /BLK1/KILO, Q</td>
<td>SUBROUTINE FIGURE</td>
</tr>
<tr>
<td>...</td>
<td>COMMON /BLK1/LIMA,R / /ALFA, BET</td>
</tr>
</tbody>
</table>
| CALL FIGURE | ...
| ... | RETURN |
| END | END |

The COMMON statement in the subroutine makes ALFA and BET share the same storage location as HEAT and
X in blank common. It makes LIMA and R share the same storage location as KILO and Q in BLK1.

The following example shows how a COMMON statement can be used to declare arrays:

COMMON / MIXED / SPOTTED(100), STRIPED(50,50)

The following example shows a valid association between subroutines in different program units. The object
lists agree in number, type, and kind of data objects:

SUBROUTINE unit1
REAL(8)  x(5)
INTEGER  J
CHARACTER str*12
TYPE(member) club(50)
COMMON / blocka / x, j, str, club
...
SUBROUTINE unit2
REAL(8)  z(5)
INTEGER  m
CHARACTER chr*12

COMPILER_OPTIONS

**Module Intrinsic Inquiry Function:** Returns a string containing the compiler options that were used for compilation.

**Module**

USE ISO_FORTRAN_ENV

**Syntax**

```
result = COMPILER_OPTIONS()
```

**Results**

The result is a scalar of type default character of processor-defined length.

The return value is a list of the compiler options that were used for compilation.

**Example**

Consider the following file named `t.f90`:

```
use ISO_FORTRAN_ENV

character (len = :), allocatable :: res

res = compiler_options ()
print *, "len of res is: ", len (res)
print *, "('<<', A, '>>')" res

deallocate (res)
end
```

The following is the output:

**On Windows:**

```
Win>ifort /exe:t /warn:alignments /assume:writeable-strings t.f90
Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory
Copyright (C) 1985-2016 Intel Corporation. All rights reserved.

Microsoft (R) Incremental Linker Version version
Copyright (C) Microsoft Corporation. All rights reserved.
```
-out:t.exe
-subsystem:console

```
Win> t.exe
len of compiler_options is:           48
</exe:t /warn:alignments /assume:writeable-strings>>
```

On Linux:
```
Lin$ ifort -o t.out -warn alignments -assume writeable-strings t.f90
Lin$ ./t.out
len of res is:           51
<<-o t.out -warn alignments -assume writeable-strings>>
```

See Also
COMPILER_VERSION
ISO_FORTRAN_ENV Module

**COMPILER_VERSION**

*Module Intrinsic Inquiry Function:* Returns a string containing the name and version number of the compiler used for compilation.

**Module**

USE ISO_FORTRAN_ENV

**Syntax**

```fortran
result = COMPILER_VERSION()
```

**Results**

The result is a scalar of type default character of processor-defined length.

The return value contains the name and version number of the compiler used for compilation.

**Example**

Consider the following file named t.f90:

```
use ISO_FORTRAN_ENV

character (len = :), allocatable :: res

res = compiler_version ()
print *, "len of res is: ", len (res)
print *, "('<<', A, '>>')", res

disable (res)
close (1)
end
```

The following is the output:
On Windows, with generic labels like user so the length displayed is not accurate:

Win>ifort /exe:t /warn:alignments /assume:writeable-strings t.f90
Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory
Copyright (C) 1985-2016 Intel Corporation. All rights reserved.

Microsoft (R) Incremental Linker Version version
Copyright (C) Microsoft Corporation. All rights reserved.

-out:t.exe
-subsystem:console
-t.obj

Win> t.exe
len of res is: 184

<<Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory>>

Win>

On Linux, with generic labels like user so the length displayed is not accurate:

Lin$ ifort -o t.out -warn alignments -assume writeable-strings t.f90
Lin$ ./t.out
len of res is: 202

<<Intel(R) Fortran Intel(R) architecture Compiler for applications running

ISO_FORTRAN_ENV Module

COMPLEX Statement

Statement: Specifies the COMPLEX data type.

Syntax

COMPLEX

COMPLEX([KIND=]  n)

COMPLEX* s

DOUBLE COMPLEX

n  Is kind 4, 8, or 16.

s  Is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8)
is specified as COMPLEX*16; COMPLEX(16) is specified as
COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is
specified, the kind of both parts is default real, and the constant is of type default complex.
DOUBLE COMPLEX is COMPLEX(8). No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

**Example**

```fortran
COMPLEX ch
COMPLEX (KIND=4),PRIVATE :: zz, yy  !equivalent to COMPLEX*8 zz, yy
COMPLEX(8) ax, by  !equivalent to COMPLEX*16 ax, by
COMPLEX(kind(4)) y(10)
complex(kind=8)  x, z(10)
```

**See Also**

DOUBLE COMPLEX

COMPLEX(4) Constants
COMPLEX(8) or DOUBLE COMPLEX Constants
Data Types, Constants, and Variables

**COMPLINT, COMPLREAL, COMPLLOG**

*Portability Functions: Return a BIT-WISE complement or logical .NOT. of the argument.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = COMPLINT (intval)
result = COMPREAL (realval)
result = COMPLLOG (logval)
```

* `intval` (Input) INTEGER(4).
* `realval` (Input) REAL(4).
* `logval` (Input) LOGICAL(4).

**Results**

The result is INTEGER(4) for COMPLINT, REAL(4) for COMPLREAL and LOGICAL(4) for COMPLLOG with a value that is the bitwise complement of the argument.

**COMQueryInterface (W*S)**

*COM Subroutine: Passes an interface identifier and returns a pointer to an object's interface.*

**Module**

USE IFCOM
USE IFWINTY

**Syntax**

```fortran
CALL COMQueryInterface (iunknown, iid, interface, status)
```
**unknown**

An IUnknown interface pointer. Must be of type INTEGER(4).

**iid**

The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

**interface**

An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**status**

The status of the operation. It can be any status returned by the IUnknown method QueryInterface. Must be of type INTEGER(4).

**See Also**

IUnknown::QueryInterface in the Microsoft* Platform SDK
Using the Intel(R) Fortran Module Wizard (COM Client) in Key Features: Fortran Language Extensions

**COMReleaseObject (W*S)**

**COM Function:** Indicates that the program is done with a reference to an object’s interface.

**Module**

USE IFCOM

**Syntax**

```fortran
result = COMReleaseObject (iunknown)
```

**iunknown**

An IUnknown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

The result type is INTEGER(4). It is the object's current reference count.

**Example**

See the example in COMInitialize.

**COMStringFromGUID (W*S)**

**COM Subroutine:** Passes a globally unique identifier (GUID) and returns a string of printable characters.

**Module**

USE IFCOM

**Syntax**

```fortran
CALL COMStringFromGUID (guid,string,status)
```

**guid**

The GUID to be converted. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).
A character variable of type CHARACTER(*), that receives the string representation of the GUID. The length of the character variable should be at least 38.

The status of the operation. If the string is too small to contain the string representation of the GUID, the value is zero. Otherwise, the value is the number of characters in the string representation of the GUID. Must be of type INTEGER(4).

The string representation of a GUID has a format like that of the following:

[c200e360-38c5-11ce-ae62-08002b2b79ef]

where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-WORD-DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

See Also
StringFromGUID2 in the Microsoft* Platform SDK

**COMUninitialize (W*S)**

**COM Subroutine:** Uninitializes the COM library.

**Module**
 USE IFCOM

**Syntax**
 CALL COMUninitialize( )

When using COM routines, this must be the last routine called.

**Example**
 See the example in COMInitialize.

**CONJG**

**Elemental Intrinsic Function (Generic):** Calculates the conjugate of a complex number.

**Syntax**
 result = CONJG (z)

z (Input) Must be of type complex.

**Results**

The result type and kind are the same as z. If z has the value (x, y), the result has the value (x, -y).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONJG</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>DCONJG</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>QCONJG</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>
Example
CONJG ((2.0, 3.0)) has the value (2.0, -3.0).
CONJG ((1.0, -4.2)) has the value (1.0, 4.2).
The following shows another example:

```
COMPLEX z1
COMPLEX(8) z2
z1 = CONJG((3.0, 5.6))       ! returns (3.0, -5.6)
z2 = DCONJG((3.0D0, 5.6D0))  ! returns (3.0D0, -5.6D0)
```

AIMAG

CONTAINS

**Statement:** Separates the body of a main program, module, submodule, or external subprogram from any internal or module procedures it may contain, or it introduces the type-bound procedure part of a derived-type definition. It is not executable.

**Syntax**
CONTAINS

Any number of internal procedures can follow a CONTAINS statement, but a CONTAINS statement cannot appear in the internal procedures themselves.

An empty CONTAINS section is allowed.

Example

```
PROGRAM OUTER
    REAL, DIMENSION(10) :: A
    ...
    CALL INNER (A)
    CONTAINS
    SUBROUTINE INNER (B)
    REAL, DIMENSION(10) :: B
    ...
    END SUBROUTINE INNER
END PROGRAM OUTER
```

See Also
Internal Procedures
Modules and Module Procedures
Main Program

CONTIGUOUS

**Statement and Attribute:** Specifies that the target of a pointer or an assumed-sized array is contiguous.

**Syntax**
The CONTIGUOUS attribute can be specified in a type declaration statement or an CONTIGUOUS statement, and takes one of the following forms:
Type Declaration Statement:

\[ \text{type, } [\text{att-ls},] \text{ CONTIGUOUS [, att-ls]} :: \text{object [, object]} \ldots \]

Statement:

\[ \text{CONTIGUOUS } [::] \text{ object [, object]} \ldots \]

- \text{type} Is a data type specifier.
- \text{att-ls} Is an optional list of attribute specifiers.
- \text{object} Is an assumed-shape array or an array pointer.

Description

This attribute explicitly indicates that an assumed-shape array is contiguous or that a pointer will only be associated with a contiguous object.

An entity can be contiguous even if \text{CONTIGUOUS} is not specified. An object is contiguous if it is one of the following:

- An object with the \text{CONTIGUOUS} attribute
- A nonpointer whole array that is not assumed-shape
- An assumed-shape array that is argument associated with an array that is contiguous
- An array allocated by an \text{ALLOCATE} statement
- An pointer associated with a contiguous target
- A nonzero-sized array section in which the following is true:
  - Its base object is contiguous.
  - It does not have a vector subscript.
  - The elements of the section, in array element order, are a subset of the base object elements that are consecutive in array element order.
  - If the array is of type character and a substring-range appears, the substring-range specifies all of the characters of the parent-string.
  - Only its final reference to a structure component, if any, has nonzero rank
  - It is not the real or imaginary part of an array of type complex.

An object is \textit{not} contiguous if it is an array subobject, and all of the following are true:

- The object has two or more elements.
- The elements of the object in array element order are not consecutive in the elements of the base object.
- The object is not of type character with length zero.
- The object is not of a derived type that has no ultimate components other than zero-sized arrays and characters with length zero.

The \text{CONTIGUOUS} attribute can make it easier to enable optimizations that rely on the memory layout of an object occupying a contiguous block of memory.

Examples

The following examples show valid \text{CONTIGUOUS} statements:

\begin{verbatim}
REAL, CONTIGUOUS, DIMENSION(:,:,): A
REAL, POINTER, CONTIGUOUS: MY_POINTER(:)
\end{verbatim}

Compatible attributes
**CONTINUE**

**Statement:** Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.

**Syntax**

```
CONTINUE
```

The statement by itself does nothing and has no effect on program results or execution sequence.

**Example**

The following example shows a CONTINUE statement:

```
DO 150 I = 1,40
   Y = Y + 1
   Z = COS(Y)
   PRINT *, Z
   IF (Y .LT. 30) GO TO 150
   GO TO 40
150 CONTINUE
```

The following shows another example:

```
DIMENSION narray(10)
DO 100 n = 1, 10
   narray(n) = 120
100 CONTINUE
```

**See Also**

END DO
DO
Execution Control

**COPYIN Clause**

**Parallel Directive Clause:** Specifies that the data in the master thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.

**Syntax**

```
COPYIN (list)
```

`list` Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The COPYIN clause applies only to common blocks declared as THREADPRIVATE.

You do not need to specify the whole THREADPRIVATE common block, you can specify named variables within the common block.
COPYPRIVATE Clause

Parallel Directive Clause: Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.

Syntax

COPYPRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables in the list must not appear in a PRIVATE or FIRSTPRIVATE clause for the SINGLE directive construct. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a COPYPRIVATE clause.

If the directive is encountered in the dynamic extent of a parallel region, variables in the list must be private in the enclosing context.

If a common block is specified, it must be declared as THREADPRIVATE; the effect is the same as if the variable names in its common block object list were specified.

The effect of the COPYPRIVATE clause on the variables in its list occurs after the execution of the code enclosed within the SINGLE construct, and before any threads in the team have left the barrier at the end of the construct.

COS

Elemental Intrinsic Function (Generic): Produces the cosine of an argument.

Syntax

result = COS (x)

x

(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

Results

The result type and kind are the same as x.

If x is of type real, the result is a value in radians.

If x is of type complex, the real part of the result is a value in radians.

<table>

<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
</tbody>
</table>
Specific Name | Argument Type | Result Type
--- | --- | ---
CDCOS \(^2\) | COMPLEX(8) | COMPLEX(8)
CQCOS | COMPLEX(16) | COMPLEX(16)

\(^1\)The setting of compiler options specifying real size can affect CCOS.
\(^2\)This function can also be specified as ZCOS.

Example
COS (2.0) has the value -0.4161468.
COS (0.567745) has the value 0.8431157.

**COSD**
*Elemental Intrinsic Function (Generic):* Produces the cosine of \(x\).

**Syntax**

result = COSD (\(x\))

\(x\) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**
The result type and kind are the same as \(x\).

Specific Name | Argument Type | Result Type
--- | --- | ---
COSD | REAL(4) | REAL(4)
DCOSD | REAL(8) | REAL(8)
QCOSD | REAL(16) | REAL(16)

Example
COSD (2.0) has the value 0.9993908.
COSD (30.4) has the value 0.8625137.

**COSH**
*Elemental Intrinsic Function (Generic):* Produces a hyperbolic cosine.

**Syntax**

result = COSH (\(x\))

\(x\) (Input) Must be of type real or complex.

**Results**
The result type and kind are the same as \(x\).

If \(x\) is of type complex, the imaginary part of the result is in radians.
### COSHAPE

**Inquiry Intrinsic Function (Generic): Returns the sizes of codimensions of a coarray.**

### Syntax

```
result = COSHAPE (coarray [, kind])
```

- `coarray` (Input) Is a coarray. It may be of any data type. It must not be an unallocated allocatable coarray.
- `kind` (Input; optional) Must be a scalar integer constant expression.

### Results

The result is an integer array of rank one whose size is equal to the corank of `coarray`. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer.

The result has a value whose \(i\)th element is equal to the size of the \(i\)th codimension of `coarray` as provided by `UCOBOUND(coarray, i) - LCOBOUND(coarray, i) + 1`.

The setting of compiler options specifying integer size can affect this function.

### Example

Consider the following coarray declaration:

```
REAL :: X (10, 20) [10, -1:8, 0:*]
```

It `NUM_IMAGES()` is 200, it has these properties:
- `RANK (X) == 2`
- `corank of X == 3`
- `SHAPE (X) == [10,20]`
- `COSHAPE (X) == [10,10,2]`
- `LCOBOUND (X) == [1, -1, 0]`
- `UCOBOUND (X) == [10, 8, 1]`

**COTAN**

*Elemental Intrinsic Function (Generic): Produces the cotangent of x.*

**Syntax**

```
result = COTAN (x)
```

- **x** (Input) Must be of type real; it cannot be zero. It must be in radians and is treated as modulo 2*pi.

**Results**

The result type and kind are the same as x.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAN (2.0) has the value -4.576575E-01.

COTAN (0.6) has the value 1.461696.

**COTAND**

*Elemental Intrinsic Function (Generic): Produces the cotangent of x.*

**Syntax**

```
result = COTAND (x)
```

- **x** (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as x.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COTAND</td>
<td>REAL(4)</td>

<td>DCOTAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAND (2.0) has the value 0.2863625E+02.

COTAND (0.6) has the value 0.9548947E+02.
COUNT
Transformational Intrinsic Function (Generic):
Counts the number of true elements in an entire array
or in a specified dimension of an array.

Syntax
result = COUNT (mask[,dim][, kind])

mask  (Input) Must be a logical array.
dim   (Input; optional) Must be a scalar integer expression with a value in
       the range 1 to n, where n is the rank of mask.
kind  (Input; optional) Must be a scalar integer constant expression.

Results
The result is an array or a scalar of type integer. If kind is present, the kind parameter of the result is that
specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor
cannot represent the result value in the kind of the result, the result is undefined.

The result is a scalar if dim is omitted or mask has rank one. A scalar result has a value equal to the number
of true elements of mask. If mask has size zero, the result is zero.

An array result has a rank that is one less than mask, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where
(d_1, d_2, ..., d_n) is the shape of mask.

Each element in an array result equals the number of elements that are true in the one dimensional array
defined by mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n).

Example
COUNT ((/.TRUE., .FALSE., .TRUE./)) has the value 2 because two elements are true.
COUNT ((/.TRUE., .TRUE., .TRUE./)) has the value 3 because three elements are true.

A is the array

```
  [ 1  5  7 ]
  [ 3  6  8 ]
```

and B is the array

```
  [ 0  5  7 ]
  [ 2  6  9 ].
```

COUNT (A .NE. B, DIM=1) tests to see how many elements in each column of A are not equal to the
elements in the corresponding column of B. The result has the value (2, 0, 1) because:

- The first column of A and B have 2 elements that are not equal.
- The second column of A and B have 0 elements that are not equal.
- The third column of A and B have 1 element that is not equal.

COUNT (A .NE. B, DIM=2) tests to see how many elements in each row of A are not equal to the elements in
the corresponding row of B. The result has the value (1, 2) because:

- The first row of A and B have 1 element that is not equal.
- The second row of A and B have 2 elements that are not equal.
The following shows another example:

```fortran
LOGICAL mask (2, 3)
INTEGER AR1(3), AR2(2), I
mask = RESHAPE((/.TRUE., .TRUE., .FALSE., .TRUE., &
     .FALSE., .FALSE./),(/2,3/))
!
! mask is the array   true false false
!                     true true false
AR1 = COUNT(mask,DIM=1) ! counts true elements by
! column yielding [2 1 0]
AR2 = COUNT(mask,DIM=2) ! counts true elements by row
! yielding [1 2]
I = COUNT( mask)        ! returns 3
```

- ALL
- ANY

**CPU_TIME**

_Intrinsic Subroutine (Generic):_ Returns a processor-dependent approximation of the processor time in seconds. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL CPU_TIME (time)
```

*time* (Output) Must be scalar and of type real.

The time returned is summed over all active threads. The result is the sum (in units of seconds) of the current process's user time and the user and system time of all its child processes, if any.

If a meaningful time cannot be returned, a processor-dependent negative value is returned.

**NOTE**

If you want to estimate performance or scaling of multithreaded applications, you should use intrinsic subroutine SYSTEM_CLOCK or portability function DCLOCK. Both of these routines return the elapsed time from a single clock.

**Example**

Consider the following:

```fortran
REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
! task to be timed
!
CALL CPU_TIME ( time_end )
WRITE (*,*) 'Time of operation was ', time_end - time_begin, ' seconds'
```

See Also
- DCLOCK
**CRITICAL Directive**

**OpenMP Fortran Compiler Directive:** Restricts access to a block of code to only one thread at a time.

**Syntax**

```fortran
!$OMP CRITICAL [((name))]  
   block  
!$OMP END CRITICAL [((name))]
```

- `name` Is the name of the critical section.
- `block` Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for a CRITICAL construct is all threads in the contention group. Region execution is restricted to a single thread at a time among all threads in the contention group, without regard to the teams to which the threads belong.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name. All unnamed CRITICAL directives map to the same name.

If a name is specified in the CRITICAL directive, the same name must appear in the corresponding END CRITICAL directive. If no name appears in the CRITICAL directive, no name can appear in the corresponding END CRITICAL directive.

Critical section names are global entities of the program. If the name specified conflicts with any other entity, the behavior of the program is undefined.

**Example**

The following example shows a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation is placed in a critical section.

Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, XAXIS and YAXIS, respectively:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,Y)
!$OMP CRITICAL(XAXIS)  
   CALL DEQUEUE(IX_NEXT, X)
!$OMP END CRITICAL(XAXIS)
!$OMP CRITICAL(YAXIS)  
   CALL DEQUEUE(IY_NEXT, Y)
!$OMP END CRITICAL(YAXIS)
!$OMP END PARALLEL
```

**See Also**

OpenMP Fortran Compiler Directives  
Syntax Rules for Compiler Directives

**CRITICAL Statement**

**Statement:** Marks the beginning of a CRITICAL construct. A CRITICAL construct limits execution of a block to one image at a time.

**Syntax**

```
[name:] CRITICAL
    block
END CRITICAL [name]
```

- **name** (Optional) Is the name of the CRITICAL construct.
- **block** Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified in a CRITICAL statement, the same name must appear in the corresponding END CRITICAL statement. If no name is specified at the beginning of a CRITICAL statement, you cannot specify one following the END CRITICAL statement. The same construct name must not be used for different named constructs in the same scoping unit.

The block of a CRITICAL construct must not contain a RETURN statement or an image control statement.

A branch within a CRITICAL construct must not have a branch target that is outside the construct.

Execution of the CRITICAL construct is completed when execution of its block is completed. A procedure that is invoked, directly or indirectly, from a CRITICAL construct must not execute an image control statement.

The processor ensures that once an image has commenced executing block, no other image can start executing block until this image has completed executing block. The image must not execute an image control statement during the execution of block. The sequence of executed statements is therefore a segment. If image S is the next to execute the construct after image N, the segment on image N precedes the segment on image S.

If more than one image executes the block of a CRITICAL construct, its execution by one image always precedes or succeeds its execution by another image. Normally no other statement ordering is needed.

**Example**

Consider the following example:

```
CONA: CRITICAL
END CRITICAL CONA
```

The definition of MY_COUNTER [1] by a particular image will always precede the reference to the same variable by the next image to execute the block.

The following example shows a way to share a large number of tasks among images:

```
INTEGER :: NUMBER_TASKS[*], TASK
IF (THIS_IMAGE() == 1) READ(*,*) NUMBER_TASKS
SYNC ALL
DO
    CRITICAL
        TASK = NUMBER_TASKS[1]
        NUMBER_TASKS[1] = TASK - 1
    END CRITICAL
    IF (TASK > 0) THEN
```

**Language Reference**

Coarrays
Using Coarrays

CSHIFT
Transformational Intrinsic Function (Generic):
Performs a circular shift on a rank-one array, or performs circular shifts on all the complete rank-one sections (vectors) along a given dimension of an array of rank two or greater.

Syntax
Elements shifted off one end are inserted at the other end. Different sections can be shifted by different amounts and in different directions.

result = CSHIFT (array, shift [,dim])

array (Input) Array whose elements are to be shifted. It can be of any data type.

shift (Input) The number of positions shifted. Must be a scalar integer or an array with a rank that is one less than array, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of array.

dim (Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer with a value in the range 1 to n, where n is the rank of array. If dim is omitted, it is assumed to be 1.

Results
The result is an array with the same type and kind parameters, and shape as array. If array has rank one, element i of the result is array(1 + MODULO (i + shift - 1, SIZE (array))). (The same shift is applied to each element.)

If array has rank greater than one, each section (s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) of the result is shifted as follows:
- By the value of shift, if shift is scalar
- According to the corresponding value in shift(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n), if shift is an array

The value of shift determines the amount and direction of the circular shift. A positive shift value causes a shift to the left (in rows) or up (in columns). A negative shift value causes a shift to the right (in rows) or down (in columns). A zero shift value causes no shift.

Example
V is the array (1, 2, 3, 4, 5, 6).

CSHIFT (V, SHIFT=2) shifts the elements in V circularly to the left by 2 positions, producing the value (3, 4, 5, 6, 1, 2). 1 and 2 are shifted off the beginning and inserted at the end.
CSHIFT (V, SHIFT= -2) shifts the elements in V circularly to the right by 2 positions, producing the value (5, 6, 1, 2, 3, 4). 5 and 6 are shifted off the end and inserted at the beginning.

M is the array

\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

CSHIFT (M, SHIFT = 1, DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & 1 \\
5 & 6 & 4 \\
8 & 9 & 7 \\
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. The elements shifted off the beginning are inserted at the end.

CSHIFT (M, SHIFT = -1, DIM = 1) produces the result

\[
\begin{bmatrix}
7 & 8 & 9 \\
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. The elements shifted off the end are inserted at the beginning.

CSHIFT (M, SHIFT = (/1, -1, 0/), DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & 1 \\
6 & 4 & 5 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position; each element in row 2 is shifted to the right by 1 position; no element in row 3 is shifted at all.

The following shows another example:

```
INTEGER array (3, 3), AR1(3, 3), AR2 (3, 3)
DATA array /1, 4, 7, 2, 5, 8, 3, 6, 9/
  !
  ! array is  1 2 3 
  !            4 5 6 
  !            7 8 9 
  !
  !AR1 = CSHIFT(array, 1, DIM = 1) ! shifts all columns 
  ! by 1 yielding 
  !    4 5 6 
  !    7 8 9 
  !    1 2 3 
  !
  !AR2=CSHIFT(array,shift=|--1, 1, 0|,DIM=2) ! shifts 
  ! each row separately 
  ! by the amount in 
  ! shift yielding 
  !    3 1 2 
  !    5 6 4 
  !    7 8 9 
```

ISHFTC

Language Reference
1343
CSMG

**Portability Function:** Performs an effective BIT-WISE store under mask.

**Module**

USE IFPORT

**Syntax**

```fortran
result = CSMG(x, y, z)
```

- `x`, `y`, `z` (Input) INTEGER(4).

**Results**

The result type is INTEGER(4). The result is equal to the following expression:

```
(x & z) | (y & ~z)
```

where "&" is a bitwise AND operation, | - bitwise OR, ~ - bitwise NOT.

The function returns the value based on the following rule: when a bit in `z` is 1, the output bit is taken from `x`. When a bit in `z` is zero, the corresponding output bit is taken from `y`.

CTIME

**Portability Function:** Converts a system time into a 24-character ASCII string.

**Module**

USE IFPORT

**Syntax**

```fortran
result = CTIME(stime)
```

- `stime` (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

**Results**

The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.

The value of `stime` can be determined by calling the TIME function. CTIME(TIME( )) returns the current time and date.

**Example**

```fortran
USE IFPORT
character (24) systime
stime = CTIME (TIME( ))
print *, 'Current date and time is ', systime
```

**See Also**

DATE_AND_TIME
**CYCLE**

**Statement:** Interrupts the current execution cycle of the innermost (or named) DO construct.

**Syntax**

```
CYCLE [name]
```

*name* (Optional) Is the name of the DO construct.

**Description**

When a CYCLE statement is executed, the following occurs:

1. The current execution cycle of the named (or innermost) DO construct is terminated. If a DO construct name is specified, the CYCLE statement must be within the range of that construct.
2. The iteration count (if any) is decremented by 1.
3. The DO variable (if any) is incremented by the value of the increment parameter (if any).

Any executable statements following the CYCLE statement (including a labeled terminal statement) are not executed.

A CYCLE statement can be labeled, but it cannot be used to terminate a DO construct.

Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

**Example**

The following example shows a CYCLE statement:

```
DO I =1, 10
   A(I) = C + D(I)
   IF (D(I) < 0) CYCLE    ! If true, the next statement is omitted
   A(I) = 0               ! from the loop and the loop is tested again.
END DO
```

The following shows another example:

```
sample_loop: do i = 1, 5
   print *,i
   if( i .gt. 3 ) cycle sample_loop
   print *,i
end do sample_loop
print *,''done!''
```

**See Also**

DO
DO WHILE
Execution Control

**DATA**

*Statement:* Assigns initial values to variables before program execution.

**Syntax**

```plaintext
DATA var-list /clist/ [[,] var-list /clist/]...
```

- **var-list**
  
  Is a list of variables or implied-DO lists, separated by commas. *var* cannot be a coarray, a dummy argument, accessed by use or host association, a function name, a function result name, an automatic variable, or a allocatable variable.

  Subscript expressions, section expressions, and substring expressions must be constant expressions.

  An implied-DO list in a DATA statement takes the following form:

  ```plaintext
  ( do-list, do-var= expr1, expr2[, expr3])
  ```

- **do-list**
  
  Is a list of one or more array elements, substrings, scalar structure components, or implied-DO lists, separated by commas. Any array elements or scalar structure components must not have a constant parent.

- **do-var**
  
  Is the name of a scalar integer variable (the implied-DO variable). It cannot be a coarray.

- **expr**
  
  Implied-DO limits must be scalar constant expressions. They may contain implied-DO variables from outer nested implied-DO lists. For more details, see Iteration Loop Control.

- **clist**
  
  Is a list of scalar integer constant expressions (or names of constants), constant structure constructors, or, for pointer objects, NULL (), separated by commas. If the constant is a binary, octal, or hexadecimal literal, the corresponding var must be of type INTEGER.

  A constant can be specified in the form `r*constant`, where *r* is a repeat specification. *r* is a nonnegative scalar integer constant (with no kind parameter). If *r* is a named constant, it must have been declared previously in the scoping unit or made accessible through use or host association. If *r* is omitted, it is assumed to be 1.

**Description**

A variable can be initialized only once in an executable program. A variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration which may change the implicit typing.

The number of constants in clist must equal the number of variables in var-list. The constants are assigned to the variables in the order in which they appear (from left to right).

The following objects cannot be initialized in a DATA statement:

- A dummy argument
- A function
- A function result
- An automatic object
- An allocatable array
- A variable that is accessible by use or host association
- A variable in a named common block (unless the DATA statement is in a block data program unit)
- A variable in blank common

Except for variables in named COMMON blocks, a named variable has the SAVE attribute if any part of it is initialized in a DATA statement. You can confirm this property by specifying the variable in a SAVE statement or a type declaration statement containing the SAVE attribute.

When an unsubscripted array name appears in a DATA statement, values are assigned to every element of that array in the order of subscript progression. If the associated constant list does not contain enough values to fill the array, a warning is issued and the remaining array elements become undefined.

Array element values can be initialized in three ways: by name, by element, or by an implied-DO list (interpreted in the same way as a DO construct).

The following conversion rules and restrictions apply to variable and constant list items:

- If the constant and the variable are both of numeric type, the following conversion occurs:
  - The constant value is converted to the data type of the variable being initialized, if necessary.
  - When a binary, octal, or hexadecimal constant is assigned to a variable or array element, the number of digits that can be assigned depends on the data type of the data item. If the constant contains fewer digits than the capacity of the variable or array element, the constant is extended on the left with zeros. If the constant contains more digits than can be stored, the constant is truncated on the left. An error results if any nonzero digits are truncated.

- If the constant and the variable are both of character type, the following conversion occurs:
  - If the length of the constant is less than the length of the variable, the rightmost character positions of the variable are initialized with blank characters.
  - If the length of the constant is greater than the length of the variable, the character constant is truncated on the right.

- If the constant is of numeric type and the variable is of character type, the following restrictions apply:
  - The character variable must have a length of one character.
  - The constant must be an integer, binary, octal, or hexadecimal constant, and must have a value in the range 0 through 255.

When the constant and variable conform to these restrictions, the variable is initialized with the character that has the ASCII code specified by the constant. (This lets you initialize a character object to any 8-bit ASCII code.)

- If the constant is a Hollerith or character constant, and the variable is a numeric variable or numeric array element, the number of characters that can be assigned depends on the data type of the data item.

  If the Hollerith or character constant contains fewer characters than the capacity of the variable or array element, the constant is extended on the right with blank characters. If the constant contains more characters than can be stored, the constant is truncated on the right.

**Example**

The following example shows the three ways that DATA statements can initialize array element values:

```fortran
DIMENSION A(10,10)
DATA A/100*1.0/    ! initialization by name
DATA A(1,1), A(10,1), A(3,3) /2*2.5, 2.0/ ! initialization by element
DATA ((A(I,J), I=1,5,2), J=1,5) /15*1.0/  ! initialization by implied-DO list
```

The following example shows DATA statements containing structure components:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

Language Reference

1347
In the following example, the first DATA statement assigns zero to all 10 elements of array A, and four asterisks followed by two blanks to the character variable STARS:

```
INTEGER A(10), B(10)
CHARACTER BELL, TAB, LF, FF, STARS*6
DATA A,STARS /10*0,'****'/
DATA BELL,TAB,LF,FF /7,9,10,12/
DATA (B(I), I=1,10,2) /5*1/
```

In this case, the second DATA statement assigns ASCII control character codes to the character variables BELL, TAB, LF, and FF. The last DATA statement uses an implied-DO list to assign the value 1 to the odd-numbered elements in the array B.

The following shows another example:

```
INTEGER n, order, alpha, list(100)
REAL coef(4), eps(2),
  pi(5), x(5,5)
CHARACTER*12 help
COMPLEX*8 cstuff
DATA  n /0/, order /3/
DATA  alpha /'A'/
DATA  coef /1.0, 2*3.0, 1.0/, eps(1) /.00001/
DATA  cstuff /(-1.0, -1.0)/
!    The following example initializes diagonal and below in
!    a 5x5 matrix:
DATA  ((x(j,i), i=1,j), j=1,5) / 15*1.0 /
DATA  pi / 5*3.14159 /
DATA  list / 100*0 /
DATA  help(1:4), help(5:8), help(9:12) /3*'HELP'/
```

Consider the following:

```
CHARACTER (LEN = 10) NAME
INTEGER, DIMENSION (0:9) :: MILES
REAL, DIMENSION (100, 100) :: SKEW
TYPE (MEMBER) MYNAME, YOURS
DATA NAME / 'JOHN DOE' /, miles / 10*0 /
DATA ((SKEW (k, j), j = 1, k), k = 1, 100) / 5050*0.0 /
DATA ((SKEW (k, j), j = k + 1, 100), k = 1, 99) / 4950*1.0 /
DATA MYNAME / MEMBER (21, 'JOHN SMITH') /
DATA YOURS % age, YOURS % name / 35, 'FRED BROWN' /
```

In this example, the character variable NAME is initialized with the value JOHN DOE with two trailing blanks to fill out the declared length of the variable. The ten elements of MILES are initialized to zero. The two-dimensional array SKEW is initialized so that its lower triangle is zero and its upper triangle is one. The structures MYNAME and YOURS are declared using the derived type MEMBER. The derived-type variable MYNAME is initialized by a structure constructor. The derived-type variable YOURS is initialized by supplying a separate value for each component.

The first DATA statement in the previous example could also be written as:

```
DATA name / 'JOHN DOE' /
DATA miles / 10*0 /
```
A pointer can be initialized as disassociated by using a DATA statement. For example:

```
INTEGER, POINTER :: P
DATA P/NULL( )/
END
```

The implied-DO limits can be any constant expressions in a DATA statement. For example:

```
DATA (A(I),I=LBOUND(A),UBOUND(A)) /10*4.0/
```

Allocating Common Blocks in section: Fortran Language Extensions

**DATE Intrinsic Procedure**

**Intrinsic Subroutine (Generic):** Returns the current date as set within the system. DATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```
CALL DATE (buf)
```

- `buf` (Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least nine bytes of storage.

The date is returned as a 9-byte ASCII character string taking the form `dd-mmm-yy`, where:

- `dd` is the 2-digit date
- `mmm` is the 3-letter month
- `yy` is the last two digits of the year

If `buf` is of numeric type and smaller than 9 bytes, data corruption can occur.

If `buf` is of character type, its associated length is passed to the subroutine. If `buf` is smaller than 9 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

**Caution**

The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.
Example

```
CHARACTER*1 DAY(9)
...
CALL DATE (DAY)
```

The length of the first array element in CHARACTER array DAY is passed to the DATE subroutine. The subroutine then truncates the date to fit into the 1-character element, producing an incorrect result.

See Also
DATE_AND_TIME

DATE portability routine

DATE Portability Routine

**Portability Function or Subroutine:** Returns the current system date. DATE can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

**Function Syntax:**

```
result = DATE( )
```

**Subroutine Syntax:**

```
CALL DATE (dstring)
```

---

**dstring**

(Output) CHARACTER. Is a variable or array containing at least nine bytes of storage.

DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where mm, dd, and yy are two-digit representations of the month, day, and year, respectively.

DATE in its subroutine form returns \textit{dstring} in the form dd-mmm-yy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yy are the last two digits of the current year.

---

**Caution**

The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```
USE IFPORT
!If today's date is March 02, 2000, the following
code prints "02-Mar-00"
CHARACTER(9) TODAY
CALL DATE(TODAY)
PRINT *, TODAY
!The next line prints "03/02/00"
PRINT *, DATE( )
```
See Also
DATE_AND_TIME

DATE intrinsic procedure

DATE4
*Portability Subroutine:* Returns the current system date.

Module
USE IFPORT

Syntax
CALL DATE4 (datestr)

*datestr* (Output) CHARACTER. Is a variable or array containing at least eleven bytes of storage.

This subroutine returns *datestr* in the form *dd-mmm-yyyy*, where *dd* is a two-digit representation of the current day of the month, *mmm* is a three-character abbreviation for the current month (for example, Jan) and *yyyy* are the four digits of the current year.

DATE_AND_TIME
*Intrinsic Subroutine (Generic):* Returns character and binary data on the real-time clock and date. Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL DATE_AND_TIME ( [date] [,time] [,zone] [,values] )

*date* (Output; optional) Must be scalar and of type default character; its length must be at least 8 to contain the complete value. Its leftmost 8 characters are set to a value of the form CCYYMMDD, where:

<table>
<thead>
<tr>
<th>CC</th>
<th>Is the century</th>
</tr>
</thead>
<tbody>
<tr>
<td>YY</td>
<td>Is the year within the century</td>
</tr>
<tr>
<td>MM</td>
<td>Is the month within the year</td>
</tr>
<tr>
<td>DD</td>
<td>Is the day within the month</td>
</tr>
</tbody>
</table>

*time* (Output; optional) Must be scalar and of type default character; its length must be at least 10 to contain the complete value. Its leftmost 10 characters are set to a value of the form hhmmss.sss, where:

<table>
<thead>
<tr>
<th>hh</th>
<th>Is the hour of the day</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm</td>
<td>Is the minutes of the hour</td>
</tr>
</tbody>
</table>
ss.sss    Is the seconds and milliseconds of the minute

_zone_

(Output; optional) Must be scalar and of type default character; its length must be at least 5 to contain the complete value. Its leftmost 5 characters are set to a value of the form +hhmm or -hhmm, where hh and mm are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively.

UTC is also known as Greenwich Mean Time.

/values_

(Output; optional) Must be of type integer. One-dimensional array with size of at least 8. The values returned in values are as follows:

<table>
<thead>
<tr>
<th>values(1)</th>
<th>Is the 4-digit year</th>
</tr>
</thead>
<tbody>
<tr>
<td>values(2)</td>
<td>Is the month of the year</td>
</tr>
<tr>
<td>values(3)</td>
<td>Is the day of the month</td>
</tr>
<tr>
<td>values(4)</td>
<td>Is the time difference with respect to Coordinated Universal Time (UTC) in minutes</td>
</tr>
<tr>
<td>values(5)</td>
<td>Is the hour of the day (range 0 to 23) - local time</td>
</tr>
<tr>
<td>values(6)</td>
<td>Is the minutes of the hour (range 0 to 59) - local time</td>
</tr>
<tr>
<td>values(7)</td>
<td>Is the seconds of the minute (range 0 to 59) - local time</td>
</tr>
<tr>
<td>values(8)</td>
<td>Is the milliseconds of the second (range 0 to 999) - local time</td>
</tr>
</tbody>
</table>

Example

Consider the following example executed on 2000 March 28 at 11:04:14.5:

```fortran
INTEGER DATE_TIME (8)
CHARACTER (LEN = 12) REAL_CLOCK (3)
CALL DATE_AND_TIME (REAL_CLOCK (1), REAL_CLOCK (2), &
                    REAL_CLOCK (3), DATE_TIME)
```

This assigns the value "20000328" to REAL_CLOCK (1), the value "110414.500" to REAL_CLOCK (2), and the value "-0500" to REAL_CLOCK (3). The following values are assigned to DATE_TIME: 2000, 3, 28, -300, 11, 4, 14, and 500.

The following shows another example:

```fortran
CHARACTER(10) t
CHARACTER(5)  z
CALL DATE_AND_TIME(TIME = t, ZONE = z)
```

See Also
GETDAT
GETTIM

1352
**Module**

```fortran
USE IFPORT
```

**Syntax**

```fortran
result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)
```

- `value` *(Input) REAL(8).* Independent variable for a Bessel function.
- `n` *(Input) INTEGER(4).* Specifies the order of the selected Bessel function computation.
- `posvalue` *(Input) REAL(8).* Independent variable for a Bessel function. Must be greater than or equal to zero.

**Results**

DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and `n`, respectively, with the independent variable `value`.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and `n`, respectively, with the independent variable `posvalue`.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).
Example

```fortran
USE IFPORT
real(8) besnum, besout
10 read *, besnum
besout = dbesj0(besnum)
print *, 'result is ',besout
goto 10
end
```

See Also
BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

DBLE

**Elemental Intrinsic Function (Generic):** Converts a number to double-precision real type.

**Syntax**

```
result = DBLE (a)
```

*a* (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.

**Results**

The result type is double precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If *a* is of type double precision, the result is the value of the *a* with no conversion (DBLE( *a*) = *a*).

If *a* is of type integer or real, the result has as much precision of the significant part of *a* as a double precision value can contain.

If *a* is of type complex, the result has as much precision of the significant part of the real part of *a* as a double precision value can contain.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBLE</td>
<td>INTEGER(1)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>INTEGER(2)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>INTEGER(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>INTEGER(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DBLE</td>
<td>REAL(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DBLEQ</td>
<td>REAL(16)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(16)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.
Specific Name 1  | Argument Type | Result Type
---|---|---

2 The setting of compiler options specifying double size can affect DBLE.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

NOTE
The result values of DBLE are defined by references to the intrinsic function REAL with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to DBLE is the same as for the intrinsic function REAL.

Example
DBLE (4) has the value 4.0.
DBLE ((3.4, 2.0)) has the value 3.4.

DCLOCK

*Portability Function:* Returns the elapsed time in seconds since the start of the current process.

Module
USE IFPORT

Syntax
result = DCLOCK()

Results
The result type is REAL(8). This routine provides accurate timing to the nearest millisecond (Windows*) or to the nearest microsecond (Linux* and macOS*), taking into account the frequency of the processor where the current process is running.

Note that the first call to DCLOCK performs calibration.

Example
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME
START_TIME = DCLOCK()
CALL FOO()
STOP_TIME = DCLOCK()
PRINT *, 'foo took:', STOP_TIME - START_TIME, 'seconds.'
See Also
DATE_AND_TIME
CPU_TIME

DCMPLX
Elemental Intrinsic Function (Specific): Converts the argument to double complex type. This function cannot be passed as an actual argument.

Syntax
result = DCMPLX (x[,y])

\( x \) (Input) Must be of type integer, real, or complex.
\( y \) (Input; optional) Must be of type integer or real. It must not be present if \( x \) is of type complex.

Results
The result type is double complex (COMPLEX(8) or COMPLEX*16).
If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If \( y \) is not specified and \( x \) is complex, the result value is CMPLX(REAL(\( x \)), AIMAG(\( x \))).
If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.
\( \text{DCMPLX}(x, y) \) has the complex value whose real part is REAL(\( x \), KIND=8) and whose imaginary part is REAL(\( y \), KIND=8).

Example
\( \text{DCMPLX} (-3) \) has the value (-3.0, 0.0).
\( \text{DCMPLX} (4.1, 2.3) \) has the value (4.1, 2.3).

DEALLOCATE
Statement: Frees the storage allocated for allocatable variables and nonprocedure pointer targets (and causes the pointers to become disassociated).

Syntax
DEALLOCATE (object[,object]...[, dealloc-opt])

\( \text{object} \) Is a structure component or the name of a variable, and must be a pointer or allocatable variable.
 dealloc-opt

(Output) Is one of the following:

- **STAT=stat-var**  
  *stat-var* is a scalar integer variable in which the status of the deallocation is stored.

- **ERRMSG=err-var**  
  *err-var* is a scalar default character value in which an error condition is stored if such a condition occurs.

**Description**

If a **STAT=** variable or **ERRMSG=** variable is specified, it must not be deallocated in the **DEALLOCATE** statement in which it appears. If the deallocation is successful, the variable is set to zero. If the deallocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the **ERRMSG=** variable contains the error condition. If no **STAT=** variable is specified and an error condition occurs, program execution terminates.

If an **ALLOCATE** or **DEALLOCATE** statement with a coarray allocatable object is executed when one or more images has initiated termination of execution, the **STAT=** variable becomes defined with the processor-dependent positive integer value of the constant **STAT_STOPPED_IMAGE** from the intrinsic module **ISO_FORTRAN_ENV**.

If any other error condition occurs during execution of the **ALLOCATE** or **DEALLOCATE** statement, the **STAT=** variable becomes defined with a processor-dependent positive integer value different from **STAT_STOPPED_IMAGE**.

It is recommended that all explicitly allocated storage be explicitly deallocated when it is no longer needed.

To disassociate a pointer that was not associated with the **ALLOCATE** statement, use the **NULLIFY** statement.

For a list of run-time errors, see Error Handling in the *Compiler Reference*.

**Example**

The following example shows deallocation of an allocatable array:

```fortran
INTEGER ALLOC_ERR
REAL, ALLOCATABLE :: A(:,), B(:, :)
...
ALLOCATE (A(10), B(-2:8,1:5))
...
DEALLOCATE(A, B, STAT = ALLOC_ERR)
```

The following shows another example:

```fortran
INTEGER ALLOCATABLE :: dataset(:, :, :)
INTEGER reactor, level, points, error
DATA reactor, level, points / 10, 50, 10 /
ALLOCATE (dataset(1:reactor,1:level,1:points), STAT = error)
DEALLOCATE (dataset, STAT = error)
```

DECLARE and NODEDECLARE

**General Compiler Directives:** DECLARE generates warnings for variables that have been used but have not been declared (like the IMPLICIT NONE statement). NODEDECLARE (the default) disables these warnings.

**Syntax**

!DIR$ DECLARE

!DIR$ NODEDECLARE

The DECLARE directive is primarily a debugging tool that locates variables that have not been properly initialized, or that have been defined but never used.

**See Also**

IMPLICIT

General Compiler Directives

Syntax Rules for Compiler Directives

Equivalent Compiler Options

DECLARE REDUCTION

**OpenMP* Fortran Compiler Directive:** Declares user-defined reductions which are identified by a reduction-identifier that can be used in a reduction clause of other directives.

**Syntax**

!$OMP DECLARE REDUCTION (reduction-identifier : type-list : combiner) [initializer-clause]

- **reduction-identifier**
  - Is a Fortran identifier, or a defined or extended operator.

- **type-list**
  - Is a comma-separated list of one or more type identifiers. These may be intrinsic types or accessible derived types. You cannot specify polymorphic and parameterized derived types, and coarrays.
  - **type-list** cannot contain a type which has previously been specified in a DECLARE REDUCTION directive with the same **reduction-identifier** if the **reduction-identifier**/type pair is accessible by use or host association.
  - If more than one type is specified, it is as if there is a separate DECLARE REDUCTION directive for each type.

- **combiner**
  - Is an assignment statement, or a subroutine name followed by an argument list. It indicates how partial results are combined into a single value.
  - There are two special identifiers that are allowed in the **combiner**:  
    - **omp_out**
      - This identifier refers to the storage that holds the resulting combined value following execution of the combiner.
    - **omp_in**
The above identifiers refer to variables that are the type of the reduction variables specified in `type-list` for the `reduction-identifier`. They denote values to be combined by executing the `combiner`.

No other identifiers are permitted in the `combiner`. Any number of literal or named constants can appear in the `combiner`.

If `combiner` is a subroutine name followed by an argument list, it is evaluated by calling the subroutine with the specified argument list. If `combiner` is an assignment statement, `combiner` is evaluated by executing the assignment statement.

The number of times the `combiner` is executed, and the order of these executions, is unspecified.

`initializer-clause` is `initializer (initializer-expression)`.

At most one `initializer-clause` can be specified.

Only the identifiers `omp_priv` and `omp_orig` are allowed in the `initializer-clause`. `omp_orig` refers to the storage of the original reduction variable that appears in the list in the REDUCTION clause that specifies `reduction-identifier`. If `omp_orig` is modified in the `initializer-clause`, the behavior is unspecified.

No other identifiers are allowed in `initializer-clause`. Any number of literal or named constants are permitted.

`initializer-expression` is one of the following identifiers:

- `omp_priv = expression`

  This identifier refers to the storage to be initialized.

- subroutine-name (argument-list)

If `initializer-expression` is a subroutine name and an argument list, the `initializer` is evaluated by executing a call to the subroutine with the specified argument list. If `initializer` is an assignment statement, it is evaluated by executing the assignment.

If `initializer-expression` is a subroutine name and an argument list, one of the arguments must be `omp_priv`, and it must be associated with an INTENT(OUT) dummy argument of the subroutine.

The number of times `initializer-expression` is evaluated and the order of the evaluations is unspecified.

The DECLARE REDUCTION directive is a specification directive. It can appear in a specification part of a subroutine, function, main program, module, or block construct.

User-defined (custom) reductions can be defined using the DECLARE REDUCTION directive. The reduction is identified by the `reduction-identifier` and the associated type from `type-list`. The `reduction-identifier` can be used in a REDUCTION clause in another OpenMP* directive anywhere it is accessible by use or host association.

A DECLARE REDUCTION directive cannot redefine a predefined `reduction-identifier` (see the table of implicitly defined reduction identifiers in the REDUCTION clause section).

If a type in `type-list` has deferred or assumed-length type parameters, the `reduction-identifier` can be used in a REDUCTION clause with a variable of the same type and kind type parameter as type, regardless of the length parameter with which the variable is declared. The length parameter of a character type must be a
constant, colon, or asterisk. An accessible reduction-identifier defined with a deferred or assumed-length character type cannot appear in another DECLARE REDUCTION directive with a type-list item of type character with the same kind type parameter.

The accessibility of a reduction-identifier is determined by the same rules as for other Fortran entities; it can be declared PUBLIC or PRIVATE, be made accessible or blocked by a USE or IMPORT statement, and it can be renamed. If the reduction-identifier is the same as a generic name that is also the name of a derived type, the accessibility of the reduction-identifier is the same as that of the generic name.

If a subroutine or function used in initializer-expression or combiner is not an intrinsic procedure, it must have an accessible interface. Defined operators and defined assignments used in initializer or combiner must have accessible interfaces. All subroutines, functions, defined operators and defined assignments used in initializer or combiner must have accessible interfaces in the subprogram in which the corresponding REDUCTION clause appears. Procedures referenced in combiner and initializer cannot be alternate return subprograms.

The initial value of a user-defined reduction is not known before it is specified. The initializer-clause can be used to specify an initial value for the reduction variable. The initializer-clause will be executed to establish initial values for the private copies of reduction list items indicated in a REDUCTION clause that specifies the reduction-identifier.

If initializer is not specified, private reduction variables are initialized as follows:

- If the reduction variable is type COMPLEX, REAL, or INTEGER, the default initializer is the value zero.
- If the reduction variable specified in list of the REDUCTION clause is LOGICAL, the default initializer is the value .FALSE..
- If the reduction variable is of a default initialized derived type, the default initializer value is used.
- Otherwise, the initial value is unspecified.

If initializer is used in a target region, then a DECLARE TARGET construct must be specified for any procedures that are executed during the execution of combiner or initializer.

If the execution of combiner or initializer results in the execution of an OpenMP* construct or an OpenMP* API call, the behavior is undefined. If the variable omp_orig is defined during execution of initializer, the behavior is unspecified.

Example

Consider that a DECLARE REDUCTION directive is used to declare a sum reduction for an integer component of a type my_type that is identified by the reduction-identifier ‘+’. It is then used in a REDUCTION clause of a parallel region to produce the sum of the thread numbers (numbered 1 thru 4) of the region:

```fortran
module types
  type my_type
    integer :: component
  end type
  interface operator(+)
    module procedure :: my_add
  end interface
!$omp declare reduction (+ : my_type : omp_out = omp_out + omp_in) initializer (omp_priv = my_type (/0/))
...
contains
  function my_add (a1, a2)
    type(my_type),intent(in) :: a1, a2
    type(my_type) :: my_add
    my_add%component = a1%component + a2%component
    return
  end function my_add
end module types
```
program main
  use types
  use omp_lib
  type(my_type) :: my_var
  !$omp parallel reduction (+ : my_var) num_threads(4)
  my_var%component = omp_get_thread_num() + 1
  !$omp end parallel
  print *, "sum of thread numbers is ", my_var%component
end program

The output of the program follows:

sum of thread numbers is 10

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
REDUCTION clause

DECLARE SIMD

OpenMP* Fortran Compiler Directive: Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.

Syntax

!$OMP DECLARE SIMD(routine-name) [clause[, clause]... ]

routine-name

Is the name of a routine (a function or subroutine). It cannot be a generic name; it must be a specific name. It also cannot be a procedure pointer or an entry name.

clause

Is an optional vectorization clause. It can be one or more of the following:

- ALIGNMENT (list [:n])
- INBRANCH | NOTINBRANCH

The INBRANCH clause specifies that the routine must always be called from inside a conditional statement of a SIMD loop.

The NOTINBRANCH clause specifies that the routine must never be called from inside a conditional statement of a SIMD loop.

If neither clause is specified, then the routine may or may not be called from inside a conditional statement of a SIMD loop.

You can only specify INBRANCH or NOTINBRANCH; you cannot specify both.

- LINEAR (linear-list[: linear-step])
- PROCESSOR (cpuid) (an Intel® language extension)
- SIMDLEN(n)
Specifies the number of concurrent arguments \((n)\) for the SIMD version of \(\text{routine-name}\). The \(n\) must be a constant positive integer expression.

If SIMDLEN is not specified, the number of concurrent arguments for the \(\text{routine-name}\) is implementation defined.

Only one SIMDLEN clause can appear in a DECLARE SIMD directive.

- **UNIFORM**: \((\text{list})\)

  Tells the compiler that the values of the specified arguments have an invariant value for all concurrent invocations of the routine in the execution of a single SIMD loop.

  The \(\text{list}\) is one or more scalar variables that are dummy arguments in the specified routine.

  Multiple UNIFORM clauses are merged as a union.

The DECLARE SIMD construct enables the creation of SIMD versions of the specified subroutine or function. You can use multiple DECLARE SIMD constructs in a single procedure to produce more than one SIMD version of a procedure. These versions can be used to process multiple arguments from a single invocation from a SIMD loop concurrently.

When \(\text{routine-name}\) is executed, it cannot have any side-effects that would change its execution for concurrent iterations of a SIMD chunk. When the routine is called from a SIMD loop, it cannot cause the execution of any OpenMP* Fortran construct.

If a DECLARE SIMD directive is specified for a routine name with explicit interface and for the definition of the routine, they must match. Otherwise, the result is unspecified.

You cannot use procedure pointers to access routines created by the DECLARE SIMD directive.

You can only specify a particular variable in at most one instance of a UNIFORM or LINEAR clause.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DECLARE TARGET**

*OpenMP* Fortran Compiler Directive: Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This directive only applies when targeting Intel® Xeon Phi™ products.

**Syntax**

It takes one of the following forms:

```fortran
!$OMP DECLARE TARGET [(extended-list)]
!$OMP DECLARE TARGET[clause[,,]clause]...
```

**extended-list**

Is a list of one or more variables, functions, subroutines, data pointers, procedure pointers, or common blocks. If you specify more than one extended-list item, they must be separated by commas. A common block name must appear between slashes (\(/ /\)); you cannot specify a blank common block. The specified extended-list items can be used inside a target region that executes on the device.
If the *extended-list* item is a function or subroutine, it must not be a generic name or entry name. A device-specific version of the routine is created that can be called from a target region.

If the *extended-list* item is a variable:

- It is mapped to a corresponding variable in the device data environment. If the variable is initialized, the corresponding variable in the device data environment is initialized with the same value.
- It can only appear in the scope in which it is declared.
- It must be declared in the Fortran scope of a module, or it must have the SAVE attribute (explicitly or implicitly).

You cannot specify the following variables in the DECLARE TARGET directive:

- A THREADPRIVATE variable
- A variable that is part of another variable (for example, an element in an array or a field of a structure)
- A variable that is an element of a common block
- A variable that appears in an EQUIVALENCE statement

If the *extended-list* item is a common block:

- It must be declared to be a common block in the same scoping unit in which the DECLARE TARGET directive appears.
- If the DECLARE TARGET directive specifying the common block name appears in one program unit, a DECLARE TARGET directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. The directive must appear after the last relevant COMMON statement in the program unit.

*clause* is one of the following:

- **TO** (*extended-list*)

  Is a comma-separated collection of one or more *list* items or procedures.

  If a *list* item is a routine then a device-specific version of the routine is created that can be called from a target region.

  If a *list* item is a variable then the original variable is mapped to a corresponding variable in the device data environment as if it had appeared in a MAP clause with the *map-type* TO on the implicit TARGET DATA construct for each device.

  The *list* item is never removed from those device data environments.

- **LINK** (*list*)

  The *list* items of a LINK clause are not mapped by the DECLARE TARGET directive. Instead, their mapping occurs only when they are mapped by TARGET DATA or TARGET constructs.

If you specify *list*, this directive can only appear in a specification part of a subroutine, function, program, or module.

If you do not specify *list*, the directive must appear in the specification part of the relevant subroutine, function, or interface block.
If a DECLARE TARGET directive is specified in an interface block for a procedure, it must match a DECLARE TARGET directive in the definition of the procedure.

If a procedure is declared in a procedure declaration statement, any DECLARE TARGET directive containing the procedure name must appear in the same specification part.

The following additional rules apply to variables and common blocks:

- The DECLARE TARGET directive must appear in the declaration section of a scoping unit in which the common block or variable is declared.
- If a variable or common block is declared with the BIND attribute, the corresponding C entities must also be specified in a DECLARE TARGET directive in the C program.

The same list item must not appear multiple times in clauses on the same directive.

The same list item must not appear in both a TO clause on one DECLARE TARGET directive and a LINK clause on another DECLARE TARGET directive.

Variables with static storage and procedures used in an OMP TARGET region are implicitly treated as OMP DECLARE TARGET:

```
MODULE VARS
  INTEGER X
END MODULE

REAL FUNCTION FOO()
END FUNCTION

!$OMP TARGET
  X = FOO()       \ X and FOO are implicitly DECLARE TARGET
!$OMP END TARGET
```

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DECODE**

*Statement*: Translates data from character to internal form. It is comparable to using internal files in formatted sequential READ statements.

**Syntax**

```
DECODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]
```

- `c` is a scalar integer expression. It is the number of characters to be translated to internal form.
- `f` is a format identifier. An error occurs if more than one record is specified.
- `b` is a scalar or array reference. If `b` is an array reference, its elements are processed in the order of subscript progression.
- `i-var` is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
**label**

Is the label of an executable statement that receives control if an error occurs.

**io-list**

Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list receives the data after translation to internal form.

The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the DECODE statement can translate depends on the data type of \( b \). For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

**Example**

In the following example, the DECODE statement translates the 12 characters in \( A \) to integer form (as specified by the FORMAT statement):

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
```

The 12 characters are stored in array \( K \):

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>K(1)</td>
<td>=</td>
<td>1234</td>
</tr>
<tr>
<td>K(2)</td>
<td>=</td>
<td>5678</td>
</tr>
<tr>
<td>K(3)</td>
<td>=</td>
<td>9012</td>
</tr>
</tbody>
</table>

**See Also**

READ

WRITE

ENCODE

**DEFAULT Clause**

**Parallel Directive Clause:** Lets you specify a scope for all variables in the lexical extent of a parallel region.

**Syntax**

```
DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
```

The specifications have the following effects:

- **PRIVATE** - Makes all named objects in the lexical extent of the parallel region, including common block variables but excluding THREADPRIVATE variables, private to a thread as if you explicitly listed each variable in a PRIVATE clause.
- **FIRSTPRIVATE** - Makes all variables in the construct that have implicitly determined data-sharing attributes firstprivate as if you explicitly listed each variable in a FIRSTPRIVATE clause.
• **SHARED** - Makes all named objects in the lexical extent of the parallel region shared among the threads in a team, as if you explicitly listed each variable in a **SHARED** clause. If you do not specify a **DEFAULT** clause, this is the default.

• **NONE** - Specifies that there is no implicit default as to whether variables are **PRIVATE** or **SHARED**. In this case, you must specify the **PRIVATE**, **SHARED**, **FIRSTPRIVATE**, **LASTPRIVATE**, or **REDUCTION** property of each variable you use in the lexical extent of the parallel region.

You can specify only one **DEFAULT** clause in a **PARALLEL** directive. You can exclude variables from a defined default by using the **PRIVATE**, **SHARED**, **FIRSTPRIVATE**, **LASTPRIVATE**, or **REDUCTION** clauses.

Variables in **THREADPRIVATE** common blocks are not affected by this clause.

### DEFINE and UNDEFINE

**General Compiler Directives:** **DEFINE** creates a symbolic variable whose existence or value can be tested during conditional compilation. **UNDEFINE** removes a defined symbol.

**Syntax**

```
!DIR$ DEFINE name[ = val]

!DIR$ UNDEFINE name
```

- **name**
  - Is the name of the variable.

- **val**
  - INTEGER(4). The value assigned to **name**.

**DEFINE** creates and **UNDEFINE** removes symbols for use with the **IF** (or **IF DEFINED**) compiler directive. Symbols defined with **DEFINE** directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.

To test whether a symbol has been defined, use the **IF DEFINED** ( **name**) directive. You can assign an integer value to a defined symbol. To test the assigned value of **name**, use the **IF** directive. **IF** test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The **DEFINE** and **UNDEFINE** directives can appear anywhere in a program, enabling and disabling symbol definitions.

**Example**

```
!DIR$ DEFINE testflag
!DIR$ IF DEFINED (testflag)
    write (*,*) 'Compiling first line'
!DIR$ ELSE
    write (*,*) 'Compiling second line'
!DIR$ ENDIF
!DIR$ UNDEFINE testflag
```

- **D compiler option**
- **Equivalent Compiler Options**
**DEFINE FILE**

**Statement:** Establishes the size and structure of files with relative organization and associates them with a logical unit number.

**Syntax**

```
DEFINE FILE u(m,n,U,asv) [,u(m,n,U,asv)] ...
```

- **u**
  - Is a scalar 32-bit integer constant or variable that specifies the logical unit number.
- **m**
  - Is a scalar integer constant or variable that specifies the number of records in the file.
- **n**
  - Is a scalar integer constant or variable that specifies the length of each record in 16-bit words (2 bytes). For files with record lengths greater than $2^{32} - 1$, the OPEN statement should be used.
- **U**
  - Specifies that the file is unformatted (binary); this is the only acceptable entry in this position.
- **asv**
  - Is a scalar integer variable, called the associated variable of the file. At the end of each direct access I/O operation, the record number of the next higher numbered record in the file is assigned to `asv`; `asv` must not be a dummy argument.

The DEFINE FILE statement is comparable to the OPEN statement. In situations where you can use the OPEN statement, OPEN is the preferable mechanism for creating and opening files.

The DEFINE FILE statement specifies that a file containing *m* fixed-length records, each composed of *n* 16-bit words, exists (or will exist) on the specified logical unit. The records in the file are numbered sequentially from 1 through *m*.

A DEFINE FILE statement does not itself open a file. However, the statement must be executed before the first direct access I/O statement referring to the specified file. The file is opened when the I/O statement is executed.

If this I/O statement is a WRITE statement, a direct access sequential file is opened, or created if necessary.

If the I/O statement is a READ or FIND statement, an existing file is opened, unless the specified file does not exist. If a file does not exist, an error occurs.

The DEFINE FILE statement establishes the variable `asv` as the associated variable of a file. At the end of each direct access I/O operation, the Fortran I/O system places in `asv` the record number of the record immediately following the one just read or written.

The associated variable always points to the next sequential record in the file (unless the associated variable is redefined by an assignment, input, or FIND statement). So, direct access I/O statements can perform sequential processing on the file by using the associated variable of the file as the record number specifier.

**Example**

```
DEFINE FILE 3(1000,48,U,NREC)
```

In this example, the DEFINE FILE statement specifies that the logical unit 3 is to be connected to a file of 1000 fixed-length records; each record is forty-eight 16-bit words long. The records are numbered sequentially from 1 through 1000 and are unformatted.

After each direct access I/O operation on this file, the integer variable NREC will contain the record number of the record immediately following the record just processed.
DELDIRQQ

**Portability Function:** Deletes a specified directory.

**Module**

USE IFPORT

**Syntax**

```fortran
result = DELDIRQQ (dir)
```

*dir*  
(Input) Character*(*). String containing the path of the directory to be deleted.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

**Example**

See the example for GETDRIVEDIRQQ.

CHANGEDRIVEQQ
UNLINK

DELETE

**Statement:** Deletes a record from a relative file.

**Syntax**

```fortran
DELETE ([UNIT=] io-unit[, REC=r][, ERR=label] [, IOSTAT=i-var])
```

*io-unit*  
Is an external unit specifier.

*r*  
Is a scalar numeric expression indicating the record number to be deleted.

*label*  
Is the label of the branch target statement that receives control if an error occurs.

*i-var*  
Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

In a relative file, the DELETE statement deletes the direct access record specified by *r*. If REC= *r* is omitted, the current record is deleted. When the direct access record is deleted, any associated variable is set to the next record number.
The DELETE statement logically removes the appropriate record from the specified file by locating the record and marking it as a deleted record. It then frees the position formerly occupied by the deleted record so that a new record can be written at that position.

**NOTE**
You must use compiler option vms for READs to detect that a record has been deleted.

**Example**
The following statement deletes the fifth record in the file connected to I/O unit 10:

```
DELETE (10, REC=5)
```

Suppose the following statement is specified:

```
DELETE (UNIT=9, REC=10, IOSTAT=IOS, ERR=20)
```

The tenth record in the file connected to unit 9 is deleted. If an error occurs, control is transferred to the statement labeled 20, and a positive integer is stored in the variable IOS.

Data Transfer I/O Statements
Branch Specifiers
vms compiler option

**DELETEMENUQQ (W*S)**
*QuickWin Function:* Deletes a menu item from a QuickWin menu.

**Module**
USE IFQWIN

**Syntax**

```
result = DELETEMENUQQ (menuID, itemID)
```

- `menuID` (Input) INTEGER(4). Identifies the menu that contains the menu item to be deleted, starting with 1 as the leftmost menu.
- `itemID` (Input) INTEGER(4). Identifies the menu item to be deleted, starting with 0 as the top menu item.

**Results**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

**Example**

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
str = 'Add to EDIT Menu'C   ! Append to 2nd menu
result = APPENDMENUQQ(2, $MENUENABLED, str, WINSTATUS)
! Delete third item (EXIT) from menu 1 (FILE)
result = DELETEMENUQQ(1, 3)
! Delete entire fifth menu (WINDOW)
result = DELETEMENUQQ(5,0)
END
```
See Also
APPENDMENUQQ
INSERTMENUQQ
MODIFYMENUFLAGSQQ
MODIFYMENUROUTINEQQ
MODIFYMENUSTRINGQQ

DELFILESQQ

**Portability Function:** Deletes all files matching the name specification, which can contain wildcards (* and ?).

**Module**
USE IFPORT

**Syntax**
```fortran
result = DELFILESQQ (files)
```

*files* (Input) Character*(*). Files to be deleted. Can contain wildcards (* and ?).

**Results**
The result type is INTEGER(2). The result is the number of files deleted.

You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

**Example**
```fortran
USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: ", len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
  WRITE(*,*) "Are you sure (Y/N)?"
  ch = GETCHARQQ()
  IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END
```

See Also
FINDFILEQQ

**DEPEND Clause**

**Parallel Directive Clause:** Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.
Syntax

It takes one of the following forms:

**In Offload Target Control Directives !$OMP TARGET, etc., and TASKING Directive !$OMP TASK:**

\[ \text{DEPEND (dependence-type : list)} \]

**In Synchronization Directive !$OMP ORDERED**

\[ \text{DEPEND (SOURCE) -or- DEPEND (SINK: vec)} \]

Can be any one of the following clauses: IN, OUT, or INOUT.

For IN, the generated task will be a dependent task of all previously generated sibling tasks that reference at least one of the list items in an OUT or INOUT clause.

For OUT and INOUT, the generated task will be a dependent task of all previously generated sibling tasks that reference at least one of the list items in an IN, OUT, or INOUT clause.

\[ \text{list} \]

Is one or more variables or non-zero length array sections. Any list items used in a DEPEND clause of the same task or sibling tasks must indicate identical storage or disjoint storage. The list items that appear in the DEPEND clause may include array sections.

Note that this enforced task dependence establishes a synchronization of accesses to each list item performed by a dependent task, with respect to accesses to the same list item performed by any previous tasks. You must properly synchronize access with respect to other concurrent accesses to each list item.

**SOURCE**

Specifies the satisfaction of cross-iteration dependences that arise from the current iteration.

**SINK**

Specifies a cross-iteration dependence, where the iteration vector vec indicates the iteration that satisfies the dependence.

\[ \text{vec} \]

Is the iteration vector. It has the form:

\[ x_1[\pm d_1], x_2[\pm d_2],..., x_n[\pm d_n] \]

where \( n \) is the value specified by the ORDERED clause in the DO loop directive, \( x_i \) denotes the loop iteration variable of the \( i \)-th nested loop associated with the loop directive, and \( d_i \) is a non-negative integer scalar constant.

If vec does not occur in the iteration space, the DEPEND clause is ignored. Note that if vec does not indicate a lexicographically earlier iteration, it can cause a deadlock.

For a vec element form of \( x_i + d_i \) or \( x_i - d_i \), the expression \( x_i + d_i \) or \( x_i - d_i \) for any value of the integer loop iteration variable \( x_i \) that can encounter the ordered construct must be computable in the loop iteration variable's type without overflow.

If a DEPEND clause appears in a TARGET or TARGET UPDATE directive, it is treated as if it had appeared on the implicit task construct that encloses the TARGET construct.
DEVICE Clause

Parallel Directive Clause: Specifies the target device for a processor control directive like TARGET.

Syntax

DEVICE (integer-expression)

integer-expression Is an integer expression. It must evaluate to a positive scalar integer value.

At most one DEVICE clause can appear in a directive that allows the clause.

If DEVICE is not specified, the default device is determined by the internal control variable (ICV) named device-num-var.

DFLOAT

Elemental Intrinsic Function (Generic): Converts an integer to double-precision real type.

Syntax

result = DFLOAT (a)

a (Input) Must be of type integer.

Results

The result type is double-precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

<table>
<thead>
<tr>
<th>Specific Name 1</th>
<th>Argument Type</th>
<th>Result Type 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>DFLOATI</td>
<td>INTEGER(1)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLOATJ</td>
<td>INTEGER(2)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLOATK</td>
<td>INTEGER(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLOATL</td>
<td>INTEGER(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

2The setting of compiler options specifying double size can affect DFLOAT.

Example

DFLOAT (-4) has the value -4.0.

See Also

REAL

DFLOATI, DFLOATJ, DFLOATK

Portability Functions: Convert an integer to double-precision real type.

Module

USE IFPORT
Syntax
result = DFLOATI (i)
result = DFLOATJ (j)
result = DFLOATK (k)

\(i\)  (Input) Must be of type INTEGER(2).
\(j\)  (Input) Must be of type INTEGER(4).
\(k\)  (Input) Must be of type INTEGER(8).

Results
The result type is double-precision real (REAL(8) or REAL*8).

See Also
DFLOAT

DIGITS
*Inquiry Intrinsic Function (Generic):* Returns the number of significant digits for numbers of the same type and kind parameters as the argument.

Syntax
result = DIGITS (x)

\(x\)  (Input) Must be of type integer or real; it can be scalar or array valued.

Results
The result is a scalar of type default integer.
The result has the value \(q\) if \(x\) is of type integer; it has the value \(p\) if \(x\) is of type real. Integer parameter \(q\) is defined in Model for Integer Data; real parameter \(p\) is defined in Model for Real Data.

Example
If \(x\) is of type REAL(4), DIGITS(x) has the value 24.

See Also
EXPONENT
RADIX
FRACTION
Data Representation Models

DIM
*Elemental Intrinsic Function (Generic):* Returns the difference between two numbers (if the difference is positive).

Syntax
result = DIM (x, y)
(Input) Must be of type integer or real.

(y) Must have the same type and kind parameters as (x).

**Results**

The result type and kind are the same as (x). The value of the result is \( x - y \) if \( x \) is greater than \( y \); otherwise, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>

<td>REAL(4)</td>
</tr>
<tr>
<td>DDIM</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QDIM</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\) Or HDIM.

\(^2\) Or JIDIM. For compatibility, IDIM can also be specified as a generic function for integer types.

**Example**

DIM (6, 2) has the value 4.

DIM (-4.0, 3.0) has the value 0.0.

The following shows another example:

```
INTEGER i
REAL r
REAL(8) d
i = IDIM(10, 5)       ! returns 5
r = DIM (-5.1, 3.7)   ! returns 0.0
d = DDIM (10.0D0, -5.0D0) ! returns 15.0D0
```

**See Also**

Argument Keywords in Intrinsic Procedures

**DIMENSION**

*Statement and Attribute:* Specifies that an object is an array, and defines the shape of the array.

**Syntax**

The DIMENSION attribute can be specified in a type declaration statement or a DIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] DIMENSION (a-spec) [ , att-ls] :: a[(a-spec)][ , a[(a-spec)]] ...```

1374
Statement:

DIMENSION [::]a(a-spec) [, a(a-spec) ] ...

**type**

Is a data type specifier.

**att-ls**

Is an optional list of attribute specifiers.

**a-spec**

Is an array specification. It can be any of the following:

- An explicit-shape specification; for example, a(10,10)
- An assumed-shape specification; for example, a(:)
- A deferred-shape specification; for example, a(:,:,)
- An assumed-size specification; for example, a(10,*)
- An assumed-rank specification; for example, a(,)
- An implicit-shape specification; for example, a(*)

For more information on array specifications, see Declaration Statements for Arrays.

In a type declaration statement, any array specification following an array overrides any array specification following DIMENSION.

**a**

Is the name of the array being declared.

**Description**

The DIMENSION attribute allocates a number of storage elements to each array named, one storage element to each array element in each dimension. The size of each storage element is determined by the data type of the array.

The total number of storage elements assigned to an array is equal to the number produced by multiplying together the number of elements in each dimension in the array specification. For example, the following statement defines ARRAY as having 16 real elements of 4 bytes each and defines MATRIX as having 125 integer elements of 4 bytes each:

```
DIMENSION ARRAY(4,4), MATRIX(5,5,5)
```

An array can also be declared in the following statements: ALLOCATABLE, AUTOMATIC, COMMON, POINTER, STATIC, TARGET.

**Example**

The following examples show type declaration statements specifying the DIMENSION attribute:

```
REAL, DIMENSION(10, 10) :: A, B, C(10, 15) ! Specification following C
                           ! overrides the one following
                           ! DIMENSION

REAL(8), DIMENSION(5,-2:2) :: A,B,C
```

The following are examples of the DIMENSION statement:

```
DIMENSION BOTTOM(12,24,10)
DIMENSION X(5,5,5), Y(4,85), Z(100)
DIMENSION MARK(4,4,4)
SUBROUTINE APROC(A1,A2,N1,N2,N3)
DIMENSION A1(N1:N2), A2(N3:*)
CHARACTER(LEN = 20) D
DIMENSION A(15), B(15, 40), C(-5:8, 7), D(15)
```
You can declare arrays by using type statements and ALLOCATABLE attributes and statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:, :)
REAL(8), ALLOCATABLE, DIMENSION( :, :, ) :: E
```

You can declare an implicit-shape constant array by using a type statement and a PARAMETER attribute, for example:

```
INTEGER, PARAMETER :: R(*) = [1, 2, 3]
```

You can also declare arrays by using type and ALLOCATABLE statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:, :)
REAL(8), ALLOCATABLE, DIMENSION( :, :, ) :: E
```

You can specify both the upper and lower dimension bounds. If, for example, one array contains data from experiments numbered 28 through 112, you could dimension the array as follows:

```
DIMENSION experiment(28:112)
```

Then, to refer to the data from experiment 72, you would reference experiment(72).

Array elements are stored in column-major order: the leftmost subscript is incremented first when the array is mapped into contiguous memory addresses. For example, consider the following statements:

```
INTEGER(2) a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

These are equivalent to:

```
INTEGER(2) a
DIMENSION a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

If `a` is placed at location decimal 1000 in memory, the preceding DATA statement produces the following mapping.

<table>
<thead>
<tr>
<th>Array element</th>
<th>Address (decimal)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a(1,0)</td>
<td>1000</td>
<td>1</td>
</tr>
<tr>
<td>a(2,0)</td>
<td>1002</td>
<td>2</td>
</tr>
<tr>
<td>a(1,1)</td>
<td>1004</td>
<td>3</td>
</tr>
<tr>
<td>a(2,1)</td>
<td>1006</td>
<td>4</td>
</tr>
<tr>
<td>a(1,2)</td>
<td>1008</td>
<td>5</td>
</tr>
<tr>
<td>a(2,2)</td>
<td>100A</td>
<td>6</td>
</tr>
</tbody>
</table>

The following DIMENSION statement defines an assumed-size array in a subprogram:

```
DIMENSION data (19, *)
```

At execution time, the array data is given the size of the corresponding array in the calling program.

The following program fragment dimensions two arrays:

```
... SUBROUTINE Subr (matrix, rows, vector)
REAL MATRIX, VECTOR
```
INTEGER ROWS  
DIMENSION MATRIX (ROWS, *), VECTOR (10),  
+  LOCAL (2, 4, 8)  
MATRIX (1, 1) = VECTOR (5)  
...

Arrays

DISPLAYCURSOR (W*S)

*Graphics Function:* Controls cursor visibility.

**Module**

USE IFQWIN

**Syntax**

result = DISPLAYCURSOR (toggle)

```
toggle  
(Input)  INTEGER(2).  Constant  that  defines  the  cursor  state.  Has  two  possible  values:  

  •  $GCURSOROFF - Makes  the  cursor  invisible  regardless  of  its  current  shape  and  mode.  
  •  $GCURSORON - Makes  the  cursor  always  visible  in  graphics  mode.  
```

**Results**

The  result  type  is  INTEGER(2).  The  result  is  the  previous  value  of  `toggle`.

Cursor  settings  hold  only  for  the  currently  active  child  window.  You  need  to  call  DISPLAYCURSOR  for  each  window  in  which  you  want  the  cursor  to  be  visible.

A  call  to  SETWINDOWCONFIG  turns  off  the  cursor.

SETWINDOWCONFIG

**DISTRIBUTE**

*OpenMP*  *Fortran Compiler Directive*: Specifies that loop iterations will  be  distributed  among  the  master  threads  of  all  thread  teams  in  a  league  created by  a  teams  construct.

**Syntax**

```
!$OMP DISTRIBUTE [clause[,, clause]... ]  
do-loop  
[!$OMP END DISTRIBUTE]
```  

clause  
Is  one  of  the  following:
• **COLLAPSE (n)**

• **DIST_SCHEDULE (kind [, chunk-size])**

  Specifies how iterations are divided.

  The *kind* must be STATIC (see SCHEDULE in **DO Directive**).

  The *chunk-size* must be a positive scalar integer expression. If specified, iterations are divided into chunks of size *chunk-size*. Chunks are assigned round-robin to the teams of the parallel region in the order of the team numbers.

  When no *chunk-size* is specified, iterations are divided into chunks that are approximately equal in size. In this case, at most one chunk is distributed to each team of the parallel region.

• **FIRSTPRIVATE (list)**

• **LASTPRIVATE ([CONDITIONAL:] list)**

• **PRIVATE (list)**

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

If an END DO directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The **DISTRIBUTE** construct inherits the restrictions of the loop construct.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a **DO** directive must be the same for all the threads in the team.

If more than one loop is associated with the **DISTRIBUTE** construct, then the iterations of all associated loops are collapsed into one larger iteration space. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

You cannot branch out of a **DO** loop associated with a **DISTRIBUTE** directive.

The binding thread set for a **DISTRIBUTE** construct is the set of master threads created by a **TEAMS** construct. A **DISTRIBUTE** region binds to the innermost enclosing team's parallel region. Only the threads that execute the binding team's parallel region participate in the execution of the loop iterations. A **DISTRIBUTE** construct must be closely nested in a team's region.

If used, the **END DISTRIBUTE** directive must appear immediately after the end of the loop. If you do not specify an **END DISTRIBUTE** directive, an **END DISTRIBUTE** directive is assumed at the end of the **do-loop**.

The **DISTRIBUTE** construct is associated with loop iterations that follow the directive. The iterations are distributed across the master threads of all teams that execute the team's parallel region to which the **DISTRIBUTE** region binds.

A list item may appear in a **FIRSTPRIVATE** or **LASTPRIVATE** clause but not both.

Parallel Processing Model for information about Binding Sets

**DISTRIBUTE PARALLEL DO**

OpenMP* Fortran Compiler Directive: Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

**Syntax**

```
!$OMP DISTRIBUTE PARALLEL DO [clause[, clause]... ]
   do-loop
   [!$OMP END DISTRIBUTE PARALLEL DO]
```

*clause* Can be any of the clauses accepted by the `DISTRIBUTE` or `PARALLEL DO` directives with identical meanings and restrictions except for `ORDERED` and `LINEAR`.

*do-loop* Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO directive is not specified, an END DISTRIBUTE PARALLEL DO directive is assumed at the end of *do-loop*.

This directive specifies a composite construct.

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DISTRIBUTE PARALLEL DO SIMD**

OpenMP* Fortran Compiler Directive: Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.

**Syntax**

```
!$OMP DISTRIBUTE PARALLEL DO SIMD [clause[, clause]... ]
   do-loop
   [!$OMP END DISTRIBUTE PARALLEL DO SIMD]
```

*clause* Can be any of the clauses accepted by the `DISTRIBUTE` or `PARALLEL DO SIMD` directives with identical meanings and restrictions.
**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of *do-loop*.

This directive specifies a composite construct.

**See Also**
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DISTRIBUTE POINT**

*General Compiler Directive:* Specifies loop distribution. It suggests a location at which a DO loop can be split.

**Syntax**

```fortran
!DIR$ DISTRIBUTE POINT
```

Loop distribution causes large loops to be distributed (split) into smaller ones. The resulting loops contain a subset of the instructions from the initial loop. Loop distribution can enable software pipelining to be applied to more loops. It can also reduce register pressure and improve both instruction and data cache use.

If the directive is placed before a loop, the compiler will determine where to distribute; data dependencies are observed.

If the directive is placed inside a loop, the distribution is performed after the directive and any loop-carried dependencies are ignored. Currently only one distribute directive is supported if the directive is placed inside the loop.

**Example**

```fortran
!DIR$ DISTRIBUTE POINT
do i =1, m
  b(i) = a(i) +1
  ....
c(i) = a(i) + b(i) ! Compiler will decide
  ! where to distribute.
  ! Data dependencies are
  ! observed
  ....
d(i) = c(i) + 1
enddo
!DIR$ DISTRIBUTE POINT
do i =1, m
  b(i) = a(i) +1
  ....
```
call sub(a, n)! Distribution will start here, 
  ! ignoring all loop-carried 
  ! dependencies 
c(i) = a(i) + b(i) 
  .... 
d(i) = c(i) + 1 
enddo

DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.

Syntax

```fortran
!$OMP DISTRIBUTE SIMD [clause[, clause]...] 
do-loop
[!$OMP END DISTRIBUTE SIMD]
```

clause Can be any of the clauses accepted by the DISTRIBUTE or SIMD directives with identical meanings and restrictions.

do-loop Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE SIMD directive is not specified, an END DISTRIBUTE SIMD directive is assumed at the end of do-loop.

This directive specifies a composite construct.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DLGEXIT (W*S)

Dialog Subroutine: Closes an open dialog box.
Module
USE IFLOGM

Syntax
CALL DLGEXIT (dlg)

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

If you want to exit a dialog box on a condition other than the user selecting the OK or Cancel button, you need to include a call to DLGEXIT from within your callback routine. DLGEXIT saves the data associated with the dialog box controls and then closes the dialog box. The dialog box is exited after DLGEXIT has returned control back to the dialog manager, not immediately after the call to DLGEXIT.

Example
SUBROUTINE EXITSUB (dlg, exit_button_id, callbacktype)
USE IFLOGM
TYPE (DIALOG) dlg
INTEGER exit_button_id, callbacktype
...
CALL DLGEXIT (dlg)

See Also
DLGSETRETURN
DLGINIT
DLGMODAL
DLGMODELESS

DLGFLUSH (W*S)
Dialog Subroutine: Updates the display of a dialog box.

Module
USE IFLOGM

Syntax
CALL DLGFLUSH (dlg[,flushall])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

flushall (Input; optional) Logical. If .FALSE. (the default), then only the controls that the dialog routines have marked as changed are updated. If .TRUE., all controls are updated with the state of the controls as known by the dialog routines. Normally, you would not set flushall to .TRUE..

When your application calls DLGSET to change a property of a control in a dialog box, the change is not immediately reflected in the displayed dialog box. Changes are applied when the dialog box is first displayed, and then after every dialog callback to the user’s code.
This design expects that, after a call to DLGMODAL or DLGMODELESS, every call to DLGSET will be made from within a callback routine, and that the callback routine finishes quickly. This is true most of the time. However, there may be cases where you want to change a control outside of a dialog callback, or from within a loop in a dialog callback.

In these cases, DLGFLUSH is required, but is not always sufficient, to update the dialog display. DLGFLUSH sends pending Windows* system messages to the dialog box and the controls that it contains. However, many display changes do not appear until after the program reads and processes these messages. A loop that processes the pending messages may be required; for example:

```fortran
use IFWINTY
use USER32
use IFLOGM

logical lNotQuit, lret
integer iret

TYPE (T_MSG) msg
lNotQuit = .TRUE.
do while (lNotQuit .AND. (PeekMessage(msg, 0, 0, 0, PM_NOREMOVE) <> 0))
   lNotQuit = GetMessage(msg, NULL, 0, 0)
   if (lNotQuit) then
      if (DLGISDLGMESSAGE(msg) .EQV. .FALSE) then
         lret = TranslateMessage(msg)
         iret = DispatchMessage(msg)
      end if
   end if
end do
```

**See Also**
DLGINIT
DLGMODAL
DLGMODELESS
DLGSET
DLGSETSUB

**DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR (W*S)**

*Dialog Functions: Return the state of the dialog control variable.*

**Module**
USE IFLOGM

**Syntax**

- `result = DLGGET (dlg,controlid,value[,index])`
- `result = DLGGETINT (dlg,controlid,value[,index])`
- `result = DLGGETLOG (dlg,controlid,value[,index])`
- `result = DLGGETCHAR (dlg,controlid,value[,index])`

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.
**controlid**
(Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

**value**
(Output) Integer, logical, or character. The value of the control's variable.

**index**
(Input; optional) Integer. Specifies the control variable whose value is retrieved. Necessary if the control has more than one variable of the same data type and you do not want to get the value of the default for that type.

**Results**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGGET functions to retrieve the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variable associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see Additional Documentation: Creating Fortran Applications that Use Windows* Features.

You can use DLGGET to retrieve the value of any variable. You can also use DLGGETINT to retrieve an integer value, or DLGGETLOG and DLGGETCHAR to retrieve logical and character values, respectively. If you use DLGGET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to retrieve a variable type that is not available, the DLGGET functions return .FALSE..

If two or more controls have the same controlid, you cannot use these controls in a DLGGET operation. In this case the function returns .FALSE..

The dialog box does not need to be open to access its control variables.

**Example**

```fortran
USE IFLOGM
INCLUDE "THISDLG.FD"
TYPE (DIALOG)  dlg
INTEGER        val
LOGICAL        retlog, is_checked
CHARACTER(256) text
...
retlog = DLGGET (dlg, IDC_CHECKBOX1, is_checked, dlg_status)
retlog = DLGGET (dlg, IDC_SCROLLBAR2, val, dlg_range)
retlog = DLGGET (dlg, IDC_STATIC_TEXT1, text, dlg_title)
...
```

**See Also**

DLGSET
DLGSETSUB
DLGINIT
DLGMODAL
DLGMODELESS

**DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)**

*Dialog Functions: Initialize a dialog box.*

**Module**

USE IFLOGM
Syntax
result = DLGINIT (id,dlg)
result = DLGINITWITHRESOURCEHANDLE (id,hinst,dlg)

id (Input) INTEGER(4). Dialog identifier. Can be either the symbolic name for the dialog or the identifier number, both listed in the Include file (with extension .FD).

dlg (Output) Derived type dialog. Contains dialog box parameters.

hinst (Input) INTEGER(HANDLE). Handle of the module instance in which the dialog resource can be found. INTEGER(HANDLE) is INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

DLGINIT must be called to initialize a dialog box before it can be used with DLGMODAL, DLGMODELESS, or any other dialog function.

DLGINIT will only search for the dialog box resource in the main application. For example, it will not find a dialog box resource that has been built into a dynamic link library.

DLGINITWITHRESOURCEHANDLE can be used when the dialog resource is not in the main application. If the dialog resource is in a dynamic link library (DLL), hinst must be the value passed as the first argument to the DLLMAIN procedure.

Dialogs can be used from any application, including console, QuickWin, and Windows* applications.

Example
USE IFLOGM
INCLUDE 'DLG1.FD'
LOGICAL retlog
TYPE (DIALOG) thisdlg
...
retlog = DLGINIT (IDD_DLG3, thisdlg)
IF (.not. retlog) THEN
    WRITE (*,*) 'ERROR: dialog not found'
ELSE
    ...

See Also
DLGEXIT
DLGMODAL
DLGMODELESS
DLGUNINIT

DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG (W*S)

Dialog Functions: Determine whether the specified message is intended for one of the currently displayed modeless dialog boxes, or a specific dialog box.

Module
USE IFLOGM
Syntax
result = DLGISDLGMESSAGE (mesg)
result = DLGISDLGMESSAGEWITHDLG (mesg, dlg)

mesg (Input) Derived type T_MSG. Contains a Windows message.
dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

Results
The result type is LOGICAL(4). The result is .TRUE. if the message is processed by the dialog box. Otherwise, the result is .FALSE. and the message should be further processed.

DGLGISDLGMESSAGE must be called in the message loop of Windows applications that display a modeless dialog box using DLGMODELESS. DLGISDLGMESSAGE determines whether the message is intended for one of the currently displayed modeless dialog boxes. If it is, it passes the message to the dialog box to be processed.

DGLGISDLGMESSAGEWITHDLG specifies a particular dialog box to check. Use DGLGISDLGMESSAGEWITHDLG when the message loop is in a main application and the currently active modeless dialog box was created by a DLL.

Example
use IFLOGM
include 'resource.fd'
type (DIALOG) dlg
type (T_MSG) mesg
integer*4 ret
logical*4 lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) /= 0 )
  ! Note that DlgIsDlgMessage must be called in order to give
  ! the dialog box first chance at the message.
  if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
    lret = TranslateMessage( mesg )
    ret  = DispatchMessage( mesg )
  end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return

See Also
DLGMODELESS
DLGMODAL, DLGMODALWITHPARENT (W*S)

**Dialog Functions:** Display a dialog box and process user control selections made within the box.

**Module**
USE IFLOGM

**Syntax**

```
result = DLGMODAL (dlg)

result = DLGMODAL (dlg, hwndParent)
```

- **dlg** (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

- **hwndParent** (Input) Integer. Specifies the parent window for the dialog box. If omitted, the value is determined in this order:
  1. If DLGMODAL is called from the callback of a modal or modeless dialog box, then that dialog box is the parent window.
  2. If it is a QuickWin or Standard Graphics application, then the frame window is the parent window.
  3. The Windows* desktop window is the parent window.

**Results**

The result type is INTEGER(4). By default, if successful, it returns the identifier of the control that caused the dialog to exit; otherwise, it returns -1. The return value can be changed with the DLGSETRETURN subroutine.

During execution, DLGMODAL displays a dialog box and then waits for user control selections. When a control selection is made, the callback routine, if any, of the selected control (set with DLGSETSUB) is called.

The dialog remains active until an exit control is executed: either the default exit associated with the OK and Cancel buttons, or DLGEXIT within your own control callbacks. DLGMODAL does not return a value until the dialog box is exited.

The default return value for DLGMODAL is the identifier of the control that caused it to exit (for example, IDOK for the OK button and IDCANCEL for the Cancel button). You can specify your own return value with DLGSETRETURN from within one of your dialog control callback routines. You should not specify -1 as your return value, because this is the error value DLGMODAL returns if it cannot open the dialog.

Use DLGMODALWITHPARENT when you want the parent window to be other than the default value (see argument hwndParent above). In particular, in an SDI or MDI Windows application, you may want the parent window to be the main application window. The parent window is disabled for user input while the modal dialog box is displayed.

**Example**

```
USE IFLOGM
INCLUDE "MYDLG.FD"
INTEGER return
TYPE (DIALOG) mydialog
...
return = DLGMODAL (mydialog)
...
```
See Also
DLGSETRETURN
DLGSETSUB
DLGINIT
DLGEXIT

**DLGMODELESS (W*S)**

*Dialog Function:* Displays a modeless dialog box.

**Module**

USE IFLOGM

**Syntax**

```fortran
result = DLGMODELESS (dlg[, nCmdShow, hwndParent])
```

*dlg (Input)* Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user. The variable passed to this function must remain in memory for the duration of the dialog box, that is from the DLGINIT call through the DLGUNINIT call.

The variable can be declared as global data in a module, as a variable with the STATIC attribute, or in a calling procedure that is active for the duration of the dialog box. It must not be an AUTOMATIC variable in the procedure that calls DLGMODELESS.

*`nCmdShow` (Input)* Integer. Specifies how the dialog box is to be shown. It must be one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the dialog box.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the dialog box.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
<tr>
<td>SW_SHOW</td>
<td>Activates the dialog box and displays it in its current size and position.</td>
</tr>
<tr>
<td>SW_SHOWMAXIMIZED</td>
<td>Activates the dialog box and displays it as a maximized window.</td>
</tr>
<tr>
<td>SW_SHOWMINIMIZED</td>
<td>Activates the dialog box and displays it as an icon.</td>
</tr>
</tbody>
</table>
### Value Description

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_SHOWMINNOACTIVE</td>
<td>Displays the dialog box as an icon. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNA</td>
<td>Displays the dialog box in its current state. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNOACTIVATE</td>
<td>Displays the dialog box in its most recent size and position. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNORMAL</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows* system restores it to its original size and position.</td>
</tr>
</tbody>
</table>

The default value is SW_SHOWNORMAL.

**hwndParent**

(Input) Integer. Specifies the parent window for the dialog box. The default value is determined in this order:

1. If DLGMODELESS is called from a callback of a modeless dialog box, then that dialog box is the parent window.
2. The Windows desktop window is the parent window.

### Results

The result type is LOGICAL(4). The value is .TRUE. if the function successfully displays the dialog box. Otherwise the result is .FALSE..

During execution, DLGMODELESS displays a modeless dialog box and returns control to the calling application. The dialog box remains active until DLGEXIT is called, either explicitly or as the result of the invocation of a default button callback.

DLGMODELESS is typically used in a Windows application. The application must contain a message loop that processes Windows messages. The message loop must call DLGISDLGMESSAGE for each message. See the example below in the Example section. Multiple modeless dialog boxes can be displayed at the same time. A modal dialog box can be displayed from a modeless dialog box by calling DLGMODAL from a modeless dialog callback. However, DLGMODELESS cannot be called from a modal dialog box callback.

DLGMODELESS also can be used in a Console, DLL, or LIB project. However, the requirements remain that the application must contain a message loop and must call DLGISDLGMESSAGE for each message. For an example of calling DLGMODELESS in a DLL project, see the Dllprgrs sample in the ...\SAMPLES\DIALOG\folder.

Use the DLG_INIT callback with DLGSETSUB to perform processing immediately after the dialog box is created and before it is displayed, and to perform processing immediately before the dialog box is destroyed.

### Example

```plaintext
use IFLOGM
include 'resource.fd'
```
type (DIALOG) dlg
type (T_MSG) mesg
integer*4 ret
logical*4 lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) )
! Note that DlgIsDlgMessage must be called in order to give
! the dialog box first chance at the message.
  if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
    lret = TranslateMessage( mesg )
    ret  = DispatchMessage( mesg )
  end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return

DLGISDLGMESSAGE

DLGSENDCTRLMESSAGE (W*S)
Dialog Function: Sends a Windows message to a
dialog box control.

Module
USE IFLOGM

Syntax
result = DLGSENDCTRLMESSAGE (dlg, controlid, msg, wparam, lparam)

dlg
  (Input) Derived type dialog. Contains dialog box parameters. The
components of the type dialog are defined with the PRIVATE
attribute, and cannot be changed or individually accessed by the user.

controlid
  (Input) Integer. Specifies the identifier of the control within the dialog
box. Can be either the symbolic name for the control or the identifier
number, both listed in the Include file (with extension .FD).

msg
  (Input) Integer. Derived type T_MSG. Specifies the message to be sent.

wparam
  (Input) Integer. Specifies additional message specific information.

lparam
  (Input) Integer. Specifies additional message specific information.
Results

The result type is INTEGER(4). The value specifies the result of the message processing and depends upon the message sent.

The dialog box must be currently active by a call to DLGMODAL or DLGMODELESS. This function does not return until the message has been processed by the control.

Example

use IFLOGM
include 'resource.fd'
type (dialog)    dlg
integer          callbacktype
integer          cref
integer          iret

if (callbacktype == dlg_init) then
    ! Change the color of the Progress bar to red
    ! NOTE: The following message succeeds only if Internet Explorer 4.0
    ! or later is installed
    cref = Z'FF'    ! Red
    iret = DlgSendCtrlMessage(dlg, IDC_PROGRESS1, PBM_SETBARCOLOR, 0, cref)
endif

Dialog Functions: Set the values of dialog control variables.

Module

USE IFLOGM

Syntax

result = DLGSET (dlg, controlid, value[, index])
result = DLGSETINT (dlg, controlid, value[, index])
result = DLGSETLOG (dlg, controlid, value[, index])
result = DLGSETCHAR (dlg, controlid, value[, index])

dlg
    (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid
    (Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

value
    (Input) Integer, logical, or character. The value of the control's variable.
index

(Input; optional) Integer. Specifies the control variable whose value is set. Necessary if the control has more than one variable of the same data type and you do not want to set the value of the default for that type.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGSET functions to set the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variables associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see Additional Documentation: Creating Fortran Applications that Use Windows* OS Features.

You can use DLGSET to set any control variable. You can also use DLGSETINT to set an integer variable, or DLGSETLOG and DLGSETCHAR to set logical and character values, respectively. If you use DLGSET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to set a variable type that is not available, the DLGSET functions return .FALSE..

Calling DLGSET does not cause a callback routine to be called for the changing value of a control. In particular, when inside a callback, performing a DLGSET on a control does not cause the associated callback for that control to be called. Callbacks are invoked automatically only by user action on the controls in the dialog box. If the callback routine needs to be called, you can call it manually after the DLGSET is executed.

If two or more controls have the same controlid, you cannot use these controls in a DLGSET operation. In this case the function returns .FALSE..

Example

```
USE IFLOGM
INCLUDE "DLGRADAR.FD"
TYPE (DIALOG)  dlg
LOGICAL        retlog
...
retlog = DLGSET (dlg, IDC_SCROLLBAR1, 400, dlg_range)
retlog = DLGSET (dlg, IDC_CHECKBOX1, .FALSE., dlg_status)
retlog = DLGSET (dlg, IDC_RADIOBUTTON1, "Hot Button", dlg_title)
...
```

DLGGET

DLGSETCTRLEVENTHANDLER (W*S)

**Dialog Function:** Assigns user-written event handlers to ActiveX controls in a dialog box.

**Module**

USE IFLOGM

**Syntax**

```
result = DLGSETCTRLEVENTHANDLER (dlg, controlid, handler, dispid[, iid])
```

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.
**controlid**
(Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file.

**handler**
(Input) Name of the routine to be called when the event occurs. It must be declared EXTERNAL.

**dispid**
(Input) Integer. Specifies the member id of the method in the event interface that identifies the event.

**iid**
(Input; optional) Derived type GUID, which is defined in the IFWINTY module. Specifies the interface identifier of the source (event) interface. If omitted, the default source interface of the ActiveX control is used.

**Results**
The result type is INTEGER(4). The result is an HRESULT describing the status of the operation.

When the ActiveX control event occurs, the handler associated with the event is called. You call DLGSETCTRLEVENTHANDLER to specify the handler to be called.

The events supported by an ActiveX control and the interfaces of the handlers are determined by the ActiveX control.

You can find this information in one of the following ways:
- By reading the documentation of the ActiveX control.
- By using a tool that lets you examine the type information of the ActiveX control, such as the OLE-COM Object Viewer.
- By using the Fortran Module Wizard to generate a module that contains Fortran interfaces to the ActiveX control, and examining the generated module.

The handler that you define in your application must have the interface that the ActiveX control expects, including calling convention and parameter passing mechanisms. Otherwise, your application will likely crash in unexpected ways because of the application's stack getting corrupted.

Note that an object is always the first parameter in an event handler. This object value is a pointer to the control's source (event) interface, not the IDispatch pointer of the control. You can use DLGGET with the DLG_IDISPATCH index to retrieve the control's IDispatch pointer.

**Example**
```
USE IFLOGM
ret = DlgSetCtrlEventHandler(            
   dlg,                         
   IDC_ACTIVEMOVIECONTROL1,     & ! Identifies the control
   ReadyStateChange,            & ! Name of the event handling routine
   -609,                        & ! Member id of the ActiveMovie's
   & ! control ReadyStateChange event.
   IID_DActiveMovieEvents2 )      ! Identifier of the source (event)
                               !   interface.
```

**DLGSETRETURN (W*S)**

**Dialog Subroutine:** Sets the return value for the DLGMODAL function from within a callback subroutine.

### Module

USE IFLOGM

### Syntax

CALL DLGSETRETURN (dlg, retval)

**dlg**

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

**retval**

(Input) Integer. Specifies the return value for DLGMODAL upon exiting.

DLGSETRETURN overrides the default return value with retval. You can set your own value as a means of determining the condition under which the dialog box was closed. The default return value for an error condition is -1, so you should not use -1 as your return value.

DLGSETRETURN should be called from within a callback routine, and is generally used with DLGEXIT, which causes the dialog box to be exited from a control callback rather than the user selecting the OK or Cancel button.

### Example

```fortran
SUBROUTINE SETRETSUB (dlg, button_id, callbacktype)
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) dlg
LOGICAL     is_checked, retlog
INTEGER     return, button_id, callbacktype
...
retlog = DLGGET(dlg, IDC_CHECKBOX4, is_checked, dlg_state)
IF (is_checked) THEN
    return = 999
ELSE
    return = -999
END IF
CALL DLGSETRETURN (dlg, return)
CALL DLGEXIT (dlg)
END SUBROUTINE SETRETSUB
```

### See Also

DLGEXIT
DLGMODAL

**DLGSETSUB (W*S)**

**Dialog Function:** Assigns your own callback subroutines to dialog controls and to the dialog box.

### Module

USE IFLOGM

---

1394
**Syntax**

```fortran
result = DLGSETSUB (dlg, controlid, value[, index])
```

`dlg` *(Input)* Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

`controlid` *(Input)* Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file, or it can be the identifier of the dialog box.

`value` *(Input)* EXTERNAL. Name of the routine to be called when the callback event occurs.

`index` *(Input; optional)* Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

When a callback event occurs (for example, when you select a check box), the callback routine associated with that callback event is called. You use DLGSETSUB to specify the subroutine to be called. All callback routines should have the following interface:

```fortran
SUBROUTINE callbackname( dlg, control_id, callbacktype)
!DIR$ ATTRIBUTES DEFAULT :: callbackname
callbackname
dlg
control_id
callbacktype
```

`callbackname` Is the name of the callback routine.

`dlg` Refers to the dialog box and allows the callback to change values of the dialog controls.

`control_id` Is the name of the control that caused the callback.

`callbacktype` *(Input; optional)* Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

The `control_id` and `callbacktype` parameters let you write a single subroutine that can be used with multiple callbacks from more than one control. Typically, you do this for controls comprising a logical group. You can also associate more than one callback routine with the same control, but you must use then use `index` parameter to indicate which callback routine to use.

The `control_id` can also be the identifier of the dialog box. The dialog box supports two `callbacktypes`, DLG_INIT and DLG_SIZECHANGE. The DLG_INIT callback is executed immediately after the dialog box is created with `callbacktype` DLG_INIT, and immediately before the dialog box is destroyed with `callbacktype` DLG_DESTROY. DLG_SIZECHANGE is called when the size of a dialog is changed.

Callback routines for a control are called after the value of the control has been updated based on the user's action.

If two or more controls have the same `controlid`, you cannot use these controls in a DLGSETSUB operation. In this case, the function returns .FALSE..
Example

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (dialog) mydialog
LOGICAL retlog
INTEGER return
EXTERNAL RADIOSUB
retlog = DLGINIT(IDD_mydlg, mydialog)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON1, RADIOSUB)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON2, RADIOSUB)
return = DLGMODAL(mydialog)
END

SUBROUTINE RADIOSUB( dlg, id, callbacktype )
!DIR$ ATTRIBUTES DEFAULT :: radiosub
USE IFLOGM
TYPE (dialog) dlg
INTEGER id, callbacktype
INCLUDE 'MYDLG.FD'
CHARACTER(256) text
LOGICAL retlog
SELECT CASE (id)
CASE (IDC_RADIO_BUTTON1)
! Radio button 1 selected by user so
! change text accordingly
  text = 'Statistics Package A'
  retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
CASE (IDC_RADIO_BUTTON2)
! Radio button 2 selected by user so
! change text accordingly
  text = 'Statistics Package B'
  retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
END SELECT
END SUBROUTINE RADIOSUB

DLGSETTITLE (W*S)

*Dialog Subroutine: Sets the title of a dialog box.*

Module
USE IFLOGM

Syntax
CALL DLGSETTITLE (dlg,title)

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

*title* (Input) Character*(*) . Specifies text to be the title of the dialog box.

Use this routine when you want to specify the title for a dialog box.
Example

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGSETTITLE(mydialog, "New Title")
...

See Also
DLGINIT
DLGMODAL
DLGMODELESS

DLGUNINIT (W*S)

Dialog Subroutine: Deallocates memory associated with an initialized dialog.

Module
USE IFLOGM

Syntax
CALL DLGUNINIT (dlg)

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

You should call DLGUNINIT when a dialog that was successfully initialized by DLGINIT is no longer needed. DLGUNINIT should only be called on a dialog initialized with DLGINIT. If it is called on an uninitialized dialog or one that has already been deallocated with DLGUNINIT, the result is undefined.

Example

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGUNINIT (mydialog)
END

DLGEXIT
DNUM

Elemental Intrinsic Function (Specific): Converts a character string to a REAL(8) value. This function cannot be passed as an actual argument.

Syntax

result = DNUM(i)

i

(Input) Must be of type character.

Results

The result type is REAL(8). The result value is the double-precision real value represented by the character string i.

Example

DNUM("3.14159") has the value 3.14159 of type REAL(8).

The following sets x to 311.0:

```
CHARACTER(3) i
DOUBLE PRECISION x
i = "311"
x = DNUM(i)
```

DO Directive

OpenMP* Fortran Compiler Directive: Specifies that the iterations of the immediately following DO loop must be executed in parallel.

Syntax

```
!$OMP DO [clause[,] clause] ... ]
do_loop
[!$OMP END DO [NOWAIT]]
```

clause

Is one of the following:

- COLLAPSE (n)
- FIRSTPRIVATE (list)
- LASTPRIVATE ([CONDITIONAL:] list)
- LINEAR (var-list[: linear-step])
- ORDERED [ (n) ]

Must be used if ordered sections are contained in the dynamic extent of the DO directive. For more information about ordered sections, see the ORDERED directive.

If n is specified, it must be a positive scalar integer constant expression.

- PRIVATE (list)
- REDUCTION (reduction-identifier : list)
- SCHEDULE ([modifier [, modifier]:] kind[, chunk_size])
Specifies how iterations of the DO loop are divided among the threads of the team. \textit{chunk\_size} must be a loop invariant positive scalar integer expression. The value of \textit{chunk\_size} must be the same for all threads in the team. The following \textit{kinds} are permitted, only some of which allow the optional parameter \textit{chunk\_size}:

<table>
<thead>
<tr>
<th>Kinds</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Divides iterations into contiguous pieces by dividing the number of iterations by the number of threads in the team. Each piece is then dispatched to a thread before loop execution begins.</td>
</tr>
<tr>
<td></td>
<td>If \textit{chunk_size} is specified, iterations are divided into pieces of a size specified by \textit{chunk_size}. The pieces are statically dispatched to threads in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>Can be used to get a set of iterations dynamically. It defaults to 1 unless \textit{chunk_size} is specified.</td>
</tr>
<tr>
<td></td>
<td>If \textit{chunk_size} is specified, the iterations are broken into pieces of a size specified by \textit{chunk}. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations.</td>
</tr>
<tr>
<td>GUIDED</td>
<td>Can be used to specify a minimum number of iterations. It defaults to 1 unless \textit{chunk_size} is specified.</td>
</tr>
<tr>
<td></td>
<td>If \textit{chunk_size} is specified, the chunk size is reduced exponentially with each succeeding dispatch. The \textit{chunk_size} specifies the minimum number of iterations to dispatch each time. If there are less than \textit{chunk_size} iterations remaining, the rest are dispatched.</td>
</tr>
<tr>
<td>AUTO\textsuperscript{1}</td>
<td>Delegates the scheduling decision until compile time or run time. The schedule is</td>
</tr>
</tbody>
</table>
### Kinds

<table>
<thead>
<tr>
<th>Kinds</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Runtime</td>
<td>Defers the scheduling decision until run time. You can choose a schedule type and chunk size at run time by using the environment variable OMP_SCHEDULE.</td>
</tr>
</tbody>
</table>

1No chunk_size is permitted for this type.

At most one SCHEDULE clause can appear. If the SCHEDULE clause is not used, the default schedule type is STATIC.

*modifier* can be one of the following:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monotonic</td>
<td>Each thread executes the chunks that it is assigned in increasing logical iteration order.</td>
</tr>
<tr>
<td>Nonmonotonic</td>
<td>Chunks are assigned to threads in any order and the behavior of an application that depends on any execution order of the chunks is unspecified.</td>
</tr>
<tr>
<td>Simd</td>
<td>When do_loop is associated with an OMP SIMD construct, the chunk_size for all chunks except the first and last chunks is:</td>
</tr>
<tr>
<td></td>
<td>new_chunk_size = (chunk_size / simd_width)*simd_width</td>
</tr>
<tr>
<td></td>
<td>where simd_width is an implementation-defined value.</td>
</tr>
<tr>
<td></td>
<td>The first chunk will have at least new_chunk_size iterations unless it is also the last chunk.</td>
</tr>
<tr>
<td></td>
<td>The last chunk may have fewer iterations than new_chunk_size.</td>
</tr>
<tr>
<td></td>
<td>If SIMD is specified and the loop is not associated with an OMP SIMD construct, the modifier is ignored.</td>
</tr>
</tbody>
</table>
**Modifier** | **Effect**
---|---
1 NONMONOTONIC can only be specified with SCHEDULE(DYNAMIC) or SCHEDULE(GUIDED).

If the schedule kind is STATIC or if the ORDERED clause appears, and if MONOTONIC does not appear, the effect will be as if MONOTONIC was specified. NONMONOTONIC cannot be specified if the ORDERED clause appears. Either MONOTONIC or NONMONOTONIC can appear but not both.

modifier cannot appear if the LINEAR clause appears.

The SIMD modifier can be used with MONOTONIC or NONMONOTONIC in either order. The SIMD modifier and the MONOTONIC modifier can be used with all kinds.

**do_loop**

Is a DO iteration (an iterative DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO directive.

The binding thread set for a DO construct is the current team. A DO loop region binds to the innermost enclosing parallel region.

If used, the END DO directive must appear immediately after the end of the loop. If you do not specify an END DO directive, an END DO directive is assumed at the end of the DO loop.

If you specify NOWAIT in the END DO directive, threads do not synchronize at the end of the parallel loop. Threads that finish early proceed straight to the instruction following the loop without waiting for the other members of the team to finish the DO directive.

Parallel DO loop control variables are block-level entities within the DO loop. If the loop control variable also appears in the LASTPRIVATE list of the parallel DO, it is copied out to a variable of the same name in the enclosing PARALLEL region. The variable in the enclosing PARALLEL region must be SHARED if it is specified in the LASTPRIVATE list of a DO directive.

Only a single SCHEDULE, COLLAPSE, or ORDERED clause can appear in a DO directive.

ORDERED (n) specifies how many loops are associated with the DO directive and it specifies that those associated loops form a doacross loop nest. n does not affect how the logical iteration space is divided.

If you specify COLLAPSE (M) ORDERED (N) for loops nested K deep, the following rules apply:

- If either M > K or N > K, the behavior is unspecified.
- N must be greater than M

A LINEAR clause or an ORDERED (n) clause can be specified on a DO directive but not both.

DO directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.
Example

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END DO directive is optional:

```fortran
!$OMP PARALLEL
!$OMP DO
   DO I=1,N
      B(I) = (A(I) + A(I-1)) / 2.0
   END DO
!$OMP END DO
!$OMP END PARALLEL
```

If there are multiple independent loops within a parallel region, you can use the NOWAIT option to avoid the implied BARRIER at the end of the DO directive, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO
   DO I=2,N
      B(I) = (A(I) + A(I-1)) / 2.0
   END DO
!$OMP END DO NOWAIT
!$OMP DO
   DO I=1,M
      Y(I) = SQRT(Z(I))
   END DO
!$OMP END DO NOWAIT
!$OMP END PARALLEL
```

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. Such programs must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO LASTPRIVATE(I)
   DO I=1,N
      A(I) = B(I) + C(I)
   END DO
!$OMP END PARALLEL
CALL REVERSE(I)
```

In this case, the value of I at the end of the parallel region equals N+1, as in the sequential case.

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
   DO I=LB,UB,ST
      CALL WORK(I)
   END DO
... 
SUBROUTINE WORK(K)
   !$OMP ORDERED
   WRITE(*,*) K
   !$OMP END ORDERED
```

In the next example, the loops over J1 and J2 are collapsed and their iteration space is executed by all threads of the current team:

```fortran
!$OMP DO COLLAPSE(2) PRIVATE(J1, J2, J3)
   DO J1 = J1_L, J1_U, J1_S
      DO J2 = J2_L, J2_U, J2_S
```

1402
DO J3 = J3_L, J3_U, J3_S
   CALL BAR(A, J1, J2, J3)
ENDDO
ENDDO
ENDDO
!$OMP END DO

Rules for General Directives that Affect DO Loops
Parallel Processing Model for information about Binding Sets

DO Statement

Statement: Marks the beginning of a DO construct. The DO construct controls the repeated execution of a block of statements or constructs. This repeated execution is called a loop.

Syntax

A DO construct takes one of the following forms:

Block Form:

[name:] DO [label[, ] [loop-control]
   block
[label] term-stmt

Nonblock Form:

DO label [,] [loop-control]
   block
[label] ex-term-stmt

(name) Is the name of the DO construct.
(label) (Optional) Is a statement label identifying the terminal statement.
(loop-control) Is one of the following:

• a loop iteration (see Iteration Loop Control)
• WHILE (see the DO WHILE statement)
• CONCURRENT (see the DO CONCURRENT statement)

(block) Is a sequence of zero or more statements or constructs that make up the DO range.

(term-stmt) Is the terminal statement for the block form of the construct.
(ex-term-stmt) Is the terminal statement for the nonblock form of the construct.

Description

The terminal statement (term-stmt) for a block DO construct is an END DO or CONTINUE statement. If the block DO statement contains a label, the terminal statement must be identified with the same label. If no label appears, the terminal statement must be an END DO statement.
If a construct name is specified in a block DO statement, the same name must appear in the terminal END DO statement. If no construct name is specified in the block DO statement, no name can appear in the terminal END DO statement.

The terminal statement (ex-term-stmt) for a nonblock DO construct is an executable statement (or construct) that is identified by the label specified in the nonblock DO statement. A nonblock DO construct can share a terminal statement with another nonblock DO construct. A block DO construct cannot share a terminal statement.

The following cannot be terminal statements for nonblock DO constructs:

- CONTINUE (allowed if it is a shared terminal statement)
- CYCLE
- END (for a program or subprogram)
- EXIT
- GO TO (unconditional or assigned)
- Arithmetic IF
- RETURN
- STOP

The nonblock DO construct is an obsolescent feature in Standard Fortran.

**Example**

The following example shows a simple block DO construct (contains no iteration count or DO WHILE statement):

```fortran
DO
  READ *, N
  IF (N == 0) STOP
  CALL SUBN
END DO
```

The DO block executes repeatedly until the value of zero is read. Then the DO construct terminates.

The following example shows a named block DO construct:

```fortran
LOOP_1: DO I = 1, N
  A(I) = C * B(I)
END DO LOOP_1
```

The following example shows a nonblock DO construct with a shared terminal statement:

```fortran
DO 20 I = 1, N
  DO 20 J = 1 + I, N
  20 RESULT(I,J) = 1.0 / REAL(I + J)
```

The following two program fragments are also examples of DO statements:

```fortran
C   Initialize the even elements of a 20-element real array
C      DIMENSION array(20)
  DO j = 2, 20, 2
    array(j) = 12.0
  END DO
C
C   Perform a function 11 times
C      DO k = -30, -60, -3
        int = j / 3
        isb = -9 - k
        array(isb) = MyFunc (int)
      END DO
```
The following shows the final value of a DO variable (in this case 11):

```fortran
DO j = 1, 10
    WRITE (*, '(I5)') j
END DO
WRITE (*, '(I5)') j
```

See Also
CONTINUE
CYCLE
EXIT
DO WHILE
DO CONCURRENT
Execution Control

DO CONCURRENT

Statement: Specifies that there are no data dependencies between the iterations of a DO loop. It takes the following form:

Syntax

```
[name:] DO[,] CONCURRENT do-concurrent-header
    block
[END DO [name]]
```

- **name** (Optional) Is the name of the DO CONCURRENT construct.
- **do-concurrent-header** Is ( [ type :: ] do-concurrent-spec [, mask-expr] )
- **type** (Optional) Is an integer data type.
- **do-concurrent-spec** Is an assignment using a triplet specification in the form index-name = do-concurrent-limit : do-concurrent-limit [ : do-concurrent-step]
- **index-name** Is a named scalar variable of type integer. It becomes defined when the index-name value set is evaluated. It has the scope of the construct.
- **do-concurrent-limit** Is a scalar integer expression.
- **do-concurrent-step** (Optional) Is a scalar integer expression.
- **mask-expr** (Optional) Is a mask expression that is scalar and of type logical.
- **block** Is a sequence of zero or more statements or constructs that make up the DO range.

If a construct name is specified in a DO CONCURRENT statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO CONCURRENT statement, no name can appear in the terminal END DO statement, if one is specified.

A procedure referenced in mask-expr must be pure, including one referenced by a defined operator. index-name can appear in mask-expr. The set of index values to be executed is the set of all index-name values for which mask-expr is true.

The DO CONCURRENT range is executed for every active combination of the index-name values.

Each execution of the range is an iteration. The executions can occur in any order.
If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive. You can branch to the END DO statement only from within the construct.

When the DO CONCURRENT construct terminates, a variable that is defined or becomes undefined during more than one iteration of the construct becomes undefined.

Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

A branch within a DO CONCURRENT construct must not have a branch target that is outside the construct.

If type appears, the index-name has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If type does not appear, the index-name must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.

The index-name of a contained FORALL or DO CONCURRENT construct must not be the same as an index-name of any of its containing FORALL or DO CONCURRENT constructs.

The following cannot appear in a DO CONCURRENT construct:

- A RETURN statement
- An image control statement
- A branch to a target outside the construct block
- A statement that may result in the deallocation of a polymorphic variable
- An input/output statement with an ADVANCE= specifier
- A reference to a nonpure procedure
- A reference to module IEEE_EXCEPTIONS procedure IEEE_GET_FLAG, IEEE_SET_HALTING_MODE, or IEEE_GET_HALTING_MODE

An EXIT statement must not appear within a DO CONCURRENT construct if it belongs to that construct or an outer construct.

The following are additional rules for DO CONCURRENT constructs:

- A variable that is referenced in an iteration must be previously defined during that iteration, or it must not be defined or become undefined during any other iteration.

A variable that is defined or becomes undefined by more than one iteration becomes undefined when the loop terminates.

- An allocatable object that is allocated in more than one iteration must be subsequently deallocated during the same iteration in which it was allocated.

An object that is allocated or deallocated in only one iteration must not be referenced, allocated, deallocated, defined, or become undefined in a different iteration.

- A pointer that is referenced in an iteration must have been pointer associated previously during that iteration, or it must not have its pointer association changed during any iteration.

A pointer that has its pointer association changed in more than one iteration has an association status of undefined when the construct terminates.

- An input/output statement must not write data to a file record or position in one iteration and read from the same record or position in a different iteration.

Records written by output statements in the range of the loop to a sequential-access file appear in the file in an indeterminate order.

The restrictions on referencing variables defined in an iteration of a DO CONCURRENT construct also apply to any procedure invoked within the loop.

These restrictions ensure no interdependencies occur that might affect code optimizations.
Note that if compiler option \-parallel (Linux* and macOS*) or /Qparallel (Windows*) is specified, the compiler will attempt to parallelize the construct.

**Example**

The following shows a DO CONCURRENT construct:

```fortran
REAL :: Q
DO CONCURRENT (I = 1:N)
  Q = B(I) + C(I)
  D(I) = Q + SIN(Q) + 2
END DO
```

**DO SIMD**

*OpenMP* Fortran Compiler Directive: Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.

**Syntax**

```
!$OMP DO SIMD [clause[, clause] ... ]
do-loop

[!$OMP END DO SIMD[NOWAIT]]
```

- **Clause**: Can be any of the clauses accepted by the DO or SIMD directives.
- **Do-loop**: Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

  All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

  The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

  You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END DO SIMD directive is not specified, an END DO SIMD directive is assumed at the end of do-loop.

You can specify the NOWAIT clause to avoid the implied barrier at the end of a loop construct.

The DO SIMD construct converts the associated DO loop to a SIMD loop in a way that is consistent with any clauses that apply to the SIMD construct. The resulting SIMD chunks and any remaining iterations will be distributed across the implicit tasks of the parallel region in a way that is consistent with any clauses that apply to the DO construct.

This directive specifies a composite construct.

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
DO WHILE

**Statement:** Executes the range of a DO construct while a specified condition remains true.

**Syntax**

```
[name:] DO [label[, ]] WHILE (expr)
   block
[END DO [name]]
```

- **name** (Optional) Is the name of the DO WHILE construct.
- **label** (Optional) Is a label specifying an executable statement in the same program unit.
- **expr** Is a scalar logical (test) expression enclosed in parentheses.
- **block** Is a sequence of zero or more statements or constructs that make up the DO range.

**Description**

If a construct name is specified in a DO WHILE statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO WHILE statement, no name can appear in the terminal END DO statement, if one is specified.

Before each execution of the DO range, the logical expression is evaluated. If it is true, the statements in the body of the loop are executed. If it is false, the DO construct terminates and control transfers to the statement following the loop.

If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive.

If no label appears in a DO WHILE statement, the DO WHILE loop must be terminated with an END DO statement.

You can transfer control out of a DO WHILE loop but not into a loop from elsewhere in the program.

**Example**

The following example shows a DO WHILE statement:

```
CHARACTER*132 LINE
...
I = 1
DO WHILE (LINE(I:I) .EQ. ' ')
   I = I + 1
END DO
```

The following examples show required and optional END DO statements:

```
RequiredOptional
DO WHILE (I .GT. J)        DO 10 WHILE (I .GT. J)
   ARRAY(I,J) = 1.0         ARRAY(I,J) = 1.0
   I = I - 1               I = I - 1
END DO                   10 END DO
```
The following shows another example:

```fortran
CHARACTER(1) input
input = ' '
DO WHILE ((input .NE. 'n') .AND. (input .NE. 'y'))
    WRITE (*, '(A)') 'Enter y or n: '
    READ (*, '(A)') input
END DO
```

**DOT_PRODUCT**

*Transformational Intrinsic Function (Generic):* Performs dot-product multiplication of numeric or logical vectors (rank-one arrays).

**Syntax**

```fortran
result = DOT_PRODUCT(vector_a, vector_b)
```

- `vector_a` (Input) Must be a rank-one array of numeric (integer, real, or complex) or logical type.
- `vector_b` (Input) Must be a rank-one array of numeric type if `vector_a` is of numeric type, or of logical type if `vector_a` is of logical type. It must be the same size as `vector_a`.

**Results**

The result is a scalar whose type depends on the types of `vector_a` and `vector_b`.

- If `vector_a` is of type integer or real, the result value is SUM (vector_a* vector_b).
- If `vector_a` is of type complex, the result value is SUM (CONJG (vector_a)* vector_b).
- If `vector_a` is of type logical, the result has the value ANY (vector_a.AND. vector_b).

If either rank-one array has size zero, the result is zero if the array is of numeric type, and false if the array is of logical type.

**Example**

DOT_PRODUCT ((/1, 2, 3/), (/3, 4, 5/)) has the value 26, calculated as follows:

\[(1 \times 3) + (2 \times 4) + (3 \times 5) = 26\]

DOT_PRODUCT ((/ (1.0, 2.0), (2.0, 3.0) /), (/ (1.0, 1.0), (1.0, 4.0) /)) has the value (17.0, 4.0).

DOT_PRODUCT ((/ .TRUE., .FALSE. /), (/ .FALSE., .TRUE. /)) has the value false.

The following shows another example:

```fortran
I = DOT_PRODUCT((/1,2,3/), (/4,5,6/)) ! returns the value 32
```

PRODUCT
DOUBLE COMPLEX

Statement: Specifies the DOUBLE COMPLEX data type.

Syntax

DOUBLE COMPLEX

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(KIND=8) or DOUBLE COMPLEX constants. (For more information, see REAL and DOUBLE PRECISION.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* binary64 format.

Example

DOUBLE COMPLEX vector, arrays(7,29)

DOUBLE COMPLEX pi, pi2 /3.141592654,6.283185308/

Valid COMPLEX(8) or DOUBLE COMPLEX constants

(547.3E0_8,-1.44_8)

(1.7039E0,-1.7039D0)

(+12739D3,0.D0)

Invalid COMPLEX(8) or DOUBLE COMPLEX constants

(1.23D0,)

Second constant missing.

(1D1,2H12)

Hollerith constants not allowed.

(1,1.2)

Neither constant is DOUBLE PRECISION; this is a valid single-precision real constant.

See Also

General Rules for Complex Constants
COMPLEX Statement
Complex Data Types
DOUBLE PRECISION
REAL

DOUBLE PRECISION

Statement: Specifies the DOUBLE PRECISION data type.
**Syntax**

DOUBLE PRECISION

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE* binary64 format is used.

For more information, see General Rules for Real Constants.

**Example**

```fortran
DOUBLE PRECISION varnam
DOUBLE PRECISION,PRIVATE :: zz
```

**Valid REAL(8) or DOUBLE PRECISION constants**

- `123456789D+5`
- `123456789E+5_8`
- `+2.7843D00`
- `-.522D-12`
- `2E200_8`
- `2.3_8`
- `3.4E7_8`

**Invalid REAL(8) or DOUBLE PRECISION constants**

- `-.25D0_2` 2 is not a valid kind type for reals.
- `+2.7182812846182` No D exponent designator is present; this is a valid single-precision constant.
- `123456789.D400` Too large for any double-precision format.
- `123456789.D-400` Too small for any double-precision format.

**See Also**

REAL Statement
REAL(8) or DOUBLE PRECISION Constants

Real Data Types

**DPROD**

**Elemental Intrinsic Function (Specific):** Produces a higher precision product. This is a specific function that has no generic function associated with it.

**Syntax**

```fortran
result = DPROD (x, y)
```
**DPROD**

**Results**
If \( x \) and \( y \) are of type REAL(4), the result type is double-precision real (REAL(8) or REAL*8). If \( x \) and \( y \) are of type REAL(8), the result type is REAL(16). The result value is equal to \( x \times y \).

The setting of compiler options specifying real size can affect this function.

**Example**

DPROD (2.0, -4.0) has the value -8.00D0.
DPROD (5.0D0, 3.0D0) has the value 15.00Q0.

The following shows another example:

```fortran
REAL(4) e
REAL(8) d
e = 123456.7
d = 123456.7D0
! DPROD (e,e) returns 15241557546.4944
! DPROD (d,d) returns 15241556774.8899992813874268904328
```

**DRAND, DRANDM**

**Portability Functions:** Return double-precision random numbers in the range 0.0 to 1.0, not including the end points.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{DRAND} (\text{iflag}) \\
\text{result} = \text{DRANDM} (\text{iflag})
\]

**iflag** (Input) INTEGER(4). Controls the way the random number is selected.

**Results**

The result type is REAL(8). DRAND and DRANDM return random numbers in the range 0.0 to 1.0, not including the end points.

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, then restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.
The intrinsic functions \texttt{RANDOM\_NUMBER} and \texttt{RANDOM\_SEED} provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

\textbf{Example}

\begin{verbatim}
USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
CALL print_rand
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,',',num
  END SUBROUTINE
END
\end{verbatim}

\textbf{See Also}
RANDOM\_NUMBER
RANDOM\_SEED

\textbf{DRANSET}

\textit{Portability Subroutine:} Sets the seed for the random number generator.

\textbf{Module}

USE IFPORT

\textbf{Syntax}

CALL DRANSET \texttt{(seed)}

\begin{verbatim}
seed
\end{verbatim}

\texttt{(Input)} REAL(8). The reset value for the seed.

\textbf{See Also}

RANGET

\textbf{DREAL}

\textit{Elemental Intrinsic Function (Specific):} Converts the real part of a double complex argument to double-precision type. \textit{This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.}

\textbf{Syntax}

result = DREAL \texttt{(a)}

\begin{verbatim}
a
\end{verbatim}

\texttt{(Input)} Must be of type double complex (\texttt{COMPLEX(8)} or \texttt{COMPLEX*16}).
Results
The result type is double precision real (REAL(8) or REAL*8).

Example
DREAL ((2.0d0, 3.0d0)) has the value 2.0d0.

See Also
REAL

DSHIFTL
Elemental Intrinsic Function (Specific): Selects the left 64 bits after shifting a 128-bit integer value to the left. This function cannot be passed as an actual argument.

Syntax
\[
\text{result} = \text{DSHIFTL} (i, j, \text{shift})
\]

\( i \)

(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

\( j \)

(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both \( i \) and \( j \) are of type integer, they must have the same kind type parameter. \( i \) and \( j \) must not both be binary, octal, or hexadecimal literal constants.

\( \text{shift} \)

(Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

Results
The result type is integer. The result value is the 64-bit value starting at bit \( 128 - \text{shift} \) of the 128-bit concatenation of the values of \( i \) and \( j \).

If either \( i \) or \( j \) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The rightmost \( \text{shift} \) bits of the result value are the same as the leftmost bits of \( i \), and the remaining bits of the result value are the same as the rightmost bits of \( j \). This is equal to IOR (SHIFTL (I, SHIFT), SHIFTR (J, BIT SIZE (J) - SHIFT)).

Example
Consider the following:

\[
\begin{align*}
\text{INTEGER}(8) & \ ILEFT / \ Z'111122221111222' / \\
\text{INTEGER}(8) & \ IRIGHT / \ Z'FFFFFFFFFFFFFFF' / \\
\text{PRINT} & \ *, \ \text{DSHIFTL} (\text{ILEFT}, \ IRIGHT, 16_8) \ ! \ prints \ 1306643199093243919
\end{align*}
\]

Model for Bit Data
**DSHIFTR**

**Elemental Intrinsic Function (Specific):** Selects the left 64 bits after shifting a 128-bit integer value to the right. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{DSHIFTR} (i, j, \text{shift})
\]

- **i** (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
- **j** (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
- **shift** (Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

**Results**

The result type is integer. The result value is the 64-bit value starting at bit 64 + \(\text{shift}\) of the 128-bit concatenation of the values of \(i\) and \(j\).

If either \(i\) or \(j\) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The leftmost \(\text{shift}\) bits of the result value are the same as the rightmost bits of \(i\), and the remaining bits of the result value are the same as the leftmost bits of \(j\). This is equal to IOR (SHIFTL (I, BIT SIZE (I) - \(\text{shift}\)), SHIFTR (J, \(\text{shift}\))).

**Example**

Consider the following:

```fortran
INTEGER(8) ILEFT / Z'111122221111222' /
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /
PRINT *, DSHIFTR (ILEFT, IRIGHT, 16_8)  ! prints 1306606910610341887
```

**See Also**

Binary, Octal, Hexadecimal, and Hollerith Constants
Model for Bit Data

**DTIME**

**Portability Function:** Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{DTIME} (\text{tarray})
\]

- **tarray** (Output) REAL(4). A rank one array with two elements:
• \textit{tarray(1)} - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
• \textit{tarray(2)} - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

**Results**

The result type is REAL(4). The result is the total CPU time, which is the sum of \textit{tarray(1)} and \textit{tarray(2)}. If an error occurs, -1 is returned.

**Example**

```
USE IFORT
REAL(4) I, TA(2)
I = DTIME(TA)
write(*,*) 'Program has been running for', I, 'seconds.'
write(*,*) ' This includes', TA(1), 'seconds of user time and', &
 & TA(2), 'seconds of system time.'
```

**See Also**

DATE_AND_TIME
CPU_TIME

### E to F

**ELEMENTAL**

**Keyword:** Asserts that a user-defined procedure is defined on scalar arguments that may be called with array arguments. An elemental procedure may be a pure procedure or an impure procedure.

**Description**

To specify an elemental procedure, use this keyword in a FUNCTION or SUBROUTINE statement.

An explicit interface must be visible to the caller of an ELEMENTAL procedure.

An elemental procedure can be passed an array, which is acted upon one element at a time.

For functions, the result must be scalar; it cannot have the POINTER or ALLOCATABLE attribute.

Dummy arguments in ELEMENTAL procedures may appear in specification expressions in the procedure.

Dummy arguments have the following restrictions:

- They must be scalar.
- They cannot have the POINTER or ALLOCATABLE attribute.
- They cannot be an alternate return specifier (*).
- They cannot be dummy procedures.

If the actual arguments are all scalar, the result is scalar. If the actual arguments are array valued, the values of the elements (if any) of the result are the same as if the function or subroutine had been applied separately, in any order, to corresponding elements of each array actual argument.
Elemental procedures are pure procedures and all rules that apply to pure procedures also apply to elemental procedures, unless you specify that the elemental procedure is IMPURE. In that case, the rules for pure procedures do not apply.

**Example**

Consider the following:

```fortran
MIN (A, 0, B) ! A and B are arrays of shape (S, T)
```

In this case, the elemental reference to the MIN intrinsic function is an array expression whose elements have the following values:

```fortran
MIN (A(I,J), 0, B(I,J)), I = 1, 2, ..., S, J = 1, 2, ..., T
```

Consider the following example:

```fortran
ELEMENTAL REAL FUNCTION F (A, B, ORDER)
REAL, INTENT (IN) :: A, B
INTEGER, INTENT (IN) :: ORDER
REAL :: TEMP (ORDER)
```

In the above, the size of TEMP depends on the specification expression that is the value of the ORDER dummy argument.

**See Also**

FUNCTION

SUBROUTINE

Determining When Procedures Require Explicit Interfaces

Optional Arguments

**ELLIPSE, ELLIPSE_W (W*S)**

*Graphics Functions:* Draw a circle or an ellipse using the current graphics color.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = ELLIPSE (control, x1, y1, x2, y2)
result = ELLIPSE_W (control, wx1, wy1, wx2, wy2)
```

- **control** (Input) INTEGER(2). Fill flag. Can be one of the following symbolic constants:
  - `$GFILLINTERIOR` - Fills the figure using the current color and fill mask.
  - `$GBORDER` - Does not fill the figure.

- **x1, y1** (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

- **x2, y2** (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

- **wx1, wy1** (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2

(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

Results
The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the ellipse is clipped or partially out of bounds, the ellipse is considered successfully drawn, and the return is 1. If the ellipse is drawn completely out of bounds, the return is 0.

The border is drawn in the current color and line style.

When you use ELLIPSE, the center of the ellipse is the center of the bounding rectangle defined by the viewport-coordinate points (x1, y1) and (x2, y2). When you use ELLIPSE_W, the center of the ellipse is the center of the bounding rectangle defined by the window-coordinate points (wx1, wy1) and (wx2, wy2). If the bounding-rectangle arguments define a point or a vertical or horizontal line, no figure is drawn.

The control option given by $GFILLINTERIOR is equivalent to a subsequent call to the FLOODFILLRGB function using the center of the ellipse as the start point and the current color (set by SETCOLORRGB) as the boundary color.

NOTE
The ELLIPSE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Ellipse routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Ellipse.

Example
The following program draws the shape shown below.

```
! compile as QuickWin or Standard Graphics application
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80;  y1 = 50
x2 = 240; y2 = 150
dummy = ELLIPSE( $GFILLINTERIOR, x1, y1, x2, y2 )
END
```

**ELSE Directive**

**Statement:** Marks an optional branch in an IF Directive Construct.

**See Also**

See IF Directive Construct.

**ELSE Statement**

**Statement:** Marks an optional branch in an IF Construct.

**See Also**

See IF Construct.

**ELSEIF Directive**

**Statement:** Marks an optional branch in an IF Directive Construct.

**See Also**

See IF Directive Construct.

**ELSE IF**

**Statement:** Marks an optional branch in an IF Construct.

**See Also**

See IF Construct.

**ELSE WHERE**

**Statement:** Marks the beginning of an ELSE WHERE block within a WHERE construct.

**Syntax**

```
[name:]WHERE (mask-expr1)
  [where-body-stmt]...
ELSE WHERE(mask-expr2) [name]
  [where-body-stmt]...
ELSE WHERE[name]
  [where-body-stmt]...
END WHERE [name]
```

- `name` Is the name of the WHERE construct.
- `mask-expr1, mask-expr2` Are logical array expressions (called mask expressions).
- `where-body-stmt` Is one of the following:
• An assignment statement of the form: array variable = array expression.
  The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
• A WHERE statement or construct

Description
Every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(.NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

Example
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE

The variables temp, pressure, and raining are all arrays.

See Also
WHERE

ENCODE
Statement: Translates data from internal (binary) form to character form. It is comparable to using internal files in formatted sequential WRITE statements.

Syntax
ENCODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]

- c Is a scalar integer expression. It is the number of characters to be translated to internal form.
- f Is a format identifier. An error occurs if more than one record is specified.
- b Is a scalar or array reference. If b is an array reference, its elements are processed in the order of subscript progression. b contains the characters to be translated to internal form.
- i-var Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
- label Is the label of an executable statement that receives control if an error occurs.
- io-list Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list contains the data to be translated to character form.
The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the ENCODE statement can translate depends on the data type of \( b \). For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

**Example**

Consider the following:

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
ENCODE(12,100,B) K(3), K(2), K(1)
```

The DECODE statement stores the 12 characters into array \( K \):

- \( K(1) = 1234 \)
- \( K(2) = 5678 \)
- \( K(3) = 9012 \)

The ENCODE statement translates the values \( K(3) \), \( K(2) \), and \( K(1) \) to character form and stores the characters in the character variable \( B \).

- \( B = '901256781234' \)

**See Also**

READ
WRITE
DECODE

**END**

*Statement: Marks the end of a program unit. It takes one of the following forms:*

**Syntax**

- `END [PROGRAM [program-name]]`
- `END [FUNCTION [function-name]]`
- `END [SUBROUTINE [subroutine-name]]`
- `END [MODULE [module-name]]`
- `END [SUBMODULE [module-name]]`
- `END [BLOCK DATA [block-data-name]]`

In main programs, function subprograms, and subroutine subprograms, END statements are executable and can be branch target statements. If control reaches the END statement in these program units, the following occurs:
In a main program, execution of the END statement initiates normal termination of the image that executes it.

In a function or subroutine subprogram, a RETURN statement is implicitly executed.

The END statement cannot be continued in a program unit, and no other statement in the program unit can have an initial line that appears to be the program unit END statement.

The END statements in a module or block data program unit are nonexecutable.

**Example**

```fortran
C   An END statement must be the last statement in a program unit:
C
PROGRAM MyProg
  WRITE (*, '("Hello, world!")')
END
C
C   An example of a named subroutine
C
SUBROUTINE EXT1 (X,Y,Z)
  Real, Dimension (100,100) :: X, Y, Z
END SUBROUTINE EXT1
```

Branch Statements
Program Termination

**END DO**

*Statement:* Marks the end of a DO or DO WHILE loop.

**Syntax**

```fortran
END DO
```

**Description**

There must be a matching END DO statement for every DO or DO WHILE statement that does not contain a label reference.

An END DO statement can terminate only one DO or DO WHILE statement. If you name the DO or DO WHILE statement, the END DO statement can specify the same name.

**Example**

The following examples both produce the same output:

```fortran
DO ivar = 1, 10
  PRINT ivar
END DO
ivar = 0
do2: DO WHILE (ivar .LT. 10)
  ivar = ivar + 1
  PRINT ivar
END DO do2
```

**See Also**

DO
DO WHILE
ENDIF Directive

**Statement:** Marks the end of an IF Directive Construct.

**See Also**
See IF Directive Construct.

END IF

**Statement:** Marks the end of an IF Construct.

**See Also**
See IF Construct.

ENDFILE

**Statement:** For sequential files, writes an end-of-file record to the file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

**Syntax**
It can have either of the following forms:

```
ENDFILE ([UNIT=] io-unit[, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

- **io-unit** (Input) Is an external unit specifier.
- **label**
  Is the label of the branch target statement that receives control if an error occurs.
- **msg-var** (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
- **i-var** (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**
If the unit specified in the ENDFILE statement is not open, the default file is opened for unformatted output.

An end-of-file record can be written only to files with sequential organization that are accessed as formatted-sequential or unformatted-segmented sequential files. An ENDFILE performed on a direct access file always truncates the file.

End-of-file records should not be written in files that are read by programs written in a language other than Fortran.

**NOTE**
If you use compiler option vms and an ENDFILE is performed on a sequential unit, an actual one byte record containing a CTRL+Z is written to the file. If this option is not specified, an internal ENDFILE flag is set and the file is truncated. The option does not affect ENDFILE on relative files; such files are truncated.
If a parameter of the ENDFILE statement is an expression that calls a function, that function must not cause an I/O statement or the EOF intrinsic function to be executed, because unpredictable results can occur.

Example

The following statement writes an end-of-file record to I/O unit 2:

```fortran
ENDFILE 2
```

Suppose the following statement is specified:

```fortran
ENDFILE (UNIT=9, IOSTAT=IOS, ERR=10)
```

An end-of-file record is written to the file connected to unit 9. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable `IOS`.

The following shows another example:

```fortran
WRITE (6, *) x
ENDFILE 6
REWIND 6
READ (6, *) y
```

BACKSPACE
REWIND
Data Transfer I/O Statements
Branch Specifiers

END FORALL

**Statement:** Marks the end of a FORALL construct.
The FORALL construct is an obsolescent language feature in Fortran 2018.

See Also
See FORALL.

END INTERFACE

**Statement:** Marks the end of an INTERFACE block.

See Also
See INTERFACE.

END TYPE

**Statement:** Specifies the end of a derived type TYPE statement.

See Also
See TYPE Statement (Derived Types).

END WHERE

**Statement:** Marks the end of a WHERE construct.
**Example**

```plaintext
WHERE (pressure <= 1.0)
    pressure = pressure + inc_pressure
    temp = temp - 5.0
ELSEWHERE
    raining = .TRUE.
END WHERE
```

Note that the variables `temp`, `pressure`, and `raining` are all arrays.

**See Also**

See WHERE.

**ENTRY**

**Statement:** Provides one or more entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram.

**Syntax**

```plaintext
ENTRY name[ ( [d-arg[,d-arg]...] ) [RESULT (r-name)] ]
```

- **name**
  - Is the name of an entry point. If RESULT is specified, this entry name must not appear in any specification statement in the scoping unit of the function subprogram.

- **d-arg**
  - (Optional) Is a dummy argument. The dummy argument can be an alternate return indicator (*) if the ENTRY statement is within a subroutine subprogram.

- **r-name**
  - (Optional) Is the name of a function result. This name must not be the same as the name of the entry point, or the name of any other function or function result. This parameter can only be specified for function subprograms.

**Description**

ENTRY statements can only appear in external procedures or module procedures.

An ENTRY statement must not appear in an executable construct.

When the ENTRY statement appears in a subroutine subprogram, it is referenced by a CALL statement. When the ENTRY statement appears in a function subprogram, it is referenced by a function reference.

An entry name within a function subprogram can appear in a type declaration statement.

Within the subprogram containing the ENTRY statement, the entry name must not appear as a dummy argument in the FUNCTION or SUBROUTINE statement, and it must not appear in an EXTERNAL or INTRINSIC statement. For example, neither of the following are valid:

1. `SUBROUTINE SUB(E)
   
   ENTRY E

   ...`

2. `SUBROUTINE SUB

   EXTERNAL E

   ENTRY E

   ...`
The procedure defined by an ENTRY statement can reference itself if the function or subroutine was defined as RECURSIVE.

Dummy arguments can be used in ENTRY statements even if they differ in order, number, type and kind parameters, and name from the dummy arguments used in the FUNCTION, SUBROUTINE, and other ENTRY statements in the same subprogram. However, each reference to a function, subroutine, or entry must use an actual argument list that agrees in order, number, and type with the dummy argument list in the corresponding FUNCTION, SUBROUTINE, or ENTRY statement.

Dummy arguments can be referred to only in executable statements that follow the first SUBROUTINE, FUNCTION, or ENTRY statement in which the dummy argument is specified. If a dummy argument is not currently associated with an actual argument, the dummy argument is undefined and cannot be referenced. Arguments do not retain their association from one reference of a subprogram to another.

**Example**

```fortran
C  This fragment writes a message indicating
C  whether num is positive or negative
   IF (num .GE. 0) THEN
      CALL Sign
   ELSE
      CALL Negative
   END IF
...
END
SUBROUTINE Sign
   WRITE (*, '*') 'It''s positive.'
   RETURN
ENTRY Negative
   WRITE (*, '*') 'It''s negative.'
   RETURN
END SUBROUTINE
```

**See Also**
- Program Units and Procedures
- ENTRY Statements in Function Subprograms
- ENTRY Statements in Subroutine Subprograms

**EOF**

*Inquiry Intrinsic Function (Generic): Checks whether a file is at or beyond the end-of-file record.*

**Syntax**

```fortran
result = EOF (unit)
```

*unit* (Input) Must be of type integer. It represents a unit specifier corresponding to an open file. It cannot be zero unless you have reconnected unit zero to a unit other than the screen or keyboard.

**Results**

The result type is default logical. The value of the result is .TRUE. if the file connected to *unit* is at or beyond the end-of-file record; otherwise, .FALSE..
Example

! Creates a file of random numbers, reads them back
   REAL x, total
   INTEGER count
   OPEN (1, FILE = 'TEST.DAT')
   DO I = 1, 20
      CALL RANDOM_NUMBER(x)
      WRITE (1, '(F6.3)') x * 100.0
   END DO
   CLOSE(1)
   OPEN (1, FILE = 'TEST.DAT')
   count = 0
   total = 0.0
   DO WHILE (.NOT. EOF(1))
      count = count + 1
      READ (1, *) value
      total = total + value
   END DO
   100 IF ( count .GT. 0) THEN
      WRITE (*,*) 'Average is: ', total / count
   ELSE
      WRITE (*,*) 'Input file is empty '
   END IF
   STOP
   END

EOSHIFT

Transformational Intrinsic Function (Generic):
Performs an end-off shift on a rank-one array, or
performs end-off shifts on all the complete rank-one
sections along a given dimension of an array of rank
two or greater. Elements are shifted off at one end of
a section and copies of a boundary value are filled in
at the other end. Different sections can have different
boundary values and can be shifted by different
amounts and in different directions.

Syntax

\[
\text{result} = \text{EOSHIFT} (\text{array, shift [, boundary][, dim]})
\]

array  (Input) Must be an array (of any data type).
shift  (Input) Must be a scalar integer or an array with a rank that is one
         less than array, and shape \((d_1, d_2, ..., d_{\text{dim}-1}, d_{\text{dim}+1}, ..., d_n)\), where
         \((d_1, d_2, ..., d_n)\) is the shape of array.
boundary

(Input; optional) Must have the same type and kind parameters as array. It must be a scalar or an array with a rank that is one less than array, and shape \((d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)\). The boundary specifies a value to replace spaces left by the shifting procedure.

If boundary is not specified, it is assumed to have the following default values (depending on the data type of array):

<table>
<thead>
<tr>
<th>array Type</th>
<th>boundary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>0</td>
</tr>
<tr>
<td>Real</td>
<td>0.0</td>
</tr>
<tr>
<td>Complex</td>
<td>(0.0, 0.0)</td>
</tr>
<tr>
<td>Logical</td>
<td>false</td>
</tr>
<tr>
<td>Character((len))</td>
<td>(len) blanks</td>
</tr>
</tbody>
</table>

dim

(Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of array. If dim is omitted, it is assumed to be 1.

Results

The result is an array with the same type and kind parameters, and shape as array.

If array has rank one, the same shift is applied to each element. If an element is shifted off one end of the array, the boundary value is placed at the other end the array.

If array has rank greater than one, each section \((s_1, s_2, ..., s_{dim-1}, ::, s_{dim+1}, ..., s_n)\) of the result is shifted as follows:

- By the value of shift, if shift is scalar
- According to the corresponding value in \(shift(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)\), if shift is an array

If an element is shifted off one end of a section, the boundary value is placed at the other end of the section.

The value of shift determines the amount and direction of the end-off shift. A positive shift value causes a shift to the left (in rows) or up (in columns). A negative shift value causes a shift to the right (in rows) or down (in columns).

Example

V is the integer array \((1, 2, 3, 4, 5, 6)\).

EOSHIFT (V, SHIFT=2) shifts the elements in V to the left by 2 positions, producing the value \((3, 4, 5, 6, 0, 0)\). 1 and 2 are shifted off the beginning and two elements with the default BOUNDARY value are placed at the end.

EOSHIFT (V, SHIFT= -3, BOUNDARY= 99) shifts the elements in V to the right by 3 positions, producing the value \((99, 99, 99, 1, 2, 3)\). 4, 5, and 6 are shifted off the end and three elements with BOUNDARY value 99 are placed at the beginning.

M is the CHARACTER(LEN=1) array

\[
\begin{bmatrix}
  1 & 2 & 3 \\
  4 & 5 & 6 \\
  7 & 8 & 9 \\
\end{bmatrix}
\]
EOSHIFT (M, SHIFT = 1, BOUNDARY = '*', DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
5 & 6 & * \\
8 & 9 & *
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. This causes the first element in each row to be shifted off the beginning, and the BOUNDARY value to be placed at the end.

EOSHIFT (M, SHIFT = -1, DIM = 1) produces the result

\[
\begin{bmatrix}
^ & ^ & ^ \\
1 & 2 & 3 \\
4 & 5 & 6
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. This causes the last element in each column to be shifted off the end and the BOUNDARY value (the default character boundary value <space>, represented by "^") to be placed at the beginning.

EOSHIFT (M, SHIFT = (/1, -1, 0/), BOUNDARY = (/ '*', '?', '/' /), DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
? & 4 & 5 \\
7 & 8 & 9
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position, causing the first element to be shifted off the beginning and the BOUNDARY value * to be placed at the end. Each element in row 2 is shifted to the right by 1 position, causing the last element to be shifted off the end and the BOUNDARY value ? to be placed at the beginning. No element in row 3 is shifted at all, so the specified BOUNDARY value is not used.

The following shows another example:

```fortran
INTEGER shift(3)
CHARACTER(1) array(3, 3), AR1(3, 3)
array = RESHAPE ((/'A', 'D', 'G', 'B', 'E', 'H', 
                 'C', 'F', 'I'/), (/3,3/))
! array is
! A B C
! D E F
! G H I
shift = (/ -1, 1, 0/)
AR1 = EOSHIFT (array, shift, BOUNDARY = (/ '*', '?', '/' /), DIM= 2)
! returns
! * A B
! E F ?
! G H I
```

TRANSPOSE

EPSILON

**Inquiry Intrinsic Function (Generic):** Returns a positive model number that is almost negligible compared to unity in the model representing real numbers.

**Syntax**

\[
\text{result} = \text{EPSILON} \ (x)
\]
x  
(Input) Must be of type real; it can be scalar or array valued.

Results
The result is a scalar of the same type and kind parameters as x. The result has the value \( b^{1-p} \). Parameters \( b \) and \( p \) are defined in Model for Real Data.

EPSILON makes it easy to select a \( \delta \) for algorithms (such as root locators) that search until the calculation is within \( \delta \) of an estimate. If \( \delta \) is too small (smaller than the decimal resolution of the data type), the algorithm might never halt. By scaling the value returned by EPSILON to the estimate, you obtain a \( \delta \) that ensures search termination.

Example
If \( x \) is of type REAL(4), EPSILON \((x)\) has the value \( 2^{-23} \).

TINY

Data Representation Models

EQUIVALENCE
Statement: Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area.

Syntax
EQUIVALENCE (equiv-list) [, (equiv-list)]...

equiv-list
Is a list of two or more variable names, array elements, or substrings, separated by commas (also called an equivalence set). If an object of derived type is specified, it must be a sequence type. Objects cannot have the TARGET attribute.

Each expression in a subscript or a substring reference must be an integer constant expression. A substring must not have a length of zero.

Description
The following objects cannot be specified in EQUIVALENCE statements:

- A dummy argument
- An allocatable variable
- An automatic object
- A pointer
- An object of nonsequence derived type
- A derived-type object that has an allocatable or pointer component at any level
- A component of a derived-type object
- A function, entry, or result name
- A named constant
- A structure component
- A subobject of any of the above objects
- A coarray
- An object with either the DLLIMPORT or DLLEXPORT attribute
A variable with the BIND attribute
A variable in a common block that has the BIND attribute

The EQUIVALENCE statement causes all of the entities in one parenthesized list to be allocated storage beginning at the same storage location.

If an equivalence object has the PROTECTED attribute, all of the objects in the equivalence set must have the PROTECTED attribute.

Association of objects depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Type of Associated Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric ^1 or numeric sequence</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence</td>
<td>Can be of either of these types ^2</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

^1Default integer, default real, double precision real, default complex, double complex, or default logical.
^2The lengths do not have to be equal.

So, objects can be associated if they are of different numeric type. For example, the following is valid:

```fortran
INTEGER A(20)
REAL Y(20)
EQUIVALENCE(A, Y)
```

Objects of default character do not need to have the same length. The following example associates character variable D with the last 4 (of the 6) characters of character array F:

```fortran
CHARACTER(LEN=4) D
CHARACTER(LEN=3) F(2)
EQUIVALENCE(D, F(1)(3:))
```

Entities having different data types can be associated because multiple components of one data type can share storage with a single component of a higher-ranked data type. For example, if you make an integer variable equivalent to a complex variable, the integer variable shares storage with the real part of the complex variable.

The same storage unit cannot occur more than once in a storage sequence, and consecutive storage units cannot be specified in a way that would make them nonconsecutive.

Intel® Fortran lets you associate character and noncharacter entities, for example:

```fortran
CHARACTER*1 char1(10)
REAL reala, realb
EQUIVALENCE (reala, char1(1))
EQUIVALENCE (realb, char1(2))
```

EQUIVALENCE statements require only the first subscript of a multidimensional array (unless the STRICT compiler directive is in effect). For example, the array declaration var(3,3), var(4) could appear in an EQUIVALENCE statement. The reference is to the fourth element of the array (var(1,2)), not to the beginning of the fourth row or column.

If you use the STRICT directive, the following rules apply to the kinds of variables and arrays that you can associate:

- If an EQUIVALENCE object is default integer, default real, double-precision real, default complex, default logical, or a sequenced derived type of all numeric or logical components, all objects in the EQUIVALENCE statement must be one of these types, though it is not necessary that they be the same type.
• If an EQUIVALENCE object is default character or a sequenced derived type of all character components, all objects in the EQUIVALENCE statement must be one of these types. The lengths do not need to be the same.
• If an EQUIVALENCE object is a sequenced derived type that is not purely numeric or purely character, all objects in the EQUIVALENCE statement must be the same derived type.
• If an EQUIVALENCE object is an intrinsic type other than the default (for example, INTEGER(1)), all objects in the EQUIVALENCE statement must be the same type and kind.

Example
The following EQUIVALENCE statement is invalid because it specifies the same storage unit for X(1) and X(2):

```fortran
REAL, DIMENSION(2) :: X
REAL :: Y
EQUIVALENCE(X(1), Y), (X(2), Y)
```

The following EQUIVALENCE statement is invalid because A(1) and A(2) will not be consecutive:

```fortran
REAL A(2)
DOUBLE PRECISION D(2)
EQUIVALENCE(A(1), D(1)), (A(2), D(2))
```

In the following example, the EQUIVALENCE statement causes the four elements of the integer array IARR to share the same storage as that of the double-precision variable DVAR:

```fortran
DOUBLE PRECISION DVAR
INTEGER(KIND=2) IARR(4)
EQUIVALENCE(DVAR, IARR(1))
```

In the following example, the EQUIVALENCE statement causes the first character of the character variables KEY and STAR to share the same storage location. The character variable STAR is equivalent to the substring KEY(1:10).

```fortran
CHARACTER KEY*16, STAR*10
EQUIVALENCE(KEY, STAR)
```

The following shows another example:

```fortran
CHARACTER name, first, middle, last
DIMENSION name(60), first(20), middle(20), last(20)
EQUIVALENCE (name(1), first(1)), (name(21), middle(1))
EQUIVALENCE (name(41), last(1))
```

Consider the following:

```fortran
CHARACTER (LEN = 4) :: a, b
CHARACTER (LEN = 3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))
```

This causes the following alignment:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>a(1:1)</td>
<td>a(2:2)</td>
<td>a(3:3)</td>
<td>a(4:4)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>b</td>
<td>b(1:1)</td>
<td>b(2:2)</td>
<td>b(3:3)</td>
<td>b(4:4)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c</td>
<td>c(1)(1:1)</td>
<td>c(1)(2:2)</td>
<td>c(1)(3:3)</td>
<td>c(2)(1:1)</td>
<td>c(2)(2:2)</td>
<td>c(2)(3:3)</td>
<td></td>
</tr>
</tbody>
</table>

Note that the fourth element of a, the first element of b, and the first element of c(2) share the same storage unit.

STRICT Directive

**ERF**

*Elemental Intrinsic Function (Generic): Returns the error function of an argument.*

**Syntax**

```fortran
result = ERF (x)
```

*x*  
(Input) Must be of type real.

**Results**

The result type and kind are the same as *x*. The result is in the range -1 to 1.

ERF returns the error function of *x* defined as follows:

\[
\frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt
\]

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERF</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERF</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERF</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ERF (1.0) has the value 0.842700794.

**See Also**

ERFC

**ERFC**

*Elemental Intrinsic Function (Generic): Returns the complementary error function of an argument.*

**Syntax**

```fortran
result = ERFC (x)
```

*x*  
(Input) Must be of type real.

**Results**

The result type and kind are the same as *x*. The result is in the range 0 to 2.

ERFC returns 1 - ERF(*x*) and is defined as follows:

\[
\frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt
\]
ERFC is provided because of the extreme loss of relative accuracy if ERF(x) is called for large x and the result is subtracted from 1.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERFC</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERFC</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERFC</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**
ERFC (1.0) has the value 0.1572992057.

**See Also**
ERF

**ERFC_SCALED**
*Elemental Intrinsic Function (Generic):* Returns the scaled complementary error function of an argument.

**Syntax**

\[
\text{result} = \text{ERFC\_SCALED} \left( x \right)
\]

\[x\]  
(Input) Must be of type real.

**Results**

The result type and kind are the same as \(x\).

The result has a value equal to a processor-dependent approximation to the exponentially-scaled complementary error function of

\[
\exp \left( \frac{-x^2}{2} \right) \int_x^\infty \exp \left( -t^2 \right) dt
\]

**NOTE**

The complementary error function is asymptotic to \(\exp \left( -X^2 \right) / \left( X \sqrt{\pi} \right)\). As such it underflows for \(X > \text{HUGE} \) when using IEEE single precision arithmetic. The exponentially-scaled complementary error function is asymptotic to \(1 / \left( X \sqrt{\pi} \right)\). As such it does not underflow until \(X > \text{HUGE} \). (X) / \sqrt{\pi}.

**Example**

ERFC_SCALED (20.0) has the approximate value 0.02817434874.

**See Also**
ERFC
ERRSNS

**Intrinsic Subroutine (Generic):** Returns information about the most recently detected I/O system error condition. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL ERRSNS ([io_err] [,sys_err] [,stat] [,unit] [,cond])

- **io_err** (Output; Optional) Is an integer variable or array element that stores the most recent Run-Time Library error number that occurred during program execution. For a listing of error numbers, see Compiler Reference: Error Handling.
  
  A zero indicates no error has occurred since the last call to ERRSNS or since the start of program execution.

- **sys_err** (Output; Optional) Is an integer variable or array element that stores the most recent system error number associated with **io_err**. This code is one of the following:
  
  - On Windows* systems, it is the value returned by GETLASTERROR( ) at the time of the error.
  - On Linux* and macOS* systems, it is an **errno** value. (See **errno(2)**.)

- **stat** (Output; Optional) Is an integer variable or array element that stores a status value that occurred during program execution. This value is always set to zero.

- **unit** (Output; Optional) Is an integer variable or array element that stores the logical unit number, if the last error was an I/O error.

- **cond** (Output; Optional) Is an integer variable or array element that stores the actual processor value. This value is always set to zero.

If you specify INTEGER(2) arguments, only the low-order 16 bits of information are returned or adjacent data can be overwritten. Because of this, it is best to use INTEGER(4) arguments.

The saved error information is set to zero after each call to ERRSNS.

**Example**

Any of the arguments can be omitted. For example, the following is valid:

```
CALL ERRSNS (SYS_ERR=I1, STAT=I2, UNIT=I4)
```

**ESTABLISHQQ**

**Portability Function:** Lets you specify a function to handle errors detected by the Run-Time Library (RTL). It lets you take appropriate steps in addition to the RTL's error-handling behavior, or it lets you replace that behavior.

**Module**

USE IFESTABLISH
Syntax

\[
\text{result} = \text{ESTABLISHQQ} \left( \text{handler\_routine}, \text{context}, \text{prev\_handler}, \text{prev\_context} \right)
\]

\text{handler\_routine} (Input) Is of type "procedure(establishqq\_handler)", which is defined in module IFESTABLISH. This is the function that will handle errors detected by the RTL.

\text{context} (Input) INTEGER(INT\_PTR\_KIND()). This is the way you pass information to the handler function for use when it is called. It can be data or a pointer to a block of data.

\text{prev\_handler} (Optional; output) Is of type "procedure(establishqq\_handler), pointer, intent(out), optional", which is defined in module IFESTABLISH. This is the previous handler function, if any.

\text{prev\_context} (Optional; output) INTEGER(INT\_PTR\_KIND()). This is the context specified for the previous handler function, if any; otherwise, zero.

Results

The result type for ESTABLISHQQ is LOGICAL(4). It indicates whether the handler was successfully established. .TRUE. means it was established successfully; .FALSE. means it was not.

The handler function is called when an error occurs. The result for the handler is set by your code in the handler. .TRUE. means that the error has been handled and the application should not issue an error message. .FALSE. means that the application should issue an error message and continue as if there had never been a handler.

After you use ESTABLISHQQ to specify an error handler function and an error occurs, the handler function is called with the following input arguments. They are set up by the RTL when it calls the handler function:

Handler Function Syntax:

\[
\text{result} = \text{Handler\_Function} \left( \text{error\_code}, \text{continuable}, \text{message\_string}, \text{context} \right)
\]

\text{Handler\_Function} is a function you supply that has a compatible interface. It must use the Intel Fortran compiler defaults for calling mechanism and argument passing. When the Intel Fortran Run-Time Library detects an error, it first calls your handler function with the following arguments:

\text{error\_code} (Input) INTEGER(4). This is the number of the error that occurred and it is the value that will be set in an IOSTAT= or STAT= specifier variable.

A list of run-time error codes can be found at List of Run-Time Error Messages.

\text{continuable} (Input) LOGICAL(4). If execution can be continued after handling this error, this argument is passed the value .TRUE., otherwise, it is passed the value .FALSE..

Do not compare this value using arithmetic equality operators; use logical data type tests or .EQV..

If an error is not continuable, the program exits after processing the error.

\text{message\_string} (Input) CHARACTER(*). This is the text of the error message as it would otherwise be displayed to the user.
The function result of the handler function is type LOGICAL(4). The handler function should return .TRUE. if it successfully handled the error; otherwise, .FALSE..

If the handler function returns .TRUE. and the error is continuable, execution of the program continues. If the handler function returns .FALSE., normal error processing is performed, such as message output to the user and possible program termination.

The handler function can be written in any language, but it must follow the Intel Fortran conventions. Note that for argument message_string, an address-sized length is passed by value after argument context.

If you want to handle errors using a C/C++ handler, use the ISO_C_BINDINGS module features to call the C/C++ routine.

**Example**

```fortran
! Compile with "-fpe0 -check bounds".
!
program example
use ifestablish
implicit none

procedure(establishqq_handler), pointer :: old_handler_1
procedure(establishqq_handler), pointer :: old_handler_2
procedure(establishqq_handler), pointer :: old_handler_3
procedure(establishqq_handler)          :: my_handler_1
procedure(establishqq_handler)          :: my_handler_2
procedure(establishqq_handler)          :: my_handler_3

ETIME

Portability Function: On single processor systems, returns the elapsed CPU time, in seconds, of the process that calls it. On multi-core or multi-processor systems, returns the elapsed wall-clock time, in seconds.

Module
USE IFPORT

Syntax
result = ETIME (array)

array

(Output) REAL(4). Must be a rank one array with two elements:
- array(1) – Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. On single processors, ETIME returns the elapsed CPU time, in seconds, of the process that calls it. On multiple processors, ETIME returns the elapsed wall-clock time, in seconds.
- array(2) – Elapsed system time, which is time spent executing privileged code (code in the Windows Executive) on single processors; on multiple processors, this value is zero.
Results
The result type is REAL(4). The result is the total CPU time, which is the sum of array(1) and array(2).

Example

```
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
write(*,*) 'Program has used', I, 'seconds of CPU time.'
write(*,*) 'This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'
```

DATE_AND_TIME

EVENT POST and EVENT WAIT

**Statements:** The EVENT POST statement allows an image to notify another image that it can proceed to work on tasks that use common resources. The EVENT WAIT statement allows an image to wait on events posted by other images. They take the following forms:

**Syntax**

EVENT POST (event-var [, sync-stat-list])

EVENT WAIT (event-var [, wait-spec-list])

event-var

Is a scalar variable of type EVENT_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.

It must not depend on the value of stat-var or err-var.

It cannot be a coindexed variable in an EVENT WAIT statement.

sync-stat-list

Is STAT=stat-var

or ERRMSG=err-var

stat-var

Is a scalar integer variable in which the status of the synchronization is stored.

err-var

Is a scalar default character variable in which explanatory text is stored if an error occurs.

wait-spec-list

Is until-spec

or sync-stat-list

until-spec

Is UNTIL_COUNT= scalar-integer-expression.

Each specifier is optional and may appear at most once in a sync-stat-list or in a wait-spec-list.

**Description**

An EVENT POST statement atomically increments the value of event-var by one. Its value is processor dependent if an error condition occurs during the execution of an EVENT POST statement. The completion of an EVENT POST statement does not in any way depend on execution of a corresponding EVEN WAIT statement.

The following actions occur during the execution of an EVENT WAIT statement:
• If UNTIL_COUNT is not specified, the threshold value is one; otherwise, it is the maximum value of one and the specified scalar-integer-expression.
• The image executing the EVENT WAIT statement waits until the value of event-var is equal to or greater than the threshold value; otherwise, an error condition occurs.
• If no error condition has occurred, event-var is atomically decremented by the threshold value.

The value of event-var is processor dependent if an error condition occurs during the execution of an EVENT WAIT statement.

An EVEN POST statement execution is initially unsatisfied. The successful execution of an EVENT WAIT statement with a threshold value of \( n \) satisfies the first \( n \) unsatisfied EVENT POST statement executions for the specified event-var. The EVENT WAIT statement delays execution of the segment following the EVENT WAIT statement to execute after the segments which precede the first \( n \) EVENT POST statement executions for the specified event-var.

Example

The following example shows the use of EVENT POST and EVENT WAIT statements to synchronize each image with its left and right neighbor. Image 1 and image NUM_IMAGES() treat each other as left and right neighbors, conceptually laying the images out in a circle.

```fortran
USE, INTRINSIC :: ISO_FORTRAN_ENV
TYPE(EVENT_TYPE) :: EVENT[*]
INTEGER :: LEFT, RIGHT
...
IF ((THIS_IMAGE().NE. 1) .AND. (THIS_IMAGE() .NE. NUM_IMAGES())) THEN
    LEFT  = THIS_IMAGE() – 1
    RIGHT = THIS_IMAGE() + 1
ELSE IF (THIS_IMAGE() == 1) THEN
    LEFT  = NUM_IMAGES()
    RIGHT = 2
ELSE IF (THIS_IMAGE()== NUM_IMAGES()) THEN
    LEFT  = NUM_IMAGES() - 1
    RIGHT = 1
END IF

EVENT POST (EVENT[LEFT])  ! Signal left neighbor you got here
EVENT POST (EVENT[RIGHT])  ! Signal right neighbor you got here
EVENT WAIT (EVENT, UNTIL_COUNT = 2) ! Wait until your neighbors have both reached this point also
```

Using Coarrays

EVENT_QUERY

Intrinsic Subroutine (Generic): Queries the event count of an event variable.

Syntax

```fortran
CALL EVENT_QUERY (event, count [, stat])
```
**event**

(Input) Must be an event variable of type EVENT_TYPE, and must not be coindexed. The event variable is accessed atomically with respect to the execution of EVENT POST statements in unordered segments, in exact analogy to atomic subroutines.

**count**

(Output) Must be an integer scalar with a decimal range no smaller than that of default integer. If no error condition occurs, count is assigned the value of the count of event, otherwise it is assigned the value -1.

**stat**

(Output; optional) Must be an integer scalar with a decimal exponent range of at least four. It must not be coindexed. If the stat argument is present, it is assigned a processor-dependent positive value if an error condition occurs, or zero if no error occurs. If an error occurs and stat is not present, error termination is initiated.

**Example**

Consider the following example:

```
CALL EVENT_QUERY (EVENT, COUNT)
```

If there have been six successful posts to EVENT, and 3 successful waits that did not specify UNTIL_COUNT= in the preceding segments, the variable COUNT will have the value 3. If there have been no successful posts or waits in the preceding segments, COUNT will have the value 0.

**See Also**

EVENT POST and EVENT WAIT

**EXECUTE_COMMAND_LINE**

_Intrinsic Subroutine: Executes a command line._

**Syntax**

```
CALL EXECUTE_COMMAND_LINE (command [, wait, exitstat, cmdstat, cmdmsg])
```

**command**

(Input) Must be a scalar of type default character. It is the command line to be executed. The interpretation is processor dependent.

**wait**

(Input; optional) Must be a scalar of type logical. If wait is present with the value FALSE and the processor supports asynchronous execution of the command, the command is executed asynchronously; otherwise it is executed synchronously.

**exitstat**

(Inout; optional) Must be a scalar of type integer. If the command is executed synchronously, exitstat is assigned the value of the processor-dependent exit status of the executed command. Otherwise, the value of exitstat is unchanged.

**cmdstat**

(Output; optional) Must be a scalar of type integer. It is assigned one of the following values:

- -1 if the processor does not support command line execution
- A processor-dependent positive value if an error condition occurs
- -2 if no error condition occurs but wait is present with the value FALSE and the processor does not support asynchronous execution.
- 0 otherwise
When `command` is executed synchronously, `EXECUTE_COMMAND_LINE` returns after the command line has completed execution. Otherwise, `EXECUTE_COMMAND_LINE` returns without waiting.

If a condition occurs that would assign a nonzero value to `cmdstat` but `cmdstat` is not present, execution is terminated.

**NOTE**

If the application has a standard console window, command output will appear in that window. On Windows systems, if the application does not have a console window, including QuickWin applications, command output will not be shown.

**Example**

```fortran
INTEGER :: CSTAT, ESTAT
CHARACTER(100) :: CMSG
CALL EXECUTE_COMMAND_LINE ("dir > dir.txt", EXITSTAT=ESTAT, &
                          CMDSTAT=CSTAT, CMDMSG=CMSG)
IF (CSTAT > 0) THEN
   PRINT *, "Command execution failed with error ", TRIM(CMSG)
ELSE IF (CSTAT < 0) THEN
   PRINT *, "Command execution not supported"
ELSE
   PRINT *, "Command completed with status ", ESTAT
END IF
END
```

In the above example, `EXECUTE_COMMAND_LINE` is called to execute a "dir" command with output redirected to a file. Since the `WAIT` argument was omitted, the call waits for the command to complete and the command’s exit status is returned in `ESTAT`. If the command cannot be executed, the error message returned in `CMMSG` is displayed, but note that this is not based on the success or failure of the command itself.

**EXIT Statement**

**Statement:** Terminates execution of a DO loop or a named construct.

**Syntax**

```fortran
EXIT [name]
```

*name* (Optional) Is the name of the DO loop or construct.

**Description**

The EXIT statement causes execution of a DO loop or a named construct to be terminated.

If *name* is specified, the EXIT statement must be within the range of that named construct. Otherwise, the EXIT statement must be within a DO loop and it exits the innermost DO within which it appears.

If a DO loop is terminated, any inner DO loops are also terminated and the DO control variables retain their last value. If a non-DO construct is terminated, any DO loops inside that construct are also terminated.
An EXIT statement must not appear within a CRITICAL or DO CONCURRENT construct if it belongs to that construct or an outer construct.

An EXIT statement can appear in any of the following constructs:

- ASSOCIATE
- BLOCK
- IF
- SELECT CASE
- SELECT TYPE

An EXIT statement cannot appear in a WHERE or FORALL construct.

**Example**

The following examples demonstrate EXIT statements.

**Example 1:**

```fortran
LOOP_A : DO I = 1, 15
    N = N + 1
    IF (N > I) EXIT LOOP_A
END DO LOOP_A
```

**Example 2:**

```fortran
INTEGER numpoints, point
REAL datarray(1000), sum
sum = 0.0
DO point = 1, 1000
    sum = sum + datarray(point)
    IF (datarray(point+1) .EQ. 0.0) EXIT
END DO
```

**Example 3:**

```fortran
DO I=1,N
    MyBlock: BLOCK
        REAL :: T
        T = A(I) + B(I)
        IF (T == 0.0) EXIT MyBlock
        C(I) = T + SQRT(T)
    END BLOCK
END DO
```

**Example 4:**

```fortran
DO CONCURRENT (I = 1:N)
    MyBlock: BLOCK
        REAL :: T
        T = A(I) + B(I)
        IF (T == 0.0) EXIT MyBlock
        C(I) = T + SQRT(T)
    END BLOCK
END DO
```

The following example shows illegal EXIT statements in DO CONCURRENT and CRITICAL:

```fortran
LOOP_1 : DO CONCURRENT (I = 1:N)
    N = N + 1
    IF (N > I) EXIT LOOP_1  ! can’t EXIT DO CONCURRENT or CRITICAL
END DO LOOP_1

LOOP_2 : DO I = 1, 15
```
CRITICAL
    N = N + 1
    IF (N > I) EXIT LOOP_2  ! can’t EXIT outer construct from inside
END CRITICAL  ! DO CONCURRENT or CRITICAL
END DO LOOP_2

See Also
DO
DO WHILE

EXIT Subroutine

**Intrinsic Subroutine (Generic):** Terminates program execution, closes all files, and returns control to the operating system. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL EXIT [([status])]
```

*status* (Output; optional) Is an integer argument you can use to specify the image exit-status value.

The exit-status value may not be accessible after program termination in some application environments.

**Example**

```fortran
INTEGER(4) exvalue
! all is well, exit with 1
exvalue = 1
CALL EXIT(exvalue)
! all is not well, exit with diagnostic -4
exvalue = -4
CALL EXIT(exvalue)
! give no diagnostic, just exit
CALL EXIT ( )
```

See Also
END
ABORT

EXP

**Elemental Intrinsic Function (Generic):** Computes an exponential value.

**Syntax**

```fortran
result = EXP (x)
```

*x* (Input) Must be of type real or complex.

**Results**

The result type and kind are the same as *x*. The value of the result is $e^x$. If *x* is of type complex, its imaginary part is regarded as a value in radians.
The setting of compiler options specifying real size can affect CEXP.

This function can also be specified as ZEXP.

Example

EXP (2.0) has the value 7.389056.
EXP (1.3) has the value 3.669297.

The following shows another example:

! Given initial size and growth rate,
! calculates the size of a colony at a given time.
   REAL sizei, sizef, time, rate
   sizei = 10000.0
   time = 40.5
   rate = 0.0875
   sizef = sizei * EXP (rate * time)
   WRITE (*, 100) sizef
100  FORMAT (' The final size is ', E12.6)
END

See Also
EXP10
LOG

EXP10

Elemental Intrinsic Function (Generic): Computes a base 10 exponential value.

Syntax

result = EXP10 (x)

x  (Input) Must be of type real or complex.

Results

The result type and kind are the same as x. The value is 10 raised to the power of x. If x is of type complex, its imaginary part is regarded as a value in radians.

Specific Name  Argument Type  Result Type
---  -----------  -------
EXP10        REAL(4)       REAL(4)
Specific Name | Argument Type | Result Type
--- | --- | ---
DEXP10 | REAL(8) | REAL(8)
QEXP10 | REAL(16) | REAL(16)
CEXP10 | COMPLEX(4) | COMPLEX(4)
CDEXP10 | COMPLEX(8) | COMPLEX(8)
CQEXP10 | COMPLEX(16) | COMPLEX(16)

¹The setting of compiler options specifying real size can affect CEXP10.

Example

EXP10 (2.0) has the value 100.00.
EXP10 (1.3) has the value 19.95262.

See Also

LOG10
EXP

EXPONENT

Elemental Intrinsic Function (Generic): Returns the exponent part of the argument when represented as a model number.

Syntax

result = EXPONENT (x)

x (Input) must be of type real.

Results

The result type is default integer. If x is not equal to zero, the result value is the exponent part of x. The exponent must be within default integer range; otherwise, the result is undefined.

If x is zero, the exponent of x is zero. For more information on the exponent part (e) in the real model, see Model for Real Data.

Example

EXPONENT (2.0) has the value 2.
If 4.1 is a REAL(4) value, EXPONENT (4.1) has the value 3.

The following shows another example:

```fortran
REAL(4) r1, r2
REAL(8) r3, r4
r1 = 1.0
r2 = 123456.7
r3 = 1.0D0
r4 = 123456789123456.7
write(*,*) EXPONENT(r1) ! prints 1
write(*,*) EXPONENT(r2) ! prints 17
write(*,*) EXPONENT(r3) ! prints 1
write(*,*) EXPONENT(r4) ! prints 47
END
```

EXTENDS_TYPE_OF

Inquiry Intrinsic Function (Generic): Inquires whether the dynamic type of an object is an extension type of the dynamic type of another object.

Syntax
result = EXTENDS_TYPE_OF (a, mold)

- a (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.
- mold (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

Results
The result type is default logical scalar.

The following determines the result value:
- If mold is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .TRUE..
- If a is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .FALSE..
- If the dynamic type of a or mold is extensible, the result is true only if the dynamic type of a is an extension type of the dynamic type of mold.

Otherwise, the result is processor dependent.

EXTERNAL

Statement and Attribute: Allows an external procedure, a dummy procedure, a procedure pointer, or a block data subprogram to be used as an actual argument. (To specify intrinsic procedures as actual arguments, use the INTRINSIC attribute.)

Syntax
The EXTERNAL attribute can be specified in a type declaration statement or an EXTERNAL statement, and takes one of the following forms:

Type Declaration Statement:
type,[att-ls,] EXTERNAL [, att-ls] :: ex-pro[, ex-pro]...

Statement:
EXTERNAL [:]ex-pro[, ex-pro]...
**Description**

In a type declaration statement, only functions can be declared EXTERNAL. However, you can use the EXTERNAL statement to declare subroutines and block data program units, as well as functions, to be external.

The name declared EXTERNAL is assumed to be the name of an external procedure, even if the name is the same as that of an intrinsic procedure. For example, if SIN is declared with the EXTERNAL attribute, all subsequent references to SIN are to a user-supplied function named SIN, not to the intrinsic function of the same name.

You can include the name of a block data program unit in the EXTERNAL statement to force a search of the object module libraries for the block data program unit at link time. However, the name of the block data program unit must not be used in a type declaration statement.

If you want to describe a routine with greater detail, use the INTERFACE statement. This statement automatically declares a routine as EXTERNAL, and provides information on result types and argument types.

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

**Example**

The following example shows type declaration statements specifying the EXTERNAL attribute:

```fortran
PROGRAM TEST
  ...
  INTEGER, EXTERNAL :: BETA
  LOGICAL, EXTERNAL :: COS
  ...
  CALL SUB(BETA)       ! External function BETA is an actual argument
```

You can use a name specified in an EXTERNAL statement as an actual argument to a subprogram, and the subprogram can then use the corresponding dummy argument in a function reference or a CALL statement; for example:

```fortran
EXTERNAL FACET
CALL BAR(FACET)
SUBROUTINE BAR(F)
EXTERNAL F
CALL F(2)
```

Used as an argument, a complete function reference represents a value, not a subprogram; for example, FUNC(B) represents a value in the following statement:

```fortran
CALL SUBR(A, FUNC(B), C)
```

The following shows another example:

```fortran
EXTERNAL MyFunc, MySub
C MyFunc and MySub are arguments to Calc
   CALL Calc (MyFunc, MySub)
C Example of a user-defined function replacing an intrinsic
C EXTERNAL SIN
   x = SIN (a, 4.2, 37)
```
FDATE

**Portability Function and Subroutine:** Returns the current date and time as an ASCII string.

### Module

**USE IFPORT**

### Syntax

**Function Syntax**

```
result = FDATE()
```

**Subroutine Syntax:**

```
CALL FDATE([string])
```

- **string** (Output; optional) Character*(*). It is returned as a 24-character string in the form:
  
  ```
  Mon Jan 31 04:37:23 2001
  ```

  Any value in `string` before the call is destroyed.

### Results

The result of the function FDATE and the value of `string` returned by the subroutine FDATE(`string`) are identical. Newline and NULL are not included in the string.

When you use FDATE as a function, declare it as:

```
CHARACTER*24 FDATE
```

### Example

```
USE IFPORT
CHARACTER*24 today
!
CALL FDATE(today)
write (*,*), 'Today is ', today
!
write (*,*), 'Today is ', fdate()
```

`DATE_AND_TIME`

**FGETC**

**Portability Function:** Reads the next available character from a file specified by a Fortran unit number.
Module
USE IFPORT

Syntax
result = FGETC (lunit,char)

lunit   (Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.
char    (Output) CHARACTER*1. Next available character in the file. If lunit is connected to a console device, then no characters are returned until the Enter key is pressed.

Results
The result type is INTEGER(4). The result is zero if the read is successful, or -1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:
EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).
If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read Portability Routines.

Example
USE IFPORT
CHARACTER inchar
INTEGER istatus
istatus = FGETC(5,inchar)
PRINT *, inchar
END

GETCHARQQ
READ

FINAL Clause
Parallel Directive Clause: Specifies that the generated task will be a final task.

Syntax
FINAL (scalar-logical-expression)

scalar-logical-expression Is a scalar logical expression. When the expression evaluates to .TRUE., it specifies that the generated task will be a final task.

All task constructs encountered during execution of a final task will generate included tasks.
Note that if a variable is used in a FINAL clause expression of a directive construct, it causes an implicit reference to the variable in all enclosing constructs.
Only a single FINAL clause can appear in the directive.

FINAL Statement
Statement: Denotes a finalization procedure that defines one or more final subroutines that are bound to a derived type. It takes the following form:
Syntax

FINAL [:] sub1 [, sub2 ]...

sub1, sub2, ...

Is a final subroutine, which is a module procedure with exactly one dummy argument of the derived type. The dummy argument cannot be INTENT(OUT), it cannot be optional, and it cannot be a pointer or allocatable. All array shape and length type parameters are assumed.

Description

A final subroutine must not have a dummy argument with the same kind type parameters and rank as the dummy argument of another final subroutine of the type.

You cannot specify a subroutine that was previously specified as a final subroutine for the derived type.

This statement is used in derived-type type-bound procedures.

A derived type is finalizable only if it has a final subroutine or a nonpointer, nonallocatable component of finalizable type. A nonpointer data entity is finalizable only if it is of finalizable type.

When an entity is finalized, the following occurs:

1. If the dynamic type of the entity has a final subroutine whose dummy argument has the same kind type parameters and rank as the entity being finalized, it is called with the entity as an actual argument
2. Otherwise, if there is an elemental final subroutine whose dummy argument has the same kind type parameters as the entity being finalized, it is called with the entity as an actual argument
3. Otherwise, no subroutine is called.

Effects of Finalization

If the entity being finalized is an array, each finalizable component of each element of that array is finalized separately.

When a pointer is deallocated, its target is finalized. When an allocatable entity is deallocated, it is finalized.

A nonpointer, nonallocatable object that is not a dummy argument or function result is finalized immediately before it would become undefined due to execution of a RETURN or END statement.

If the entity is of extended type and the parent type is finalizable, the parent component is finalized.

A nonpointer, nonallocatable local variable of a BLOCK construct is finalized immediately before it would become undefined due to termination of the BLOCK construct.

The following rules also apply:

- If an executable construct references a function, the result is finalized after execution of the innermost executable construct containing the reference.
- If an executable construct references a structure constructor or array constructor, the entity created by the constructor is finalized after execution of the innermost executable construct containing the reference.
- If a specification expression in a scoping unit references a function, the result is finalized before execution of the executable constructs in the scoping unit.
- If a specification expression in a scoping unit references a structure constructor or array constructor, the entity created by the constructor is finalized before execution of the executable constructs in the scoping unit.
- If image execution is terminated, either by an error or by execution of a ERROR STOP, STOP, or END PROGRAM statement, any entities that exist immediately before termination are not finalized.
Example
The following example declares two module subroutines to be final:

```fortran
TYPE MY_TYPE
... ! Component declarations
CONTAINS
   FINAL :: CLEAN1, CLEAN2
END TYPE MY_TYPE
```

Type-Bound Procedures

FIND

**Statement:** Positions a direct access file at a particular record and sets the associated variable of the file to that record number. It is comparable to a direct access READ statement with no I/O list, and it can open an existing file. No data transfer takes place.

**Syntax**

```
FIND ([UNIT]=io-unit, REC=r[, ERR=label] [, IOSTAT=i-var])
```

- `io-unit` Is a logical unit number. It must refer to a relative organization file (see Unit Specifier).
- `r` Is the direct access record number. It cannot be less than one or greater than the number of records defined for the file (see Record Specifier).
- `label` Is the label of the executable statement that receives control if an error occurs.
- `i-var` Is a scalar integer variable that is defined as a positive integer if an error occurs, and as zero if no error occurs (see I/O Status Specifier).

Example

In the following example, the FIND statement positions logical unit 1 at the first record in the file. The file's associated variable is set to one:

```
FIND(1, REC=1)
```

In the following example, the FIND statement positions the file at the record identified by the content of INDX. The file's associated variable is set to the value of INDX:

```
FIND(4, REC=INDX)
```

I/O Control List
FINDLOC
Transformational Intrinsic Function (Generic):
Finds the location of a specified value in an array.

Syntax
result = FINDLOC (array, value, dim [, mask, kind, back])
result = FINDLOC (array, value[, mask, kind, back])

array (Input) Must be an array of intrinsic type.
value (Input) Must be scalar and in type conformance with array.
dim (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array. The corresponding actual argument must not be an optional dummy argument.
mask (Input; optional) Must be of type logical and conformable with array.
kind (Input; optional) Must be a scalar integer constant expression.
back (Input; optional) Must be a scalar of type logical.

Results
The result is integer. If kind is present, the kind type parameter is that specified by the value of kind. Otherwise, the kind type parameter is that of default integer type. If dim does not appear, the result is an array of rank one and of size equal to the rank of array; otherwise, the result is of rank n - 1 and shape (d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n), where (d_1, d_2,...d_n) is the shape of array.
The result of FINDLOC (array, value) is a rank-one array whose element values are the values of the subscripts of an element of array whose value matches value. If there is such a value, the i-th subscript returned is in the range 1 to e_i, where e_i is the extent of the i-th dimension of array. If no elements match value or if array has size zero, all elements of the result are zero.
The result of FINDLOC (array, value, MASK = mask) is a rank-one array whose element values are the values of the subscripts of an element of array, corresponding to a true element of mask, whose value matches value. If there is such a value, the i-th subscript returned is in the range 1 to e_i, where e_i is the extent of the i-th dimension of array. If no elements match value, or array has size zero, or every element of mask has the value .FALSE., all elements of the result are zero.
If ARRAY has rank one, the result of FINDLOC (array, value, DIM = dim [, MASK = mask]) is a scalar whose value is equal to that of the first element of FINDLOC (array, value [, MASK = mask]). Otherwise, the value of element (s_1, s_2,...s_{dim-1}, s_{dim+1},...s_n) of the result is equal to FINDLOC (array (s_1, s_2,...s_{valuedim-1}, :, s_{dim+1},...s_n), value, DIM = 1 [, MASK = mask (s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n)])
If both array and value are of type logical, the comparison is performed with the .EQV. operator; otherwise, the comparison is performed with the == operator. If the value of the comparison is true, that element of array matches value.
If only one element matches value, that element’s subscripts are returned. If more than one element matches value and back is absent or present with the value .FALSE., the element whose subscripts are returned is the first element, taken in array element order. If back is present with the value .TRUE., the element whose subscripts are returned is the last element, taken in array element order.
The setting of compiler options specifying integer size can affect this function.
Example
The value of FINDLOC ([2, 6, 4, 6], VALUE = 6) is [2].
The value of FINDLOC ([2, 6, 4, 6], VALUE = 6, BACK = .TRUE.) is [4].
If A has the value

\[
\begin{bmatrix}
0 & -5 & 7 & 7 \\
3 & 4 & -1 & 2 \\
1 & 5 & 6 & 7 \\
\end{bmatrix}
\]

and M has the value

\[
\begin{bmatrix}
T & T & F & T \\
T & T & F & T \\
T & T & F & T \\
\end{bmatrix}
\]

then FINDLOC (A, 7, MASK = M) is [1, 4] and FINDLOC (A, 7, MASK = M, BACK = .TRUE.) is [3, 4].
This is independent of the declared lower bounds for A.
The value of FINDLOC ([2, 6, 4], VALUE = 6, DIM = 1) is 2.
If B has the value

\[
\begin{bmatrix}
1 & 2 & -9 \\
2 & 3 & 6 \\
\end{bmatrix}
\]

then FINDLOC (B, VALUE = 2, DIM = 1) is [2, 1, 0] and FINDLOC (B, VALUE = 2, DIM = 2) is [2, 1].
This is independent of the declared lower bounds for B.

MINLOC

FINDFILEQQ
Portability Function: Searches for a specified file in the directories listed in the path contained in the environment variable.

Module
USE IFPORT

Syntax
result = FINDFILEQQ (filename, varname, pathbuf)

filename (Input) Character*(*). Name of the file to be found.

varname (Input) Character*(*). Name of an environment variable containing the path to be searched.

pathbuf (Output) Character*(*). Buffer to receive the full path of the file found.
Results

The result type is INTEGER(4). The result is the length of the string containing the full path of the found file returned in `pathbuf`, or 0 if no file is found.

Example

```fortran
USE IFPORT
CHARACTER(256) pathname
INTEGER(4) pathlen
pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)
WRITE (*,*) pathname
END
```

FIRSTPRIVATE

**Parallel Directive Clause:** Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.

**Syntax**

FIRSTPRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different threads are initialized to the value the variable had upon entering the parallel region.

To avoid race conditions, which are caused by unintended sharing of data, concurrent updates of the original variable must be synchronized with the read of the original variable that occurs as a result of the FIRSTPRIVATE clause.

If the original variable has the POINTER attribute, the new variable receives the same association status of the original variable as if by pointer assignment.

If the original variable does not have the POINTER attribute, initialization of the new variable occurs as if by intrinsic assignment, unless the original variable has the allocation status of "not currently allocated". In this case, the new variable also has the status of "not currently unallocated".

The following are restrictions for the FIRSTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a FIRSTPRIVATE clause.
- A variable that is private within a parallel region must not appear in a FIRSTPRIVATE clause in a worksharing construct if any of the worksharing regions arising from the worksharing construct ever bind to any of the parallel regions arising from the parallel construct.
• A variable that appears in a REDUCTION clause of a PARALLEL construct must not appear in a FIRSTPRIVATE clause in a worksharing or task construct if any of the worksharing or task regions arising from the worksharing or task construct ever bind to any of the parallel regions arising from the parallel construct.
• A variable that appears in a REDUCTION clause in a WORKSHARE construct must not appear in a FIRSTPRIVATE clause in a task construct encountered during execution of any of the worksharing regions arising from the worksharing construct.
• Assumed-size arrays must not appear in a PRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
• If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

**NOTE**
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

**Example**
Consider the following:

```
A = 3
B = 4
!$OMP PARALLEL PRIVATE(A) FIRSTPRIVATE(B)
```

In this case, variable A has an undefined value at the beginning of the parallel region. However, variable B has the value 4, which was specified in the serial region preceding the parallel region.

**See Also**
PRIVATE clause
LASTPRIVATE clause

**FIXEDFORMLINESIZE**

*General Compiler Directive:* Sets the line length for fixed-form Fortran source code.

**Syntax**

```
!DIR$ FIXEDFORMLINESIZE: {72 | 80 | 132}
```

You can set FIXEDFORMLINESIZE to 72 (the default), 80, or 132 characters. The FIXEDFORMLINESIZE setting remains in effect until the end of the file, or until it is reset.

The FIXEDFORMLINESIZE directive sets the source-code line length in include files, but not in USE modules, which are compiled separately. If an include file resets the line length, the change does not affect the host file.

This directive has no effect on free-form source code.

**Example**

```
!DIR$ NOFREEFORM
!DIR$ FIXEDFORMLINESIZE:132
WRITE (*,*) 'Sentence that goes beyond the 72nd column without continuation.'
```

**FLOAT**

**Elemental Intrinsic Function (Generic):** Converts an integer to REAL(4).

**See Also**

REAL

**FLOODFILL, FLOODFILL_W (W*S)**

**Graphics Functions:** Fill an area using the current color index and fill mask.

**Module**

USE IFQWIN

**Syntax**

result = FLOODFILL (x, y, bcolor)
result = FLOODFILL_W (wx, wy, bcolor)

\[
\begin{align*}
x, y & \quad \text{(Input) INTEGER(2). Viewport coordinates for fill starting point.} \\
bcolor & \quad \text{(Input) INTEGER(2). Color index of the boundary color.} \\
wx, wy & \quad \text{(Input) REAL(8). Window coordinates for fill starting point.}
\end{align*}
\]

**Results**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color bcolor, or if the starting point lies outside the clipping region).

FLOODFILL begins filling at the viewport-coordinate point (x, y). FLOODFILL_W begins filling at the window-coordinate point (wx, wy). The fill color used by FLOODFILL and FLOODFILL_W is set by SETCOLOR. You can obtain the current fill color index by calling GETCOLOR. These functions allow access only to the colors in the palette (256 or less). To access all available colors on a VGA (262,144 colors) or a true color system, use the RGB functions FLOODFILLRGB and FLOODFILLRGB_W.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current graphics color index set by SETCOLOR. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color bcolor.

---

**NOTE**

The FLOODFILL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the FloodFill routine by including the IFWIN module, you need to specify the routine name as MSFWIN$FloodFill.
Example

USE IFQWIN
INTEGER(2) status, bcolor, red, blue
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
red = 4
blue = 1
status = SETCOLOR(red)
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLOR()
status = SETCOLOR (blue)
xinterior = 160; yinterior = 100
status = FLOODFILL (xinterior, yinterior, bcolor)
END

SETFILLMASK

FLOODFILLRGB, FLOODFILLRGB_W (W*S)

Graphics Functions: Fill an area using the current Red-Green-Blue (RGB) color and fill mask.

Module
USE IFQWIN

Syntax
result = FLOODFILLRGB (x,y,color)
result = FLOODFILLRGB_W (wx,wy,color)

x, y     (Input) INTEGER(2). Viewport coordinates for fill starting point.

color     (Input) INTEGER(4). RGB value of the boundary color.

wx, wy     (Input) REAL(8). Window coordinates for fill starting point.

Results
The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color color, or if the starting point lies outside the clipping region).

FLOODFILLRGB begins filling at the viewport-coordinate point (x, y). FLOODFILLRGB_W begins filling at the window-coordinate point (wx, wy). The fill color used by FLOODFILLRGB and FLOODFILLRGB_W is set by SETCOLORRGB. You can obtain the current fill color by calling GETCOLORRGB.
If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current color set by SETCOLORRGB. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color color.

Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) status
INTEGER(4) result, bcolor
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
result = SETCOLORRGB(Z'008080') ! red
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLORRGB( )
result = SETCOLORRGB (Z'FF0000') ! blue
xinterior = 160; yinterior = 100
result = FLOODFILLRGB (xinterior, yinterior, bcolor)
END

FLOOR
Elemental Intrinsic Function (Generic): Returns the greatest integer less than or equal to its argument.

Syntax
result = FLOOR (a[,kind])

a
(Input) Must be of type real.

kind
(Input; optional) Must be a scalar integer constant expression.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the greatest integer less than or equal to a.

The setting of compiler options specifying integer size can affect this function.
Example
FLOOR (4.8) has the value 4.
FLOOR (-5.6) has the value -6.
The following shows another example:

```
I = FLOOR(3.1)  ! returns 3
I = FLOOR(-3.1) ! returns -4
```

See Also
CEILING

**FLUSH Directive**

*OpenMP* Fortran Compiler Directive: Identifies synchronization points at which the threads in a team must provide a consistent view of memory.

**Syntax**

```
!$OMP FLUSH [(list)]
```

*list* Is the name of one or more variables to be flushed. Names must be separated by commas.

The binding thread set for a FLUSH construct is the encountering thread.

The FLUSH directive must appear at the precise point in the code at which the synchronization is required. To avoid flushing all variables, specify a *list*.

Thread-visible variables are written back to memory at the point at which this directive appears. Modifications to thread-visible variables are visible to all threads after this point. Subsequent reads of thread-visible variables fetch the latest copy of the data.

Thread-visible variables include the following data items:

- Globally visible variables (common blocks and modules)
- Local variables that do not have the SAVE attribute but have had their address taken and saved or have had their address passed to another subprogram
- Local variables that do not have the SAVE attribute that are declared shared in a parallel region within the subprogram
- Dummy arguments
- All pointer dereferences

The FLUSH directive is implied for the following directives (unless the NOWAIT keyword is used):

- ATOMIC and END ATOMIC
- BARRIER
- CRITICAL and END CRITICAL
- END DO
- END PARALLEL
- END SECTIONS
- END SINGLE
- END WORKSHARE
- ORDERED and END ORDERED
- PARALLEL and END PARALLEL
- PARALLEL DO and END PARALLEL DO
- PARALLEL SECTIONS and END PARALLEL SECTIONS
- TARGET
• TARGET DATA
• TARGET ENTER DATA on entry
• TARGET EXIT DATA on exit
• TARGET UPDATE on entry if TO is present and on exit if FROM is present

Example
The following example uses the FLUSH directive for point-to-point synchronization between pairs of threads:

```
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(ISYNC)
  IAM = OMP_GET_THREAD_NUM( )
  ISYNC(IAM) = 0
!$OMP BARRIER
  CALL WORK( )
  C I AM DONE WITH MY WORK, SYNCHRONIZE WITH MY NEIGHBOR
  ISYNC(IAM) = 1
!$OMP FLUSH(ISYNC)
  C WAIT TILL NEIGHBOR IS DONE
  DO WHILE (ISYNC(NEIGH) .EQ. 0)
    !$OMP FLUSH(ISYNC)
  END DO
!$OMP END PARALLEL
```

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

FLUSH Statement
Statement: Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. It takes one of the following forms:

Syntax
FLUSH([UNIT=]io-unit [, ERR=label] [, IOMSG=msg-var] [IOSTAT=i-var])

FLUSH io-unit

io-unit (Input) Is an external unit specifier.

label (Input) Is the label of the branch target statement that receives control if an error occurs.

msg-var (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

The FLUSH statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

This statement has no effect on file position.
**FLUSH Subroutine**

*Portability Subroutine:* Flushes the contents of an external unit buffer into its associated file.

**Module**

USE IFPORT

**Syntax**

CALL FLUSH (lunit)

- **lunit** (Input) INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.

**NOTE**

The flush is performed in a non-blocking mode. In this mode, the command may return before the physical write is completed. If you want to use a blocking mode of FLUSH use COMMITQQ.

**See Also**

COMMITQQ

**FMA and NOFMA**

*General Compiler Directives:* FMA tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions. NOFMA disables the generation of FMA instructions.

**Syntax**

!DIR$ FMA

!DIR$ NOFMA

These directives affect the current program unit but they also apply to subsequent program units in the source file, unless and until a program unit containing another FMA or NOFMA directive is encountered. Once a NOFMA directive has been specified, it is in effect from that point forward. The setting impacts later routines in the source file. For example, consider that the following are in the same source file:

```fortran
real function fms_mul2( a, b, c, d)
    implicit none
    real :: a, b, c, d
!
! the default !dir$ fma leads to fma generation:
! this is transformed into FMS(a,b,FMA(c,d,0))
!
!dir$ nofma
fms_mul2 = a*b - c*d ! no fma generation here
end function fms_mul2

real function fms_mul( a, b, c, d)
    implicit none
```

Intel® Fortran Compiler 19.0 Developer Guide and Reference

1464
The NOFMA directive specified in fms_mul will also impact the routine fms_mul. You must explicitly specify the FMA directive to override the effect of the NOFMA directive.

**See Also**
- General Compiler Directives
- Syntax Rules for Compiler Directives
- fma, Qfma compiler option

### FOCUSQQ (W*S)

**QuickWin Function:** Sets focus to the window with the specified unit number.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{FOCUSQQ (iunit)}
\]

**iunit**

(Input) INTEGER(4). Unit number of the window to which the focus is set. Unit numbers 0, 5, and 6 refer to the default startup window.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Units 0, 5, and 6 refer to the default window only if the program does not specifically open them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

Unlike SETACTIVEQQ, FOCUSQQ brings the specified unit to the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when on I/O statement is executed on that unit. For example:

```fortran
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**See Also**
- SETACTIVEQQ
- INQFOCUSQQ
FOR__SET_FTN_ALLOC

**Run-Time Function:** Lets you specify your own routine to dynamically allocate common blocks. This function is especially useful when you are sharing libraries.

**Syntax**

```fortran
result = FOR__SET_FTN_ALLOC(alloc_routine)
```

- `alloc_routine` *(Input)* Character. Is the name of a user-defined allocation routine. The routine takes the same arguments as the routine prototype `_FTN_ALLOC`, which is defined in module IFCORE. For more information on `_FTN_ALLOC` and its arguments, see Allocating Common Blocks.

**Results**

The result has the same type as the type of the argument. The return value is a pointer to the previous allocation routine you specified for allocation of COMMONs, or to a null pointer if you did not specify a previous allocation routine.

The caller of FOR__SET_FTN_ALLOC must include a USE IFCOMMONALLOC statement. The allocation routine should include ISO_C_BINDING so it can correctly declare the arguments.

This function takes precedence over `_FTN_ALLOC`.

**Example**

The following shows an example of a user-defined routine that can be used with FOR__SET_FTN_ALLOC.

Note that you must compile the program using option `[-Q]dyncom` to name the commons you want to be dynamically allocated.

```fortran
! User's allocation routine
!
subroutine my_Fortran_alloc_routine (mem, size, name)
    use, intrinsic :: ISO_C_BINDING
    implicit none
    type(C_PTR), intent(OUT) :: mem
    integer(C_INT), intent(INOUT) :: size
    character, dimension(*), intent(IN) :: name
    ! Users would put their allocation code here. This example text does not contain code to allocate memory.
end subroutine my_Fortran_alloc_routine

! This routine uses module IFCOMMONALLOC to swap allocation routines for dynamic COMMONs.
!
subroutine swap_alloc_routines( for_old )
    use ifcommonalloc
    use, intrinsic :: ISO_C_BINDING
    implicit none
    logical for_old
```
procedure(alloc_rtn) :: my_Fortran_alloc_routine

! Where to save the old one.
!
! Do the swap
!
print *, "my_Fortran_alloc_routine"
if (for_old) then

FOR_DESCRIPTOR_ASSIGN (W*S)
Run-Time Subroutine: Creates an array descriptor in memory.

Module

USE IFCORE
Syntax

CALL FOR_DESCRIPTOR.Assign (dp, base, size, reserved, rank, dims_info)

dp
(Input) A Fortran pointer to an array; the array can be of any data type.

base
(Input) INTEGER(4) or INTEGER(8). The base address of the data being described by dp.

Note that a Fortran pointer describes both the location and type of the data item.

size
(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).

reserved
(Input) INTEGER(4). A logical bitwise OR combination of the following constants, which are defined in IFCORE.F90:

- FOR_DESCRIPTOR_ARRAY_DEFINED - Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.
- FOR_DESCRIPTOR_ARRAY_NODEALLOC - Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

```fortran
integer, pointer :: p(:)
integer, target :: t
p => t       ! t cannot be deallocated
allocate(p(10)) ! t can be deallocated
```

If the bit is set, the array cannot be deallocated.

- FOR_DESCRIPTOR_ARRAY_CONTIGUOUS - Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

rank
(Input) INTEGER(4). The rank of the array pointed to.

dims_info
(Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```fortran
TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND !Lower bound for the dimension
  INTEGER(4) UPPERBOUND !Upper bound for the dimension
  INTEGER(4) STRIDE !Stride for the dimension
END TYPE FOR_DIMS_INFO
```

The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

Example

```fortran
use IFCORE
common/c_array/ array
real(8) array(5,5)
```
external init_array
call init_array()
do i=1,5
   do j=1,5
      print *,i,j, array(i,j)
   end do
end do

dims_info(1)%LOWERBOUND = 11
 dims_info(1)%UPPERBOUND = 15
dims_info(1)%STRIDE = 1

dims_info(2)%LOWERBOUND = -5
 dims_info(2)%UPPERBOUND = -1
dims_info(2)%STRIDE = 1

call FOR_DESCRIPTOR_ASSIGN(p_array, &
   LOC(array), &
   SIZEOF(array(1,1)), &
   FOR_DESCRIPTOR_ARRAY_DEFINED .or. &
   FOR_DESCRIPTOR_ARRAY_NODEALLOC .or. &
   FOR_DESCRIPTOR_ARRAY_CONTIGUOUS, &
   2, &
   dims_info )
p_array = p_array + 1
call c_print_array()

POINTER - Fortran

FOR_GET_FPE

**Run-Time Function:** Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.

**Module**
USE IFCORE

**Syntax**
result = FOR_GET_FPE( )

**Results**
The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFPORT module file.

To set floating-point exception flags after program initialization, use FOR_SET_FPE.

**Example**
USE IFCORE
INTEGER*4 FPE_FLAGS
FPE_FLAGS = FOR_GET_FPE ( )

See Also
FOR_SET_FPE

FOR_GET_HBW_AVAILABILITY

**Run-Time Function:** Returns the availability of High Bandwidth (HBW) memory for a program.

**Module**
USE IFCORE

**Syntax**
result = FOR_GET_HBW_AVAILABILITY( )

**Results**
The result type is INTEGER(4). The return value will be one of the following:

- FOR_K_HBW_AVAILABLE if HBW memory is available on this node.
- FOR_K_HBW_NO_ROUTINES if the routines needed for HBW memory allocation are not linked in (for example, there is no libmemkind).
- FOR_K_HBW_NOT_AVAILABLE if HBW memory is not available on this node.
If the return value indicates that High Bandwidth (HBW) memory is available, it does not guarantee that type of memory will be used for the allocated target through the life of the program. That is, if the node runs out of HBM memory, regular heap memory will be used.

Example

Consider the following:

```fortran
program hbw_availability
    use ifcore
    integer(4) :: i4_hbw_availability
    i4_hbw_availability = for_get_hbw_availability()
    print *,"Results of for_get_hbw_availability():"
    select case (i4_hbw_availability)
        case (FOR_K_HBW_AVAILABLE)
            print *,"    HBM is available."
        case (FOR_K_HBW_NO_ROUTINES)
            print *,"    The libmemkind routines needed for hbw memory allocation are not linked-in."
        case (FOR_K_HBW_NOT_AVAILABLE)
            print *,"    HBM is NOT available on this node."
    end select
end program hbw_availability
```

ATTRIBUTES MEMKIND
FOR_SET_FASTMEM_POLICY
Using HBW Memory

**FOR_GET_HBW_SIZE**

**Run-Time Function:** Returns the available free high bandwidth memory and the total high bandwidth memory that is available on a node of the High Bandwidth Memory partition. This function is only available on Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing).

**Module**

USE IFCORE

**Syntax**

```fortran
status = FOR_GET_HBW_SIZE(partition, total, free)
```

**partition**

(Input) Must be of type INTEGER(4). Set its value to 1 to receive information about the High Bandwidth Memory partition.

**total**

(Output) Must be of type INTEGER(8). It gets set to the number of bytes of memory on the system that can be allocated in the High Bandwidth Memory partition.

**free**

(Output) Must be of type INTEGER(8). It gets set to the number of available unallocated bytes of memory on the system that can be allocated in the High Bandwidth Memory partition.
Results

The result type is INTEGER(4). status has the value 0 if the call was successful. Upon failure, status is set to an error code as documented in the memkind(3) man page.

FOR_GET_HBW_SIZE is defined by the following Fortran interface block:

```fortran
interface
    function for_get_hbw_size (partition, total, free) &
    &        result(istat)  bind(C,name='hbw_get_size')
use iso_c_binding
implicit none
integer(C_INT)        :: istat
integer(C_INT), value :: partition     ! partition == 1 for HBW
integer(C_SIZE_T)     :: total, free
end function hbw_get_size
end interface
```

FOR_GET_HBW_SIZE calls the libmemkind function hbw_get_size as follows:

```c
#include <memkind.h>
int hbw_get_size(int partition, size_t * total, size_t * free) {             // partition=1
  for HBM
  memkind_t kind;
  int stat = memkind_get_kind_by_partition(partition, &kind);
  if(stat==0) stat = memkind_get_size(kind, total, free);
  return stat;
}
```

Using HBW Memory

FOR_GET_MEMKIND

Run-Time Function: Returns the requested allocation memory space for an array.

Module

USE IFCORE

Syntax

result = FOR_GET_MEMKIND (variable)

variable Must be an array with either the ALLOCATABLE or POINTER attribute.

Results

The result type is INTEGER(4). The return value will be one of the following:

- FOR_K_MEMKIND_DDR if variable should be allocated in DDR memory (Double Data Rate Random Access Memory).
- FOR_K_MEMKIND_HBW if variable should be allocated in HBW memory (High Band Width memory).

If variable does not have the ALLOCATABLE or the POINTER attribute, the result is undefined.

You can request that an array with the ALLOCATABLE or the POINTER attribute should be allocated to HBW or DDR memory by specifying one of the following preceding the ALLOCATE statement for the array:

- ATTRIBUTES MEMKIND directive
- MEMKIND directive
Example

In the following example, the array R has been given the attribute HBW but later, R is allocated in DDR memory:

```fortran
USE IFCORE
REAL, ALLOCATABLE :: R(:)
!DIR$ ATTRIBUTES MEMKIND:HBW :: R

PRINT *, FOR_K_MEMKIND_DDR, FOR_K_MEMKIND_HBW  ! prints 0   1
PRINT *, FOR_GET_MEMKIND(R)                      ! prints 1 for HBW
!DIR$ MEMKIND:DDR
ALLOCATE(R(1000))
PRINT *, FOR_GET_MEMKIND(R)                      ! prints 0 for DDR
END
```

In the following example, we cannot set ATTRIBUTES MEMKIND on a pointer but we can use the MEMKIND directive on the ALLOCATE statement:

```fortran
REAL, POINTER :: PR(:)
PRINT *, FOR_GET_MEMKIND(PR)  ! prints 0 for DDR
!DIR$ MEMKIND:HBW             ! legal on ALLOCATE of pointer PR
ALLOCATE(PR(1000))
PRINT *, FOR_GET_MEMKIND(PR)  ! prints 1 for HBW
END
```

See Also

ATTRIBUTES MEMKIND
MEMKIND directive
Using HBW Memory

FOR_IFCORE_VERSION

Portability Function: Returns the version of the Fortran run-time library (ifcore).

Module

USE IFPORT

Syntax

```fortran
result = FOR_IFCORE_VERSION (string)
```

where

- `result` is the result type
- `string` (Output) Character*(*). The version information for the Fortran run-time library (ifcore).

Results

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If `string` is not long enough to contain the version information, the result is truncated on the right. If `string` is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.
**Example**

Consider the following:

```fortran
program what_ifcore
    use ifport
    integer       :: res
    character*56  :: str

    res = for_ifcore_version( str )
    print "(3A)", "", str, ""
end program what_ifcore
```

The above example will produce a result similar to the following, depending on spacing and the actual version information:

'Intel Fortran RTL Core Library Vvv.m-eeeMmm dd yyyy '

where:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>vv</td>
<td>Is a major version number</td>
<td></td>
</tr>
<tr>
<td>m</td>
<td>Is a minor version number</td>
<td></td>
</tr>
<tr>
<td>eee</td>
<td>Is an edit number</td>
<td></td>
</tr>
<tr>
<td>Mmm</td>
<td>Is a three-character abbreviation for the month</td>
<td></td>
</tr>
<tr>
<td>dd</td>
<td>Is a two-digit day of the month</td>
<td></td>
</tr>
<tr>
<td>yyyy</td>
<td>Is a four-digit year</td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

FOR_IFCORE_VERSION

**FOR_IFPORT_VERSION**

*Portability Function:* Returns the version of the Fortran portability library (ifport).

**Module**

USE IFPORT

**Syntax**

```fortran
result = FOR_IFPORT_VERSION (string)
```

*string*  
(Output) Character*(*). The version information for the Fortran portability library (ifport).

**Results**

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If *string* is not long enough to contain the version information, the result is truncated on the right. If string is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.
Example

Consider the following:

```fortran
program what_ifport
    use ifport
    integer :: res
    character*56 :: str
    res = for_ifport_version( str )
    print "(3A)", ",", str, ","
end program what_ifport
```

The above example will produce a result similar to the following, depending on spacing and the actual version information:

```
'Intel Fortran portability library       Vvv.m-eeeMmm dd yyyy '
```

where:

- **vv** is a major version number
- **m** is a minor version number
- **eee** is an edit number
- **Mmm** is a three-character abbreviation for the month
- **dd** is a two-digit day of the month
- **yyyy** is a four-digit year

See Also

- `FOR_IFPORT_VERSION`
- `FOR_LFENCE`

**FOR_LFENCE**

**Run-Time Subroutine:** Inserts a memory load fence instruction that ensures completion of preceding load instructions.

**Syntax**

```fortran
CALL FOR_LFENCE ()
```

Using this subroutine guarantees that in program order, every load instruction that precedes the load fence instruction is globally visible before any load instruction that follows the load fence.

**FOR_MFENCE**

**Run-Time Subroutine:** Inserts a memory fence instruction that ensures completion of all preceding load and store instructions.

**Module**

```fortran
USE IFCORE
```

**Syntax**

```fortran
CALL FOR_MFENCE ()
```
**Syntax**

CALL FOR_MFENCE ()

Using this subroutine guarantees that in program order, every load and store instruction that precedes the memory fence instruction is globally visible before any load or store instruction that follows the memory fence can proceed.

---

**for_rtl_finish_**

**Run-Time Function:** Cleans up the Fortran run-time environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.

**Syntax**

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```c
result = for_rtl_finish_ ();
```

**Results**

The result is an I/O status value. For information on these status values, see Error Handling: Using the IOSTAT Value and Fortran Exit Codes.

To initialize the Fortran run-time environment, use function for_rtl_init_.

---

**Example**

Consider the following C code:

```c
int io_status;
int for_rtl_finish_ ();
io_status = for_rtl_finish_ ();
```

**See Also**

for_rtl_init_

---

**for_rtl_init_**

**Run-Time Subroutine:** Initializes the Fortran run-time environment and causes Fortran procedures and subroutines to behave the same as when called from a Fortran main program. On Linux* and macOS*, it also establishes handlers and floating-point exception handling.

**Syntax**

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```c
CALL for_rtl_init_ (argcount, actarg)
```

- `argcount` Is a command-line parameter describing the argument count.
- `actarg` Is a command-line parameter describing the actual arguments.

To clean up the Fortran run-time environment, use function for_rtl_finish_.

---
Consider the following C code:

```c
int argc;
char **argv;
void for_rtl_init_ (int *, char **);
for_rtl_init_ (&argc, argv);
```

See Also
for_rtl_finish_

---

**FOR_SET_FASTMEM_POLICY**

*Run-Time Function:* Sets or gets the value of the Fortran Run-Time Library (RTL) FASTMEM/MEMKIND:HBW policy mode, which is the desired action to occur when an ALLOCATE statement requests FASTMEM/HBW memory, but it is not available to the program or node.

**Module**

USE IFCORE

**Syntax**

```fortran
result = FOR_SET_FASTMEM_POLICY(mode)
```

*mode* Must be of type INTEGER(4). It is either a new policy value, or a request to return the current value. It must be one of the following:

- **FOR_K_FASTMEM_INFO** - Tells the Fortran RTL to return the current FASTMEM policy value.
- **FOR_K_FASTMEM_NORETRY** - Tells the Fortran RTL to issue an error if FASTMEM is not available.
- **FOR_K_FASTMEM_RETRY_WARN** - Tells the Fortran RTL to warn if FASTMEM is not available, then use the default memory allocator.
- **FOR_K_FASTMEM_RETRY** - Tells the Fortran RTL that if FASTMEM is not available, silently use the default memory allocator.

**Results**

The result type is INTEGER(4). The return value represents the previous setting of the Fortran Run-Time Library FASTMEM policy mode, unless the argument is **FOR_K_FASTMEM_INFO**, in which case the return value represents the current setting.

**Example**

Consider the following:

```fortran
program fastmem_policy
use ifcore
integer(4) :: old_policy

print *,"Print the current Results of initial for_set_fastmem_policy(FOR_K_FASTMEM_INFO):"
old_policy = for_set_fastmem_policy(FOR_K_FASTMEM_INFO)
select case (i4_old_policy)
    case (FOR_K_FASTMEM_NORETRY)
```
print *, "    Issue a Severe error if FASTMEM is not available."
case (FOR_K_FASTMEM_RETRY_WARN)
print *, "    Issue a Warning if FASTMEM is not available, then use the default memory allocator."
case (FOR_K_FASTMEM_RETRY_WARN)
print *, "    If FASTMEM is not available, then silently use the default memory allocator."
end select
print *, "Set the FASTMEM policy to RETRY_WARN:"
old_policy = for_set_fastmem_policy(FOR_K_FASTMEM_RETRY_WARN)

end program fastmem_policy

ATTRIBUTES MEMKIND
FOR_GET_HBW_AVAILABILITY
Using HBW Memory

FOR_SET_FPE

Run-Time Function: Sets the floating-point exception flags. This routine can be called from a C or Fortran program.

Module
USE IFCORE

Syntax
result = FOR_SET_FPE (a)

a Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

Results
The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file.
To get the current settings of the floating-point exception flags, use FOR_GET_FPE.

Example
USE IFCORE
INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS
OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)

The following example program is compiled without any fpe options. However, it uses calls to for_set_fpe to enable the same flags as when compiling with option fpe:0. The new flags can be verified by compiling the program with option -fpe:0.

program samplefpe
use ifcore
implicit none

INTEGER(4) :: ORIGINAL_FPE_FLAGS, NEW_FPE_FLAGS
INTEGER(4) :: CURRENT_FPE_FLAGS, PREVIOUS_FPE_FLAGS
NEW_FPE_FLAGS = FPE_M_TRAP_UND + FPE_M_TRAP_OVF + FPE_M_TRAP_DIV0 &
             + FPE_M_TRAP_INV + FPE_M_ABRUPT_UND + FPE_M_ABRUPT_DMZ
ORIGINAL_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
CURRENT_FPE_FLAGS = FOR_GET_FPE ()

print *,"The original FPE FLAGS were:"
CALL PRINT_FPE_FLAGS(ORIGINAL_FPE_FLAGS)

print *,"The new FPE FLAGS are:"
CALL PRINT_FPE_FLAGS(CURRENT_FPE_FLAGS)

!! restore the fpe flag to their original values
PREVIOUS_FPE_FLAGS = FOR_SET_FPE (ORIGINAL_FPE_FLAGS)
end

subroutine PRINT_FPE_FLAGS(fpe_flags)
use ifcore
implicit none
integer(4)   :: fpe_flags
character(3) :: toggle

print 10, fpe_flags, fpe_flags
10 format(X,'FPE FLAGS = 0X',Z8.8," B'",B32.32)

if ( IAND(fpe_flags, FPE_M_TRAP_UND) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_TRAP_UND    ":", toggle

if ( IAND(fpe_flags, FPE_M_TRAP_OVF) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_TRAP_OVF    ":", toggle

if ( IAND(fpe_flags, FPE_M_TRAP_DIV0) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_TRAP_DIV0   ":", toggle

if ( IAND(fpe_flags, FPE_M_TRAP_INV) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_TRAP_INV    ":", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_UND) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_UND ":", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_DMZ) .ne. 0 ) then
    toggle = "ON"
else
    toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_DMZ":", toggle
end
write(*,*) "  FPE_ABRUPT_UND  :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_OVF) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) "  FPE_ABRUPT_OVF  :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_DIV0) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) "  FPE_ABRUPT_DIV0  :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_INV) .ne. 0 ) then ! ABRUPT_DMZ
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) "  FPE_ABRUPT_INV  :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_DMZ) .ne. 0 ) then ! ABRUPT_DMZ
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) "  FPE_ABRUPT_DMZ  :", toggle, "  (ftz related)"
end subroutine PRINT_FPE_FLAGS

The following shows the output from the above program:

>ifort set_fpe_sample01.f90
>set_fpe_sample01.exe

The original FPE FLAGS were:
FPE FLAGS = 0X00000000 B'00000000000000000000000000000000
FPE_TRAP_UND :OFF
FPE_TRAP_OVF :OFF
FPE_TRAP_DIV0 :OFF
FPE_TRAP_INV :OFF
FPE_ABRUPT_UND :OFF
FPE_ABRUPT_OVF :OFF
FPE_ABRUPT_DIV0 :OFF
FPE_ABRUPT_INV :OFF
FPE_ABRUPT_DMZ :OFF (ftz related)

The new FPE FLAGS are:
FPE FLAGS = 0X0011000F B'00000000000100010000000000000000
FPE_TRAP_UND :ON
FPE_TRAP_OVF :ON
FPE_TRAP_DIV0 :ON
FPE_TRAP_INV :ON
FPE_ABRUPT_UND :ON
FPE_ABRUPT_OVF :OFF
FPE_ABRUPT_DIV0 :ON
FPE_ABRUPT_INV :OFF
FPE_ABRUPT_DMZ :ON (ftz related)
The following example builds a library that has to have a particular setting of the fpe flags internally, and has to work with user programs built with any combination of the fpe flags.

```fortran
!-- file USE.F90 starts here
subroutine use_denorms
  use, intrinsic :: ieee_arithmetic
  use ifcore

  use, intrinsic :: ieee_features, only: ieee_denormal
  implicit none

  !---- Declaration for use in example code

  integer  i
  !---- End declarations for example code

  integer(4) :: orig_flags, off_flags, not_flags, new_flags
  if (ieee_support_denormal()) then
    print *, "Denormals already supported"
  else
    orig_flags = for_get_fpe()
    off_flags = IOR(FPE_M_ABRUPT_UND, FPE_M_ABRUPT_DMZ)
    off_flags = IOR(off_flags,        FPE_M_TRAP_UND)
    off_flags = IOR(off_flags,        FPE_M_MSG_UND)
    not_flags = NOT(off_flags)        ! "INOT" is the 16-bit version!
    new_flags  = IAND(orig_flags, not_flags)
    orig_flags = for_set_fpe(new_flags)
    if (ieee_support_denormal()) then
      print *, "Denormals are now supported"
    else
      print *, "Error: Denormals still not supported after FOR_SET_FPE call"
    end if
  end if

  !-- Begin example of user code using denorms
  1      FORMAT(1X,Z)
  2      FORMAT("Use denormals",1X,E40.25)
  x = 0.0
  y = tiny(x)
  ! Print as real values
  !       print 2, x, y
  ! Expect non-zero numbers
  !
  do i = 1, 20
    y = y / 2.0
    print 1,y
  enddo
  !-- End example of user code using denorms
end subroutine use_denorms
!-- end of file USE.F90
```

        else
            print *, "Denormals are now NOT supported, should flush to zero"
        end if
    else
        print *, "Denormals already not supported"
    end if

    !-- Begin example of user code doing flush-to-zero

    1      FORMAT(1X,Z)
    2      FORMAT("Flush to zero",1X,E40.25)

    x = 0.0
    y = tiny(x)

    ! Print as real values
    !
    print 2, x, y

    ! Expect zeros
    !
    do i = 1, 20
        y = y / 2.0
    print 1,y
    enddo

    !-- End example of user code doing flush-to-zero

end subroutine flush_denorms
!-- end of file FLUSH.F90
program example
  implicit none
  call use_denoms       ! Will use denoms
  call flush_denoms     ! Will flush
  call use_denoms       ! Will also flush, but WON'T use denoms!
end program example
  !-- end of file MAIN.F90

You can specify the following lines to compile and link the above program:

ifort -c -fpic -no-ftz -fpe3   use.f90
ifort -c -fpic -ftz            flush.f90
ifort -c -fpic                 main.f90
ifort -o main.exe main.o use.o flush.o

FOR_SET_REENTRANCY

Run-Time Function: Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits. This routine can be called from a C or Fortran program.

Module
USE IFCORE

Syntax
result = FOR_SET_REENTRANCY (mode)

mode

Must be of type INTEGER(4) and contain one of the following options:

FOR_K_REENTRANCY_NONE
Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will not be reentered due to asynchronous system traps (ASTs) or threads within the application.

FOR_K_REENTRANCY_SYNCH
Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.

FOR_K_REENTRANCY_THREAD
Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.

FOR_K_REENTRANCY_INFO
Tells the Fortran RTL to return the current reentrancy mode.
Results
The result type is INTEGER(4). The return value represents the previous setting of the Fortran Run-Time Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in which case the return value represents the current setting.

You must be using an RTL that supports the level of reentrancy you desire. For example, FOR_SET_REENTRANCY ignores a request for thread protection (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe RTL.

Example

```fortran
PROGRAM SETREENT
USE IFCORE
INTEGER*4 MODE
CHARACTER*10 REENT_TXT(3) /'NONE    ','ASYNCH  ','THREADED'/
PRINT*, 'Setting Reentrancy mode to ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
PRINT*, 'Previous Reentrancy mode was ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
PRINT*, 'Current Reentrancy mode is ', REENT_TXT(MODE+1)
END
```

FOR_SFENCE

**Run-Time Subroutine:** Inserts a memory store fence instruction that ensures completion of preceding store instructions.

Module

USE IFCORE

Syntax

CALL FOR_SFENCE ()

Using this subroutine guarantees that in program order, every store instruction that precedes the store fence instruction is globally visible before any store instruction that follows the store fence.

FORALL

**Statement and Construct:** The FORALL statement and construct is an element-by-element generalization of the masked array assignment in the WHERE statement and construct. It allows more general array shapes to be assigned, especially in construct form. The FORALL construct is an obsolescent language feature in Fortran 2018.

Syntax

**Statement:**

```
FORALL (triplet-spec[, triplet-spec] ...[, mask-expr]) assign-stmt
```

**Construct:**

```
[name:] FORALL (triplet-spec[, triplet-spec] ...[, mask-expr])
  forall-body-stmt
  [forall-body-stmt]...
```
END FORALL [name]

triplet-spec

Is a triplet specification with the following form:

[type::] subscript-name = subscript-1: subscript-2[: stride]

The type is an optional integer data type. If type appears, the subscript-name has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If type does not appear, the subscript-name must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.

The subscript-name is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The subscripts and stride cannot contain a reference to any subscript-name in triplet-spec.

The stride cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

mask-expr

Is a logical array expression (called the mask expression). If it is omitted, the value .TRUE. is assumed. The mask expression can reference the subscript name in triplet-spec.

Description

If a construct name is specified in the FORALL statement, the same name must appear in the corresponding END FORALL statement.

A FORALL statement is executed by first evaluating all bounds and stride expressions in the triplet specifications, giving a set of values for each subscript name. The FORALL assignment statement is executed for all combinations of subscript name values for which the mask expression is true.

The FORALL assignment statement is executed as if all expressions (on both sides of the assignment) are completely evaluated before any part of the left side is changed. Valid values are assigned to corresponding elements of the array being assigned to. No element of an array can be assigned a value more than once.

A FORALL construct is executed as if it were multiple FORALL statements, with the same triplet specifications and mask expressions. Each statement in the FORALL body is executed completely before execution begins on the next FORALL body statement.

Any procedure referenced in the mask expression or FORALL assignment statement must be pure.

Pure functions can be used in the mask expression or called directly in a FORALL statement. Pure subroutines cannot be called directly in a FORALL statement, but can be called from other pure procedures.

Starting with Fortran 2018, the FORALL statement and construct are obsolescent features.
Example

The following example, which is not expressible using array syntax, sets diagonal elements of an array to 1:

```fortran
REAL, DIMENSION(N, N) :: A
FORALL (I=1:N)  A(I, I) = 1
```

Consider the following:

```fortran
FORALL(I = 1:N, J = 1:N, A(I, J) .NE. 0.0) B(I, J) = 1.0 / A(I, J)
```

This statement takes the reciprocal of each nonzero element of array A(1:N, 1:N) and assigns it to the corresponding element of array B. Elements of A that are zero do not have their reciprocal taken, and no assignments are made to corresponding elements of B.

Every array assignment statement and WHERE statement can be written as a FORALL statement, but some FORALL statements cannot be written using just array syntax. For example, the preceding FORALL statement is equivalent to the following:

```fortran
WHERE(A /= 0.0) B = 1.0 / A
```

However, the following FORALL example cannot be written using just array syntax:

```fortran
FORALL(I = 1:N, J = 1:N) H(I, J) = 1.0/REAL(I + J - 1)
```

This statement sets array element H(I, J) to the value 1.0/REAL(I + J - 1) for values of I and J between 1 and N.

Consider the following:

```fortran
TYPE MONARCH
  INTEGER, POINTER :: P
END TYPE MONARCH

TYPE(MONARCH), DIMENSION(8) :: PATTERN
INTEGER, DIMENSION(8), TARGET :: OBJECT

FORALL(J=1:8) PATTERN(J)%P => OBJECT(1+IEOR(J-1,2))
```

This FORALL statement causes elements 1 through 8 of array PATTERN to point to elements 3, 4, 1, 2, 7, 8, 5, and 6, respectively, of OBJECT. IEOR can be referenced here because it is pure.

The following example shows a FORALL construct:

```fortran
FORALL(I = 3:N + 1, J = 3:N + 1)
  C(I, J) = C(I, J + 2) + C(I, J - 2) + C(I + 2, J) + C(I - 2, J)
  D(I, J) = C(I, J)
END FORALL
```

The assignment to array D uses the values of C computed in the first statement in the construct, not the values before the construct began execution.

WHERE

FORMAT

**Statement:** Specifies the form of data being transferred and the data conversion (editing) required to achieve that form.

**Syntax**

FORMAT (format-list)
format-list

Is a list of one or more of the following edit descriptors, separated by commas or slashes (/):

| Data edit descriptors: | I, B, O, Z, F, E, EN, ES, D, G, L, and A. |
| Control edit descriptors: | T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q. |
| String edit descriptors: | H, 'c', and "c", where c is a character constant. |

A comma can be omitted in the following cases:
- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Edit descriptors can be nested and a repeat specification can precede data edit descriptors, the slash edit descriptor, or a parenthesized list of edit descriptors.

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see the OPEN statement.

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $,+, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

Whenever an edit descriptor requires an integer constant, you can specify an expression enclosed in angle brackets (< and >). For more information, see Variable Format Expressions.

The integer expression can be any valid Fortran expression, including function calls and references to dummy arguments, with the following restrictions:
- Expressions cannot be used with the H edit descriptor.
• Expressions cannot contain graphical relational operators (such as > and <).

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement.

The following tables summarize the different kinds of edit descriptors:

### Data Edit Descriptors

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>
</tr>
<tr>
<td>B</td>
<td>Bw[].m</td>
<td>Transfers binary values.</td>
</tr>
<tr>
<td>D</td>
<td>Dw.d</td>
<td>Transfers real values with D exponents.</td>
</tr>
<tr>
<td>E</td>
<td>Ew.d[Ee]</td>
<td>Transfers real values with E exponents.</td>
</tr>
<tr>
<td>EN</td>
<td>ENw.d[Ee]</td>
<td>Transfers real values with engineering notation.</td>
</tr>
<tr>
<td>ES</td>
<td>ESw.d[Ee]</td>
<td>Transfers real values with scientific notation.</td>
</tr>
<tr>
<td>F</td>
<td>Fw.d</td>
<td>Transfers real values with no exponent.</td>
</tr>
<tr>
<td>G</td>
<td>Gw.d[Ee]</td>
<td>Transfers values of all intrinsic types.</td>
</tr>
<tr>
<td>I</td>
<td>Iw[].m</td>
<td>Transfers decimal integer values.</td>
</tr>
<tr>
<td>L</td>
<td>Lw</td>
<td>Transfers logical values: on input, transfers characters; on output, transfers T or F.</td>
</tr>
<tr>
<td>O</td>
<td>Ow[].m</td>
<td>Transfers octal values.</td>
</tr>
<tr>
<td>Z</td>
<td>Zw[].m</td>
<td>Transfers hexadecimal values.</td>
</tr>
</tbody>
</table>

1\(w\) is the field width.

\(m\) is the minimum number of digits that must be in the field (including zeros).

\(d\) is the number of digits to the right of the decimal point.

\(E\) is the exponent field.

\(e\) is the number of digits in the exponent.

### Control Edit Descriptors

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>BN</td>
<td>BN</td>
<td>Ignores embedded and trailing blanks in a numeric input field.</td>
</tr>
<tr>
<td>BZ</td>
<td>BZ</td>
<td>Treats embedded and trailing blanks in a numeric input field as zeros.</td>
</tr>
<tr>
<td>Code</td>
<td>Form</td>
<td>Effect</td>
</tr>
<tr>
<td>------</td>
<td>------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>P</strong></td>
<td><strong>kP</strong></td>
<td>Interprets certain real numbers with a specified scale factor.</td>
</tr>
<tr>
<td><strong>Q</strong></td>
<td><strong>Q</strong></td>
<td>Returns the number of characters remaining in an input record.</td>
</tr>
<tr>
<td><strong>S</strong></td>
<td><strong>S</strong></td>
<td>Reinvokes optional plus sign (+) in numeric output fields; counters the action of SP and SS.</td>
</tr>
<tr>
<td><strong>SP</strong></td>
<td><strong>SP</strong></td>
<td>Writes optional plus sign (+) into numeric output fields.</td>
</tr>
<tr>
<td><strong>SS</strong></td>
<td><strong>SS</strong></td>
<td>Suppresses optional plus sign (+) in numeric output fields.</td>
</tr>
<tr>
<td><strong>T</strong></td>
<td><strong>Tn</strong></td>
<td>Tabs to specified position.</td>
</tr>
<tr>
<td><strong>TL</strong></td>
<td><strong>TLn</strong></td>
<td>Tabs left the specified number of positions.</td>
</tr>
<tr>
<td><strong>TR</strong></td>
<td><strong>TRn</strong></td>
<td>Tabs right the specified number of positions.</td>
</tr>
<tr>
<td><strong>X</strong></td>
<td><strong>nX</strong></td>
<td>Skips the specified number of positions.</td>
</tr>
<tr>
<td><strong>$</strong></td>
<td><strong>$</strong></td>
<td>Suppresses trailing carriage return during interactive I/O.</td>
</tr>
<tr>
<td><strong>:</strong></td>
<td><strong>:</strong></td>
<td>Terminates format control if there are no more items in the I/O list.</td>
</tr>
<tr>
<td><strong>/</strong></td>
<td><strong>[r]/</strong></td>
<td>Terminates the current record and moves to the next record.</td>
</tr>
</tbody>
</table>
| \ | \ | Continues the same record; same as $.

**String Edit Descriptors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>H</strong></td>
<td><strong>nHch[ch...]</strong></td>
<td>Transfers characters following the <strong>H</strong> edit descriptor to an output record.</td>
</tr>
<tr>
<td><strong>'c'</strong></td>
<td><strong>'c'</strong></td>
<td>Transfers the character literal constant (between the delimiters) to an output record.</td>
</tr>
</tbody>
</table>

\(^2\) These delimiters can also be quotation marks (".

**Example**

```plaintext```
INTEGER width, value
width = 2
read (*,i) width, value
```plaintext```
! if the input is 3123, prints 123, not 12

1 format ( i1, i<width>)
  print *, value
END

FP_CLASS

Elemental Intrinsic Function (Generic): Returns the class of an IEEE* real (binary32, binary64, and binary128) argument. This function cannot be passed as an actual argument.

Syntax

result = FP_CLASS (x)

x (Input) Must be of type real.

Results

The result type is INTEGER(4). The return value is one of the following:

<table>
<thead>
<tr>
<th>Class of Argument</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signaling NaN</td>
<td>FOR_K_FP_SNAN</td>
</tr>
<tr>
<td>Quiet NaN</td>
<td>FOR_K_FP_QNAN</td>
</tr>
<tr>
<td>Positive Infinity</td>
<td>FOR_K_FP_POS_INF</td>
</tr>
<tr>
<td>Negative Infinity</td>
<td>FOR_K_FP_NEG_INF</td>
</tr>
<tr>
<td>Positive Normalized Number</td>
<td>FOR_K_FP_POS_NORM</td>
</tr>
<tr>
<td>Negative Normalized Number</td>
<td>FOR_K_FP_NEG_NORM</td>
</tr>
<tr>
<td>Positive Denormalized Number</td>
<td>FOR_K_FP_POS_DENORM</td>
</tr>
<tr>
<td>Negative Denormalized Number</td>
<td>FOR_K_FP_NEG_DENORM</td>
</tr>
<tr>
<td>Positive Zero</td>
<td>FOR_K_FP_POS_ZERO</td>
</tr>
<tr>
<td>Negative Zero</td>
<td>FOR_K_FP_NEG_ZERO</td>
</tr>
</tbody>
</table>

The preceding return values are defined in file for_fpclass.for.

Example

FP_CLASS (4.0_8) has the value 4 (FOR_K_FP_POS_NORM).
FPUTC

Portability Function: Writes a character to the file specified by a Fortran external unit, bypassing normal Fortran input/output.

Module

USE IFPORT

Syntax

result = FPUTC (lunit, char)

lunit (Input) INTEGER(4). Unit number of a file.
char (Output) Character*(*). Variable whose value is to be written to the file corresponding to lunit.

Results

The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

EINVAL - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read Input and Output Routines in Overview of Portability Routines.

Example

use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit, file = 'fputc.dat')
do i = 1,26
   char1 = char(123-i)
i4 = fputc(1,char1) !make valid writes
   if (i4.ne.0) iflag = 1
endo
rewind (1)
read (1,'(a)') string
print *, string

See Also
I/O Formatting

FRACTION

Elemental Intrinsic Function (Generic): Returns the fractional part of the model representation of the argument value.

Syntax

result = FRACTION (x)

x (Input) Must be of type real.
Results

The result type and kind are the same as \( x \).

The result has the value \( x \times b^e \). Parameters \( b \) and \( e \) are defined in Model for Real Data.

If \( x \) has the value zero, the result has the value zero.

Example

If 3.0 is a REAL(4) value, FRACTION (3.0) has the value 0.75.

The following shows another example:

```fortran
REAL result
result = FRACTION(3.0) ! returns 0.75
result = FRACTION(1024.0) ! returns 0.5
```

FREE

Intrinsic Subroutine (Specific): Frees a block of memory that is currently allocated. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

```fortran
CALL FREE (addr)
```

\( addr \) (Input) Must be of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This value is the starting address of the memory block to be freed, previously allocated by MALLOC.

If the freed address was not previously allocated by MALLOC, or if an address is freed more than once, results are unpredictable.

Example

```fortran
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
```

FREEFORM and NOFREEFORM

General Compiler Directives: FREEFORM specifies that source code is in free-form format. NOFREEFORM specifies that source code is in fixed-form format.

Syntax

```fortran
!DIR$ FREEFORM
!DIR$ NOFREEFORM
```
When the FREEFORM or NOFREEFORM directives are used, they remain in effect for the remainder of the program unit, or until the opposite directive is used. When in effect, they apply to include files, but do not affect USE modules, which are compiled separately.

**Example**

Consider the following:

```fortran
SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
! is in column 1 and fixed form
!     X is in column 7
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ FREEFORM          ! what follows is freeform
!DIR$ ASSUME (MOD(NX,8) .EQ. 0)
! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
DO J=J1,J2
  DO I=I1,I2
    A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
  ENDDO
ENDDO
!DIR$ NOFREEFORM            ! and now back to fixed form
END SUBROUTINE F
```

Equivalent Compiler Options

**FSEEK**

*Portability Function:* Repositions a file specified by a Fortran external unit.

**Module**

USE IFPORT

**Syntax**

```
result = FSEEK (lunit,offset,from)
```

- **lunit** *(Input)* INTEGER(4). External unit number of a file.
- **offset** *(Input)* INTEGER(4) or INTEGER(8). Offset in bytes, relative to *from*, that is to be the new location of the file marker.
- **from** *(Input)* INTEGER(4). A position in the file. It must be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Variable</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SEEK_SET</td>
<td>Positions the file relative to the beginning of the file.</td>
</tr>
</tbody>
</table>
**Value** | **Variable** | **Position**
--- | --- | ---
1 | SEEK_CUR | Positions the file relative to the current position.
2 | SEEK_END | Positions the file relative to the end of the file.

**Results**

The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:

EINVAL: The specified unit is invalid (either not already open, or an invalid unit number), or the from parameter is invalid.

The file specified in lunit must be open.

**Example**

```
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1,file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1,offset,ipos)
if (.NOT. stat) then
  istat=fgetc(1,ichar)
  print *, 'data is ',ichar
end if
```

**FSTAT**

*Portability Function:* Returns detailed information about a file specified by a external unit number.

**Module**

USE IFPORT

**Syntax**

```
result = FSTAT (lunit,statb)
```

(*Input*) INTEGER(4). External unit number of the file to examine.

(*Output*) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of statb contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W<em>S: Always 0 L</em>X: System dependent</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
<td>Values or Notes</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W*S: Always 0</td>
</tr>
<tr>

</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed¹</td>
<td>W*S: Only available on non-FAT file systems; undefined on FAT systems</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified¹</td>
<td>W*S: Same as stat(10)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change¹</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
</tbody>
</table>

¹Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINVAL (lunit is not a valid unit number, or is not open).
The access mode (the third element of `statb`) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Constant</th>

</tbody>
</table>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

**Example**

```fortran
USE IFPORT
integer(4) statarray(12), istat
OPEN (unit=1,file='datfile.dat')
ISTAT = FSTAT (1, statarray)
if (.NOT. istat) then
   print *, statarray
end if
```

**See Also**
INQUIRE
STAT

**FTELL, FTELLI8**

*Portability Functions:* Return the current position of a file.

**Module**

USE IFPORT

**Syntax**

```fortran
result = FTELL (lunit)
result = FTELLI8 (lunit)
```

**lunit** (Input) INTEGER(4). External unit number of a file.

**Results**

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

EINVAL: lunit is not a valid unit number, or is not open.

**FULLPATHQQ**

*Portability Function:* Returns the full path for a specified file or directory.

**Module**

USE IFPORT

**Syntax**

```fortran
result = FULLPATHQQ (name, pathbuf)
```
name

(Input) Character(*). Item for which you want the full path. Can be the name of a file in the current directory, a relative directory or file name, or a network uniform naming convention (UNC) path.

pathbuf

(Output) Character(*). Buffer to receive full path of the item specified in name.

Results

The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails. This function does not verify that the resulting path and file name are valid nor that they exist.

The length of the full path depends upon how deeply the directories are nested on the drive you are using. If the full path is longer than the character buffer provided to return it (pathbuf), FULLPATHQQ returns only that portion of the path that fits into the buffer.

Check the length of the path before using the string returned in pathbuf. If the longest full path you are likely to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the largest possible path buffer with the following statements:

```
USE IFPORT
CHARACTER($MAXPATH) pathbuf
```

$MAXPATH is a symbolic constant defined in IFPORT.F90 as 260.

Example

```
USE IFPORT
USE IFCORE
CHARACTER($MAXPATH) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) len
DO WHILE (.TRUE.)
  WRITE (*,*) ' Enter filename (Hit & RETURN to exit): '
  len = GETSTRQQ(file)
  IF (len .EQ. 0) EXIT
  len = FULLPATHQQ(file, buf)
  IF (len .GT. 0) THEN
    WRITE (*,*) buf(1:len)
  ELSE
    WRITE (*,*) 'Can''t get full path'
    EXIT
  END IF
  
  Split path
  WRITE (*,*)
  len = SPLITPATHQQ(buf, drive, dir, name, ext)
  IF (len .NE. 0) THEN
    WRITE (*, 900) ' Drive: ', drive
    WRITE (*, 900) ' Directory: ', dir(1:len)
    WRITE (*, 900) ' Name: ', name
    WRITE (*, 900) ' Extension: ', ext
  ELSE
    WRITE (*, *) 'Can''t split path'
```

SPLITPATHQQ

FUNCTION
Statement: The initial statement of a function subprogram. A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression.

Syntax
[prefix [prefix]] FUNCTION name [([d-arg-list])] [suffix]
  [specification-part]
  [execution-part]
[CONTAINS
  [internal-subprogram-part]]
END [FUNCTION [name]]

prefix

(Optional) Is any of the following:
- A data type specifier
- ELEMENTAL
  Acts on one array element at a time. This is a restricted form of pure procedure.
- IMPURE
  Asserts that the procedure has side effects.
- MODULE
  Indicates a separate module procedure. See separate module procedures.
- NON_RECURSIVE
  Indicates the function is not recursive.
- PURE
  Asserts that the procedure has no side effects.
- RECURSIVE
  Permits direct and indirect recursion to occur. If a function is directly recursive and array valued, and RESULT is not specified, any reference to the function name in the executable part of the function is a reference to the function result variable.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if lang-binding is specified in suffix.
**name**

Is the name of the function. If RESULT is specified, the function name must not appear in any specification statement in the scoping unit of the function subprogram.

The function name can be followed by the length of the data type. The length is specified by an asterisk (*) followed by any unsigned, nonzero integer that is a valid length for the function's type. For example, REAL FUNCTION LGFUNC*8 (Y, Z) specifies the function result as REAL(8) (or REAL*8).

This optional length specification is not permitted if the length has already been specified following the keyword CHARACTER.

**d-arg-list**

(Optional) Is a list of one or more dummy arguments.

If there are no dummy arguments, no suffix, and no RESULT variable, the parentheses can be omitted. For example, the following is valid:

```fortran
FUNCTION F
```

**suffix**

(Optional) Takes one of the following forms:

```
[RESULT (r-name)] lang-binding
```

Where:

- **r-name** (Optional) Is the name of the function result. This name must not be the same as the function name.

- **lang-binding** Takes the following form:
  ```fortran
  BIND (C [, NAME=ext-name])
  ```

  Where:
  - **ext-name** Is a character scalar constant expression that can be used to construct the external name.

**specification-part**

Is one or more specification statements.

**execution-part**

Is one or more executable constructs or statements.

**internal-subprogram-part**

Is one or more internal subprograms (defining internal procedures). The `internal-subprogram-part` is preceded by a CONTAINS statement.

**Description**

The type and kind parameters (if any) of the function's result can be defined in the FUNCTION statement or in a type declaration statement within the function subprogram, but not both. If no type is specified, the type is determined by implicit typing rules in effect for the function subprogram.

Execution begins with the first executable construct or statement following the FUNCTION statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

If you specify CHARACTER(LEN=*) as the type of the function, the function assumes the length declared for it in the program unit that invokes it. This type of the resulting character function can have different lengths when it is invoked by different program units. An assumed-length character function cannot be directly recursive.
If the character length is specified as an integer constant, the value must agree with the length of the function specified in the program unit that invokes the function. If no length is specified, a length of 1 is assumed.

If the function is array-valued or a pointer, the declarations within the function must state these attributes for the function result name. The specification of the function result attributes, dummy argument attributes, and the information in the procedure heading collectively define the interface of the function.

The value of the result variable is returned by the function when it completes execution. Certain rules apply depending on whether the result is a pointer, as follows:

- If the result is a pointer, its allocation status must be determined before the function completes execution. The function must associate a target with the pointer, or cause the pointer to be explicitly disassociated from a target.

  If the pointer result points to a TARGET with the INTENT(IN) attribute, the function can give the result a value but the caller is not allowed to change the value pointed to.

- The shape of the value returned by the function is determined by the shape of the result variable when the function completes execution.

- If the result is not a pointer, its value must be defined before the function completes execution. If the result is an array, all the elements must be defined. If the result is a derived-type structure, all the components must be defined.

A function subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A function can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

Example

The following example uses the Newton-Raphson iteration method (\( F(X) = \cosh(X) + \cos(X) - A = 0 \)) to get the root of the function:

```fortran
FUNCTION ROOT(A)
    X  = 1.0
    DO
        EX = EXP(X)
        EMINX = 1./EX
        ROOT  = X - ((EX+EMINX)*.5+COS(X)-A)/((EX-EMINX)*.5-SIN(X))
        IF (ABS((X-ROOT)/ROOT) .LT. 1E-6) RETURN
        X  = ROOT
    END DO
END
```

In the preceding example, the following formula is calculated repeatedly until the difference between \( X_i \) and \( X_{i+1} \) is less than 1.0E-6:

\[
X_{i+1} = X_i - \frac{\cos(X_i) + \cos(X_i) - A}{\sinh(X_i) - \sin(X_i)}
\]

The following example shows an assumed-length character function:

```fortran
CHARACTER*(*) FUNCTION REDO(CARG)
    CHARACTER*1 CARG
    DO I=1,LEN(REDO)
        REDO(I:I) = CARG
    END DO
END
```

Language Reference

1501
This function returns the value of its argument, repeated to fill the length of the function.

Within any given program unit, all references to an assumed-length character function must have the same length. In the following example, the REDO function has a length of 1000:

```fortran
CHARACTER*1000 REDO, MANYAS, MANYZS
MANYAS = REDO('A')
MANYZS = REDO('Z')
```

Another program unit within the executable program can specify a different length. For example, the following REDO function has a length of 2:

```fortran
CHARACTER HOLD*6, REDO*2
HOLD = REDO('A')//REDO('B')//REDO('C')
```

The following example shows a dynamic array-valued function:

```fortran
FUNCTION SUB (N)
    REAL, DIMENSION(N) :: SUB
    ...
END FUNCTION
```

The following shows another example:

```fortran
INTEGER Divby2
10   PRINT *, 'Enter a number'
   READ *, i
   Print *, Divby2(i)
   GOTO 10
END

C
C     This is the function definition
C
INTEGER FUNCTION Divby2 (num)
Divby2=num / 2
END FUNCTION
```

The following example shows an allocatable function with allocatable arguments:

```fortran
MODULE AP
CONTAINS

FUNCTION ADD_VEC(P1,P2)
    ! Function to add two allocatable arrays of possibly differing lengths.
    ! The arrays may be thought of as polynomials (coefficients)
    REAL, ALLOCATABLE :: ADD_VEC(:), P1(:), P2(:)

    ! This function returns an allocatable array whose length is set to
    ! the length of the larger input array.
    ALLOCATE(ADD_VEC(MAX(SIZE(P1), SIZE(P2))))
    M = MIN(SIZE(P1), SIZE(P2))
    ! Add up to the shorter input array size
    ADD_VEC(:M) = P1(:M) + P2(:M)
    ! Use the larger input array elements afterwards (from P1 or P2)
    IF(SIZE(P1) > M) THEN
        ADD_VEC(M+1:) = P1(M+1:)
    ELSE IF(SIZE(P2) > M) THEN
        ADD_VEC(M+1:) = P2(M+1:)
    END IF

END FUNCTION
```
PROGRAM TEST
USE AP
REAL, ALLOCATABLE :: P(:), Q(:), R(:), S(:)
ALLOCATE(P(3))
ALLOCATE(Q(2))
ALLOCATE(R(3))
ALLOCATE(S(3))
!
! Notice that P and Q differ in length
P = (/4,2,1/)  ! P = X**2 + 2X + 4
Q = (//-1,1/)  ! Q =         X - 1
PRINT *, 'Result should be: 3.000000 3.000000 1.000000'  
PRINT *, 'Coefficients are: ', ADD_VEC(P, Q)  ! X**2 + 3X + 3
!
P = (/1,1,1/)  ! P = X**2 + X + 1
R = (/2,2,2/)  ! R = 2X**2 + 2X + 2
S = (/3,3,3/)  ! S = 3X**2 + 3X + 3
PRINT *, 'Result should be: 6.000000 6.000000 6.000000'  
PRINT *, 'Coefficients are: ', ADD_VEC(ADD_VEC(P,R), S)
END

Consider the following example:

module mymodule
  type :: vec
    integer :: x(3)
  contains
    procedure :: at
  end type vec
contains
  function at( this, i ) result( p )
    implicit none
    class(vec), intent(in), target :: this
    integer, intent(in) :: i
    integer, pointer :: p
    p => this%x(i)
  end function at
end module mymodule

program test
use mymodule
implicit none
type(vec) :: myvec
myvec%x = [1,2,3]
!
! pointer returned by function at gives the correct values: 1, 2, and 3
write(6,*), myvec%at(1), myvec%at(2), myvec%at(3)
!
! changing any array element is an error
myvec%at(1) = 4
myvec%at(2) = 5
GAMMA

Elemental Intrinsic Function (Generic): Returns the gamma value of its argument.

Syntax

result = GAMMA (x)

x          (Input) Must be of type real. It must not be zero or a negative number.

Results

The result type and kind are the same as x.
The result has a value equal to a processor-dependent approximation to the gamma function of x,

\[
\Gamma(X) = \begin{cases} 
\int_0^\infty t^{X-1} \exp(-t) \, dt & X > 0 \\
\int_0^\infty t^{X-1} \exp(-t) - \sum_{k=0}^{\infty} \frac{(-t)^k}{k!} \, dt & -n - 1 < X < -n, n \text{ an integer} \geq 0
\end{cases}
\]

Example

GAMMA (1.0) has the approximate value 1.000.

GENERIC

Statement: Declares a generic interface that is bound to a derived type-bound procedure. It takes the following form:

Syntax

GENERIC [, access-spec]:: generic-spec => binding-name1 [, binding-name2]...
access-spec
((Optional) Is the PUBLIC or PRIVATE attribute. Only one can be specified.

generic-spec
Is an explicit INTERFACE statement using one of the following:

- generic-name
  The generic-name cannot be the name of a nongeneric binding of the type. For more information, see Defining Generic Names for Procedures.
- OPERATOR (op)
  Type-bound generic operators cannot have the NOPASS attribute. The dynamic type of the passed-object dummy argument determines which actual procedure is called. For more information, see Defining Generic Operators.
- ASSIGNMENT (=)
  See Defining Generic Assignment.

The same generic-spec can be used in several generic bindings within a single derived-type definition. In this case, every occurrence of the same generic-spec must have the same accessibility.

binding-spec1, binding-spec2,...
Is the name of the type-bound procedure. Each specific binding-name must have the passed-object dummy argument.

Example
Consider the following:

```
TYPE MY_TYPE2
  ...
  CONTAINS
    PROCEDURE :: MYPROC => MYPROC1
    PROCEDURE,PASS(C) :: UPROC => UPROC1
    GENERIC :: OPERATOR(+) => MYPROC, UPROC
  END TYPE MY_TYPE2
  ...
  TYPE,EXTENDS(MY_TYPE2) :: MY_TYPE3
  ...
  CONTAINS
    PROCEDURE :: MYPROC => MYPROC2
    PROCEDURE,PASS(C) :: UPROC => UPROC2
  END TYPE MY_TYPE3
```

The type MY_TYPE3 inherits the generic operator '+'. Invoking the generic (+) invokes the specific type-bound procedure. For entities of type MY_TYPE3, that invokes the overriding actual procedure (MYPROC2 or UPROC2).

See Also
Type-Bound Procedures

GERROR

Run-Time Subroutine: Returns a message for the last error detected by a Fortran run-time routine.
Module
USE IFCORE

Syntax
CALL GERROR (string)

string (Output) Character*(*) Message corresponding to the last detected error.

The last detected error does not necessarily correspond to the most recent function call. The compiler resets string only when another error occurs.

Example
USE IFCORE
character*40 errtext
character char1
integer*4 iflag, i4
...!Open unit 1 here
i4=fgetc(1,char1)
if (i4) then
   iflag = 1
   Call GERROR (errtext)
   print *, errtext
end if

See Also
PERROR
IERRNO

GETACTIVEQQ (W*S)
QuickWin Function: Returns the unit number of the currently active child window.

Module
USE IFQWIN

Syntax
result = GETACTIVEQQ( )

Results
The result type is INTEGER(4). The result is the unit number of the currently active window. If no child window is active, it returns the parameter QWIN$NOACTIVEWINDOW (defined in IFQWIN.F90).

See Also
SETACTIVEQQ
GETHWNDQQ

GETARCINFO (W*S)
Graphics Function: Determines the endpoints (in viewport coordinates) of the most recently drawn arc or pie.
Module
USE IFQWIN

Syntax
result = GETARCINFO (lpstart, lpend, lppaint)

lpstart  (Output) Derived type xycoord. Viewport coordinates of the starting point of the arc.
lpend  (Output) Derived type xycoord. Viewport coordinates of the end point of the arc.
lppaint  (Output) Derived type xycoord. Viewport coordinates of the point at which the fill begins.

Results
The result type is INTEGER(2). The result is nonzero if successful. The result is zero if neither the ARC nor the PIE function has been successfully called since the last time CLEARSCREEN or SETWINDOWCONFIG was successfully called, or since a new viewport was selected.

GETARCINFO updates the lpstart and lpendxycoord derived types to contain the endpoints (in viewport coordinates) of the arc drawn by the most recent call to the ARC or PIE functions. The xycoord derived type, defined in IFQWIN.F90, is:

```
TYPE xycoord
   INTEGER(2) xcoord
   INTEGER(2) ycoord
END TYPE xycoord
```

The returned value in lppaint specifies a point from which a pie can be filled. You can use this to fill a pie in a color different from the border color. After a call to GETARCINFO, change colors using SETCOLORRGB. Use the new color, along with the coordinates in lppaint, as arguments for the FLOODFILLRGB function.

Example
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
TYPE (xycoord) xystart, xyend, xyfillpt
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 80
x4 = 90; y4 = 180
status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
status = GETARCINFO(xystart, xyend, xyfillpt)
END

See Also
ARC
FLOODFILLRGB
GETCOLORRGB
GRSTATUS
PIE
SETCOLORRGB
GETARG

**Intrinsic Subroutine:** Returns the specified command-line argument (where the command itself is argument number zero). Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL GETARG (n, buffer[, status])
```

- **n** (Input) Must be a scalar of type integer. This value is the position of the command-line argument to retrieve. The command itself is argument number 0.
- **buffer** (Output) Must be a scalar of type default character. Its value is the returned command-line argument.
- **status** (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status.

If there were no errors, `status` returns the number of characters in the retrieved command-line argument before truncation or blank-padding. (That is, `status` is the original number of characters in the command-line argument.) Errors return a value of -1. Errors include specifying an argument position less than 0 or greater than the value returned by IARGC.

GETARG returns the \( n \)th command-line argument. If \( n \) is zero, the name of the executing program file is returned.

GETARG returns command-line arguments as they were entered. There is no case conversion.

If the command-line argument is shorter than `buffer`, GETARG pads `buffer` on the right with blanks. If the argument is longer than `buffer`, GETARG truncates the argument on the right. If there is an error, GETARG fills `buffer` with blanks.

**Example**

Assume a command-line invocation of `PROG1 -g -c -a`, and that `buffer` is at least five characters long. The following calls to GETARG return the corresponding arguments in `buffer` and `status`:

<table>
<thead>
<tr>
<th>Statement</th>
<th>String returned in <code>buffer</code></th>
<th>Length returned in <code>status</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL GETARG (0, buffer, status)</td>
<td>PROG1</td>
<td>5</td>
</tr>
<tr>
<td>CALL GETARG (1, buffer)</td>
<td>-g</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (2, buffer, status)</td>
<td>-c</td>
<td>2</td>
</tr>
<tr>
<td>CALL GETARG (3, buffer)</td>
<td>-a</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (4, buffer, status)</td>
<td>all blanks</td>
<td>-1</td>
</tr>
</tbody>
</table>

- GET_COMMAND
GET_COMMAND_ARGUMENT

GETBKCOLOR (W*S)

**Graphics Function:** Returns the current background color index for both text and graphics output.

**Module**

USE IFQWIN

**Syntax**

```plaintext
result = GETBKCOLOR()
```

**Results**

The result type is INTEGER(4). The result is the current background color index.

GETBKCOLOR returns the current background color index for both text and graphics, as set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTEGB.

**NOTE**

The GETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetBkColor.

**Example**

```plaintext
USE IFQWIN
INTEGER(4) bcindex
bcindex = GETBKCOLOR()
```

**See Also**

GETBKCOLORRGB
SETBKCOLOR
GETCOLOR
GETTEXTCOLOR
REMAPALLPALETTEGB, REMAPPALETTEGB

GETBKCOLORRGB (W*S)

**Graphics Function:** Returns the current background Red-Green-Blue (RGB) color value for both text and graphics.

**Module**

USE IFQWIN
Syntax

result = GETBKCOLORRGB( )

Results

The result type is INTEGER(4). The result is the RGB value of the current background color for both text and graphics.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B G G G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB and returned with GETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB and returned with GETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETBKCOLOR, SETCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) back, fore, oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETCOLORRGB(Z'FF') ! red
! reverse the screen
back = GETBKCOLORRGB()
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)
oldcolor = SETCOLORRGB(back)
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

GETBKCOLOR
GETC

*Portability Function:* Reads the next available character from external unit 5, which is normally connected to the console.

**Module**
USE IFPORT

**Syntax**
result = GETC (char)

(Output) Character*. First character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

**Results**
The result type is INTEGER(4). The result is zero if successful, or -1 if an end-of-file was detected.

**Example**
```
use IFPORT
character ans, errtxt*40
print *, 'Enter a character: '
ISTAT = GETC (ans)
if (istat) then
   call gerror(errtxt)
end if
```

**See Also**
GETCHARQQ
GETSTRQQ

GETCHARQQ

*Run-Time Function:* Returns the next keystroke.

**Module**
USE IFCORE

**Syntax**
result = GETCHARQQ  

**Results**
The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character. If the key pressed is a function or direction key, a hex Z’00’ or Z’E0’ is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.
If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn’t there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQQ in your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application. The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQQ.

**Example**

```fortran
! Program to demonstrate GETCHARQQ
USE IFCORE
CHARACTER(1) key / 'A' / 
PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)
WRITE (*,*) ' Type a key: (or q to quit)'
! Read keys until ESC or q is pressed
DO WHILE (ICHAR (key) .NE. ESC)
  key = GETCHARQQ()
  ! Some extended keys have no ASCII representation
  IF(ICHAR(key) .EQ. NOREP) THEN
    key = GETCHARQQ()
    WRITE (*,900) 'Not ASCII. Char = NA'
    WRITE (*,*)
  ELSE
    WRITE (*,900) 'ASCII. Char = ' 
    WRITE (*,901) key
  END IF
  IF (key .EQ. 'q' ) THEN
    EXIT
  END IF
END DO
900 FORMAT (1X, A, ")
901 FORMAT (A)
END
```

**GETCOLOR (W*S)**

*Graphics Function: Returns the current graphics color index.*
Module
USE IFQWIN

Syntax
result = GETCOLOR( )

Results
The result type is INTEGER(2). The result is the current color index, if successful; otherwise, -1.

GETCOLOR returns the current color index used for graphics over the background color as set with SETCOLOR. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

Example

! Program to demonstrate GETCOLOR
PROGRAM COLORS
USE IFQWIN
INTEGER(2) loop, loop1, status, color
LOGICAL(4) winstat
REAL rnd1, rnd2, xnum, ynum
type (windowconfig) wc
status = SETCOLOR(INT2(0))
! Color random pixels with 15 different colors
DO loop1 = 1, 15
  color = INT2(MOD(GETCOLOR() +1, 16))
  status = SETCOLOR (color) ! Set to next color
DO loop = 1, 75
! Set color of random spot, normalized to be on screen
  CALL RANDOM(rnd1)
  CALL RANDOM(rnd2)
  winstat = GETWINDOWCONFIG(wc)
  xnum = wc%numxpixels
  ynum = wc%numypixels
  status = &
  SETPIXEL(INT2(rnd1*xnum+1),INT2(rnd2*ynum))
  status = &
  SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum+1))
  status = &
  SETPIXEL(INT2(rnd1*xnum-1),INT2(rnd2*ynum))
  status = &
  SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum-1))
END DO
END DO
END

SETCOLOR
**GETCOLORRGB (W*S)**

**Graphics Function:** Returns the current graphics color Red-Green-Blue (RGB) value (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB).

**Module**

USE IFQWIN

**Syntax**

```fortran
result = GETCOLORRGB( )
```

**Results**

The result type is INTEGER(4). The result is the RGB value of the current graphics color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B G G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETCOLORRGB returns the RGB color value of graphics over the background color (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB), set with SETCOLORRGB. GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB.

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) fore, oldcolor
numfonts = INITIALIZEFONTS ( )
oldcolor = SETCOLORRGB(Z'FF')   ! set graphics
           ! color to red
fore = GETCOLORRGB( )
oldcolor = SETBKCOLORRGB(fore)  ! set background
           ! to graphics color
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB (Z'FF0000') ! set graphics
```
CALL OUTGTEXT("hello, world")
END

GET_COMMAND

*Intrinsic Subroutine*: Returns the entire command that was used to invoke the program.

**Syntax**

CALL GET_COMMAND ([command, length, status])

- **command** (Output; optional) Must be a scalar of type default character. If specified, its value is the entire command that was used to invoke the program. If the command cannot be determined, its value is all blanks.

- **length** (Output; optional) Must be a scalar of type integer. If specified, its value is the significant length of the command that was used to invoke the program. This length includes trailing blanks, but it does not include any truncation or padding used in the command. If the command length cannot be determined, its value is zero.

- **status** (Output; optional) Must be a scalar of type integer. If specified, its value is -1 if the command argument is present and has a length less than the significant length of the command. If the command cannot be retrieved, its value is positive; otherwise, it is assigned the value zero.

**Example**

See the example in COMMAND_ARGUMENT_COUNT.

GET_COMMAND_ARGUMENT

GET_COMMAND_ARGUMENT

*Intrinsic Subroutine*: Returns a command line argument of the command that invoked the program. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL GET_COMMAND_ARGUMENT (number[, value, length, status])
number (Input) Must be a scalar of type integer. It must be non-negative and less than or equal to the value returned by the COMMAND_ARGUMENT_COUNT function. Its value is the position of the command-line argument to retrieve. The command itself is argument number zero.

value (Output; optional) Must be a scalar of type default character. If specified, its value is the returned command-line argument or all blanks if the value is unknown.

length (Output; optional) Must be a scalar of type integer. If specified, its value is the length of the returned command-line argument or zero if the length of the argument is unknown. This length includes significant trailing blanks. It does not include any truncation or padding that occurs when the argument is assigned to the value argument.

status (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. It is assigned the value -1 if the value argument is present and has a length less than the significant length of the command argument specified by number. It is assigned a processor-dependent positive value if the argument retrieval fails. Otherwise, it is assigned the value zero.

GET_COMMAND_ARGUMENT returns command-line arguments as they were entered. There is no case conversion.

Example
See the example in COMMAND_ARGUMENT_COUNT.

GETCONTROLFPQQ
Portability Subroutine: Returns the floating-point processor control word.

Module
USE IFPORT

Syntax
CALL GETCONTROLFPQQ (controlword)

controlword (Output) INTEGER(2). Floating-point processor control word.

The floating-point control word is a bit flag that controls various modes of the floating-point processor.

The control word can be any of the following constants (defined in IFPORT.F90):
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z'1000'</td>
<td><strong>Infinity control mask</strong></td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z'1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z'0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z'0300'</td>
<td><strong>Precision control mask</strong></td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z'0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z'0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z'0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z'0C00'</td>
<td><strong>Rounding control mask</strong></td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z'0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z'0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z'0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z'0000'</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z'003F'</td>
<td><strong>Exception mask</strong></td>
</tr>
<tr>

<td>Z'0010'</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z'0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be disabled by setting the control bits to 1 with SETCONTROLFPQQ.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues.

You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings.
Example

USE IFPORT
INTEGER(2) control
CALL GETCONTROLFPQQ (control)
! if not rounding down
IF (IAND(control, FPCW$DOWN) .NE. FPCW$DOWN) THEN
  control = IAND(control, NOT(FPCW$MCW_RC)) ! clear all
  !  rounding
  control = IOR(control, FPCW$DOWN)         !  set to
  !  round down
CALL SETCONTROLFPQQ(control)
END IF
END

See Also

GETCURRENTPOSITION, GETCURRENTPOSITION_W (W*S)

*Graphics Subroutines*:

Return the coordinates of the current graphics position.

Module

USE IFQWIN

Syntax

CALL GETCURRENTPOSITION (s)
CALL GETCURRENTPOSITION_W (s)

s
(Output) Derived type xycoord. Viewport coordinates of current graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord   ! x-coordinate
  INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

LINETO, MOVETO, and OUTGTEXT all change the current graphics position. It is in the center of the screen when a window is created.

Graphics output starts at the current graphics position returned by GETCURRENTPOSITION or GETCURRENTPOSITION_W. This position is not related to normal text output (from OUTTEXT or WRITE, for example), which begins at the current text position (see SETTEXTPOSITION). It does, however, affect graphics text output from OUTGTEXT.

Example

```
! Program to demonstrate GETCURRENTPOSITION
USE IFQWIN
TYPE (xycoord) position
INTEGER(2) result
result = LINETO(INT2(300), INT2(200))
```
CALL GETCURRENTPOSITION( position )
IF (position%xcoord .GT. 50) THEN
    CALL MOVETO(INT2(50), position%ycoord, position)
    WRITE(*,*) "Text unaffected by graphics position"
END IF
result = LINETO(INT2(300), INT2(200))
END

See Also

GETCWD

Portability Function: Returns the path of the current working directory.

Module
USE IFPORT

Syntax
result = GETCWD (dirname)

dirname (Output) Character (*). Name of the current working directory path, including drive letter.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Example
USE IFPORT
character*30 dirname
! variable dirname must be long enough to hold entire string
integer(4) istat
ISTAT = GETCWD (dirname)
IF (ISTAT == 0) write *, 'Current directory is ',dirname

See Also
GETDRIVEDIRQQ

GETDAT

Portability Subroutine: Returns the date.

Module
USE IFPORT

Syntax
CALL GETDAT (iyr, imon, iday)
iyr
(Output) INTEGER(4) or INTEGER(2). Year (xxxxAD).

imon
(Output) INTEGER(4) or INTEGER(2). Month (1-12).

iday
(Output) INTEGER(4) or INTEGER(2). Day of the month (1-31).

This subroutine is thread-safe.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example

! Program to demonstrate GETDAT and GETTIM
USE IFPORT
INTEGER(4) tmpday, tmpmonth, tmpyear
INTEGER(4) tmphour, tmpminute, tmpsecond, tmphund
CHARACTER(1) mer
CALL GETDAT(tmpyear, tmpmonth, tmpday)
CALL GETTIM(tmphour, tmpminute, tmpsecond, tmphund)
IF (tmphour .GT. 12) THEN
   mer = 'p'
   tmphour = tmphour - 12
ELSE
   mer = 'a'
END IF
WRITE (*, 900) tmpmonth, tmpday, tmpyear
900 FORMAT(I2, '/', I2.2, '/', I4.4)
WRITE (*, 901) tmphour, tmpminute, tmpsecond, tmphund, mer
901 FORMAT(I2, ':', I2.2, ':', I2.2, ':', I2.2, ', ',
   A, 'm')
END

GETDRIVEDIRQQ

Portability Function: Returns the path of the current working directory on a specified drive.

Module
USE IFPORT
Syntax

result = GETDRIVEDIRQQ (drivedir)

**drivedir**  
(Input; output) Character*(*)  
On input, the drive whose current working directory path is to be returned. On output, the string containing the current directory on that drive in the form d:\dir.

Results

The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory on the specified drive. Zero is returned if the path is longer than the size of the character buffer **drivedir**.

You specify the drive from which to return the current working directory by putting the drive letter into **drivedir** before calling GETDRIVEDIRQQ. To make sure you get information about the current drive, put the symbolic constant FILE$CURDRIVE (defined in IFPORT.F90) into **drivedir**.

Because drives are identified by a single alphabetic character, GETDRIVEDIRQQ examines only the first letter of **drivedir**. For instance, if **drivedir** contains the path c:\fps90\bin, GETDRIVEDIRQQ ( **drivedir**) returns the current working directory on drive C and disregards the rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive specified in **drivedir**. If the full path is longer than the length of **drivedir**, GETDRIVEDIRQQ returns only the portion of the path that fits into **drivedir**. If you are likely to encounter a long path, allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* and macOS* systems, the function gets a path only when symbolic constant FILE$CURDRIVE has been applied to **drivedir**.

Example

```fortran
!  Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
!  Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length .GT. 0) THEN
   WRITE (*,*) 'Current directory is: '
   WRITE (*,*) dir
ELSE
   WRITE (*,*) 'Failed to get current directory'
END IF
END
```

- SPLITPATHQQ
GETDRIVESIZEQQ

**Portability Function:** Returns the total size of the specified drive and space available on it.

**Module**
USE IFPORT

**Syntax**

```fortran
result = GETDRIVESIZEQQ(drive, total, avail)
```

- **drive** (Input) Character*(*) String containing the letter of the drive to get information about.
- **total** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Total number of bytes on the drive.
- **avail** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Number of bytes of available space on the drive.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The data types and dimension (if any) specified for the `total` and `avail` arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of `drive`. The drive letter can be uppercase or lowercase. You can use the constant FILE$CURDRIVE (defined in IFPORT.F90) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

**Example**

```fortran
! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A, A)') ' Drives available: ', drives
! Cycle through them for free space and write to console
DO i = 1, 26
   adrive = drives(i:i)
   status = .FALSE.
   WRITE (*,'(A, A, A, \')') ' Drive ', CHAR(i + 64), ':'
   IF (adrive .NE. ' ') THEN
      status = GETDRIVESIZEQQ(adrive, total, avail)
   END IF
END IF
```

1522
IF (status) THEN
  WRITE (*,*) avail, ' of ', total, ' bytes free.'
ELSE
  WRITE (*,*) 'Not available'
END IF
END DO
END

GETDRIVES

Portability Function: Reports which drives are available to the system.

Module
USE IFPORT

Syntax
result = GETDRIVES() 

Results
The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.

The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A CD' is returned.

On Linux* and macOS* systems, the function returns a string filled with spaces.

Example
See the example for GETDRIVESIZE.

GETENV

Portability Subroutine: Returns the value of an environment variable.

Module
USE IFPORT

Syntax
CALL GETENV (ename, evalue)
**GET_ENVIRONMENT_VARIABLE**

**Intrinsic Subroutine:** Gets the value of an environment variable.

**Syntax**

```plaintext
CALL GET_ENVIRONMENT_VARIABLE (name [, value, length, status, trim_name])
```

- **name** *(Input)* Must be a scalar of type default character. It is the name of the environment variable.
- **value** *(Output; optional)* Must be a scalar of type default character. If specified, it is assigned the value of the environment variable specified by `name`. If the environment variable does not exist, `value` is assigned all blanks.
- **length** *(Output; optional)* Must be a scalar of type integer. If specified, its value is the length of the environment variable, if it exists; otherwise, `length` is set to 0.
- **status** *(Output; optional)* Must be a scalar of type integer. If specified, it is assigned a value of 0 if the environment variable exists and either has no value or its value is successfully assigned to `value`. It is assigned a value of -1 if the `value` argument is present and has a length less than the significant length of the environment variable value. It is assigned a value of 1 if the environment variable does not exist. For other error conditions, it is assigned a processor-dependent value greater than 2.
- **trim_name** *(Input; optional)* Must be a scalar of type logical. If the value is FALSE, then trailing blanks in name are considered significant. Otherwise, they are not considered part of the environment variable's name.

**Example**

The following program asks for the name of an environment variable. If the environment variable exists in the program's environment, it prints out its value:

```fortran
program print_env_var
    character name*20, val*40
    integer len, status
    call getenvvar(name, val, len, status)
    write(*,*) 'The', name, 'variable points to ', val
end program print_env_var
```
write (*,*) 'enter the name of the environment variable' 
read (*,*) name

call get_environment_variable (name, val, len, status, .true.)
if (status .ge. 2) then
   write (*,*) 'get_environment_variable failed: status = ', status
   stop
end if
if (status .eq. 1) then
   write (*,*) 'env var does not exist'
   stop
end if
if (status .eq. -1) then
   write (*,*) 'env var length = ', len, ' truncated to 40'
   len = 40
end if
if (len .eq. 0) then
   write (*,*) 'env var exists but has no value'
   stop
end if
write (*,*) 'env var value = ', val (1:len)
end

When the above program is invoked, the following line is displayed:

\begin{verbatim}
enter the name of the environment variable
\end{verbatim}

The following shows an example of what could be displayed if you enter "HOME".

- On a Linux* or macOS* system:
  \begin{verbatim}
  env var value = /home/our_space/usr4
  \end{verbatim}
- On a Windows* system:
  \begin{verbatim}
  env var value = C:/
  \end{verbatim}

The following shows an example of what could be displayed if you enter "PATH".

- On a Linux or macOS* system:
  \begin{verbatim}
  env var length = 307 truncated to 40
  env var value = /site/our_space/usr4/progs/build_area
  \end{verbatim}
- On a Windows system:
  \begin{verbatim}
  env var length = 829 truncated to 40
  env var value = C:\OUR_SPACE\BUILD_AREA\build_objects\GETENVQQ
  \end{verbatim}

**GETENVQQ**

*Portability Function: Returns the value of an environment variable.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{GETENVQQ} (\text{varname}, \text{value})
\]

\begin{itemize}
  \item \textit{varname} (Input) Character*(*). Name of environment variable.
\end{itemize}
value (Output) Character*(*) Value of the specified environment variable, in uppercase.

Results

The result type is INTEGER(4). The result is the length of the string returned in value. Zero is returned if the given variable is not defined.

GETENVQQ searches the list of environment variables for an entry corresponding to varname. Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQQ uses the C runtime routine getenv and SETENVQQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system’s environment.

Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQQ.

GETENVQQ and SETENVQQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

Example

```fortran
! Program to demonstrate GETENVQQ and SETENVQQ
USE IFPORT
USE IFCORE
INTEGER(4) lenv, lval
CHARACTER(80) env, val, enval
WRITE (*,900) ' Enter environment variable name to create, & modify, or delete: '
   lenv = GETSTRQQ(env)
IF (lenv .EQ. 0) STOP
WRITE (*,900) ' Value of variable (ENTER to delete): '
   lval = GETSTRQQ(val)
IF (lval .EQ. 0) val = ' '
enval = env(1:lenv) // '=' // val(1:lval)
IF (SETENVQQ(enval)) THEN
   lval = GETENVQQ(env(1:lenv), val)
   IF (lval .EQ. 0) THEN
      WRITE (*,**) 'Can''t get environment variable'
   ELSE IF (lval .GT. LEN(val)) THEN
      WRITE (*,**) 'Buffer too small'
   ELSE
      WRITE (*,**) env(1:lenv), ': ', val(1:lval)
      WRITE (*,**) 'Length: ', lval
   END IF
ELSE
   WRITE (*,**) 'Can''t set environment variable'
```

1526
GETEXCEPTIONPTRSQQ (W*S)

**Run-Time Function:** Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.

**Module**

USE IFCORE

**Syntax**

```fortran
result = GETEXCEPTIONPTRSQQ( )
```

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the *eptr* argument to routine TRACEBACKQQ to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling GETEXCEPTIONPTRSQQ is only valid within a user-defined handler that was established with SIGNALQQ or a direct call to the C rtl signal( ) function.

For a full description of exceptions and error handling, see Compiler Reference: Error Handling.

**Example**

```fortran
PROGRAM SIGTEST
USE IFCORE
...
R3 = 0.0E0
STS = SIGNALQQ(MY_HANDLER)
! Cause a divide by zero exception
R1 = 3.0E0/R3
...
END
INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM)
USE IFCORE
...
EPTRS = GETEXCEPTIONPTRSQQ()
...
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)
...
MY_HANDLER = 1
END
```

GETCONTROLFPQQ
SIGNALFPQQ

GETEXITQQ (W*S)

QuickWin Function: Returns the setting for a QuickWin application's exit behavior.

Module
USE IFQWIN

Syntax
result = GETEXITQQ()

Results
The result type is INTEGER(4). The result is exit mode with one of the following constants (defined in IFQWIN.F90):

- QWIN$EXITPROMPT - Displays a message box that reads "Program exited with exit status n. Exit Window?", where n is the exit status from the program.
  If you choose Yes, the application closes the window and terminates. If you choose No, the dialog box disappears and you can manipulate the window as usual. You must then close the window manually.
- QWIN$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN$EXITPERSIST - Leaves the application open without displaying a message box.

The default for both QuickWin and Console Graphics applications is QWIN$EXITPROMPT.

Example

! Program to demonstrate GETEXITQQ
USE IFQWIN
INTEGER i
i = GETEXITQQ()
SELECT CASE (i)
  CASE (QWIN$EXITPROMPT)
    WRITE(*, *) "Prompt on exit."
  CASE (QWIN$EXITNOPERSIST)
    WRITE(*,*) "Exit and close."
  CASE (QWIN$EXITPERSIST)
    WRITE(*,*) "Exit and leave open."
END SELECT
END

See Also
SETEXITQQ

GETFILEINFOFPQQ

Portability Function: Returns information about the specified file. File names can contain wildcards (*) and ?.

Module
USE IFPORT
Syntax

result = GETFILEINFOQQ (files, buffer, handle)

files

(Input) Character*(*). Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).

buffer

(Output) Derived type FILE$INFO or derived type FILE$INFOI8. Information about a file that matches the search criteria in files. The derived type FILE$INFO is defined in IFPORT.F90 as follows:

<table>
<thead>
<tr>
<th>TYPE FILE$INFO</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(4) CREATION ! CREATION TIME (-1 on FAT)</td>
</tr>
<tr>
<td>INTEGER(4) LASTWRITE ! LAST WRITE TO FILE</td>
</tr>
<tr>
<td>INTEGER(4) LASTACCESS ! LAST ACCESS (-1 on FAT)</td>
</tr>
<tr>
<td>INTEGER(4) LENGTH ! LENGTH OF FILE</td>
</tr>
<tr>
<td>INTEGER(4) PERMIT ! FILE ACCESS MODE</td>
</tr>
<tr>
<td>CHARACTER(255) NAME ! FILE NAME</td>
</tr>
</tbody>
</table>

END TYPE FILE$INFO

The derived type FILE$INFOI8 is defined in IFPORT.F90 as follows:

<table>
<thead>
<tr>
<th>TYPE FILE$INFOI8</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(4) CREATION ! CREATION TIME (-1 on FAT)</td>
</tr>
<tr>
<td>INTEGER(4) LASTWRITE ! LAST WRITE TO FILE</td>
</tr>
<tr>
<td>INTEGER(4) LASTACCESS ! LAST ACCESS (-1 on FAT)</td>
</tr>
<tr>
<td>INTEGER(8) LENGTH ! LENGTH OF FILE</td>
</tr>
<tr>
<td>INTEGER(4) PERMIT ! FILE ACCESS MODE</td>
</tr>
<tr>
<td>CHARACTER(255) NAME ! FILE NAME</td>
</tr>
</tbody>
</table>

END TYPE FILE$INFOI8

handle

(Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Control mechanism. One of the following constants, defined in IFPORT.F90:

- FILE$FIRST - First matching file found.
- FILE$LAST - Previous file was the last valid file.
- FILE$ERROR - No matching file found.

Results

The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.

The derived-type element variables FILE$INFO%CREATION, FILE$INFO%LASTWRITE, and FILE$INFO %LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively.

To break the time and date into component parts, call UNPACKTIMEQQ. FILE$INFO%LENGTH contains the length of the file in bytes. FILE$INFO%PERMIT contains a set of bit flags describing access information about the file as follows:

<table>
<thead>
<tr>
<th>Bit flag</th>
<th>Access information for the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE$ARCHIVE</td>
<td>Marked as having been copied to a backup device.</td>
</tr>
</tbody>
</table>
Bit flag | Access information for the file
--- | ---
FILE$DIR | A subdirectory of the current directory. Each MS-DOS* directory contains two special files, "." and "..". These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory's parent directory.
FILE$HIDDEN | Hidden. It does not appear in the directory list you request from the command line, the Microsoft* visual development environment browser, or File Manager.
FILE$READONLY | Write-protected. You can read the file, but you cannot make changes to it.
FILE$SYSTEM | Used by the operating system.
FILE$VOLUME | A logical volume, or partition, on a physical disk drive. This type of file appears only in the root directory of a physical device.

You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILE$INFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILE$INFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERRORQQ to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

Example

```fortran
USE IFPORT
USE IFCORE
   CALL SHOWPERMISSION( )
END

! SUBROUTINE to demonstrate GETFILEINFOQQ
SUBROUTINE SHOWPERMISSION( )
USE IFPORT
CHARACTER(80) files
INTEGER(KIND=INT_PTR_KIND( )) handle
INTEGER(4) length
CHARACTER(5) permit
TYPES (FILE$INFO) info
   WRITE (*, 900) ' Enter wildcard of files to view: '
   900 FORMAT (A, 
   length = GETSTRQQ(files)
   handle = FILE$FIRST

   DO WHILE (.TRUE.)
      length = GETFILEINFOQQ(files, info, handle)
      IF ((handle .EQ. FILE$LAST) .OR. 
           (handle .EQ. FILE$ERROR)) THEN
```

1530
SELECT CASE (GETLASTERRORQQ( ))
    CASE (ERR$NOMEM)
        WRITE ('*',*) 'Out of memory'
    CASE (ERR$NOENT)
        EXIT
    CASE DEFAULT
        WRITE ('*',*) 'Invalid file or path name'
END SELECT
END IF
permit = ' ' 
IF ((info%permit .AND. FILE$HIDDEN) .NE. 0) &
    permit(1:1) = 'H'
IF ((info%permit .AND. FILE$SYSTEM) .NE. 0) &
    permit(2:2) = 'S'
IF ((info%permit .AND. FILE$READONLY) .NE. 0) &
    permit(3:3) = 'R'
IF ((info%permit .AND. FILE$ARCHIVE) .NE. 0) &
    permit(4:4) = 'A'
IF ((info%permit .AND. FILE$DIR) .NE. 0) &
    permit(5:5) = 'D'
WRITE ('*', 9000) info%name, info%length, permit
9000 FORMAT (1X, A5, I9, ' ',A6)
END DO
END SUBROUTINE

SETFILEACCESSQQ
SETFILETIMEQQ
UNPACKTIMEQQ

GETFILLMASK (W*S)

Graphics Subroutine: Returns the current pattern used to fill shapes.

Module
USE IFQWIN

Syntax
CALL GETFILLMASK (mask)

mask

(Output) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in mask, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of mask becomes the top 8 bits of the pattern, and the eighth element (byte) of mask becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of 0 are unchanged. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).
Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1) style(8), array(8)
INTEGER(2) i
style = 0
style(1) = Z'F'
style(3) = Z'F'
style(5) = Z'F'
style(7) = Z'F'
CALL SETFILLMASK (style)
...
CALL GETFILLMASK (array)
WRITE (*, *) 'Fill mask in bits: '
DO i = 1, 8
   WRITE (*, '(B8)') array(i)
END DO
END

See Also

FLOODFILLRGB
PIE
POLYGON
RECTANGLE
SETFILLMASK

GETFONTINFO (W*S)

*Graphics Function: Returns the current font characteristics.*

Module
USE IFQWIN

Syntax
result = GETFONTINFO (font)

*Output* Derived type FONTINFO. Set of characteristics of the current font. The FONTINFO derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE FONTINFO
  INTEGER(4) type   ! 1 = truetype, 0 = bit map
  INTEGER(4) ascent ! Pixel distance from top to baseline
  INTEGER(4) pixwidth ! Character width in pixels,
                     ! 0=proportional
  INTEGER(4) pixheight ! Character height in pixels
  INTEGER(4) avgwidth ! Average character width in pixels
  CHARACTER(81) filename ! File name including path
  CHARACTER(32) facename ! Font name
  LOGICAL(1) italic ! .TRUE. if current font formatted italic
  LOGICAL(1) emphasized ! .TRUE. if current font
END TYPE
```
Results

The result type is INTEGER(2). The result is zero if successful; otherwise, -1.

You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETFONTINFO.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
TYPE (FONTINFO) info
INTEGER(2)  numfonts, return, line_spacing
numfonts = INITIALIZEFONTS ( )
return = GETFONTINFO(info)
line_spacing = info%pixheight + 2
END

GETGID

Portability Function: Returns the group ID of the user of a process.

Module

USE IFPORT

Syntax

result = GETGID( )

Results

The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  Note that on Windows systems, domain accounts and local accounts can overlap.
- On Linux* and macOS* systems, this function returns the group identity for the current process.

Example

USE IFPORT
ISTAT = GETGID( )
GETGTEXTEXTENT (W*S)

**Graphics Function:** Returns the width in pixels that would be required to print a given string of text (including any trailing blanks) with OUTGTEXT using the current font.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETGTEXTEXTENT}(\text{text})
\]

\text{result} \quad \text{(Input) Character*(*). Text to be analyzed.}

**Results**

The result type is INTEGER(2). The result is the width of text in pixels if successful; otherwise, -1 (for example, if fonts have not been initialized with INITIALIZEFONTS).

This function is useful for determining the size of text that uses proportionally spaced fonts. You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETGTEXTEXTENT.

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status, pwidth
CHARACTER(80) text
status = INITIALIZEFONTS()
status = SETFONT('t''Arial''h22w10')
pwidth = GETGTEXTEXTENT('How many pixels wide is this?')
WRITE(*,*) pwidth
END
```

**See Also**

GETFONTINFO
OUTGTEXT
SETFONT
INITIALIZEFONTS
GETGTEXTROTATION

GETGTEXTROTATION (W*S)

**Graphics Function:** Returns the current orientation of the font text output by OUTGTEXT.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETGTEXTROTATION}()
\]

Intel® Fortran Compiler 19.0 Developer Guide and Reference
Results

The result type is INTEGER(4). It is the current orientation of the font text output in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 tenths of degrees (90°) is straight up, 1800 tenths of degrees (180°) is upside-down and left, 2700 tenths of degrees (270°) is straight down, and so forth.

The orientation for text output with OUTGTEXT is set with SETGTEXTRODUCTION.

Example

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER ang
REAL rang
ang = GETGTEXTRODUCTION( )
rang = FLOAT(ang)/10.0
WRITE(*,*) "Text tilt in degrees is: ", rang
END
```

SETFONT
SETGTEXTRODUCTION

GETHWNDQQ (W*S)

*QuickWin Function*: Converts a window unit number into a Windows* handle.

Module

USE IFQWIN

Syntax

```
result = GETHWNDQQ (unit)
```

(unit) INTEGER(4). The window unit number. If `unit` is set to QWIN $FRAMEWINDOW (defined in IFQWIN.F90), the handle of the frame window is returned.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a true Windows handle to the window. If `unit` is not open, it returns -1.

GETACTIVEQQ
GETUNITQQ
SETACTIVEQQ

GETIMAGE, GETIMAGE_W (W*S)

*Graphics Subroutines*: Store the screen image defined by a specified bounding rectangle.

Module

USE IFQWIN
Syntax

CALL GETIMAGE (x1,y1,x2,y2,image)
CALL GETIMAGE_W (wx1,wy1,wx2,wy2,image)

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

image (Output) INTEGER(1). Array of single-byte integers. Stored image buffer.

GETIMAGE defines the bounding rectangle in viewport-coordinate points (x1,y1) and (x2,y2).
GETIMAGE_W defines the bounding rectangle in window-coordinate points (wx1,wy1) and (wx2,wy2).

The buffer used to store the image must be large enough to hold it. You can determine the image size by calling IMAGESIZE at run time, or by using the formula described under IMAGESIZE. After you have determined the image size, you can dimension the buffer accordingly.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1), ALLOCATABLE:: buffer (:)
INTEGER(2) status, x, y, error
INTEGER(4) imsize
x = 50
y = 30
status = ELLIPSE ($GFILLINTERIOR, INT2(x-15), &
INT2(y-15), INT2(x+15), INT2(y+15))
imsize = IMAGESIZE (INT2(x-16), INT2(y-16), &
INT2(x+16), INT2(y+16))
ALLOCATE(buffer (imsize), STAT = error)
IF (error .NE. 0) THEN
  STOP 'ERROR: Insufficient memory'
END IF
CALL GETIMAGE (INT2(x-16), INT2(y-16), &
INT2(x+16), INT2(y+16), buffer)
END

See Also
IMAGESIZE
PUTIMAGE

GETLASTERROR

Portability Function: Returns the last error set.

Module
USE IFPORT

1536
Syntax

\[ \text{result} = \text{GETLASTERROR}( ) \]

Results

The result type is INTEGER(4). The result is the integer corresponding to the last run-time error value that was set.

For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining \text{errno}. Your application can then take appropriate action based upon the error number.

\[ \text{GETLASTERROR} \]

\textbf{Portability Function:} Returns the last error set by a run-time procedure.

Module

USE IFPORT

Syntax

\[ \text{result} = \text{GETLASTERROR}( ) \]

Results

The result type is INTEGER(4). The result is the most recent error code generated by a run-time procedure.

Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERROR retrieves the most recent error message. The error constants are defined in \texttt{IFPORT.F90}. The following table shows some library routines and the errors each routine produces:

<table>
<thead>
<tr>

**GETLINESTYLE (W*S)**

*Graphics Function:* Returns the current graphics line style.

**Module**

USE IFQWIN

**Syntax**

result = GETLINESTYLE( )

**Results**

The result type is INTEGER(2). The result is the current line style.
GETLINESTYLE retrieves the mask (line style) used for line drawing. The mask is a 16-bit number, where each bit represents a pixel in the line being drawn.

If a bit is 1, the corresponding pixel is colored according to the current graphics color and logical write mode; if a bit is 0, the corresponding pixel is left unchanged. The mask is repeated for the entire length of the line. The default mask is Z'FFFF' (a solid line). A dashed line can be represented by Z'FF00' (long dashes) or Z'F0F0' (short dashes).

The line style is set with SETLINESTYLE. The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

The line style retrieved by GETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE or PIE.

**Example**

```! Build as Graphics
USE IFQWIN
INTEGER(2) lstyle
lstyle = GETLINESTYLE()
WRITE (*, 100) lstyle, lstyle
100 FORMAT (1X, 'Line mask in Hex ', Z4, ' and binary ', B16)
END```

**See Also**
LINETO
POLYGON
RECTANGLE
SETCOLORRGB
SETFILLMASK
SETLINESTYLE
SETWRITEMODE

**GETLINEWIDTHQQ (W*S)**

*Graphics Function:* Gets the current line width or the line width set by the last call to SETLINEWIDTHQQ.

**Module**
USE IFQWIN

**Syntax**

```result = GETLINEWIDTHQQ( )```

**Results**

The result is of type INTEGER(4). It contains the current width of the line in pixels.

If there is no call to SETLINEWIDTHQQ in the program (or on that particular graphics window), it returns 1. (The default width of a line drawn by any graphics routine is 1 pixel.)

**See Also**
SETLINEWIDTHQQ (W*S)
GETLOG

Portability Subroutine: Returns the user's login name.

Module
USE IFPORT

Syntax
CALL GETLOG (name)  (Output) Character*(*). User's login name.

name (Output) Character*(*). User's login name.

The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it is truncated. The actual parameter corresponding to name should be long enough to hold the login name. If the supplied actual parameter is too short to hold the login name, the login name is truncated.

If the login name is shorter than the actual parameter corresponding to name, the login name is padded with blanks at the end, until it reaches the length of the actual parameter.

If the login name cannot be determined, all blanks are returned.

Example

use IFPORT
character*20 username
CALL GETLOG (username)
print *, "You logged in as ",username

GETPHYSCOORD (W*S)

Graphics Subroutine: Translates viewport coordinates to physical coordinates.

Module
USE IFQWIN

Syntax
CALL GETPHYSCOORD (x,y,s)  (Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.

x,y (Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.

s (Output) Derived type xycoord. Physical coordinates of the input viewport position. The xycoord derived type is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
    INTEGER(2) xcoord   ! x-coordinate
    INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.
Example

! Program to demonstrate GETPHYSCOORD, GETVIEWCOORD, 
! and GETWINDOWCOORD. Build as QuickWin or Standard 
! Graphics
USE IFQWIN
TYPE (xycoord) viewxy, physxy
TYPE (wxycoord) windxy
CALL SETVIEWPORT(INT2(80), INT2(50), &
    INT2(240), INT2(150))

! Get viewport equivalent of point (100, 90)
CALL GETVIEWCOORD (INT2(100), INT2(90), viewxy)

! Get physical equivalent of viewport coordinates
CALL GETPHYSCOORD (viewxy%xcoord, viewxy%ycoord, &
    physxy)

! Get physical equivalent of viewport coordinates
CALL GETWINDOWCOORD (viewxy%xcoord, viewxy%ycoord, &
    windxy)

! Write viewport coordinates
WRITE (*,*) viewxy%xcoord, viewxy%ycoord
! Write physical coordinates
WRITE (*,*) physxy%xcoord, physxy%ycoord
! Write window coordinates
WRITE (*,*) windxy%wx, windxy%wy
END

GETPID

Portability Function: Returns the process ID of the current process.

Module
USE IFPORT

Syntax
result = GETPID( )

Results
The result type is INTEGER(4). The result is the process ID number of the current process.

Example
USE IFPORT
INTEGER(4) istat
istat = GETPID()
GETPIXEL, GETPIXEL_W (W*S)

**Graphics Functions:** Return the color index of the pixel at a specified location.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = GETPIXEL (x, y)
result = GETPIXEL_W (wx, wy)
```

|x, y| (Input) INTEGER(2). Viewport coordinates for pixel position.
|---|--|
|wx, wy| (Input) REAL(8). Window coordinates for pixel position.

**Results**

The result type is INTEGER(2). The result is the pixel color index if successful; otherwise, -1 (if the pixel lies outside the clipping region, for example).

Color routines without the RGB suffix, such as GETPIXEL, use color indexes, not true color values, and limit you to colors in the palette, at most 256. To access all system colors, use SETPIXELRGB to specify an explicit Red-Green-Blue value and retrieve the value with GETPIXELRGB.

**NOTE**

The GETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetPixel.

**See Also**

GETPIXELRGB
GRSTATUS
REMAPALLPALETTERGB, REMAPPALETTERGB
SETCOLOR
GETPIXELS
SETPIXEL

GETPIXELRGB, GETPIXELRGB_W (W*S)

**Graphics Functions:** Return the Red-Green-Blue (RGB) color value of the pixel at a specified location.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = GETPIXELRGB (x,y)
result = GETPIXELRGB_W (wx,wy)
```

|x, y| (Input) INTEGER(2). Viewport coordinates for pixel position.
**wx, wy**

(Input) REAL(8). Window coordinates for pixel position.

**Results**

The result type is INTEGER(4). The result is the pixel's current RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETPIXELRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELRGB returns the true color value of the pixel, set with SETPIXELRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixel's position and the current configuration of the screen.

SETPIXELRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) pixcolor, rseed
INTEGER(2) status
REAL rnd1, rnd2
LOGICAL(4) winstat
TYPE (windowconfig) wc
CALL GETTIM (status, status, status, INT2(rseed))
CALL SEED (rseed)
CALL RANDOM (rnd1)
CALL RANDOM (rnd2)
! Get the color index of a random pixel, normalized to
! be in the window. Then set current color to that
! pixel color.
winstat = GETWINDOWCONFIG(wc)
xnum = wc%numxpixels
ynum = wc%numypixels
pixcolor = GETPIXELRGB( INT2( rnd1*xnum ), INT2( rnd2*ynum ))
status = SETCOLORRGB (pixcolor)
END
```

**See Also**

SETPIXELRGB
GETPIXELSRGB
SETPIXELSRGB
GETPIXEL, GETPIXEL_W
GETPIXELS (W*S)

**Graphics Subroutine:** Returns the color indexes of multiple pixels.

**Module**

USE IFQWIN

**Syntax**

CALL GETPIXELS (n, x, y, color)

- **n** (Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other arguments.
- **x, y** (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to get.
- **color** (Output) INTEGER(2). Array to be filled with the color indexes of the pixels at x and y.

GETPIXELS fills in the array color with color indexes of the pixels specified by the two input arrays x and y. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If the pixel is outside the clipping region, the value placed in the color array is undefined. Calls to GETPIXELS with n less than 1 are ignored. GETPIXELS is a much faster way to acquire multiple pixel color indexes than individual calls to GETPIXEL.

The range of possible pixel color index values is determined by the current video mode and palette, at most 256 colors. To access all system colors you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function such as SETPIXELSRGB and retrieve the value with GETPIXELSRGB, rather than a palette index with a non-RGB color function.

**See Also**

GETPIXELSRGB
SETPIXELSRGB
GETPIXEL
SETPIXELS

GETPIXELSRGB (W*S)

**Graphics Subroutine:** Returns the Red-Green-Blue (RGB) color values of multiple pixels.

**Module**

USE IFQWIN

**Syntax**

CALL GETPIXELSRGB (n, x, y, color)

- **n** (Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other argument arrays.
- **x, y** (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels.
color (Output) INTEGER(4). Array to be filled with RGB color values of the pixels at \(x\) and \(y\).

GETPIXELS fills in the array \(color\) with the RGB color values of the pixels specified by the two input arrays \(x\) and \(y\). These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the values you retrieve with GETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 B B B B B B G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELSRGB is a much faster way to acquire multiple pixel RGB colors than individual calls to GETPIXELRGB. GETPIXELSRGB returns an array of true color values of multiple pixels, set with SETPIXELSRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixels’ positions and the current configuration of the screen.

SETPIXELSRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) color(50), result
INTEGER(2) x(50), y(50), status
TYPE (xycoord) pos
result = SETCOLORRGB(Z'FF')
CALL MOVETO(INT2(0), INT2(0), pos)
status = LINETO(INT2(100), INT2(200))
! Get 50 pixels at line 30 in viewport
DO i = 1, 50
  x(i) = i-1
  y(i) = 30
END DO
CALL GETPIXELSRGB(300, x, y, color)
! Move down 30 pixels and redisplay pixels
DO i = 1, 50
  y(i) = y(i) + 30
END DO
CALL SETPIXELSRGB (50, x, y, color)
END
```

SETPIXELS

GETPOS, GETPOSI8

*Portability Functions:* Return the current position of a file.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{GETPOS} (\text{lunit})
\]
\[
\text{result} = \text{GETPOSI8} (\text{lunit})
\]

\text{lunit} \hspace{1cm} \text{(Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and the file must be connected.}

**Results**

The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the offset, in bytes, from the beginning of the file. If an error occurs, the result value is -1 and the following error code is returned in errno:

EINVAL: \text{lunit} is not a valid unit number, or is not open.

These functions are equivalent to FTELL, FTELLI8.

GETSTATUSFPQQ (W*S)

*Portability Subroutine:* Returns the floating-point processor status word.

**Module**

USE IFPORT

**Syntax**

CALL GETSTATUSFPQQ (status)

\text{status} \hspace{1cm} \text{(Output) INTEGER(2). Floating-point processor status word.}

The floating-point status word shows whether various floating-point exception conditions have occurred. The compiler initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>Z'003F'</td>
<td>Status Mask (set all flags to 1)</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>Z'0001'</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>Z'0002'</td>
<td>A denormal (very small number) occurred</td>
</tr>
</tbody>
</table>
Parameter name | Hex value | Description
---|---|---
FPSW$ZERODIVIDE | Z’0004’ | A divide by zero occurred
FPSW$OVERFLOW | Z’0008’ | An overflow occurred
FPSW$UNDERFLOW | Z’0010’ | An underflow occurred
FPSW$INEXACT | Z’0020’ | Inexact precision occurred

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause runtime errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

**Example**

```fortran
! Program to demonstrate GETSTATUSFPQQ
USE IFPORT
INTEGER(2) status
CALL GETSTATUSFPQQ(status)
! check for divide by zero
IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
  WRITE (*,*) 'Divide by zero occurred. Look & for NaN or signed infinity in resultant data.'
END IF
END
```

**See Also**

SETCONTROLFPQQ
GETCONTROLFPQQ
SIGNALQQ
CLEARSTATUSFPQQ

**GETSTRQQ**

Run-Time Function: Reads a character string from the keyboard using buffered input.

**Module**

USE IFCORE

**Syntax**

```
result = GETSTRQQ (buffer)
```
buffer  (Output) Character*(*) character string returned from keyboard, padded on the right with blanks.

Results
The result type is INTEGER(4). The result is the number of characters placed in buffer.
The function does not complete until you press Return or Enter.

Example

! Program to demonstrate GETSTRQQ
USE IFCORE
USE IFPORT
INTEGER(4) length, result
CHARACTER(80) prog, args
WRITE (*, '(A, ,)') ' Enter program to run: '
length = GETSTRQQ (prog)
WRITE (*, '(A, ,)') ' Enter arguments: '
length = GETSTRQQ (args)
result = RUNQQ (prog, args)
IF (result .EQ. -1) THEN
  WRITE (*,*) 'Couldn''t run program'
ELSE
  WRITE (*, '(A, Z4, A)') 'Return code : ', result, 'h'
END IF
END

GETCHARQQ
PEEKCHARQQ

GETTEXTCOLOR (W*S)

.Graphics Function: Returns the current text color index.

Module
USE IFQWIN

Syntax
result = GETTEXTCOLOR()

Results
The result type is INTEGER(2). It is the current text color index.

GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.
The default text color index is 15, which is associated with white unless the user remaps the palette.
NOTE
The GETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetTextColor.

See Also
OUTTEXT
REMAPPALETTERGB
SETCOLOR
SETTEXTCOLOR

GETTEXTCOLORRGB (W*S)

**Graphics Function:** Returns the Red-Green-Blue (RGB) value of the current text color (used with OUTTEXT, WRITE and PRINT).

Module
USE IFQWIN

Syntax

```
result = GETTEXTCOLORRGB()
```

Results

The result type is INTEGER(4). It is the RGB value of the current text color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>00000000</td>
<td>BB</td>
<td>BB</td>
<td>BB</td>
<td>BB</td>
<td>GG</td>
<td>GG</td>
<td>GG</td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFFFF' full-intensity for all three, resulting in bright white.

GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB. The RGB color value used for graphics is set and returned with SETCOLORRGB and GETCOLORRGB. SETCOLORRGB controls the color used by the graphics function OUTGTEXT, while SETTEXTCOLORRGB controls the color used by all other text output functions. The RGB background color value for both text and graphics is set and returned with SETBKCOLORRGB and GETBKCOLORRGB.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETCOLORRGB) sets the color to a color value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.
Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) oldtextc, oldbackc, temp
TYPE (rccoord) curpos
! Save color settings
oldtextc = GETTEXTCOLORRGB()
oldbackc = GETBKCOLORRGB()
CALL CLEARSSCREEN( $GCLEARSCREEN )
! Reset colors
temp = SETTEXTCOLORRGB(Z'00FFFF')  ! full red + full green
   ! = full yellow text
temp = SETBKCOLORRGB(Z'FF0000')    ! blue background
CALL SETTEXTPosition( INT2(4), INT2(15), curpos)
CALL OUTTEXT( 'Hello, world')
! Restore colors
temp = SETTEXTCOLORRGB(oldtextc)
temp = SETBKCOLORRGB(oldbackc)
END

See Also
SETTEXTCOLORRGB
GETBKCOLORRGB
GETCOLORRGB
GETTEXTCOLOR

GETTEXTPosition (W*S)

*Graphics Subroutine: Returns the current text position.*

Module
USE IFQWIN

Syntax
CALL GETTEXTPosition (s)

s (Output) Derived type rccoord. Current text position. The derived type rccoord is defined in IFQWIN.F90 as follows:

```
TYPE rccoord
   INTEGER(2) row   ! Row coordinate
   INTEGER(2) col   ! Column coordinate
END TYPE rccoord
```

The text position given by coordinates (1, 1) is defined as the upper-left corner of the text window. Text output from the OUTTEXT function (and WRITE and PRINT statements) begins at the current text position. Font text is not affected by the current text position. Graphics output, including OUTGTEXT output, begins at the current graphics output position, which is a separate position returned by GETCURRENTPOSITION.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
TYPE (rccoord) textpos
CALL GETTEXTPosition (textpos)
END
See Also
SETTEXTPOSITION
GETCURRENTPOSITION
OUTTEXT
WRITE
SETTEXTWINDOW

GETTEXTWINDOW (W*S)

*Graphics Subroutine: Finds the boundaries of the current text window.*

Module
USE IFQWIN

Syntax
CALL GETTEXTWINDOW (r1,c1,r2,c2)

r1, c1 (Output) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

r2, c2 (Output) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

Output from OUTTEXT and WRITE is limited to the text window. By default, this is the entire window, unless the text window is redefined by SETTEXTWINDOW.

The window defined by SETTEXTWINDOW has no effect on output from OUTGTEXT.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) top, left, bottom, right
DO i = 1, 10
  WRITE(*,*) "Hello, world"
END DO
! Save text window position
CALL GETTEXTWINDOW (top, left, bottom, right)
! Scroll text window down seven lines
CALL SCROLLTEXTWINDOW (INT2(-7))
! Restore text window
CALL SETTEXTWINDOW (top, left, bottom, right)
WRITE(*,*) "At beginning again"
END

See Also
GETTEXTPOSITION
OUTTEXT
WRITE
SCROLLTEXTWINDOW
SETTEXTPOSITION
SETTEXTWINDOW
WRAPON
GETTIM

Portability Subroutine: Returns the time.

Module
USE IFPORT

Syntax
CALL GETTIM (ihr, imin, isec, i100th)

*ihr* (Output) INTEGER(4) or INTEGER(2). Hour (0-23).

*imin* (Output) INTEGER(4) or INTEGER(2). Minute (0-59).

*isec* (Output) INTEGER(4) or INTEGER(2). Second (0-59).

*i100th* (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example
See the example in GETDAT.

ETIME
GMTIME
ITIME
LTIME
RTC
SECONDS portability routine
TIME portability routine
TIMEF
GETTIMEOFDAY

Portability Subroutine: Returns seconds and microseconds since 00:00 Jan 1, 1970.

Module

USE IFPORT

Syntax

CALL GETTIMEOFDAY (ret, err)

(ret) INTEGER(4). One-dimensional array with 2 elements used to contain numeric time data. The elements of ret are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ret(1)</td>
<td>Seconds</td>
</tr>
<tr>
<td>ret(2)</td>
<td>Microseconds</td>
</tr>
</tbody>
</table>

(err) INTEGER(4).

If an error occurs, err contains a value equal to -1 and array ret contains zeros.

On Windows* systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

GETUID

Portability Function: Returns the user ID of the calling process.

Module

USE IFPORT

Syntax

result = GETUID( )

Results

The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  - Note that on Windows systems, domain accounts and local accounts can overlap.
- On Linux* and macOS* systems, this function returns the user identity for the current process.

Example

USE IFPORT
integer(4) istat
istat = GETUID( )
GETUNITQQ (W*S)

QuickWin Function: Returns the unit number corresponding to the specified Windows* handle.

Module
USE IFQWIN

Syntax
result = GETUNITQQ (whandle)

whandle 
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The Windows handle to the window; this is a unique ID.

Results
The result type is INTEGER(4). The result is the unit number corresponding to the specified Windows handle. If whandle does not exist, it returns -1.

This routine is the inverse of GETHWNDQQ.

See Also
GETHWNDQQ

GETVIEWCOORD, GETVIEWCOORD_W (W*S)

Graphics Subroutines: Translate physical coordinates or window coordinates to viewport coordinates.

Module
USE IFQWIN

Syntax
CALL GETVIEWCOORD (x, y, s)
CALL GETVIEWCOORD_W (wx, wy, s)

x, y 
(Input) INTEGER(2). Physical coordinates to be converted to viewport coordinates.

wx, wy 
(Input) REAL(8). Window coordinates to be converted to viewport coordinates.

s 
(Output) Derived type xycoord. Viewport coordinates. The xycoord derived type is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord  ! x-coordinate
  INTEGER(2) ycoord  ! y-coordinate
END TYPE xycoord
```

Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Physical coordinates refer to the whole screen. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.
**Example**
See the example program in **GETPHYSCOORD**.

**See Also**
GETPHYSCOORD
GETWINDOWCOORD

**GETWINDOWCONFIG (W*S)**

*QuickWin Function:* Returns the properties of the current window.

**Module**
USE IFQWIN

**Syntax**
```
result = GETWINDOWCONFIG (wc)
```

*(Output) Derived type windowconfig. Contains window properties.*

The windowconfig derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE windowconfig
   INTEGER(2) numxpixels             ! Number of pixels on x-axis
   INTEGER(2) numypixels             ! Number of pixels on y-axis
   INTEGER(2) numtextcols            ! Number of text columns available
   INTEGER(2) numtextrows            ! Number of text rows available
   INTEGER(2) numcolors              ! Number of color indexes
   INTEGER(4) fontsize               ! Size of default font. Set to QWIN$EXTENDFONT when specifying
                                    ! extended attributes, in which case extendfontsize sets
                                    ! the font size
   CHARACTER(80) title               ! The window title
   INTEGER(2) bitsperpixel           ! The number of bits per pixel
   INTEGER(2) numvideopages          ! Unused
   INTEGER(2) mode                   ! Controls scrolling mode
   INTEGER(2) adapter                ! Unused
   INTEGER(2) monitor                ! Unused
   INTEGER(2) memory                ! Unused
   INTEGER(2) environment            ! Unused

   INTEGER(2) extendfontsize         ! Takes the same values as fontsize, when fontsize is set
   CHARACTER(32) extendfontname      ! The name of the desired font
END TYPE windowconfig
```

1555
INTEGER(4) extendfontattributes  ! Font attributes such as bold
                        ! and italic
END TYPE windowconfig

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE. (for example, if there is no active child window).

GETWINDOWCONFIG returns information about the active child window. If you have not set the window properties with SETWINDOWCONFIG, GETWINDOWCONFIG returns default window values.

A typical set of values would be 1024 x pixels, 768 y pixels, 128 text columns, 48 text rows, and a font size of 8x16 pixels. The resolution of the display and the assumed font size of 8x16 pixels generates the number of text rows and text columns. The resolution (in this case, 1024 x pixels by 768 y pixels) is the size of the virtual window. To get the size of the physical window visible on the screen, use GETWSIZEQQ. In this case, GETWSIZEQQ returned the following values: (0,0) for the x and y position of the physical window, 25 for the height or number of rows, and 71 for the width or number of columns.

The number of colors returned depends on the video drive. The window title defaults to "Graphic1" for the default window. All of these values can be changed with SETWINDOWCONFIG.

Note that the bitsperpixel field in the windowconfig derived type is an output field only, while the other fields return output values to GETWINDOWCONFIG and accept input values from SETWINDOWCONFIG.

Example

!Build as QuickWin or Standard Graphics App.
USE IFQWIN
LOGICAL(4) status
TYPE (windowconfig) wc
status = GETWINDOWCONFIG(wc)
IF(wc%numtextrows .LT. 10) THEN
  wc%numtextrows = 10
  status = SETWINDOWCONFIG(wc)
IF(.NOT. status ) THEN   ! if setwindowconfig error
  status = SETWINDOWCONFIG(wc)   ! reset
  setwindowconfig with corrected values
ENDIF
ENDIF
WRITE('**') 'Error: Cannot increase text rows to 10'
END IF
END IF
END

SETACTIVEQQ

GETWINDOWCOORD (W*S)

Graphics Subroutine: Converts viewport coordinates to window coordinates.
Module
USE IFQWIN

Syntax
CALL GETWINDOWCOORD (x, y, s)

\( x, y \)

(Input) INTEGER(2). Viewport coordinates to be converted to window coordinates.

\( s \)

(Output) Derived type \texttt{wxycoord}. Window coordinates. The \texttt{wxycoord} derived type is defined in \texttt{IFQWIN.F90} as follows:

\begin{verbatim}
  TYPE wxycoord
    REAL(8) wx   ! x-coordinate
    REAL(8) wy   ! y-coordinate
  END TYPE wxycoord
\end{verbatim}

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with \texttt{SETVIEWPORT}. Both take integer coordinate values. Window coordinates refer to a window sized with \texttt{SETWINDOW} or \texttt{SETWSIZEQQ}. Window coordinates are floating-point values and allow easy scaling of data to the window area.

Example
See the example program in \texttt{GETPHYSCOORD}.

SETWINDOW

GETWRITEMODE (W*S)

\textbf{Graphics Function:} Returns the current logical write mode, which is used when drawing lines with the \texttt{LINETO}, \texttt{POLYGON}, and \texttt{RECTANGLE} functions.

Module
USE IFQWIN

Syntax
result = GETWRITEMODE( )

Results
The result type is INTEGER(2). The result is the current write mode. Possible return values are:

- \$GPSET - Causes lines to be drawn in the current graphics color. (default)
- \$GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- \$GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- \$GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
• $GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

The default value is $GPSET. These constants are defined in IFQWIN.F90.

The write mode is set with SETWRITEMODE.

Example

! Build as QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) mode
mode = GETWRITEMODE()
END

GRSTATUS

GETWSIZEQQ (W*S)

QuickWin Function: Returns the size and position of a window.

Module
USE IFQWIN

Syntax
result = GETWSIZEQQ (unit, ireq, winfo)

unit

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5 and 6 refer to the default startup window only if you have not explicitly opened them with the OPEN statement. To access information about the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW, defined in IFQWIN.F90.

ireq

(Input) INTEGER(4). Specifies what information is obtained. The following symbolic constants, defined in IFQWIN.F90, are available:

• QWIN$SIZEMAX - Gets information about the maximum window size.
• QWIN$SIZECURR - Gets information about the current window size.
Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

```
TYPE QWININFO
  INTEGER(2) TYPE  ! request type (controls
                  !   SETWSIZEQQ)
  INTEGER(2) X     ! x coordinate for upper left
  INTEGER(2) Y     ! y coordinate for upper left
  INTEGER(2) H     ! window height
  INTEGER(2) W     ! window width
END TYPE QWININFO
```

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.
The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.
The height and width returned for a frame window reflects the size in pixels of the client area excluding any borders, menus, and status bar at the bottom of the frame window. You should adjust the values used in SETWSIZEQQ to take this into account.
The client area is the area actually available to place child windows.

SETWSIZEQQ

GMTIME
Portability Subroutine: Returns the Greenwich mean time in an array of time elements.

Module
USE IFPORT

Syntax
CALL GMTIME (stime, tarray)

stime
(Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.

tarray
(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of tarray are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tarray(1)</td>
<td>Seconds (0-61, where 60-61 can be returned for leap seconds)</td>
</tr>
<tr>
<td>tarray(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>tarray(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>Element</td>
<td>Value</td>
</tr>
<tr>
<td>----------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>tarray(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>tarray(5)</td>
<td>Month (0-11)</td>
</tr>
<tr>
<td>tarray(6)</td>
<td>Number of years since 1900</td>
</tr>
<tr>
<td>tarray(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>tarray(8)</td>
<td>Day of year (0-365)</td>
</tr>
<tr>
<td>tarray(9)</td>
<td>Daylight saving flag (0 if standard time, 1 if daylight saving time)</td>
</tr>
</tbody>
</table>

**Caution**

This subroutine may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Example**

```fortran
use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
! 00:00:00 GMT January 1, 1970
stime = time()
CALL GMTIME (stime, timearray)
print *, timearray
end
```

**See Also**

DATE_AND_TIME

**GOTO - Assigned**

**Statement:** Transfers control to the statement whose label was most recently assigned to a variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

```
GOTO var[,,] (label-list)
```

- **var**
  - Is a scalar integer variable.

- **label-list**
  - Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the assigned GO TO statement. The same label can appear more than once in this list.

The variable must have a statement label value assigned to it by an ASSIGN statement (not an arithmetic assignment statement) before the GO TO statement is executed.

If a list of labels appears, the statement label assigned to the variable is not checked against the labels in the list.
Both the assigned GO TO statement and its associated ASSIGN statement must be in the same scoping unit.

**Example**

The following example is equivalent to **GO TO 200**:  

```fortran
ASSIGN 200 TO IGO
GO TO IGO
```

The following example is equivalent to **GO TO 450**:  

```fortran
ASSIGN 450 TO IBEG
GO TO IBEG, (300,450,1000,25)
```

The following example shows an invalid use of an assigned variable:

```fortran
ASSIGN 10 TO I
J = I
GO TO J
```

In this case, variable J is not the variable assigned to, so it cannot be used in the assigned GO TO statement.

The following shows another example:

```fortran
ASSIGN 10 TO N
GOTO N
10  CONTINUE
```

The following example uses an assigned GOTO statement with a *label-list* but it is not checked against the value of VIEW:

```fortran
ASSIGN 300 TO VIEW
GOTO VIEW (100, 200, 400) ! this will go to label 300
```

**See Also**

Obsolescent Language Features in Fortran 2003 and Fortran 95  
GOTO - Computed GOTO  
GOTO - Unconditional GOTO  
Execution Control  

**GOTO - Computed**

**Statement:** Transfers control to one of a set of labeled branch target statements based on the value of an expression. It is an obsolescent feature in Fortran 95.

**Syntax**

```
GOTO (label-list) [,] expr
```

*label-list*  
Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the computed GO TO statement. (Also called the transfer list.) The same label can appear more than once in this list.

*expr*  
Is a scalar numeric expression in the range 1 to *n*, where *n* is the number of statement labels in *label-list*. If necessary, it is converted to integer data type.
When the computed GO TO statement is executed, the expression is evaluated first. The value of the expression represents the ordinal position of a label in the associated list of labels. Control is transferred to the statement identified by the label. For example, if the list contains (30,20,30,40) and the value of the expression is 2, control is transferred to the statement identified with label 20.

If the value of the expression is less than 1 or greater than the number of labels in the list, control is transferred to the next executable statement or construct following the computed GO TO statement.

**Example**

The following example shows valid computed GO TO statements:

```fortran
GO TO (12,24,36), INDEX
GO TO (320,330,340,350,360), SITU(J,K) + 1
```

The following shows another example:

```fortran
next = 1
C
C The following statement transfers control to statement 10:
C
GO TO (10, 20) next
...
10 CONTINUE
...
20 CONTINUE
```

**See Also**

Obsolescent Language Features in Fortran 2003 and Fortran 95
GOTO - Unconditional GOTO
Execution Control

**GOTO - Unconditional**

**Statement:** Transfers control to the same branch target statement every time it executes.

**Syntax**

```
GO TO label
```

- `label` is the label of a valid branch target statement in the same scoping unit as the GO TO statement.

The unconditional GO TO statement transfers control to the branch target statement identified by the specified label.

**Example**

The following are examples of GO TO statements:

```
GO TO 7734
GO TO 99999
```

The following shows another example:

```fortran
integer(2) in
10 print *, 'enter a number from one to ten: '
   read *, in
   select case (in)
   case (1:10)
      exit
```
```fortran
  case default
    print *, 'wrong entry, try again'
    goto 10
  end select
```

GOTO - Computed GOTO
Execution Control

**GRSTATUS (W*S)**

*Graphics Function: Returns the status of the most recently used graphics routine.*

**Module**

USE IFQWIN

**Syntax**

```fortran
  result = GRSTATUS()
```

**Results**

The result type is INTEGER(2). The result is the status of the most recently used graphics function.

Use GRSTATUS immediately following a call to a graphics routine to determine if errors or warnings were generated. Return values less than 0 are errors, and values greater than 0 are warnings.

The following symbolic constants are defined in the IFQWIN.F90 module file for use with GRSTATUS:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GRFILEWRITEERROR</td>
<td>Error writing bitmap file</td>
</tr>
<tr>
<td>$GRFILEOPENERROR</td>
<td>Error opening bitmap file</td>
</tr>
<tr>
<td>$GRIMAGEREADERROR</td>
<td>Error reading image</td>
</tr>
<tr>
<td>$GRBITMAPDISPLAYERROR</td>
<td>Error displaying bitmap</td>
</tr>
<tr>
<td>$GRBITMAPTOOLARGE</td>
<td>Bitmap too large</td>
</tr>
<tr>
<td>$GRIMPROPERBITMAPFORMAT</td>
<td>Improper format for bitmap file</td>
</tr>
<tr>
<td>$GRFILEREADERERROR</td>
<td>Error reading file</td>
</tr>
<tr>
<td>$GRNOBITMAPFILE</td>
<td>No bitmap file</td>
</tr>
<tr>
<td>$GRINVALIDIMAGEBUFFER</td>
<td>Image buffer data inconsistent</td>
</tr>
<tr>
<td>$GRINSUFFICIENTMEMORY</td>
<td>Not enough memory to allocate buffer or to complete a fill operation</td>
</tr>
<tr>
<td>$GRINVALIDPARAMETER</td>
<td>One or more parameters invalid</td>
</tr>
<tr>
<td>$GRMODENOTSUPPORTED</td>
<td>Requested video mode not supported</td>
</tr>
<tr>
<td>$GRERROR</td>
<td>Graphics error</td>
</tr>
<tr>
<td>$GROK</td>
<td>Success</td>
</tr>
<tr>
<td>Constant</td>
<td>Meaning</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>$GRNOOUTPUT</td>
<td>No action taken</td>
</tr>
<tr>
<td>$GRCLIPPED</td>
<td>Output was clipped to viewport</td>
</tr>
<tr>
<td>$GRPARAMETERALTERED</td>
<td>One or more input parameters was altered to be within range, or pairs of parameters were interchanged to be in the proper order</td>
</tr>
</tbody>
</table>

After a graphics call, compare the return value of GRSTATUS to $GROK. to determine if an error has occurred. For example:

```fortran
IF ( GRSTATUS .LT. $GROK ) THEN
  ! Code to handle graphics error goes here
ENDIF
```

The following routines cannot give errors, and they all set GRSTATUS to $GROK:

- DISPLAYCURSOR
- GETCOLORRGB
- GETTEXTCOLOR
- OUTTEXT
- GETBKCOLOR
- GETTEXTCOLORRGB
- WRAPON
- GETCOLORRGB
- GETTEXTPARAMETER

The following table lists some other routines with the error or warning messages they produce for GRSTATUS:

<table>
<thead>
<tr>
<th>Function</th>
<th>Possible GRSTATUS error codes</th>
<th>Possible GRSTATUS warning codes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC, ARC_W</td>
<td>$GRINVALIDPARAMETER</td>
<td>$GRNOOUTPUT</td>

H to I

HOSTNAM

**Portability Function:** Returns the current host computer name. This function can also be specified as HOSTNM.

**Module**
USE IFPORT

**Syntax**

```
result = HOSTNAM (name)
```

(name) (Output) Character*(*) . Name of the current host. Should be at least as long as MAX_HOSTNAM_LENGTH + 1. MAX_HOSTNAM_LENGTH is defined in the IFPORT module.

**Results**

The result type is INTEGER(4). The result is zero if successful. If name is not long enough to contain all of the host name, the function truncates the host name and returns -1.
Example

```fortran
use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
```

**HUGE**

*Inquiry Intrinsic Function (Generic): Returns the largest number in the model representing the same type and kind parameters as the argument.*

**Syntax**

```fortran
result = HUGE (x)
```

*Input* Must be of type integer or real; it can be scalar or array valued.

**Results**

The result is a scalar of the same type and kind parameters as `x`. If `x` is of type integer, the result has the value `r q - 1`. If `x` is of type real, the result has the value `(1 - b^{-p}) b^{e_{max}}`.

Integer parameters `r` and `q` are defined in *Model for Integer Data*; real parameters `b`, `p`, and `e_{max}` are defined in *Model for Real Data*.

**Example**

If `X` is of type REAL(4), `HUGE (X)` has the value `(1 - 2^{-24}) \times 2^{128}`.

**See Also**

TINY
Data Representation Models

**HYPOT**

*Elemental Intrinsic Function (Generic): Returns the value of the Euclidean distance of the arguments.*

**Syntax**

```fortran
result = HYPOT (x, y)
```

*Input* Must be of type real.

*Input* Must be of type real. It must be the same type and kind as `x`.

**Results**

The result type and kind are the same as `x`.

The result has a value equal to a processor-dependent approximation to the Euclidean distance, $\sqrt{x^2 + y^2}$, without undue overflow or underflow.

**Example**

HYPOT (3.0, 4.0) has the approximate value 5.0.
IACHAR

**Elemental Intrinsic Function (Generic):** Returns the position of a character in the ASCII character set, even if the processor’s default character set is different. In Intel® Fortran, IACHAR is equivalent to the ICHAR function.

**Syntax**

```fortran
result = IACHAR (c [, kind])
```

- `c` (Input) Must be of type character of length 1.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If `c` is in the ASCII collating sequence, the result is the position of `c` in that sequence and satisfies the inequality (0 .le. IACHAR(c) .le. 127).

The results must be consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE(C, D) is true, IACHAR(C) .LE. IACHAR(D) is also true.

**Example**

IACHAR ( 'Y' ) has the value 89.
IACHAR ( '%' ) has the value 37.

IALL

IALL

**Transformational Intrinsic Function (Generic):** Reduces an array with a bitwise AND operation.

**Syntax**

```fortran
result = IALL (array, dim [, mask])
result = IALL (array [, mask])
```

- `array` (Input) Must be an array of type integer.
- `dim` (Input) Must be a scalar integer with a value in the range 1 <= `dim` <= `n`, where `n` is the rank of `array`. The corresponding actual argument must not be an optional dummy argument.
- `mask` (Input; optional) Must be of type logical and conformable with `array`. 
Results

The result has the same type and kind parameters as array. It is scalar if dim does not appear or if array has rank one; otherwise, the result is an array of rank n - 1 and shape [d₁, d₂, ..., dᵣ₋₁, dᵣ₊₁, ..., dₙ] where [d₁, d₂, ..., dₙ] is the shape of array.

If array has size zero the result value is equal to NOT (INT (0, KIND (array))). Otherwise, the result of IALL (array) has a value equal to the bitwise AND of all the elements of array.

The result of IALL (array, MASK=mask) has a value equal to IALL (PACK (array, mask)).

The result of IALL (array, DIM=dim [, MASK=mask]) has a value equal to that of IALL (array [, MASK=mask]) if array has rank one. Otherwise, the value of element (s₁, s₂, ..., sᵣ₋₁, sᵣ₊₁, ..., sₙ) of the result is equal to IALL (array(s₁, s₂, ..., sᵣ₋₁, ::, sᵣ₊₁, ..., sₙ), MASK=mask(s₁, s₂, ..., sᵣ₋₁, ::, sᵣ₊₁, ..., sₙ)).

Example

IALL ([14, 13, 11]) has the value 8. IALL ([14, 13, 11], MASK=[.true., .false., .true]) has the value 10.

IANY
IPARITY

IAND

Elemental Intrinsic Function (Generic): Performs a logical AND on corresponding bits. This function can also be specified as AND.

Syntax

result = IAND (i, j)

i  (Input) Must be of type integer or logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j  (Input) Must be of type integer or logical, or a binary, octal, or hexadecimal literal constant.

If both i and j are of type integer or logical, they must have the same kind type parameter. If the kinds of i and j do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. i and j must not both be binary, octal, or hexadecimal literal constants.

Results

If both i and j are of type integer or logical, the result type and kind are the same as i. If either i or j is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining i and j bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>IAND (i, j)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIAND</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIAND</td>

<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIAND</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

1^Or HIAND.

**Example**

IAND (2, 3) has the value 2.
IAND (4, 6) has the value 4.

The following shows another example:

```fortran
INTEGER(1) i, m
INTEGER result
INTEGER(2) result2
i = 1
m = 3
result = IAND(i,m) ! returns an integer of default type
! (INTEGER(4) unless reset by user) whose
! value = 1
result2 = IAND(i,m) ! returns an INTEGER(2) with value = 1
```

IPARITY

**IANY**

*Transformational Intrinsic Function (Generic):*
Reduces an array with a bitwise OR operation.

**Syntax**

```fortran
result = IANY (array, dim [, mask])
result = IANY (array[, mask])
```

`array` (Input) Must be an array of type integer.

`dim` (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array. The corresponding actual argument must not be an optional dummy argument.

`mask` (Input; optional) Must be of type logical and conformable with array.
Results
The result has the same type and kind parameters as array. It is scalar if dim does not appear; otherwise, the result is an array of rank n - 1 and shape \([d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n]\) where \([d_1, d_2, ..., d_n]\) is the shape of array.

The result of IANY(array) is the bitwise OR of all the elements of array. If array has size zero, the result value is equal to zero.

The result of IANY(array, MASK=mask) has a value equal to IANY(PACK(array, mask)).

The result of IANY(array, DIM=dim, MASK=mask) has a value equal to that of IANY(array, MASK=mask) if array has rank one. Otherwise, the value of element \((s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)\) of the result is equal to IANY \((s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)\) if \((s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)\) has a value equal to IANY \((array(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n))\).

Example
IANY([14, 13, 8]) has the value 15. IANY([14, 13, 8], MASK=[.true., .false., .true]) has the value 14.

IALL
IPARITY

IARGC

Inquiry Intrinsic Function (Specific): Returns the index of the last command-line argument. It cannot be passed as an actual argument. This function can also be specified as IARG or NUMARG.

Syntax
result = IARGC()

Results
The result type is INTEGER(4). The result is the index of the last command-line argument, which is also the number of arguments on the command line. The command is not included in the count. For example, IARGC returns 3 for the command-line invocation of PROG1 -g -c -a.

IARGC returns a value that is 1 less than that returned by NARGS.

Example
integer(4) no_of_arguments
no_of_arguments = IARGC()
print *, 'total command line arguments are ', no_of_arguments

For a command-line invocation of PROG1 -g -c -a, the program above prints:

    total command line arguments are 3

**IBCHNG**

*Elemental Intrinsic Function (Generic):* Reverses the value of a specified bit in an integer.

**Syntax**

\[ \text{result} = \text{IBCHNG}\ (i, pos) \]

- **i**
  - (Input) Must be of type integer or of type logical (which is treated as an integer). This argument contains the bit to be reversed.

- **pos**
  - (Input) Must be of type integer. This argument is the position of the bit to be changed. The rightmost (least significant) bit of \( i \) is in position 0.

**Results**

The result type and kind are the same as \( i \). The result is equal to \( i \) with the bit in position \( pos \) reversed.

For more information, see *Bit Functions*.

**Example**

```
INTEGER J, K
J = IBCHNG(10, 2)     ! returns 14 = 1110
K = IBCHNG(10, 1)     ! returns 8 = 1000
```

**IBCLR**

*Elemental Intrinsic Function (Generic):* Clears one bit to zero.

**Syntax**

\[ \text{result} = \text{IBCLR}\ (i, pos) \]

- **i**
  - (Input) Must be of type integer or of type logical (which is treated as an integer).

- **pos**
  - (Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(\( i \)).
The rightmost (least significant) bit of \( i \) is in position 0.

**Results**

The result type and kind are the same as \( i \). The result has the value of the sequence of bits of \( i \), except that bit \( pos \) of \( i \) is set to zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**IBITS**

*Elemental Intrinsic Function (Generic): Extracts a sequence of bits (a bit field).*

**Syntax**

```
result = IBITS (i,pos,len)
```

\( i \)  
(Input) Must be of type integer.
(Input) Must be of type integer. It must not be negative and \( pos + len \) must be less than or equal to BIT_SIZE(\( i \)).

The rightmost (least significant) bit of \( i \) is in position 0.

\( len \)

(Input) Must be of type integer. It must not be negative.

**Results**

The result type and kind are the same as \( i \). The result has the value of the sequence of \( len \) bits in \( i \), beginning at \( pos \), right-adjusted and with all other bits zero.

For more information, see [Bit Functions](#).

The model for the interpretation of an integer value as a sequence of bits is shown in [Model for Bit Data](#).

ICHAR

Elemental Intrinsic Function (Generic): Returns the position of a character in the processor’s character set.

Syntax
```
result = ICHAR (c [, kind])
```

c \hspace{1cm} (Input) Must be of type character of length 1.

kind \hspace{1.2cm} (Input; optional) Must be a scalar integer constant expression.
Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer.

The result value is the position of c in the processor's character set. c is in the range zero to n - 1, where n is the number of characters in the character set.

For any characters C and D (capable of representation in the processor), C .LE. D is true only if ICHAR(C) .LE. ICHAR(D) is true, and C .EQ. D is true only if ICHAR(C) .EQ. ICHAR(D) is true.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<td>INTEGER(2)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

¹This specific function cannot be passed as an actual argument.

Example
ICHAR ( 'W' ) has the value 87.
ICHAR ( '#' ) has the value 35.

IDATE Intrinsic Procedure
Intrinsic Subroutine (Generic): Returns three integer values representing the current month, day, and year. IDATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL IDATE (i, j, k)

i (Output) Must be of type integer. It is the current month.

j (Output) Must be of type integer with the same kind type parameter as i. It is the current day.

k (Output) Must be of type integer with the same kind type parameter as i. It is the current year.

The current month is returned in i; the current day in j. The last two digits of the current year are returned in k.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.
Example
If the current date is September 16, 1999, the values of the integer variables upon return are: $I = 9$, $J = 16$, and $K = 99$.

See Also
DATE intrinsic procedure

DATE_AND_TIME
GETDAT

IDATE portability routine

IDATE Portability Routine
Portability Subroutine: Returns the month, day, and year of the current system. IDATE can be used as a portability subroutine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module
USE IFPORT

Syntax
CALL IDATE (i, j, k)
-or-
CALL IDATE (iarray)

i (Output) INTEGER(4). Is the current system month.

j (Output) INTEGER(4). Is the current system day.

k (Output) INTEGER(4). Is the current system year as an offset from 1900.

iarray (Output) INTEGER(4). Is a three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is greater than or equal to 1969 and is returned as 2 digits.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
Consider the following:

```
use IFPORT
integer(4) imonth, iday, iyear, darray(3)
! If the date is July 11, 1999:
CALL IDATE(IMONTH, IDAY, IYEAR)
```
IDATE intrinsic procedure

IDATE4
Portability Subroutine: Returns the month, day, and year of the current system.

Module
USE IFPORT

Syntax
CALL IDATE4 (i,j,k)
-or-
CALL IDATE4 (iarray)

i (Output) INTEGER(4). The current system month.

j (Output) INTEGER(4). The current system day.

k (Output) INTEGER(4). The current system year as an offset from 1900.

iarray (Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

IDENT
General Compiler Directive: Specifies a string that identifies an object module. The compiler places the string in the identification field of an object module when it generates the module for each source program unit.

Syntax
!DIR$ IDENT string

string Is a character constant containing printable characters. The number of characters is limited by the length of the source line.
Only the first IDENT directive is effective; the compiler ignores any additional IDENT directives in a program unit or module.

See Also
General Compiler Directives
Syntax Rules for Compiler Directives

**IDFLOAT**

*Portability Function: Converts an INTEGER(4) argument to double-precision real type.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{IDFLOAT} (i)
\]

\[i\] (Input) Must be of type INTEGER(4).

**Results**

The result type is double-precision real (REAL(8) or REAL*8).

See Also
DFLOAT

**IEEE_CLASS**

*Elemental Module Intrinsic Function (Generic): Returns the IEEE class.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
\text{result} = \text{IEEE_CLASS} (x)
\]

\[x\] (Input) Must be of type REAL.

**Results**

The result is of type TYPE(IEEE_CLASS_TYPE). The result value is one of the following:

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_QUIET_NAN</td>
<td>IEEE_POSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_POSITIVE_INF</td>
<td>IEEE_NEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_NEGATIVE_INF</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

IEEE_CLASS does not return IEEE_OTHER_VALUE in Intel® Fortran.
Example
IEEE_CLASS(1.0) has the value IEEE_POSITIVE_NORMAL.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_COPY_SIGN

Elemental Module Intrinsic Function (Generic):
Returns an argument with a copied sign. This is equivalent to the IEEE copysign function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_COPY_SIGN (x, y)

x          (Input) Must be of type REAL.
y          (Input) Must be of type REAL.

Results
The result type and kind are the same as x. The result has the value x with the sign of y. This is true even for IEEE special values, such as NaN or infinity.
The flags information is returned as a set of 1-bit flags.

Example
The value of IEEE_COPY_SIGN (X, 3.0) is ABS (X), even when X is NaN.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_FLAGS

Portability Function: Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of IEEE Standard 754-1985 arithmetic in a Fortran program.

Module
USE IFPORT

Syntax
result = IEEE_FLAGS (action, mode, in, out)

action          (Input) Character*(*). One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.

(Input) Character*(*) (Input) Character*(*). One of the following literal values: 'direction', 'precision', or 'exception'.

(Input) Character*(*) (Input) Character*(*). One of the following literal values: 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive', 'extended', 'double', 'single', or ' ', which represents an unused (null) value.

(Output) Must be at least CHARACTER*9. One of the literal values listed for in.

The descriptions for the values allowed for in and out can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nearest'</td>
<td>Rounding direction flags</td>
</tr>
<tr>
<td>'tozero'</td>
<td></td>
</tr>
<tr>
<td>'negative'</td>
<td>Rounding precision flags</td>
</tr>
<tr>
<td>'positive'</td>
<td></td>
</tr>
<tr>
<td>'single'</td>
<td></td>
</tr>
<tr>
<td>'double'</td>
<td></td>
</tr>
<tr>
<td>'extended'</td>
<td></td>
</tr>
<tr>
<td>'inexact'</td>
<td>Math exception flags</td>
</tr>
<tr>
<td>'underflow'</td>
<td></td>
</tr>
<tr>
<td>'overflow'</td>
<td></td>
</tr>
<tr>
<td>'division'</td>
<td></td>
</tr>
<tr>
<td>'invalid'</td>
<td>All math exception flags above</td>
</tr>
<tr>
<td>'all'</td>
<td>The math exception flags:</td>
</tr>
<tr>
<td>'common'</td>
<td>'invalid', 'division', 'overflow',</td>
</tr>
<tr>
<td></td>
<td>and 'underflow'</td>
</tr>
</tbody>
</table>

The values for in and out depend on the action and mode they are used with. The interaction of the parameters can be summarized as follows:

<table>
<thead>
<tr>
<th>Value of action</th>
<th>Value of mode</th>
<th>Value of in</th>
<th>Value of out</th>
<th>Functionality and return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>

<td>-------------</td>
<td>--------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>CLEAR</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears the mode. Sets rounding to 'nearest'. Returns 0 if successful.</td>
</tr>
<tr>
<td></td>
<td>'exception'</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Null (' ')</td>
<td>Clears the mode. Returns 0 if successful.</td>
</tr>
<tr>
<td></td>
<td>'precision'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears the mode. Sets precision to 'double' (W<em>S) or 'extended' (L</em>X, M*X). Returns 0 if successful.</td>
</tr>
<tr>
<td>CLEARALL</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears all flags. Sets rounding to 'nearest', sets precision to 'double' (W<em>S) or 'extended' (L</em>X, M*X), and sets all exception flags to 0. Returns 0 if successful.</td>
</tr>
</tbody>
</table>

**Results**

IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.
The flags information is returned as a set of 1-bit flags.

**Example**

The following example gets the highest priority exception that has a flag raised. It passes the input argument *in* as a null string:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)
```

The following example sets the rounding direction to the default ('nearest'):

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out, in
iflag = ieee_flags('clear','direction', '', '' )
```

The following example clears all exceptions:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear','exception', 'all', '' )
```

The following example restores default direction and precision settings, and sets all exception flags to 0:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '')
```

The following example detects an underflow exception:

```fortran
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'
```

### IEEE_GET_FLAG

**Elemental Module Intrinsic Subroutine (Generic):** Returns whether an exception flag is signaling.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_GET_FLAG (flag, flag_value)
flag

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of
the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

flag_value

(Output) Must be of type default logical. If the exception in 'flag' is
signaling, the result is true; otherwise, false.

Example
Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL ON
...
CALL IEEE_GET_FLAG(IEEE_INVALID, ON)

If flag IEEE_INVALID is signaling, the value of ON is true; if it is quiet, the value of ON is false.

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_HALTING_MODE

Elemental Module Intrinsic Subroutine
(Generic): Stores the halting mode for an exception.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_GET_HALTING_MODE (flag, halting)

flag

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of
the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

halting

(Output) Must be of type default logical. If the exception in "flag"
causes halting, the result is true; otherwise, false.

Example
Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)   ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT) ! Restores halting

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
**IEEE_GET_ROUNDING_MODE**  
**Intrinsic Module Subroutine (Generic):** Stores the current IEEE rounding mode. This is an impure subroutine.

**Module**  
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**  
CALL IEEE_GET_ROUNDING_MODE (round_value)

round_value (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It returns one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, or IEEE_UP; otherwise, IEEE_OTHER.

The result can only be used if IEEE_SET_ROUNDING_MODE is invoked.

**Example**  
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC  
TYPE(IEEE_ROUND_TYPE) ROUND  
...
CALL IEEE_GET_ROUNDING_MODE(ROUND) ! Stores the rounding mode  
CALL IEEE_SET_ROUNDING_MODE(IEEE_UP) ! Resets the rounding mode  
...
CALL IEEE_SET_ROUNDING_MODE(VALUE) ! Restores the previous rounding mode
```

**See Also**  
IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_GET_STATUS**  
**Intrinsic Module Subroutine (Generic):** Stores the current state of the floating-point environment. This is an impure subroutine.

**Module**  
USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**  
CALL IEEE_GET_STATUS (status_value)

status_value (Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). It stores the floating-point status. The result can only be used if IEEE_SET_STATUS is invoked.
Example
Consider the following:

```fortran
USE, INTRINIC :: IEEE_EXCEPTIONS    ! Can also use IEEE_ARITHMETIC
TYPE(IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS(STATUS)   ! Stores the floating-point status
CALL IEEE_SET_FLAG(IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS(STATUS)   ! Restores the floating-point status
```

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_GET_UNDERFLOW_MODE**

*Intrinsic Module Subroutine (Generic):* Stores the current underflow mode. This is an impure subroutine.

Module
USE, INTRINIC :: IEEE_ARITHMETIC

Syntax
```
CALL IEEE_GET_UNDERFLOW_MODE (gradual)
```

- **gradual**  
  (Output) Must be default logical scalar.

  The result is true if the current underflow mode is gradual (IEEE denormals are allowed) and false if the current underflow mode is abrupt (underflowed results are set to zero).

Example
Consider the following:

```fortran
USE, INTRINIC :: IEEE_EXCEPTIONS
LOGICAL GRAD
...
CALL IEEE_GET_UNDERFLOW_MODE(GRAD)
IF (GRAD) THEN ! underflows are gradual
  ...
ELSE ! underflows are abrupt
  ...
END IF
```

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_HANDLER**

*Portability Function:* Establishes a handler for IEEE exceptions.

Module
USE IFPORT
Syntax

result = IEEE_HANDLER (action, exception, handler)

action (Input) Character*(*). One of the following literal IEEE actions: 'GET', 'SET', or 'CLEAR'. For more details on these actions, see IEEE_FLAGS.

exception (Input) Character*(*). One of the following literal IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all' (which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division'). The flags 'all' or 'common' should only be used for actions SET or CLEAR.

handler (Input) The address of an external signal-handling routine.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appear in the following table (defined in the IFPORT module):

<table>
<thead>
<tr>
<th>Constant Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>Invalid operation</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>Divide-by-zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>Numeric overflow</td>
</tr>
<tr>
<td>FPE$UNDERFLOW</td>
<td>Numeric underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>Inexact result (precision)</td>
</tr>
</tbody>
</table>

'GET' actions return the location of the current handler routine for exception cast to an INTEGER.

Example

The following example creates a handler routine and sets it to trap divide-by-zero:

```fortran
PROGRAM TEST_IEEE
  REAL :: X, Y, Z
  CALL FPE_SETUP
  X = 0.
  Y = 1.
  Z = Y / X
END PROGRAM
SUBROUTINE FPE_SETUP
  USE IFPORT
  IMPLICIT NONE
  INTERFACE
    SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
      INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
    END SUBROUTINE
  END INTERFACE
  INTEGER IR
  IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE
```
END SUBROUTINE FPE_SETUP
SUBROUTINE FPE_HANDLER(SIG, CODE)
  USE IFPORT
  IMPLICIT NONE
  INTEGER SIG, CODE
  IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *, 'Occurred divide by zero.'
  CALL ABORT
END SUBROUTINE FPE_HANDLER

IEEE_FLAGS

IEEE_ISFINITE

Elemental Module Intrinsic Function (Generic):

Returns whether an IEEE value is finite.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_ISFINITE (x)

x  (Input) Must be of type REAL.

Results
The result type is default logical. The result has the value true if the value of x is finite; otherwise, false.

An IEEE value is finite if IEEE_CLASS(x) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_POSITIVE_NORMAL</th>
<th>IEEE_NEGATIVE_DENORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_NORMAL</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_DENORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

Example
IEEE_ISFINITE (-2.0) has the value true.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_ISNAN

Elemental Module Intrinsic Function (Generic):

Returns whether an IEEE value is Not-a-Number (NaN).

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_ISNAN (x)
\( x \)  
(Input) Must be of type REAL.

**Results**
The result type is default logical. The result has the value true if the value of \( x \) is NaN; otherwise, false.

**Example**
IEEE_IS_NAN (SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

**See Also**
IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_IS_NEGATIVE**

*Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is negative.*

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
result = IEEE_IS_NEGATIVE (x)  
\( x \)  
(Input) Must be of type REAL.

**Results**
The result type is default logical. The result has the value true if the value of \( x \) is negative; otherwise, false.  
An IEEE value is negative if IEEE_CLASS(x) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_NEGATIVE_NORMAL</th>
<th>IEEE_NEGATIVE_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_DENORMAL</td>
<td>IEEE_NEGATIVE_INF</td>
</tr>
</tbody>
</table>

**Example**
IEEE_IS_NEGATIVE (2.0) has the value false.

**See Also**
IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_IS_NORMAL**

*Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is normal.*

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
result = IEEE_IS_NORMAL (x)
\( x \)  
(Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if the value of \( x \) is normal; otherwise, false.

An IEEE value is normal if IEEE_CLASS(\( x \)) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_POSITIVE_NORMAL</th>
<th>IEEE_POSITIVE_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

**Example**

IEEE_IS_NORMAL (SQRT(-2.0)) has the value false if IEEE_SUPPORT_SQRT (-2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_LOGB**

**Elemental Module Intrinsic Function (Generic):**  
Returns a floating-point value equal to the unbiased exponent of the argument. This is equivalent to the IEEE logb function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
\text{result} = \text{IEEE_LOGB} (x)
\]

\( x \)  
(Input) Must be of type REAL.

**Results**

The result type and kind are the same as \( x \). The result has the value of the unbiased exponent of \( x \) if the value of \( x \) is not zero, infinity, or NaN. The value of the result is equal to EXPONENT(\( x \)) - 1.

If \( x \) is equal to 0, the result is -infinity if IEEE_SUPPORT_INF(\( x \)) is true; otherwise, -HUGE(\( x \)). In either case, the IEEE_DIVIDE_BY_ZERO exception is signaled.

**Example**

IEEE_LOGB (3.4) has the value 1.0; IEEE_LOGB (4.0) has the value 2.0.

**See Also**

IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_NEXT_AFTER**

**Elemental Module Intrinsic Function (Generic):**

Returns the next representable value after \( X \) toward \( Y \). This is equivalent to the IEEE nextafter function.
Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_NEXT_AFTER (x, y)

x  
  (Input) Must be of type REAL.

y  
  (Input) Must be of type REAL.

Results
The result type and kind are the same as x. If x is equal to y, the result is x; no exception is signaled. If x is not equal to y, the result has the value of the next representable neighbor of x toward y. The neighbors of zero (of either sign) are both nonzero.

The following exceptions are signaled under certain cases:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Signalled</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_OVERFLOW</td>
<td>When X is finite but IEEE_NEXT_AFTER(X,Y) is infinite</td>
</tr>
<tr>
<td>IEEE_UNDERFLOW</td>
<td>When IEEE_NEXT_AFTER(X,Y) is denormalized</td>
</tr>
<tr>
<td>IEEE_INEXACT</td>
<td>In both the above cases</td>
</tr>
</tbody>
</table>

Example
The value of IEEE_NEXT_AFTER (2.0, 3.0) is 2.0 + EPSILON (X).

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REM
Elemental Module Intrinsic Function (Generic):
Returns the result of an exact remainder operation.
This is equivalent to the IEEE remainder function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_REM (x, y)

x  
  (Input) Must be of type REAL.

y  
  (Input) Must be of type REAL with a radix that is the same as that of x.

Results
The result type is real with the kind type parameter of whichever argument has greater precision.

Regardless of the rounding mode, the result value is x - y*N, where N is the integer nearest to the value x / y. If |N – x / y | = 1/2, N is even. If the result value is zero, the sign is the same as x.
Example
The value of IEEE.Rem (5.0,4.0) is 1.0; the value of IEEE.Rem (2.0,1.0) is 0.0; the value of IEEE.Rem (3.0,2.0) is -1.0.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_RINT
Elemental Module Intrinsic Function (Generic):
Returns an integer value rounded according to the current rounding mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_RINT (x)

x (Input) Must be of type REAL.

Results
The result type and kind are the same as x. The value of the result is x rounded to an integer according to the current rounding mode. If the result value is zero, the sign is the same as x.

Example
If the current rounding mode is IEEE_UP, the value of IEEE_RINT (2.2) is 3.0.
If the current rounding mode is IEEE_NEAREST, the value of IEEE_RINT (2.2) is 2.0.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SCALB
Elemental Module Intrinsic Function (Generic):
Returns the exponent of a radix-independent floating-point number. This is equivalent to the IEEE scalb function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SCALB (x,i)

x (Input) Must be of type REAL.
i (Input) Must be of type INTEGER.
Results
The result type and kind are the same as \( x \). The result is \( x \) multiplied by \( 2^{*i} \), if the value can be represented as a normal number.

If \( x \ (2^{*i}) \) is too small and there is a loss of accuracy, the exception IEEE_UNDERFLOW is signaled. The result value is the nearest number that can be represented with the same sign as \( x \).

If \( x \) is finite and \( x \ (2^{*i}) \) is too large, an IEEE_OVERFLOW exception occurs. If IEEE_SUPPORT_INF \( (x) \) is true, the result value is infinity with the same sign as \( x \); otherwise, the result value is SIGN (HUGE\( (x) \), \( x \)).

If \( x \) is infinite, the result is the same as \( x \); no exception is signaled.

Example
The value of IEEE_SCALB \( (2.0,3) \) is 16.0.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SELECTED_REAL_KIND

Transformational Module Intrinsic Function (Generic): Returns the value of the kind parameter of an IEEE REAL data type.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
\[
\text{result} = \text{IEEE_SELECTED_REAL_KIND} \ (\{p\},\{r\},\{\text{radix}\})
\]

\( p \)  (Input; optional) Must be scalar and of type INTEGER.

\( r \)  (Input; optional) Must be scalar and of type INTEGER.

\( \text{radix} \)  (Input; optional) Must be scalar and of type INTEGER.

At least argument \( p \) or \( r \) must be present.

Results
If \( p \) or \( r \) is absent, the result is as if the argument was present with the value zero. If \( \text{radix} \) is absent, there is no requirement on the radix of the selected kind.

The result is a scalar of type default integer. The result has a value equal to a value of the kind parameter of an IEEE real data type with decimal precision, as returned by the function PRECISION, of at least \( p \) digits, a decimal exponent range, as returned by the function RANGE, of at least \( r \), and a \( \text{radix} \), as returned by the function RADIX, of \( \text{radix} \).

If no such kind type parameter is available on the processor, the result is as follows:

- -1 if the precision is not available
- -2 if the exponent range is not available
- -3 if neither the precision nor the exponent range is available
- -4 if one but not both of the precision and the exponent range is available
- -5 if the \( \text{radix} \) is not available

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision.
Example
IEEE_SELECTED_REAL_KIND (6, 70, 2) = 8.

SELECTED_REAL_KIND
Model for Real Data
  for information on the real model.

IEEE_SET_FLAG

Elemental Module Intrinsic Function (Generic):
Assigns a value to an exception flag. This is a pure subroutine.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_SET_FLAG (flag, flag_value)

flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
  IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
  IEEE_OVERFLOW, or IEEE_UNDERFLOW.

flag_value (Output) Must be of type default logical. If it has the value true, the exception in 'flag' is set to signal; otherwise, the exception is set to be quiet.

Example
Consider the following:
USE, INTRINSIC :: IEEE_EXCEPTIONS   ! Can also use module IEEE_ARITHMETIC
...
CALL IEEE_SET_FLAG (IEEE_INVALID, .TRUE.) ! Sets the IEEE_INVALID flag to signal

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_HALTING_MODE

Elemental Module Intrinsic Function (Generic):
Controls halting or continuation after an exception.
This is a pure subroutine.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_SET_HALTING_MODE (flag, halting)
flag  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW

halting  (Input) Must be scalar and of type default logical. If the value is true, the exception specified in FLAG will cause halting; otherwise, execution will continue after this exception.

Example
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting
```

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SET_ROUNDING_MODE**

*Intrinsic Module Subroutine (Generic):* Sets the IEEE rounding mode. This is an impure subroutine.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
CALL IEEE_SET_ROUNDING_MODE (round_value)

round_value  (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It specifies one of the following IEEE floating-point rounding values:
IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, IEEE_UP, or IEEE_OTHER.

Example
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE (IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE (ROUND)  ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE (IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE (VALUE)  ! Restores the previous rounding mode
```
IEEE_SET_STATUS

_Intrinsic Module Subroutine (Generic): Restores the state of the floating-point environment. This is an impure subroutine._

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_STATUS (status_value)

*status_value* (Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). Its value must be set in a previous invocation of IEEE_GET_STATUS.

**Example**

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS (STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG (IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS (STATUS) ! Restores the floating-point status
```

IEEE_SET_UNDERFLOW_MODE

_Intrinsic Module Subroutine (Generic): Sets the current underflow mode. This is an impure subroutine._

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

CALL IEEE_SET_UNDERFLOW_MODE (gradual)

*gradual* (Input) Must be scalar and of type default logical. If it is true, the current underflow mode is set to gradual underflow (denormals may be produced on underflow). If it is false, the current underflow mode is set to abrupt (underflowed results are set to zero).

**Example**

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL :: SG
...
CALL IEEE_GET_UNDERFLOW_MODE (SG) ! Stores underflow mode
CALL IEEE_SET_UNDERFLOW_MODE (.FALSE.) ! Resets underflow mode
...
! Abrupt underflows happens here
CALL IEEE_SET_UNDERFLOW_MODE (SG) ! Restores previous undeflow mode
```
**IEEE_SUPPORT_DATATYPE**

*Inquiry Module Intrinsic Function (Generic):*

Returns whether the processor supports IEEE arithmetic.

**Module**

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
```

**Syntax**

```fortran
result = IEEE_SUPPORT_DATATYPE ([x])
```

- `x` (Input; optional) Must be scalar and of type REAL.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor supports IEEE arithmetic for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor supports IEEE arithmetic for real variables of the same kind type parameter as `x`; otherwise, false.

If real values are implemented according to the IEEE standard except that underflowed values flush to zero (abrupt) instead of being denormal.

**Example**

`IEEE_SUPPORT_DATATYPE (3.0)` has the value true.

**See Also**

- IEEE_ARITHMETIC Intrinsic Module
- IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SUPPORT_DENORMAL**

*Inquiry Module Intrinsic Function (Generic):*

Returns whether the processor supports IEEE denormalized numbers.

**Module**

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
```

**Syntax**

```fortran
result = IEEE_SUPPORT_DENORMAL ([x])
```

- `x` (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for real variables of the same kind type parameter as `x`; otherwise, false.
IEEE_SUPPORT_DENORMAL() and IEEE_SUPPORT_DENORMAL(0.0_16) return .TRUE. even though Intel® Fortran's implementation does not signal when an underflow results in a REAL(16) denormal value. Intel® Fortran’s implementation does signal when an underflow results in a REAL(16) zero.

**Example**

IEEE_SUPPORT_DENORMAL() has the value true if IEEE denormalized numbers are supported for all real types.

**See Also**

### IEEE_SUPPORT_DIVIDE

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE divide.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_DIVIDE ( [x] )
```

*x*  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for real variables of the same kind type parameter as *x*; otherwise, false.

**Example**

IEEE_SUPPORT_DIVIDE() has the value true if IEEE divide is supported for all real types.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

### IEEE_SUPPORT_FLAG

*Transformational Module Intrinsic Function (Generic):*  
*Returns whether the processor supports IEEE exceptions.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

```fortran
result = IEEE_SUPPORT_FLAG ( flag [, x] )
```

Language Reference 1599
**flag**

(Input) Must be a scalar of type TYPE (IEEE_FLAG_TYPE). Its value is one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

**x**

(Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports detection of the exception specified by "flag" for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports detection of the exception specified by "flag" for real variables of the same kind type parameter as x; otherwise, false.

**Example**

IEEE_SUPPORT_FLAG (IEEE_UNDERFLOW) has the value true if the IEEE_UNDERFLOW exception is supported for all real types.

**See Also**

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

---

**IEEE_SUPPORT_HALTING**

_Documentation for TRANSFORMATIONAL MODULE INTRINSIC FUNCTION (Generic): Returns whether the processor supports IEEE halting._

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

result = IEEE_SUPPORT_HALTING(flag)

**flag**

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

**Results**

The result is a scalar of type default logical. The result has the value true if the processor supports the ability to control halting after the exception specified by "flag"; otherwise, false.

**Example**

IEEE_SUPPORT_HALTING (IEEE_UNDERFLOW) has the value true if halting is supported after an IEEE_UNDERFLOW exception.

**See Also**

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
IEEE_SUPPORT_INF

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE infinities.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_INF ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports IEEE infinities (positive and negative) for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports IEEE infinities for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_INF( ) has the value true if IEEE infinities are supported for all real types.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_IO

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE base conversion rounding during formatted I/O.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_IO ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports base conversion rounding during formatted input and output for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports base conversion rounding during formatted input and output for real variables of the same kind type parameter as x; otherwise, false.
The base conversion rounding applies to modes IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.
Example
IEEE_SUPPORT_IO ( ) has the value true if base conversion rounding is supported for all real types during formatted I/O.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_NAN
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE Not-a-Number feature.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_NAN ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports NaNs for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports NaNs for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_NAN () has the value true if IEEE NaNs are supported for all real types.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE-support_rounding
Transformational Module Intrinsic Function (Generic): Returns whether the processor supports IEEE rounding mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_ROUNDING (round_value [, x])

round_value (Input) Must be of type TYPE(IEEE_ROUND_TYPE). It specifies one of the following rounding modes:
IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.
x

(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports the rounding mode specified by round_value for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports the rounding mode specified by round_value for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_ROUNDING (IEEE_DOWN) has the value true if rounding mode IEEE_DOWN is supported for all real types.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_SQRT

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE SQRT (square root).

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_SQRT ( [x] )

x

(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor implements SQRT in accord with the IEEE standard for all real values; otherwise, false.
If x is specified, the result has the value true if the processor implements SQRT in accord with the IEEE standard for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_SQRT ( ) has the value true if IEEE SQRT is supported for all real types.

See Also
IEEE_ARITHMETIC Intrinsic Module

IEEE_SUPPORT_STANDARD

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE features defined in the standard.
Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_STANDARD ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. The result has the value true if the results of all the following functions are true (x can be omitted):

- IEEE_SUPPORT_DATATYPE([x])
- IEEE_SUPPORT_DENORMAL([x])
- IEEE_SUPPORT_DIVIDE([x])
- IEEE_SUPPORT_FLAG(flag [, x])\(^1\)
- IEEE_SUPPORT_HALTING(flag)\(^1\)
- IEEE_SUPPORT_INF([x])
- IEEE_SUPPORT_NAN([x])
- IEEE_SUPPORT_ROUNDING(round_value [, x])\(^2\)
- IEEE_SUPPORT_SQRT([x])

\(^1\) "flag" must be a valid value
\(^2\) "round_value" must be a valid value

Otherwise, the result has the value, false.

Example
IEEE_SUPPORT_STANDARD () has the value false if both IEEE and non-IEEE real kinds are supported.

IEEE_SUPPORT_UNDERFLOW_CONTROL
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports the ability to control the underflow mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_UNDERFLOW_CONTROL ([x])
Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports controlling the underflow mode for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports controlling the underflow mode for real variables of the same kind type parameter as x; otherwise, false.

**Example**

IEEE_SUPPORT_UNDERFLOW_CONTROL () has the value true if controlling the underflow mode is supported for all real types.

---

**IEEE_UNORDERED**

**Elemental Module Intrinsic Function (Generic):**

Returns whether one or more of the arguments is Not-a-Number (NaN). This is equivalent to the IEEE unordered function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
result = IEEE_UNORDERED (x,y)
\]

- \(x\) (Input) Must be of type REAL.
- \(y\) (Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if \(x\) or \(y\) is a NaN, or both are NaNs; otherwise, false.

**Example**

IEEE_UNORDERED (0.0, SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

---

**IEEE_VALUE**

**Elemental Module Intrinsic Function (Generic):**

Creates an IEEE value.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC
**Syntax**

result = IEEE_VALUE (x, class)

- **x** (Input) Must be of type REAL.
- **class** (Input) Must be of type TYPE (IEEE_CLASS_TYPE). Its value is one of the following:

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEEQUIET_NAN</td>
<td>IEEEPOSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEEPOSITIVE_INF</td>
<td>IEEENEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEENEGATIVE_INF</td>
<td>IEEEPOSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEEPOSITIVE_NORMAL</td>
<td>IEEENEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

**Results**

The result type and kind are the same as x. The result value is an IEEE value as specified by "class".

When IEEE_VALUE returns a signaling NaN, it is processor dependent whether or not invalid is signaled and processor dependent whether or not the signaling NaN is converted to a quiet NaN.

**Example**

IEEE_VALUE (1.0,IEEE_POSITIVE_INF) has the value +infinity.

**See Also**
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEOR**

*Elemental Intrinsic Function (Generic): Performs an exclusive OR on corresponding bits. This function can also be specified as XOR or IXOR.*

**Syntax**

result = IEOR (i,j)

- **i** (Input) Must be of type integer, logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.
- **j** (Input) Must be of type integer or logical, or a binary, octal, or hexadecimal literal constant.

If both i and j are of type integer or logical, they must have the same kind type parameter. If the kinds of i and j do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. i and j must not both be binary, octal, or hexadecimal literal constants.

**Results**

The result is the same as i if i is of type integer or logical; otherwise, the result is the same as j. If either i or j is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.
The result value is derived by combining $i$ and $j$ bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>$i$</th>
<th>$j$</th>
<th>$IEOR\ (i, j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIEOR$^1$</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIEOR$^2$</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIEOR$^3$</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIEOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

$^1$Or BIXOR
$^2$Or HIEOR, HIXOR, or IIIXOR
$^3$Or JIXOR

**Example**

IEOR (12, 7) has the value 11; binary 1100 exclusive OR with binary 0111 is binary 1011.

The following shows another example:

```
INTEGER I
I = IEOR(240, 90)  ! returns 170
     ! IEOR (B'11110000', B'1011010') == B'10101010'
```

The following shows an example using alternate option XOR:

```
INTEGER i, j, k
i = 3             ! B'011'
j = 5             ! B'101'
k = XOR(i, j)     ! returns 6 = B'110'
```

**IERRNO**

*Portability Function:* Returns the number of the last detected error from any routines in the IFPORT module that return error codes.

**Module**

USE IFPORT
Syntax

\texttt{result = IERRNO( )}

Results

The result type is \texttt{INTEGER(4)}. The result value is the last error code from any portability routines that return error codes. These error codes are analogous to \texttt{errno} on a Linux* or macOS* system. The module \texttt{IFPORT.F90} provides parameter definitions for the following \texttt{errno} names (typically found in \texttt{errno.h} on Linux systems):

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>1</td>
<td>Insufficient permission for operation</td>
</tr>
<tr>
<td>ENOENT</td>
<td>2</td>
<td>No such file or directory</td>
</tr>
<tr>
<td>ESRCH</td>
<td>3</td>
<td>No such process</td>
</tr>
<tr>
<td>EIO</td>
<td>5</td>
<td>I/O error</td>
</tr>
<tr>
<td>E2BIG</td>
<td>7</td>
<td>Argument list too long</td>
</tr>
<tr>
<td>ENOEXEC</td>
<td>8</td>
<td>File is not executable</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>12</td>
<td>Not enough resources</td>
</tr>
<tr>
<td>EACCES</td>
<td>13</td>
<td>Permission denied</td>
</tr>
<tr>
<td>EXDEV</td>
<td>18</td>
<td>Cross-device link</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>20</td>
<td>Not a directory</td>
</tr>
<tr>
<td>EINVAL</td>
<td>22</td>
<td>Invalid argument</td>
</tr>
</tbody>
</table>

The value returned by \texttt{IERRNO} is updated only when an error occurs. For example, if an error occurs on a \texttt{GETLOG} call and then two \texttt{CHMOD} calls succeed, a subsequent call to \texttt{IERRNO} returns the error for the \texttt{GETLOG} call.

Examine \texttt{IERRNO} immediately after returning from a portability routine. \texttt{IERRNO} is set on a per thread basis.

Example

```fortran
USE IFPORT
CHARACTER*20 username
INTEGER(4) ierrval
ierrval=0 !initialize return value
CALL GETLOG(username)
IF (IERRNO( ) == ierrval) then
   print *, 'User name is ',username
   exit
ELSE
   ierrval = ierrno()
   print *, 'Error is ',ierrval
END IF
```
IF - Arithmetic

**Statement:** Conditionally transfers control to one of three statements, based on the value of an arithmetic expression. It is an obsolescent language feature in Standard Fortran.

**Syntax**

IF (expr) label1,label2,label3

- **expr**
  - Is a scalar numeric expression of type integer or real (enclosed in parentheses).

- **label1, label2, label3**
  - Are the labels of valid branch target statements that are in the same scoping unit as the arithmetic IF statement.

**Description**

All three labels are required, but they do not need to refer to three different statements. The same label can appear more than once in the same arithmetic IF statement.

During execution, the expression is evaluated first. Depending on the value of the expression, control is then transferred as follows:

<table>
<thead>
<tr>
<th>If the Value of expr is:</th>
<th>Control Transfers To:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 0</td>
<td>Statement label1</td>
</tr>
<tr>
<td>Equal to 0</td>
<td>Statement label2</td>
</tr>
<tr>
<td>Greater than 0</td>
<td>Statement label3</td>
</tr>
</tbody>
</table>

**Example**

The following example transfers control to statement 50 if the real variable THETA is less than or equal to the real variable CHI. Control passes to statement 100 only if THETA is greater than CHI.

```fortran
IF (THETA-CHI) 50,50,100
```

The following example transfers control to statement 40 if the value of the integer variable NUMBER is even. It transfers control to statement 20 if the value is odd.

```fortran
IF (NUMBER / 2*2 - NUMBER) 20,40,20
```

The following statement transfers control to statement 10 for n < 10, to statement 20 for n = 10, and to statement 30 for n > 10:

```fortran
IF (n-10) 10, 20, 30
```

The following statement transfers control to statement 10 if n <= 10, and to statement 30 for n > 10:

```fortran
IF (n-10) 10, 10, 30
```

SELECT CASE...END SELECT
Execution Control
Obsolescent Language Features in Fortran 2003 and Fortran 95
IF - Logical

**Statement:** Conditionally executes one statement based on the value of a logical expression. (This statement was called a logical IF statement in FORTRAN 77.)

**Syntax**

```fortran
IF (expr) stmt
```

- **expr**
  - Is a scalar logical expression enclosed in parentheses.

- **stmt**
  - Is any complete, unlabeled, executable Fortran statement, except for the following:
    - A CASE, DO, IF, FORALL, or WHERE construct
    - Another IF statement
    - The END statement for a program, function, or subroutine

When an IF statement is executed, the logical expression is evaluated first. If the value is true, the statement is executed. If the value is false, the statement is not executed and control transfers to the next statement in the program.

**Example**

The following examples show valid IF statements:

```fortran
IF (J.GT.4 .OR. J.LT.1) GO TO 250
IF (REF(J,K) .NE. HOLD) REF(J,K) = REF(J,K) * (-1.5D0)
IF (ENDRUN) CALL EXIT
```

The following shows another example:

```fortran
USE IFPORT
INTEGER(4) istat, errget
character(inchar)
real x
istat = getc(inchar)
IF (istat) errget = -1
...  ! IF (x.GT. 2.3) call new_subr(x)
...  
```

**See Also**

IF Construct
Execution Control

**IF Clause**

**Parallel Directive Clause:** Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.

**Syntax**

```fortran
IF ([directive-name-modifier:] scalar-logical-expression)
```
**directive-name-modifier**  
Names the associated construct that the IF clause applies to. Currently, you can specify one of the following associated constructs: PARALLEL, TARGET DATA, TARGET, TARGET UPDATE, TARGET ENTER DATA, TARGET EXIT DATA, TASK, or TASKLOOP.

**scalar-logical-expression**  
Must be a scalar logical expression that evaluates to .TRUE. or .FALSE..

At most one IF clause can appear in a non-combined directive. In combined directives, IF clauses with different **directive-name-modifiers** can occur, at most one for each constituent directive making up the combined directive where IF is allowed.

**Description**

The effect of the IF clause depends on the construct to which it is applied:

- For combined or composite constructs, the IF clause only applies to the semantics of the construct named in the **directive-name-modifier** if one is specified.
- If no **directive-name-modifier** is specified for a combined or composite construct then the IF clause applies to all constructs to which an IF clause can apply.

The following are additional rules that apply to specific OpenMP Fortran directives:

- For the CANCEL OpenMP* Fortran directive, if **scalar-logical-expression** evaluates to false, the construct does not request cancellation. Note that **directive-name-modifier** cannot specify CANCEL.
- For the PARALLEL OpenMP Fortran directive:
  - The enclosed code section is executed in parallel only if **scalar-logical-expression** evaluates to .TRUE.. Otherwise, the parallel region is serialized. If this clause is not used, the region is executed as if an IF(.TRUE.) clause were specified.
  - This clause is evaluated by the master thread before any data scope attributes take effect.
- For the TARGET OpenMP Fortran directive, if **scalar-logical-expression** evaluates to .FALSE., the target region is not executed by the device. It is executed by the encountering task.
- For the TARGET DATA OpenMP Fortran directive, if **scalar-logical-expression** evaluates to .FALSE., the new device data environment is not created.
- For the TARGET UPDATE OpenMP Fortran directive, if **scalar-logical-expression** evaluates to .FALSE., the TARGET UPDATE directive is ignored.
- For the TASK OpenMP Fortran directive:
  - The enclosed code section is to be executed in parallel only if **scalar-logical-expression** evaluates to .TRUE.. If this clause is not used, the region is executed as if an IF(.TRUE.) clause was specified.
  - If **scalar-logical-expression** evaluates to .FALSE., the encountering thread must suspend the current task region and begin execution of the generated task immediately. The suspended task region will not be resumed until the generated task is completed.
  - This clause is evaluated by the master thread before any data scope attributes take effect.

**IF Construct**

**Statement:** Conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. (This construct was called a block IF statement in FORTRAN 77.)

**Syntax**

```
[name:] IF (expr) THEN
  block
[ELSE IF (expr) THEN [name]
```

1611
block] [ELSE [name] block] END IF [name]  

(Optional) Is the name of the IF construct.

name

Is a scalar logical expression enclosed in parentheses.

expr

Is a sequence of zero or more statements or constructs.

block

Description

If a construct name is specified at the beginning of an IF THEN statement, the same name must appear in the corresponding END IF statement. If a construct name is specified on an ELSE IF or ELSE statement, the same name must appear in the corresponding IF THEN and END IF statements.

The same construct name must not be used for different named constructs in the same scoping unit.

Depending on the evaluation of the logical expression, one block or no block is executed. The logical expressions are evaluated in the order in which they appear, until a true value is found or an ELSE or END IF statement is encountered.

Once a true value is found or an ELSE statement is encountered, the block immediately following it is executed and the construct execution terminates.

If none of the logical expressions evaluate to true and no ELSE statement appears in the construct, no block in the construct is executed and the construct execution terminates.

NOTE

No additional statement can be placed after the IF THEN statement in a block IF construct. For example, the following statement is invalid in the block IF construct:

```
IF (e) THEN I = J
```

This statement is translated as the following logical IF statement:

```
IF (e) THEN I = J
```

You cannot use branching statements to transfer control to an ELSE IF statement or ELSE statement. However, you can branch to an END IF statement from within the IF construct.

The following figure shows the flow of control in IF constructs:
You can include an IF construct in the statement block of another IF construct, if the nested IF construct is completely contained within a statement block. It cannot overlap statement blocks.
Example

The following example shows the simplest form of an IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (ABS(ADJU) .GE. 1.0E-6) THEN</td>
</tr>
<tr>
<td>block</td>
<td>TOTERR = TOTERR + ABS(ADJU)</td>
</tr>
<tr>
<td>QUEST = ADJU/FNDVAL</td>
<td></td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

This construct conditionally executes the block of statements between the IF THEN and the END IF statements.

The following shows another example:

```fortran
! Simple block IF:
IF (i .LT. 10) THEN
  ! the next two statements are only executed if i < 10
  j = i
  slice = TAN (angle)
END IF
```

The following example shows a named IF construct:

```fortran
BLOCK_A: IF (D > 0.0) THEN
  ! Initial statement for named construct
  RADIANS = ACOS(D)
  ! These two statements
  DEGREES = ACOSD(D)
  ! form a block
END IF BLOCK_A
  ! Terminal statement for named construct
```

The following example shows an IF construct containing an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (NAME .LT. 'N') THEN</td>
</tr>
<tr>
<td>block1</td>
<td>IFRONT = IFRONT + 1</td>
</tr>
<tr>
<td>FRLET(IFRONT) = NAME(1:2)</td>
<td></td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>IBACK = IBACK + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

Block1 consists of all the statements between the IF THEN and ELSE statements. Block2 consists of all the statements between the ELSE and the END IF statements.

If the value of the character variable NAME is less than 'N', block1 is executed. If the value of NAME is greater than or equal to 'N', block2 is executed.

The following example shows an IF construct containing an ELSE IF THEN statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td>F = A - B</td>
<td></td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. B/2.) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = B/2.</td>
</tr>
<tr>
<td>F = A - B/2.</td>
<td></td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B, but A is greater than B/2, block2 is executed. If A is not greater than B and A is not greater than B/2, neither block1 nor block2 is executed. Control transfers directly to the next executable statement after the END IF statement.
The following shows another example:

```fortran
! Block IF with ELSE IF statements:
IF (j .GT. 1000) THEN
  ! Statements here are executed only if J > 1000
ELSE IF (j .GT. 100) THEN
  ! Statements here are executed only if J > 100 and j <= 1000
ELSE IF (j .GT. 10) THEN
  ! Statements here are executed only if J > 10 and j <= 100
ELSE
  ! Statements here are executed only if j <= 10
END IF
```

The following example shows an IF construct containing several ELSE IF THEN statements and an ELSE statement:

```
<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td></td>
<td>F = A - B</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. C) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = C</td>
</tr>
<tr>
<td></td>
<td>F = A - C</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. Z) THEN</td>
</tr>
<tr>
<td>block3</td>
<td>D = Z</td>
</tr>
<tr>
<td></td>
<td>F = A - Z</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block4</td>
<td>D = 0.0</td>
</tr>
<tr>
<td></td>
<td>F = A</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>
```

If A is greater than B, block1 is executed. If A is not greater than B but is greater than C, block2 is executed. If A is not greater than B or C but is greater than Z, block3 is executed. If A is not greater than B, C, or Z, block4 is executed.

The following example shows a nested IF construct:

```
<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .LT. 100) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>INRAN = INRAN + 1</td>
</tr>
<tr>
<td>IF (expr2) THEN</td>
<td>IF (ABS(A-AVG) .LE. 5.) THEN</td>
</tr>
<tr>
<td>block1a</td>
<td>INAVG = INAVG + 1</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block1b</td>
<td>OUTAVG = OUTAVG + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>OUTRAN = OUTRAN + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>
```

If A is less than 100, the code immediately following the IF is executed. This code contains a nested IF construct. If the absolute value of A minus AVG is less than or equal to 5, block1a is executed. If the absolute value of A minus AVG is greater than 5, block1b is executed.

If A is greater than or equal to 100, block2 is executed, and the nested IF construct (in block1) is not executed.

The following shows another example:

```fortran
! Nesting of constructs and use of an ELSE statement following
! a block IF without intervening ELSE IF statements:
IF (i .LT. 100) THEN
  ! Statements here are executed only if I < 100
```

1615
! Statements here executed only if i < 100
IF (j .LT. 10) THEN
  ! Statements here executed only if i < 100 and j < 10
  END IF
ELSE
  ! Statements here executed only if i >= 100
IF (j .LT. 10) THEN
  ! Statements here executed only if i >= 100 and j < 10
  END IF
  ! Statements here executed only if i >= 100
ENDIF

IF - Arithmetic

IF Directive Construct

General Compiler Directive: A conditional compilation construct that begins with an IF or IF DEFINED directive. IF tests whether a logical expression is .TRUE. or .FALSE.. IF DEFINED tests whether a symbol has been defined.

Syntax

!DIR$ IF (expr) -or- !DIR$ IF DEFINED (name)

  block
  ![DIR$ ELSEIF (expr)
    block] ...
  ![DIR$ ELSE
    block]
!DIR$ ENDIF

expr Is a logical expression that evaluates to .TRUE. or .FALSE..
name Is the name of a symbol to be tested for definition.
block Are executable statements that are compiled (or not) depending on the value of logical expressions in the IF directive construct.

The IF and IF DEFINED directive constructs end with an ENDIF directive and can contain one or more ELSEIF directives and at most one ELSE directive. If the logical condition within a directive evaluates to .TRUE. at compilation, and all preceding conditions in the IF construct evaluate to .FALSE., then the statements contained in the directive block are compiled.

A name can be defined with a DEFINE directive, and can optionally be assigned an integer value. If the symbol has been defined, with or without being assigned a value, IF DEFINED (name) evaluates to .TRUE.; otherwise, it evaluates to .FALSE..

If the logical condition in the IF or IF DEFINED directive is .TRUE., statements within the IF or IF DEFINED block are compiled. If the condition is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.
If the logical expression in an ELSEIF directive is .TRUE., statements within the ELSEIF block are compiled. If the expression is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If control reaches an ELSE directive because all previous logical conditions in the IF construct evaluated to .FALSE., the statements in an ELSE block are compiled unconditionally.

You can use any Fortran logical or relational operator or symbol in the logical expression of the directive, including: .LT., <, .GT., >, .EQ., ==, .LE., <=, .GE., >=, .NE., /=, .EQV., .NEQV., .NOT., .AND., .OR., and .XOR.. The logical expression can be as complex as you like, but the whole directive must fit on one line.

**Example**

```fortran
! When the following code is compiled and run,
! the output is:
! Or this compiled if all preceding conditions .FALSE.
!
!DIR$ DEFINE flag=3
!DIR$ IF (flag .LT. 2)
  WRITE (*,*) "This is compiled if flag less than 2."
!DIR$ ELSEIF (flag >= 8)
  WRITE (*,*) "Or this compiled if flag greater than &
or equal to 8."
!DIR$ ELSE
  WRITE (*,*) "Or this compiled if all preceding &
conditions .FALSE."
!DIR$ ENDIF
END
```

IF Construct
General Compiler Directives
Syntax Rules for Compiler Directives

**IF DEFINED Directive**

**Statement:** Marks the start of an IF Directive Construct.

**See Also**

See IF Directive Construct.

**IFIX**

*Elemental Intrinsic Function (Generic):* Converts a single-precision real argument to an integer by truncating.

**See Also**

See INT.

**IFLOATI, IFLOATJ**

*Portability Functions:* Convert an integer to single-precision real type.

**Module**

USE IFPORT
Syntax
result = IFLOATI (i)
result = IFLOATJ (j)

i          (Input) Must be of type INTEGER(2).
j          (Input) Must be of type INTEGER(4).

Results
The result type is single-precision real (REAL(4) or REAL*4).

See Also
DFLOAT
ILEN

Inquiry Intrinsic Function (Generic): Returns the length (in bits) of the two's complement representation of an integer.

Syntax
result = ILEN (i)

i     Must be of type integer.

Results
The result type and kind are the same as i. The result value is (LOG2( i+ 1 )) if i is not negative; otherwise, the result value is (LOG2( - i)).

Example
ILEN (4) has the value 3.
ILEN (-4) has the value 2.

IMAGE_INDEX
Transformational Intrinsic Function (Generic): Converts cosubscripts to an image index.

Syntax
result = IMAGE_INDEX (coarray,sub)

coarray     (Input) Must be a coarray; it can be of any type.
sub     (Input) Must be a rank-one integer array of size equal to the corank of coarray.

Results
The result is default integer scalar. The result is the index of the corresponding image if the value of sub is a valid sequence of cosubscripts for coarray. Otherwise, the result is zero.

Example
If coarray D is declared as D [0:*] and coarray C is declared as C(5,10) [10, 0:9, 0:*], IMAGE_INDEX (D, [0]) has the value 1 and IMAGE_INDEX (C, [3, 1, 2]) has the value 213 (on any image).
IMAGESIZE, IMAGESIZE_W (W*S)

Graphics Functions: Return the number of bytes needed to store the image inside the specified bounding rectangle. IMAGESIZE is useful for determining how much memory is needed for a call to GETIMAGE.

Module
USE IFQWIN

Syntax
result = IMAGESIZE (x1,y1,x2,y2)
result = IMAGESIZE_W (wx1,wy1,wx2,wy2)

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of image.
x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of image.
wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of image.
wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of image.

Results
The result type is INTEGER(4). The result is the storage size of an image in bytes.

IMAGESIZE defines the bounding rectangle in viewport-coordinate points (x1, y1) and (x2, y2).
IMAGESIZE_W defines the bounding rectangle in window-coordinate points (wx1, wy1) and (wx2, wy2).
IMAGESIZE_W defines the bounding rectangle in terms of window-coordinate points (wx1, wy1) and (wx2, wy2).

Example
See the example in GETIMAGE.

IMPLICIT

Statement: Overrides the default implicit typing rules for names. (The default data type is INTEGER for names beginning with the letters I through N, and REAL for names beginning with any other letter.)

Syntax
The IMPLICIT statement takes one of the following forms:

IMPLICIT type(a[,a]...)[,type(a[,a]...)]...

IMPLICIT NONE
**type**

Is a data type specifier (CHARACTER(*) is not allowed).

**a**

Is a single letter, a dollar sign ($), or a range of letters in alphabetical order. The form for a range of letters is $a_1-a_2$, where the second letter follows the first alphabetically (for example, A-C).

The dollar sign can be used at the end of a range of letters, since IMPLICIT interprets the dollar sign to alphabetically follow the letter Z. For example, a range of X-$ would apply to identifiers beginning with the letters X, Y, Z, or $.

In Intel® Fortran, the parentheses around the list of letters are optional.

**Description**

The IMPLICIT statement assigns the specified data type (and kind parameter) to all names that have no explicit data type and begin with the specified letter or range of letters. It has no effect on the default types of intrinsic procedures.

When the data type is CHARACTER*len, len is the length for character type. The len is an unsigned integer constant or an integer specification expression enclosed in parentheses. The range for len is 1 to $2^{31}-1$ on IA-32 architecture; 1 to $2^{63}-1$ on Intel® 64 architecture.

Names beginning with a dollar sign ($) are implicitly INTEGER.

The IMPLICIT NONE statement disables all implicit typing defaults. When IMPLICIT NONE is used, all names in a program unit must be explicitly declared. An IMPLICIT NONE statement must precede any PARAMETER statements, and there must be no other IMPLICIT statements in the scoping unit.

**NOTE**

To receive diagnostic messages when variables are used but not declared, you can specify compiler option warn declarations instead of using IMPLICIT NONE.

The following IMPLICIT statement represents the default typing as specified by the Fortran Standard for names when they are not explicitly typed:

```
IMPLICIT INTEGER (I-N), REAL (A-H, O-Z)
```

**Example**

The following are examples of the IMPLICIT statement:

```
IMPLICIT DOUBLE PRECISION (D) IMPLICIT COMPLEX (S,Y), LOGICAL(1) (L,A-C)
IMPLICIT CHARACTER*32 (T-V)
IMPLICIT CHARACTER*2 (W)
IMPLICIT TYPE(COLORS) (E-F), INTEGER (G-H)
```

The following shows another example:

```
SUBROUTINE FF (J)
IMPLICIT INTEGER (a-b), CHARACTER*(J+1) (n), TYPE(fried) (c-d)
TYPE fried
INTEGER e, f
REAL g, h
END TYPE
age = 10 ! integer
name = 'Paul' ! character
c%e = 1 ! type fried, integer component
```

warn declarations compiler option

**IMPORT**

**Statement:** Controls accessibility of host entities in a submodule, module procedure, a contained procedure, a block construct, or in the interface body of an interface block. It takes the following form:

**Syntax**

```
IMPORT [::] import-name-list
IMPORT,ONLY: import-name-list
IMPORT,NONE
IMPORT,ALL
```

*import-name-list* (Input) Is the name of one or more entities accessible in the host scoping unit.

An IMPORT statement can appear in a submodule, module procedure, a contained procedure, the specification part of a BLOCK construct, or in an interface body. It can not appear in the specification part of a main program, external procedure, module, or block data except in an interface body.

An IMPORT statement must appear after any USE statements, and before any other specification statements. Each of the named entities must be an accessible entity in the host scoping unit. Within an interface body each named entity must be explicitly declared before the interface body, or accessible by use or host association in the host containing the IMPORT statement.

If IMPORT, ONLY appears within a scoping unit, all other IMPORT statements in that scoping unit must be IMPORT, ONLY statements. An entity is host associated in a scoping unit which contains an IMPORT, ONLY statement if it appears in an *import-name-list* in that scoping unit.

If IMPORT, NONE is specified, no entities in the host are accessible by host association in that scoping unit. This is the default behavior for interface bodies for a dummy or external procedure. IMPORT, NONE must not appear in the specification part of a submodule.

If an IMPORT, ALL or an IMPORT, NONE statement appears in a scoping unit, it must be the only IMPORT statement in that scoping unit.

If *import-name-list* is not specified, and if ALL, ONLY, or NONE are not specified, all of the accessible named entities in the host scoping unit are imported unless they are made inaccessible by an entity of the same name in the local scope. This is the default behavior for a nested scoping unit, other than an interface body, for a dummy or external procedure.

If IMPORT, ALL is specified, all entities in the host are accessible by host association. If an entity is made accessible by an IMPORT, ALL statement or by its name appearing in an *import-name-list*, it cannot be made inaccessible by declaring another entity with the same name in the local scope.

If an IMPORT statement with an *import-name-list* appears, only the named entities are available by host association.

**Examples**

The following examples show how the IMPORT statement can be applied.

```fortran
module mymod
  type mytype
    integer comp
  end type mytype
interface
```
subroutine sub (arg)
   import
   type(mytype) :: arg
end subroutine sub
end interface
end module mymod

module host
   integer :: i, j, k
   contains
   subroutine sub1 ()
      import :: i, j
      k = i + j ! only i and j are host associated, k is local to sub1
   end subroutine
   subroutine sub2 ()
      import, none
      k = i + j ! i, j, and k are local to sub2
   end subroutine
   subroutine sub3 ()
      import all
      k = i + j ! i, j, and k are all host associated
   end subroutine
   subroutine sub4 ()
      import, only : i
      import, only : j
      k = i + j ! i and j are host associated, k is local
   end subroutine
end module

**IMPURE**

*Keyword:* Asserts that a user-defined procedure has side effects.

**Description**

This kind of procedure is specified by using the prefix IMPURE in a FUNCTION or SUBROUTINE statement. By default all user-defined procedures are impure, that is, they are allowed to have side effects, except for elemental procedures.

An IMPURE elemental procedure has the restrictions that apply to elemental procedures, but it does not have any of the restrictions of PURE elemental procedures.

An impure elemental procedure can have side effects and it can contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement or an ERROR STOP statement
- An image control statement

An impure elemental procedure cannot be referenced in a context that requires a procedure to be pure; for example:

- It cannot be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It cannot be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, or finalization.
- It cannot be passed as an actual argument to a pure procedure.
Example

module my_rand_mod
integer, save :: my_rand_seed (8)
contains
impure elemental subroutine my_rand (r)
! my_rand updates module variable my_rand_seed (an array)
! and returns the next value of a “pseudo” random sequence in
! output dummy argument r
    real, intent(out) :: r
    ! code goes here
end subroutine my_rand
end module my_rand_mod

FUNCTION
SUBROUTINE

IN_REDUCTION
Specifies that a task participates in a reduction. The
IN_REDUCTION clause is a reduction participating
clause.

Syntax

IN_REDUCTION (reduction-identifier : list)

Arguments reduction-identifier and list are defined in REDUCTION clause. All the common restrictions for the
REDUCTION clause apply to this clause.

A list item that appears in an IN_REDUCTION clause of a TASK construct must appear in a TASK_REDUCTION
clause of a construct associated with a TASKGROUP region that includes the participating task in its
taskgroup set. The construct associated with the innermost region that meets this condition must specify the
same operator or intrinsic as the IN_REDUCTION clause.

In the following example, the IN_REDUCTION clause at (3) must name the same operator (+) and variable
(a) as in the TASK_REDUCTION clause in (2). The IN_REDUCTION clause at (4) must name the same
operator (*) and variable (a) as in the TASK_REDUCTION clause in (1).

```plaintext
!$omp taskgroup task_reduction(*:a)       ! (1) *:a
...                                        
!$omp taskgroup task_reduction(+:a)        ! (2) +:a
!$omp task task_reduction(+:a)             ! (3) +:a matches (2)
        a = a + x
!$omp end task                             ! ends (3) +:a
...                                        
!$omp end taskgroup                        ! ends (2) +:a
...                                        
!$omp task task_reduction(*:a)              ! (4) *:a matches (1)
        a = a * y
!$omp end task                             ! ends (4) *:a
!$omp end taskgroup                        ! ends (1) *:a
```

INCHARQQ (W*S)
*QuickWin Function*: Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering.

Module
USE IFQWIN

Syntax

\[
\text{result} = \text{INCHARQQ}( )
\]

Results

The result type is INTEGER(2). The result is the ASCII key code.

The keystroke is read from the child window that currently has the focus. You must call INCHARQQ before the keystroke is made (INCHARQQ does not read the keyboard buffer). This function does not echo its input. For function keys, INCHARQQ returns 0xE0 as the upper 8 bits, and the ASCII code as the lower 8 bits.

For direction keys, INCHARQQ returns 0xF0 as the upper 8 bits, and the ASCII code as the lower 8 bits. To allow direction keys to be read, you must use the PASSDIRKEYSQQ function. The escape characters (the upper 8 bits) are different from those of GETCHARQQ. Note that console applications do not need, and cannot use PASSDIRKEYSQQ.

Example

```fortran
use IFQWIN
integer*4 res
integer*2 exchar
character*1 ch, ch1

print *,"Type X to exit, S to scroll, D to pass Direction keys"

123 continue
exchar = incharqq()
! check for escapes
! 0xE0 0x?? is a function key
! 0xF0 0x?? is a direction key
ch = char(rshift(exchar,8) .and. Z'00FF')
ch1 = char(exchar .and. Z'00FF')

if (ichar(ch) .eq. 224) then
  print *,"Function key = ",ichar(ch), " ",ichar(ch1)," ",ch1
  goto 123
endif

if (ichar(ch) .eq. 240) then
  print *,"direction key = ",ichar(ch), " ",ichar(ch1)," ",ch1
```

Intel® Fortran Compiler 19.0 Developer Guide and Reference

1624
goto 123
endif

print *,"other key = ",ichar(ch)," ",ichar(ch1)," ",ch1

if(ch1 .eq. 'S') then
  res = passdirkeysqq(.false.)
  print *, "Entering Scroll mode"
endif

if(ch1 .eq. 'D') then
  res = passdirkeysqq(.true.)
  print *, "Entering Direction keys mode"
endif

if(ch1 .ne. 'X') go to 123
end

PASSDIRKEYSQQ

INCLUDE

Statement: Directs the compiler to stop reading statements from the current file and read statements in an included file or text module.

Syntax
The INCLUDE line takes the following form:

```
INCLUDE 'filename[/[NO]LIST]'
```

filename

Is a character string specifying the name of the file to be included; it must not be a named constant.

The form of the file name must be acceptable to the operating system, as described in your system documentation.

[NO]LIST

Specifies whether the incorporated code is to appear in the compilation source listing. In the listing, a number precedes each incorporated statement. The number indicates the "include" nesting depth of the code. The default is /NOLIST. /LIST and /NOLIST must be spelled completely.

You can only use /[NO]LIST if you specify compiler option vms (which sets OpenVMS defaults).

Description
An INCLUDE line can appear anywhere within a scoping unit. The line can span more than one source line, but no other statement can appear on the same line. The source line cannot be labeled.

An included file or text module cannot begin with a continuation line, and each Fortran statement must be completely contained within a single file.
An included file or text module can contain any source text, but it cannot begin or end with an incomplete Fortran statement.

The included statements, when combined with the other statements in the compilation, must satisfy the statement-ordering restrictions shown in Statements.

Included files or text modules can contain additional INCLUDE lines, but they must not be recursive. INCLUDE lines can be nested until system resources are exhausted.

When the included file or text module completes execution, compilation resumes with the statement following the INCLUDE line.

You can use modules instead of include files to achieve encapsulation of related data types and procedures. For example, one module can contain derived type definitions as well as special operators and procedures that apply to those types. For information on how to use modules, see Program Units and Procedures.

Example

In the following example, a file named COMMON.FOR (in the current working directory) is included and read as input.

Including Text from a File

<table>
<thead>
<tr>
<th>Main Program File</th>
<th>COMMON.FOR File</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM</td>
<td>INTEGER, PARAMETER :: M=100</td>
</tr>
<tr>
<td></td>
<td>REAL, DIMENSION(M) :: Z</td>
</tr>
<tr>
<td>CALL CUBE</td>
<td>REAL, DIMENSION(M) :: X, Y</td>
</tr>
<tr>
<td>DO I = 1, M</td>
<td>COMMON X, Y</td>
</tr>
<tr>
<td>Z(I) = X(I) + SQRT(Y(I))</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>END DO</td>
<td></td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SUBROUTINE CUBE</th>
</tr>
</thead>
<tbody>
<tr>
<td>INCLUDE 'COMMON.FOR'</td>
</tr>
<tr>
<td>DO I=1,M</td>
</tr>
<tr>
<td>X(I) = Y(I)**3</td>
</tr>
<tr>
<td>END DO</td>
</tr>
<tr>
<td>RETURN</td>
</tr>
<tr>
<td>END</td>
</tr>
</tbody>
</table>

The file COMMON.FOR defines a named constant M, and defines arrays X and Y as part of blank common.

The following example program declares its common data in an include file. The contents of the file INCLUDE.INC are inserted in the source code in place of every INCLUDE 'INCLUDE.INC' line. This guarantees that all references to common storage variables are consistent.

| INTEGER i |
| REAL x    |
| INCLUDE 'INCLUDE.INC' |
| DO i = 1, 5 |
| READ (*', '(F10.5)') x |
| CALL Push (x) |
| END DO    |

MODULE
INDEX

Elemental Intrinsic Function (Generic): Returns the starting position of a substring within a string.

Syntax

\[
\text{result} = \text{INDEX} \ (\text{string}, \ \text{substring} \ [, \ \text{back}] \ [, \ \text{kind}])
\]

- **string** (Input) Must be of type character.
- **substring** (Input) Must be of type character.
- **back** (Input; optional) Must be of type logical.
- **kind** (Input; optional) Must be a scalar integer constant expression.

Results

The result is of type integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \( \text{back} \) does not appear (or appears with the value false), the value returned is the minimum value of \( I \) such that \( \text{string}(I : I + \text{LEN} (\text{substring}) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN} (\text{string}) < \text{LEN} (\text{substring}) \), zero is returned. If \( \text{LEN} (\text{substring}) = 0 \), 1 is returned.

If \( \text{back} \) appears with the value true, the value returned is the maximum value of \( I \) such that \( \text{string}(I : I + \text{LEN} (\text{substring}) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN}(\text{string}) < \text{LEN} (\text{substring}) \), zero is returned. If \( \text{LEN} (\text{substring}) = 0 \), \( \text{LEN} (\text{string}) + 1 \) is returned.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX ¹</td>
<td>CHARACTER</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying integer size can affect this function.

Example

INDEX ('FORTRAN', 'O', BACK = .TRUE.) has the value 2.

INDEX ('XXXX', " ", BACK = .TRUE.) has the value 5.

The following shows another example:

\[
\begin{align*}
\text{I} &= \text{INDEX}('\text{banana}', '\text{an}', \ \text{BACK} = .\text{TRUE}.) \ \text{! returns 4} \\
\text{I} &= \text{INDEX}('\text{banana}', '\text{an}') \ \text{! returns 2}
\end{align*}
\]

See Also

SCAN

INITIALIZEFONTS (W*S)

Module
USE IFQWIN

Syntax
result = INITIALIZEFONTS( )

Results
The result type is INTEGER(2). The result is the number of fonts initialized.

All fonts on Windows systems become available after a call to INITIALIZEFONTS. Fonts must be initialized with INITIALIZEFONTS before any other font-related library function (such as GETFONTINFO, GETGTEXTEXTENT, SETFONT, OUTGTEXT) can be used.

The font functions affect the output of OUTGTEXT only. They do not affect other Fortran I/O functions (such as WRITE) or graphics output functions (such as OUTTEXT).

For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

Example
! build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
numfonts = INITIALIZEFONTS()
WRITE (*,*) numfonts
END

See Also
SETFONT
OUTGTEXT

INITIALSETTINGS (W*S)
QuickWin Function: Initializes QuickWin.

Module
USE IFQWIN

Syntax
result = INITIALSETTINGS( )

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can change the initial appearance of an application's default frame window and menus by defining an INITIALSETTINGS function. Do not use INITIALSETTINGS to open or change the properties of child windows.

If no user-defined INITIALSETTINGS function is supplied, QuickWin calls a predefined INITIALSETTINGS routine to control the default frame window and menu appearance. You do not need to call INITIALSETTINGS if you define it, since it will be called automatically during initialization.

APPENDMENUQQ
INSERTMENUQQ
INLINE, FORCEINLINE, and NOINLINE

General Compiler Directives: Tell the compiler to perform the specified inlining on routines within statements or DO loops.

Syntax

```
!DIR$ INLINE [RECURSIVE]
!DIR$ FORCEINLINE [RECURSIVE]
!DIR$ NOINLINE
```

The INLINE directive specifies that the routines can be inlined. The FORCEINLINE directive specifies that a routine should be inlined whenever the compiler can do so. This condition can also be specified by using compiler option [Q]inline-forceinline. The NOINLINE directive specifies that a routine should not be inlined. These directives apply only to the immediately following statement or DO construct. All statements within the immediately following DO construct are affected. If keyword RECURSIVE is specified, the specified inlining is performed when the routine calls itself directly or indirectly. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

**Caution**

When you use directive FORCEINLINE, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Example

Consider the following:

```
!DIR$ INLINE
A = F(B) + G(C)  ! inline the call to function F and inline the call to function G

!DIR$ INLINE
DO I = 1, N
    CALL F1 (G1(A), G2(A)) ! inline the call to F1 and the function executions of G1 and G2
!DIR$ NOINLINE
    DO J = 1, M
        M(J) = F (M(J)) ! do not inline this call to F (M is a data array)
    END DO
    M(I) = F2 (X) ! F2 gets inlined from the directive before DO I
!DIR$ FORCEINLINE RECURSIVE
    CALL F3 () ! F3 must be inlined and it calls itself recursively so inline those calls too
END DO
```

### INMAX

**Portability Function:** Returns the maximum positive value for an integer.

**Module**

USE IFPORT

**Syntax**

```fortran
result = INMAX (i)
```

*i* (Input) INTEGER(4).

**Results**

The result type is INTEGER(4). The result is the maximum 4-byte signed integer value for the argument.

### INQFOCUSQQ (W*S)

**QuickWin Function:** Determines which window has the focus.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = INQFOCUSQQ (unit)
```

*unit* (Output) INTEGER(4). Unit number of the window that has the I/O focus.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero. The function fails if the window with the focus is associated with a closed unit.

Unit numbers 0, 5, and 6 refer to the default window only if the program has not specifically opened them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

The window with focus is always in the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```fortran
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```
By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**See Also**
FOCUSQQ

**INQUIRE**

*Statement:* Returns information on the status of specified properties of a file, logical unit, or directory. It takes one of the following forms:

**Syntax**

**Inquiring by File:**

**Inquiring by Unit:**

**Inquiring by Directory:**

INQUIRE (DIRECTORY=dir, EXIST=ex [, DIRSPEC=dirspec] [, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, SIZE=sz] [, IOSTAT=i-var])

**Inquiring by Output List:**

INQUIRE (IOLENGTH=len) out-item-list

**name**

Is a scalar default character expression specifying the name of the file for inquiry. For more information, see FILE Specifier and STATUS Specifier.

**label**

Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

**id-var**

Is a scalar integer expression identifying a data transfer operation that was returned using the ID= specifier in a previous asynchronous READ or WRITE statement. For more information, see ID Specifier.

**msg-var**

Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

**sz**

Is a scalar integer variable that is assigned the size of the file in file storage units. For more information, see Size Specifier.

**i-var**

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. For more information, see I/O Status Specifier.

**def**

Is a scalar default character expression specifying a default file pathname string. (For more information, see the DEFAULTFILE specifier.)

**slist**

Is one or more of the following inquiry specifiers (each specifier can appear only once):
io-unit

Is an external unit specifier. The unit does not have to exist, nor does it need to be connected to a file. If the unit is connected to a file, the inquiry encompasses both the connection and the file.

dir

Is a scalar default character expression specifying the name of the directory for inquiry. If you are inquiring by directory, it must be present.

ex

Is a scalar default logical variable that is assigned the value .TRUE. if dir names a directory that exists; otherwise, ex is assigned the value .FALSE.. If you are inquiring by directory, it must be present. For more information, see the EXIST Specifier.

dirspect

Is a scalar default character variable that is assigned the value of the full directory specification of dir if ex is assigned the value .TRUE.. This specifier can only be used when inquiring by directory.

len

(Output) Is a scalar integer variable that is assigned a value corresponding to the length of an unformatted, direct-access record resulting from the use of the out-item-list in a WRITE statement.

The value is suitable to use as a RECL specifier value in an OPEN statement that connects a file for unformatted, direct access.

The unit of the value is 4-byte longwords, by default. However, if you specify compiler option assume byterecl, the unit is bytes.

out-item-list

(Output) Is a list of one or more output items (see I/O Lists).

Description

The control specifiers ([UNIT=] io-unit, ERR= label, and IOSTAT= i-var) and inquiry specifiers can appear anywhere within the parentheses following INQUIRE. However, if the UNIT keyword is omitted, the io-unit must appear first in the list.
An INQUIRE statement can be executed before, during, or after a file is connected to a unit. The specifier values returned are those that are current when the INQUIRE statement executes.

To get file characteristics, specify the INQUIRE statement after opening the file.

**Example**

The following are examples of INQUIRE statements:

```fortran
INQUIRE (FILE='FILE_B', EXIST=EXT)
INQUIRE (4, FORM=FM, IOSTAT=IOS, ERR=20)
INQUIRE (IOLENGTH=LEN) A, B
```

In the last statement, you can use the length returned in LEN as the value for the RECL specifier in an OPEN statement that connects a file for unformatted direct access. If you have already specified a value for RECL, you can check LEN to verify that A and B are less than or equal to the record length you specified.

The following shows another example:

```fortran
! This program prompts for the name of a data file.
! The INQUIRE statement then determines whether
! the file exists. If it does not, the program
! prompts for another file name.
CHARACTER*12 fname
LOGICAL exists

! Get the name of a file:
100 WRITE (*, '(1X, A)') 'Enter the file name: '
   READ (*, '(A)') fname

! INQUIRE about file's existence:
   INQUIRE (FILE = fname, EXIST = exists)
   IF (.NOT. exists) THEN
      WRITE (*,'(2A/)') ' >> Cannot find file ', fname
      GOTO 100
   END IF
   END
```

**INSERTMENUQQ (W*S)**

*QuickWin Function:* Inserts a menu item into a QuickWin menu and registers its callback routine.
Module
USE IFQWIN

Syntax
result = INSERTMENUQQ (menuID, itemID, flag, text, routine)

menuID  (Input) INTEGER(4). Identifies the menu in which the item is inserted, starting with 1 as the leftmost menu.

itemID  (Input) INTEGER(4). Identifies the position in the menu where the item is inserted, starting with 0 as the top menu item.

flag  (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results section below). The following constants are available:
• $MENUGRAYED - Disables and grays out the menu item.
• $MENUDISABLED - Disables but does not gray out the menu item.
• $MENUENABLED - Enables the menu item.
• $MENUSEPARATOR - Draws a separator bar.
• $MENUCHECKED - Puts a check by the menu item.
• $MENUNCHECKED - Removes the check by the menu item.

text  (Input) Character*. Menu item name. Must be a null-terminated C string, for example, words of text'C.

routine  (Input) EXERNAL. Callback subroutine that is called if the menu item is selected. You can assign the following predefined routines to menus:
• WINPRINT - Prints the program.
• WINSAVE - Saves the program.
• WINEXIT - Terminates the program.
• WINSELECTTEXT - Selects text from the current window.
• WINSELECTGRAPHICS - Selects graphics from the current window.
• WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZEToFit - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.
Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.

Menus and menu items must be defined in order from left to right and top to bottom. For example, INSERTMENUQQ fails if you try to insert menu item 7 when 5 and 6 are not defined yet. For a top-level menu item, the callback routine is ignored if there are subitems under it.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to INSERTMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY(ALT+R in the example) as an alternative to selecting the item with the mouse.

Example

```fortran
USE IFQWIN
LOGICAL(4)     :: status
CHARACTER (80) :: text_input

! insert new item into Menu 5 (Window)
status= INSERTMENUQQ(5, 5, $MENUCHECKED, 'New Item:Status 5_5'C, WINSTATUS)
! insert new menu in position 2
status= INSERTMENUQQ(2, 0, $MENUENABLED, 'New Menu:2_0'C, NUL)
! insert new menu in position 3, and mark it disabled & grayed
status= INSERTMENUQQ(3, 0, IOR($MENUGRAYED,$MENUDISABLED), 'New Disabled Menu:3_0'C, NUL)
! insert new item under the new menu 2 in position 1
status= INSERTMENUQQ(2, 1, $MENUENABLED, 'New Item:Print'C, WINPRINT)
! insert separator bar under the new menu 2 in position 2
status= INSERTMENUQQ(2, 2, $MENUSEPARATOR, 'New Separator'C, NUL)
! insert new item under the new menu 2 in position 3
status= INSERTMENUQQ(2, 3, IOR($MENUCHECKED,$MENUENABLED), 'New Item:Select Text'C, &
WINSELECTTEXT)
! insert new item under the new menu 2 in position 5
status= INSERTMENUQQ(2, 4, $MENUENABLED, 'New Item:Copy Selected Text'C, WINCOPY)
! insert new item under the new menu 2 in position 6
status= INSERTMENUQQ(2, 5, $MENUENABLED, 'New Item:Paste Selected Text'C, WIPASTE)

write(*,'("Enter (or cut and paste) a text value: ")',advance='no')
read (*,"(A)") text_input
write(*,'("You just entered: ", A1, A, A1) "",trim(text_input),"")
END
```

**INT**

*Elemental Intrinsic Function (Generic):* Converts a value to integer type.

**Syntax**

\[
\text{result} = \text{INT}(\text{a}[,\text{kind}])
\]

- \(\text{a}\) (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
- \(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of \(\text{a}\) as follows:

- If \(\text{a}\) is of type integer, INT(\(\text{a}\)) = \(\text{a}\).
- If \(\text{a}\) is of type real and |\(\text{a}\)| < 1, INT(\(\text{a}\)) has the value zero.
  - If \(\text{a}\) is of type real and |\(\text{a}\)| >=1, INT(\(\text{a}\)) is the integer whose magnitude is the largest integer that does not exceed the magnitude of \(\text{a}\) and whose sign is the same as the sign of \(\text{a}\).
- If \(\text{a}\) is of type complex, INT(\(\text{a}\)) is the value obtained by applying the preceding rules (for a real argument) to the real part of \(\text{a}\).
- If \(\text{a}\) is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of \(\text{a}\) as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by \(\text{a}\) is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by \(\text{a}\) is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.

¹These specific functions cannot be passed as actual arguments.
²This function can also be specified as HFIX.
³The setting of compiler options specifying integer size or real size can affect IFIX.
⁴For compatibility with older versions of Fortran, IFIX is treated as a generic function.
⁵Or JINT.
⁶The setting of compiler options specifying integer size can affect INT, IDINT, and IQINT.
⁷Or JIFIX.
⁸Or JIDINT. For compatibility with older versions of Fortran, IDINT can also be specified as a generic function.
⁹Or JIQINT. For compatibility with older versions of Fortran, IQINT can also be specified as a generic function.
¹⁰For compatibility, these functions can also be specified as generic functions.

If the argument is a binary, octal, or hexadecimal constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

INT (-4.2) has the value -4.
INT (7.8) has the value 7.

**INTC**

*Portability Function:* Converts an INTEGER(4) argument to INTEGER(2) type.
Module
USE IFPORT

Syntax
result = INTC (i)

i    (Input) INTEGER(4). A value or expression.

Results
The result type is INTEGER(2). The result is the value of i with type INTEGER(2). Overflow is ignored.

INT_PTR_KIND

Inquiry Intrinsic Function (Specific): Returns the INTEGER KIND that will hold an address. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = INT_PTR_KIND( )

Results
The result type is default integer. The result is a scalar with the value equal to the value of the kind parameter of the integer data type that can represent an address on the targeted platform.

The result value is 4 on IA-32 target architecture; 8 on Intel® 64 architecture.

Example

REAL A(100)
POINTER (P, A)
INTEGER (KIND=INT_PTR_KIND()) SAVE_P
P = MALLOC (400)
SAVE_P = P

INTEGER Statement

Statement: Specifies the INTEGER data type.

Syntax
INTEGER
INTEGER([KIND=]  n)
INTEGER* n

n    Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind which holds the constant.
The default kind can also be changed by using the INTEGER directive or compiler options specifying integer size.

**Example**

```fortran
! Entity-oriented declarations:
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER (2) :: k=4
INTEGER (2), PARAMETER :: limit=12

! Attribute-oriented declarations:
INTEGER days, hours
INTEGER (2):: k=4, limit
DIMENSION days(:), hours(:)
POINTER days, hours
PARAMETER (limit=12)
```

**See Also**
- INTEGER Directive
- Integer Data Types
- Integer Constants

**INTEGER Directive**

*General Compiler Directive: Specifies the default integer kind.*

**Syntax**

```fortran
!DIR$ INTEGER:{ 2 | 4 | 8 }
```

The INTEGER directive specifies a size of 2 (KIND=2), 4 (KIND=4), or 8 (KIND=8) bytes for default integer numbers.

When the INTEGER directive is in effect, all default integer variables are of the kind specified. Only numbers specified or implied as INTEGER without KIND are affected.

The INTEGER directive can only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module or a block data program unit. INTEGER cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

The default logical kind is the same as the default integer kind. So, when you change the default integer kind you also change the default logical kind.

**Example**

```fortran
INTEGER i            ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)   ! still a 4-byte integer
                    ! not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
  !DIR$ INTEGER:2
  INTEGER j          ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```
INTEGERTORGB (W*S)

*QuickWin Subroutine:* Converts an RGB color value into its red, green, and blue components.

**Module**

USE IFQWIN

**Syntax**

CALL INTEGERTORGB (rgb, red, green, blue)

- **rgb** (Input) INTEGER(4). RGB color value whose red, green, and blue components are to be returned.
- **red** (Output) INTEGER(4). Intensity of the red component of the RGB color value.
- **green** (Output) INTEGER(4). Intensity of the green component of the RGB color value.
- **blue** (Output) INTEGER(4). Intensity of the blue component of the RGB color value.

INTEGERTORGB separates the four-byte RGB color value into the three components as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0</td>
<td>B B B B B B B</td>
<td>G G G G G G G</td>
<td>G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Example**

! build as a QuickWin App.
USE IFQWIN
INTEGER (4) r, g, b
CALL INTEGERTORGB (2456, r, g, b)
write(*,*) r, g, b
END

**INTENT**

*Statement and Attribute:* Specifies the intended use of one or more dummy arguments.

**Syntax**

The INTENT attribute can be specified in a type declaration statement or an INTENT statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-1s,] INTENT (intent-spec) [, att-1s] :: d-arg[, d-arg]...
```

**Statement:**

```
INTENT (intent-spec) [:] d-arg[, d-arg] ...
```

- `type` Is a data type specifier.
- `att-1s` Is an optional list of attribute specifiers.
- `intent-spec` Is one of the following specifiers:
  - **IN**
    - Specifies that the dummy argument will be used only to provide data to the procedure. The dummy argument must not be redefined (or become undefined) during execution of the procedure.
    - Any associated actual argument must be definable.
  - **OUT**
    - Specifies that the dummy argument will be used to pass data from the procedure back to the calling program. The dummy argument is undefined on entry, although it may have subcomponents that are initialized by default. An undefined argument must be defined before it is referenced in the procedure.
    - Any associated actual argument must be definable.
  - **INOUT**
    - Specifies that the dummy argument can both provide data to the procedure and return data to the calling program.
    - Any associated actual argument must be definable.
- `d-arg` Is the name of a dummy argument or dummy pointer. It cannot be a dummy procedure.

**Description**

The INTENT statement can only appear in the specification part of a subprogram or interface body.

If no INTENT attribute is specified for a dummy argument, its use is subject to the limitations of the associated actual argument.

If a function specifies a defined operator, the dummy arguments must have intent IN.

If a subroutine specifies defined assignment, the first argument must have intent OUT or INOUT, and the second argument must have intent IN or the VALUE attribute, or both IN and the VALUE attribute.
An entity with the INTENT (OUT) attribute must not be an allocatable coarray or have a subobject that is an allocatable coarray. It must not be of, or have a subcomponent of, type EVENT_TYPE or type LOCK_TYPE from the ISO_FORTRAN_ENV module.

A non-pointer dummy argument with intent IN (or a subobject of such a dummy argument) must not appear as any of the following:
- A DO variable
- The variable of an assignment statement
- The pointer-object of a pointer assignment statement
- An object or STAT variable in an ALLOCATE or DEALLOCATE statement
- An input item in a READ statement
- A variable name in a NAMELIST statement if the namelist group name appears in a NML specifier in a READ statement
- An internal file unit in a WRITE statement
- A definable variable in an INQUIRE statement
- An IOSTAT or SIZE specifier in an I/O statement
- An actual argument in a reference to a procedure with an explicit interface if the associated dummy argument has intent OUT or INOUT

INTENT on a pointer dummy argument refers to the pointer association status of the pointer and has no effect on the value of the target of the pointer.

A pointer dummy argument with intent IN (or a subobject of such a pointer argument) must not appear as any of the following:
- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
- An object in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

A pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute. During the execution of the procedure, it is pointer associated with the actual argument.

If an actual argument is an array section with a vector subscript, it cannot be associated with a dummy array that is defined or redefined (has intent OUT or INOUT).

On entry to a routine, given an INTENT(OUT) dummy argument:
- If it is a pointer, it should be deallocated.
- If it is an allocatable, all of its allocatable subcomponents should be deallocated, and then it should also be deallocated.
- If it is a non-pointer, non-allocatable, all its allocatable subcomponents should be deallocated, and then default initialization should be applied, as specified by the program.

Example

The following example shows type declaration statements specifying the INTENT attribute:

```fortran
SUBROUTINE TEST(I, J)
   INTEGER, INTENT(IN) :: I
   INTEGER, INTENT(OUT), DIMENSION(I) :: J
END SUBROUTINE TEST
```

The following are examples of the INTENT statement:

```fortran
SUBROUTINE TEST(A, B, X)
   INTENT(INOUT) :: A, B
...
SUBROUTINE CHANGE(FROM, TO)
   USE EMPLOYEE_MODULE
```
The following shows another example:

```fortran
SUBROUTINE AVERAGE(value, data1, cube_ave)
  TYPE DATA
    INTEGER count
    REAL avg
  END TYPE
  TYPE(DATA) data1
    REAL tmp
  ! value cannot be changed, while cube_ave must be defined
  ! before it can be used. Data1 is defined when the procedure is
  ! invoked, and becomes redefined in the subroutine.
  INTENT(IN)::value; INTENT(OUT)::cube_ave
  INTENT(INOUT)::data1
  ! count number of times AVERAGE has been called on the data set
  ! being passed.
  tmp = data1%count*data1%avg + value
  data1%count = data1%count + 1
  data1%avg = tmp/data1%count
  cube_ave = data1%avg**3
END SUBROUTINE
```

**INTERFACE**

*Statement:* Defines an explicit interface for an external or dummy procedure. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.

**Syntax**

```fortran
INTERFACE [generic-spec]
  [interface-body]...
  [[MODULE]PROCEDURE [::]name-list]...
END INTERFACE [generic-spec]
```

`generic-spec` (Optional) Is one of the following:

- A generic name
  
  For information on generic names, see Defining Generic Names for Procedures.
- OPERATOR ( op)
Defines a generic operator (\textit{op}). It can be a defined unary, defined binary, or extended intrinsic operator. For information on defined operators, see \textbf{Defining Generic Operators}.

- \textbf{ASSIGNMENT (=)}

Defines generic assignment. For information on defined assignment, see \textbf{Defining Generic Assignment}.

\begin{itemize}
  \item \textbf{interface-body}
  
  Is one or more function or subroutine subprograms or a procedure pointer. A function must end with \texttt{END FUNCTION} and a subroutine must end with \texttt{END SUBROUTINE}.

  The subprogram must \textit{not} contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

  The subprogram can contain a USE statement. It can also contain the prefix \texttt{MODULE} before \texttt{FUNCTION} or \texttt{SUBROUTINE} to indicate a separate module procedure.

  \item \textbf{name-list}
  
  Is the name of one or more procedures or module procedures that are accessible in the host. The \texttt{MODULE} keyword is only allowed if the interface block specifies a \textit{generic-spec} and has a host that is a module, or accesses a module by use association.

  The characteristics of module procedures are not given in interface blocks, but are assumed from the module subprogram definitions or the USE associated interfaces.
\end{itemize}

\textbf{Description}

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

A \textit{generic-spec} can only appear in the \texttt{END INTERFACE} statement if one appears in the \texttt{INTERFACE} statement; they must be identical.

The characteristics specified for the external or dummy procedure must be consistent with those specified in the procedure's definition.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

Internal, module, and intrinsic procedures are all considered to have explicit interfaces. External procedures have implicit interfaces by default; when you specify an interface block for them, their interface becomes explicit. A procedure must not have more than one explicit interface in a given scoping unit. This means that you cannot include internal, module, or intrinsic procedures in an interface block, unless you want to define a generic name for them.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

A interface block containing \textit{generic-spec} specifies a generic interface for the following procedures:

- The procedures within the interface block
  
  Any generic name, defined operator, or equals symbol that appears is a generic identifier for all the procedures in the interface block. For the rules on how any two procedures with the same generic identifier must differ, see \textbf{Unambiguous Generic Procedure References}.

- The module procedures listed in the \texttt{MODULE PROCEDURE} statement
The module procedures must be accessible by a USE statement. To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

The following rules apply to interface blocks containing pure procedures:

- The interface specification of a pure procedure must declare the INTENT of all dummy arguments except pointer and procedure arguments.
- A procedure that is declared pure in its definition can also be declared pure in an interface block. However, if it is not declared pure in its definition, it must not be declared pure in an interface block.

Example

The following example shows a simple procedure interface block with no generic specification:

```fortran
SUBROUTINE SUB_B (B, FB)
  REAL B
  ...
INTERFACE
  FUNCTION FB (GN)
    REAL FB, GN
  END FUNCTION
END INTERFACE
```

The following shows another example:

```fortran
!An interface to an external subroutine SUB1 with header:
!SUBROUTINE SUB1(I1,I2,R1,R2)
!INTEGER I1,I2
!REAL R1,R2
INTERFACE
  SUBROUTINE SUB1(int1,int2,real1,real2)
    INTEGER int1,int2
    REAL real1,real2
  END SUBROUTINE SUB1
END INTERFACE
INTEGER int
...
```

Procedure Interfaces
Procedures that Require Explicit Interfaces
Use and Host Association

INTERFACE TO

**Statement:** Identifies a subprogram and its actual arguments before it is referenced or called.
Syntax
INTERFACE TO subprogram-stmt
  [formal-declarations]
END

subprogram-stmt Is a function or subroutine declaration statement.
formal-declarations (Optional) Are type declaration statements (including optional attributes) for the arguments.

The INTERFACE TO block defines an explicit interface, but it contains specifications for only the procedure declared in the INTERFACE TO statement. The explicit interface is defined only in the program unit that contains the INTERFACE TO statement.

The recommended method for defining explicit interfaces is to use an INTERFACE block.

Example
Consider that a C function that has the following prototype:

```
extern void Foo (int i);
```

The following INTERFACE TO block declares the Fortran call to this function:

```
INTERFACE TO SUBROUTINE Foo [C.ALIAS: '_Foo'] (I)
  INTEGER*4 I
END
```

See Also
INTERFACE

INTRINSIC

Statement and Attribute: Allows the specific name of an intrinsic procedure to be used as an actual argument.

Syntax
The INTRINSIC attribute can be specified in a type declaration statement or an INTRINSIC statement, and takes one of the following forms:

Type Declaration Statement:
```
type,[att-ls,] INTRINSIC [, att-ls] :: in-pro[, in-pro]...
```

Statement:
```
INTRINSIC [::] in-pro[, in-pro] ...
```

<table>
<thead>
<tr>
<th>type</th>
<th>Is a data type specifier.</th>
</tr>
</thead>
<tbody>
<tr>
<td>att-ls</td>
<td>Is an optional list of attribute specifiers.</td>
</tr>
<tr>
<td>in-pro</td>
<td>Is the name of an intrinsic procedure.</td>
</tr>
</tbody>
</table>

Description
In a type declaration statement, only functions can be declared INTRINSIC. However, you can use the INTRINSIC statement to declare subroutines, as well as functions, to be intrinsic.

The name declared INTRINSIC is assumed to be the name of an intrinsic procedure. If a generic intrinsic function name is given the INTRINSIC attribute, the name retains its generic properties.
Some specific intrinsic function names cannot be used as actual arguments. For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures.

**Example**

The following example shows a type declaration statement specifying the INTRINSIC attribute:

```fortran
PROGRAM EXAMPLE
  ...
  REAL(8), INTRINSIC :: DACOS
  ...
  CALL TEST(X, DACOS) ! Intrinsic function DACOS is an actual argument
```

The following example shows an INTRINSIC statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL CTN</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td>INTRINSIC SIN, COS</td>
<td>Y = F(X)</td>
</tr>
<tr>
<td></td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,SIN,SINE)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>FUNCTION CTN(X)</td>
</tr>
<tr>
<td></td>
<td>CTN = COS(X)/SIN(X)</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,COS,COSINE)</td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,CTN,COTANGENT)</td>
<td></td>
</tr>
</tbody>
</table>

Note that when TRIG is called with a second argument of SIN or COS, the function reference F(X) references the Standard Fortran library functions SIN and COS; but when TRIG is called with a second argument of CTN, F(X) references the user function CTN.

The following shows another example:

```fortran
INTRINSIC SIN, COS
REAL X, Y, R
! SIN and COS are arguments to Calc2:
  R = Calc2 (SIN, COS)
```

**INUM**

*Elemental Intrinsic Function (Specific):* Converts a character string to an INTEGER(2) value. This function cannot be passed as an actual argument.

**Syntax**

`result = INUM(i)`
i

(Input) Must be of type character.

Results
The result type is INTEGER(2). The result value is the INTEGER(2) value represented by the character string i.
If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example
INUM ("451") has the value 451 of type INTEGER(2).

IOR
Elemental Intrinsic Function (Generic): Performs an inclusive OR on corresponding bits. This function can also be specified as OR.

Syntax
result = IOR (i, j)

i

(Input) Must be of type integer, logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j

(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both i and j are of type integer, they must have the same kind type parameter. If the kinds of i and j do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. i and j must not both be binary, octal, or hexadecimal literal constants.

Results
The result is the same as i if i is of type integer; otherwise, the result is the same as j. If either i or j is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining i and j bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>IOR (i, j)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>

IPARITY

**IPARITY**

*Transformational Intrinsic Function (Generic):*

*Returns the result of a bitwise exclusive OR operation.*

**Syntax**

```
result = IPARITY (array, dim [, mask])
result = IPARITY (array[, mask])
```

- `array` *(Input)* Must be an array of type integer.
- `dim` *(Input)* Must be a scalar integer with a value in the range $1 \leq \text{dim} \leq n$, where $n$ is the rank of `array`. The corresponding actual argument must not be an optional dummy argument.
- `mask` *(Input; optional)* Must be of type logical and conformable with `array`.

**Results**

The result has the same type and kind parameters as `array`. It is scalar if `dim` does not appear; otherwise, the result has rank $n - 1$ and shape $[d_1, d_2, ..., d_{\text{dim}-1}, d_{\text{dim}+1}, ..., d_n]$ where $[d_1, d_2, ..., d_n]$ is the shape of `array`.

The result of IPARITY `array`) has a value equal to the bitwise exclusive OR of all the elements of `array`. If `array` has size zero, the result value is equal to zero.

The result of IPARITY `array, MASK=mask`) has a value equal to IPARITY (PACK `array, mask`).

The result of IPARITY `array, DIM=dim [, MASK=mask`) has a value equal to that of IPARITY `array, MASK=mask`) if `array` has rank one. Otherwise, the value of element $(s_1, s_2, ..., s_{\text{dim}-1}, s_{\text{dim}+1}, ..., s_n)$ of the result is equal to IPARITY `array (s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n) [, MASK = mask (s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)])`. 
Example
IPARITY ([14, 13, 8]) has the value 11. IPARITY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 6.

IPXFARGC
POSIX Function: Returns the index of the last command-line argument.

Module
USE IFPOSIX

Syntax
result = IPXFARGC()

Results
The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.

See Also
PXGETARG
IPXFCONST
POSIX Function: Returns the value associated with a constant defined in the C POSIX standard.

Module
USE IFPOSIX

Syntax
result = IPXFCONST(constname)

constname (Input) Character. The name of a C POSIX standard constant.

Results
The result type is INTEGER(4). If constname corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is -1.

See Also
PXGETARG
PXFCONST

IPXFLENTRIM
POSIX Function: Returns the index of the last non-blank character in an input string.
Module
USE IFPOSIX

Syntax
result = IPXFLENTIRM (string)

string (Input) Character. A character string.

Results
The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument string, or zero if all characters in string are blank characters.

IPXFWEXITSTATUS (L*X, M*X)
POSIX Function: Returns the exit code of a child process.

Module
USE IFPOSIX

Syntax
result = IPXFWEXITSTATUS (istat)

istat (Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results
The result type is INTEGER(4). The result is the low-order eight bits of the output argument of PXFWAIT or PXFWAITPID.
The IPXFWEXITSTATUS function should only be used if PXFWIFEXITED returns TRUE.

Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
    print *," I am a child process"
    print *," My child's pid is", IPID_RET
call PXFGETPPID(IPID_RET,IERROR)
    print *," The pid of my parent is",IPID_RET
    print *," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
    print *," I am a parent process"
    print *," My parent pid is ", IPID_RET
    print *," I am creating the process with pid", IPID
    print *," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The child with pid ", IPID_RET," has exited"
    if( PXFWIFEXITED(ISTAT) ) then
print *, "The child exited normally"
   istat_ret = IPXFWEXITSTATUS(ISTAT)
   print 10, "The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A, Z)
end program

IPXFWSTOPSIG (L*X, M*X)

**POSIX Function:** Returns the number of the signal that caused a child process to stop.

**Module**
USE IFPOSIX

**Syntax**
result = IPXFWSTOPSIG (istat)

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

**Results**
The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop.
The IPXFWSTOPSIG function should only be used if PXWFIFSTOPPED returns TRUE.

See Also
PXFWAIT
PXFWAITPID
PXFWIFSTOPPED

IPXFWTERMSIG (L*X, M*X)

**POSIX Function:** Returns the number of the signal that caused a child process to terminate.

**Module**
USE IFPOSIX

**Syntax**
result = IPXFWTERMSIG (istat)

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

**Results**
The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.
The IPXFWTERMSIG function should only be used if PXFWIFSIGNALED returns TRUE.

PXFWIFSIGNALED

IRAND, IRANDM

Portability Functions: Return random numbers in the range 0 through (2**31)-1, or 0 through (2**15)-1 if called without an argument.

Module
USE IFPORT

Syntax
result = IRAND ([iflag])
result = IRANDM ([iflag])

iflag (Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If iflag is omitted, it is assumed to be 0, and the return range is 0 through (2**15)-1 (inclusive).

Results
The result type is INTEGER(4). If iflag is 1, the generator is restarted and the first random value is returned. If iflag is 0, the next random number in the sequence is returned. If iflag is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

Example
USE IFPORT
INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND (flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do

IS_CONTIGUOUS
Inquiry Intrinsic Function (Generic): Tests the contiguity of an array.

Syntax
result = IS_CONTIGUOUS (array)

array  
(Input) Is an array; it can be of any data type. If it is a pointer, it must be associated.

Results
The result is default logical scalar. The result has the value .TRUE. if array is contiguous; otherwise, .FALSE..

Example
After the pointer assignment MY_P => TARGET (2:20:4), IS_CONTIGUOUS (MY_P) has the value .FALSE..

See Also
CONTIGUOUS

IS_IOSTAT_END
Elemental Intrinsic Function (Generic): Tests for an end-of-file condition.

Syntax
result = IS_IOSTAT_END(i)

i  
(Input) Must be of type integer.
Results
The result type is default logical. The value of the result is true only if \( i \) is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-file condition.

Example

```
INTEGER IO_STATUS
...
READ (20, IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_END (IO_STATUS)) THEN
  ...                               ! process end of file
ENDIF
...                               ! process data read
```

IS_IOSTAT_EOR

*Elemental Intrinsic Function (Generic): Tests for an end-of-record condition.*

**Syntax**

\[
\text{result} = \text{IS_IOSTAT_EOR}(i)
\]

\( i \)  
(Input) Must be of type integer.

Results
The result type is default logical. The value of the result is true only if \( i \) is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-record condition.

Example

```
INTEGER IO_STATUS
...
READ (30, ADVANCE='YES', IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_EOR (IO_STATUS)) THEN
  ...                               ! process end of record
ENDIF
...                               ! process data read
```

ISATTY

*Portability Function: Checks whether a logical unit number is a terminal.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{ISATTY}(\text{lunit})
\]

\( \text{lunit} \)  
(Input) INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.
Results
The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..
If lunit is out of range or is not connected, zero is returned.

ISHA
Elemental Intrinsic Function (Generic):
Arithmetically shifts an integer left or right by a specified number of bits.

Syntax
result = ISHA (i, shift)

i
(Input) Must be of type integer. This argument is the value to be shifted.

shift
(Input) Must be of type integer. This argument is the direction and distance of shift.
Positive shifts are left (toward the most significant bit); negative shifts are right (toward the least significant bit).

Results
The result type and kind are the same as i. The result is equal to i shifted arithmetically by shift bits.
If shift is positive, the shift is to the left; if shift is negative, the shift is to the right. If shift is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. If the shift is to the left, zeros are shifted in on the right. If the shift is to the right, copies of the sign bit (0 for non-negative i; 1 for negative i) are shifted in on the left.

The kind of integer is important in arithmetic shifting because sign varies among integer representations (see the following example). If you want to shift a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

Example

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = -128     ! equal to 10000000
j = -32768   ! equal to 10000000 00000000
res1 = ISHA (i, -4) ! returns 11111000 = -8
res2 = ISHA (j, -4) ! returns 11111000 10100000 = -2048
```

See Also
ISHC
ISHL
ISHFT
ISHFTC
ISHC
Elemental Intrinsic Function (Generic): Rotates an integer left or right by specified number of bits. Bits shifted out one end are shifted in the other end. No bits are lost.

Syntax
result = ISHC (i, shift)

i  (Input) Must be of type integer. This argument is the value to be rotated.
shift  (Input) Must be of type integer. This argument is the direction and distance of rotation.
Positive rotations are left (toward the most significant bit); negative rotations are right (toward the least significant bit).

Results
The result type and kind are the same as i. The result is equal to i circularly rotated by shift bits.
If shift is positive, i is rotated left shift bits. If shift is negative, i is rotated right shift bits. Bits shifted out one end are shifted in the other. No bits are lost.
The kind of integer is important in circular shifting. With an INTEGER(4) argument, all 32 bits are shifted. If you want to rotate a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

Example

<table>
<thead>
<tr>
<th>INTEGER(1) i, res1</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(2) j, res2</td>
</tr>
<tr>
<td>i = 10 ! equal to 00001010</td>
</tr>
<tr>
<td>j = 10 ! equal to 00000000 00001010</td>
</tr>
<tr>
<td>res1 = ISHC (i, -3) ! returns 01000001 = 65</td>
</tr>
<tr>
<td>res2 = ISHC (j, -3) ! returns 01000000 00000001 = ! 16385</td>
</tr>
</tbody>
</table>

ISHFTC

ISHFT
Elemental Intrinsic Function (Generic): Performs a logical shift.

Syntax
result = ISHFT (i, shift)

i  (Input) Must be of type integer.
shift  (Input) Must be of type integer. The absolute value for shift must be less than or equal to BIT_SIZE(i).
Results

The result type and kind are the same as \( i \). The result has the value obtained by shifting the bits of \( i \) by \( \text{shift} \) positions. If \( \text{shift} \) is positive, the shift is to the left; if \( \text{shift} \) is negative, the shift is to the right. If \( \text{shift} \) is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. Zeros are shifted in from the opposite end.

ISHFT with a positive \( \text{shift} \) can also be specified as LSHIFT (or LSHFT). ISHFT with a negative \( \text{shift} \) can also be specified as RSHIFT (or RSHFT) with \( | \text{shift} | \).

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>

BIT_SIZE

ISHFTC

ISHA

ISHC

ISHFTC

**Elemental Intrinsic Function (Generic):** Performs a circular shift of the rightmost bits.

**Syntax**

```fortran
result = ISHFTC (i, shift[], size)
```

\( i \) (Input) Must be of type integer.
**shift**

(Input) Must be of type integer. The absolute value of *shift* must be less than or equal to *size*.

**size**

(Input; optional) Must be of type integer. The value of *size* must be positive and must not exceed BIT_SIZE(*i*). If *size* is omitted, it is assumed to have the value of BIT_SIZE(*i*).

**Results**

The result type and kind are the same as *i*. The result value is obtained by circular shifting the *size* rightmost bits of *i* by *shift* positions. If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.

No bits are lost. Bits in *i* beyond the value specified by *size* are unaffected.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>

res1 = ISHFTC (i, 2, 3)   ! rotates the 3 rightmost
! bits by 2 (left) and
! returns 00001001 = 9
res1 = ISHFTC (i, -2, 3)  ! rotates the 3 rightmost
! bits by -2 (right) and
! returns 00001100 = 12
res2 = ISHFTC (j, 2, 3)   ! rotates the 3 rightmost
! bits by 2 and returns
! 00000000 00001001 = 9
```

**See Also**

BIT_SIZE
ISHFT
MVBITS
ISHL

**Elemental Intrinsic Function (Generic):** Logically shifts an integer left or right by the specified bits. Zeros are shifted in from the opposite end.

**Syntax**

```
result = ISHL (i, shift)
```

- `i` (Input) Must be of type integer. This argument is the value to be shifted.
- `shift` (Input) Must be of type integer. This argument is the direction and distance of shift.

  If positive, `i` is shifted left (toward the most significant bit). If negative, `i` is shifted right (toward the least significant bit).

**Results**

The result type and kind are the same as `i`. The result is equal to `i` logically shifted by `shift` bits. Zeros are shifted in from the opposite end.

Unlike circular or arithmetic shifts, which can shift ones into the number being shifted, logical shifts shift in zeros only, regardless of the direction or size of the shift. The integer kind, however, still determines the end that bits are shifted out of, which can make a difference in the result (see the following example).

**Example**

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10   ! equal to 00001010
j = 10   ! equal to 00000000 00001010
res1 = ISHL (i, 5)   ! returns 01000000 = 64
res2 = ISHL (j, 5)   ! returns 00000001 01000000 = 320
```

ISHFTC

**ISNAN**

**Elemental Intrinsic Function (Generic):** Tests whether IEEE* real (binary32, binary64, and binary128) numbers are Not-a-Number (NaN) values.

**Syntax**

```
result = ISNAN (x)
```

- `x` (Input) Must be of type real.

**Results**

The result type is default logical. The result is `.TRUE.` if `x` is an IEEE NaN; otherwise, the result is `.FALSE.`.
Example

```
LOGICAL A
DOUBLE PRECISION B
...
A = ISNAN(B)
```

A is assigned the value .TRUE. if B is an IEEE NaN; otherwise, the value assigned is .FALSE..

**ITIME**

*Portability Subroutine:* Returns the time in numeric form.

**Module**

USE IFPORT

**Syntax**

```
CALL ITIME (array)
```

*array* (Output) INTEGER(4). A rank one array with three elements used to store numeric time data:

- *array*(1) - the hour
- *array*(2) - the minute
- *array*(3) - the second

**Example**

```
USE IFPORT
  INTEGER(4) time_array(3)
  CALL ITIME (time_array)
  write(*,10) time_array
10 format (1X,I2,:,I2,:,I2)
END
```

**See Also**

DATE_AND_TIME

**IVDEP**

*General Compiler Directive:* Assists the compiler's dependence analysis of iterative DO loops.

**Syntax**

```
!DIR$ IVDEP [: option]
```

*option* Is LOOP or BACK. This argument is only available on processors using IA-32 architecture.

The IVDEP directive is an assertion to the compiler's optimizer about the order of memory references inside a DO loop.

IVDEP:LOOP implies no loop-carried dependencies. IVDEP:BACK implies no backward dependencies.

When no *option* is specified, the following occurs:
• The compiler begins dependence analysis by assuming all dependences occur in the same forward direction as their appearance in the normal scalar execution order. This contrasts with normal compiler behavior, which is for the dependence analysis to make no initial assumptions about the direction of a dependence.

!DIR$ IVDEP with no option can also be spelled !DIR$ INIT_DEP_FWD (INITialize DEPendences ForWarD). The IVDEP directive is applied to a DO loop in which the user knows that dependences are in lexical order. For example, if two memory references in the loop touch the same memory location and one of them modifies the memory location, then the first reference to touch the location has to be the one that appears earlier lexically in the program source code. This assumes that the right-hand side of an assignment statement is "earlier" than the left-hand side.

The IVDEP directive informs the compiler that the program would behave correctly if the statements were executed in certain orders other than the sequential execution order, such as executing the first statement or block to completion for all iterations, then the next statement or block for all iterations, and so forth. The optimizer can use this information, along with whatever else it can prove about the dependences, to choose other execution orders.

Example

In the following example, the IVDEP directive provides more information about the dependences within the loop, which may enable loop transformations to occur:

```fortran
!DIR$ IVDEP
DO I=1, N
   A(INDARR(I)) = A(INDARR(I)) + B(I)
END DO
```

In this case, the scalar execution order follows:

1. Retrieve INDARR(I).
2. Use the result from step 1 to retrieve A(INDARR(I)).
4. Add the results from steps 2 and 3.
5. Store the results from step 4 into the location indicated by A(INDARR(I)) from step 1.

IVDEP directs the compiler to initially assume that when steps 1 and 5 access a common memory location, step 1 always accesses the location first because step 1 occurs earlier in the execution sequence. This approach lets the compiler reorder instructions, as long as it chooses an instruction schedule that maintains the relative order of the array references.

J to L

J to L

JABS

*Portability Function: Returns an absolute value.*
Module
USE IFPORT

Syntax
result = JABS (i)

i (Input) INTEGER(4). A value.

Results
The result type is INTEGER(4). The value of the result is | i |.

JDATE
Portability Function: Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.

Module
USE IFPORT

Syntax
result = JDATE ( )

Results
The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.

The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
! Sets julian to today's julian date
USE IFPORT
CHARACTER*8 julian
julian = JDATE( )

See Also
DATE_AND_TIME

JDATE4
Portability Function: Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.
Module
USE IFPORT

Syntax
result = JDATE4( )

Results
The result type is character with length 10. The result is the Julian date, in the form YYYYDDD, followed by three spaces.
The Julian date is a seven-digit number whose first four digits are the year, and whose final three represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 1999032.

See Also
DATE_AND_TIME

JNUM
Elemental Intrinsic Function (Specific): Converts a character string to an INTEGER(4) value. This function cannot be passed as an actual argument.

Syntax
result = JNUM (i)
i
  (Input) Must be of type character.

Results
The result type is INTEGER(4). The result value is the integer value represented by the character string i.
If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example
JNUM ("46616") has the value 46616 of type INTEGER(4).

KILL
Portability Function: Sends a signal to the process given by ID.

Module
USE IFPORT

Syntax
result = KILL (pid, signum)
pid
  (Input) INTEGER(4). ID of a process to be signaled.
signum
  (Input) INTEGER(4). A signal value. For the definition of signal values, see the SIGNAL function.
Results
The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error code. Possible
error codes are:
• EINVAL: The signum is not a valid signal number, or PID is not the same as getpid( ) and signum does not equal SIGKILL.
• ESRCH: The given PID could not be found.
• EPERM: The current process does not have permission to send a signal to the process given by PID.
On Windows* systems, arbitrary signals can be sent only to the calling process (where pid= getpid( )). Other
processes can send only the SIGKILL signal ( signum= 9), and only if the calling process has permission.

Example

```
USE IFPORT
integer(4) id_number, sig_val, istat
id_number=getpid( )
ISTAT = KILL (id_number, sig_val)
```

See Also
SIGNAL
RAISEQQ
SIGNALQQ

KIND

_Inquiry Intrinsic Function (Generic): Returns the kind parameter of the argument._

Syntax

```
result = KIND (x)
```

x  
(Input) Can be of any intrinsic type.

Results
The result is a scalar of type default integer. The result has a value equal to the kind type parameter value of x.

Example

KIND (0.0) has the kind value of default real type.
KIND (12) has the kind value of default integer type.
The following shows another example:

```
INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)  ! still a 4-byte integer
    ! not affected by setting in subroutine
END
SUBROUTINE INTEGER2( )
    !DIR$INTEGER:2
    INTEGER j ! a 2-byte integer
    WRITE(*,*) KIND(j)
END SUBROUTINE
```

KNUM

Elemental Intrinsic Function (Specific): Converts a character string to an INTEGER(8) value.

Syntax

result = KNUM (i)

i               (Input) Must be of type character.

Results

The result type is INTEGER(8). The result value is the integer value represented by the character string i. If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example

KNUM ("46616") has the value 46616 of type INTEGER(8).

LASTPRIVATE

Parallel Directive Clause: Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.

Syntax

LASTPRIVATE ([CONDITIONAL:] list)

CONDITIONAL           Is an optional modifier specifying that the last value assigned to a list item can be from the sequentially last iteration of the associated loops or the lexically last section construct.

list                      Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

If CONDITIONAL is present, list items must be scalar of intrinsic type (INTEGER, REAL, COMPLEX, LOGICAL, and CHARACTER) and they must have neither the POINTER nor the ALLOCATABLE attribute.
Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel region is exited, each variable has the value provided by the sequentially last section or loop iteration.

Multiple LASTPRIVATE clauses are allowed on all of the directives that accept them. A list item may not appear in more than one LASTPRIVATE clause. LASTPRIVATE (CONDITIONAL:A,B) is equivalent to LASTPRIVATE(CONDITIONAL:A) LASTPRIVATE(CONDITIONAL:B).

LASTPRIVATE (CONDITIONAL:list) can appear in the following directives:

- OMP DISTRIBUTE
- OMP DO
- OMP SECTIONS
- OMP SIMD
- OMP TASKLOOP
- Any and all of the combination directives of the above directives

The OMP PARALLEL directive does not allow the LASTPRIVATE clause.

If the original variable has the POINTER attribute, its update occurs as if by pointer assignment.

If the original variable does not have the POINTER attribute, its update occurs as if by intrinsic assignment.

When a LASTPRIVATE clause without the CONDITIONAL modifier appears in a worksharing or a SIMD directive, the value of each new list item from the sequentially last iteration of the associated loops, or the lexically last section, is assigned to the original list item.

When the CONDITIONAL modifier is specified, the final value written by the sequentially last iteration or lexically last section that writes to a list item, if any, is assigned to the original list item.

When the CONDITIONAL modifier is not specified, list items that are not assigned a value by the sequentially last iteration of the loops, or by the lexically last section, have unspecified values after the construct.

Therefore, variables specified in the list of a LASTPRIVATE clause that contains a CONDITIONAL modifier should be variables that are conditionally assigned to in the loop/region/sections. The variables in the list of a LASTPRIVATE clause that does not contain a CONDITIONAL modifier should be variables that are unconditionally assigned to in the loop or sections.

Subobjects that are not assigned a value by the last iteration of the DO or the lexically last SECTION of the SECTIONS directive are undefined after the construct.

The original variable becomes defined at the end of the construct if there is an implicit barrier at that point. To avoid race conditions, concurrent reads or updates of the original variable must be synchronized with the update of the original variable that occurs as a result of the LASTPRIVATE clause.

If the LASTPRIVATE clause is used in a construct for which NOWAIT is specified, accesses to the original variable may create a data race. To avoid this, synchronization must be inserted to ensure that the sequentially last iteration or lexically last section construct has stored and flushed that variable.

The following are restrictions for the LASTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that is private within a parallel region, or that appears in the REDUCTION clause of a PARALLEL construct, must not appear in a LASTPRIVATE clause on a worksharing construct if any of the corresponding worksharing regions ever binds to any of the corresponding parallel regions.
- A variable that appears in a LASTPRIVATE clause must be definable.
- An original variable with the ALLOCATABLE attribute must be in the allocated state at entry to the construct containing the LASTPRIVATE clause. The variable in the sequentially last iteration or lexically last section must be in the allocated state upon exit from that iteration or section with the same bounds as the corresponding original variable.
- Assumed-size arrays must not appear in a PRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
• If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

**NOTE**
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

**NOTE**
If a variable appears in a LASTPRIVATE clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a *map-type* of FROM.

**Example**
Consider the following:

```c
!$OMP DO PRIVATE(I) LASTPRIVATE(B)
    DO I = 1, 1000
        B = I
    ENDDO
!$OMP END DO
```

In this case, after the construct is exited, variable B has the value 1000.

Consider the following:

```c
!$OMP SECTIONS LASTPRIVATE(B)
!$OMP SECTION
    B = 2
!$OMP SECTION
    B = 4
!$OMP SECTION
    D = 6
!$OMP END SECTIONS
```

In this case the thread that executes the lexically last SECTION updates the original variable B to have a value of 4. However, variable D was not specified in the LASTPRIVATE clause, so it has an undefined value after the construct is exited.

Consider the following example:

```c
P = 0
!$OMP DO PRIVATE(I), FIRSTPRIVATE(P), LASTPRIVATE(CONDITIONAL:P)
    DO I = 1, 1000
        IF (A(I) .EQ. B) THEN
            P = I
            EXIT
        END IF
    ENDDO
!$OMP END DO
```

After the loop, P will be the index of the first element of A to match B; if no match is found, P will be zero.

**See Also**
PRIVATE Clause
FIRSTPRIVATE clause
**LBOUND**

**Inquiry Intrinsic Function (Generic):** Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.

**Syntax**

```
result = LBOUND (array [, dim] [, kind])
```

- **array** (Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer.

- **dim** (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.

- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If dim is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of array. Each element in the result corresponds to a dimension of array.

If array is an array section or an array expression that is not a whole array or array structure component, each element of the result has the value 1.

If array is a whole array or array structure component, LBOUND (array, dim) has a value equal to the lower bound for subscript dim of array (if dim is nonzero or array is an assumed-size array of rank dim). Otherwise, the corresponding element of the result has the value 1.

If LBOUND is invoked for an assumed-rank object that is associated with a scalar and dim is absent, the result is a zero-sized array. LBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if dim is present because the rank of a scalar is zero and dim must be >= 1.

The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following:

```fortran
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

LBOUND(ARRAY_A) is (1, 5). LBOUND(ARRAY_A, DIM=2) is 5.

LBOUND(ARRAY_B) is (2, -3). LBOUND(ARRAY_B (5:8, :)) is (1,1) because the arguments are array sections.

The following shows another example:

```fortran
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = LBOUND (ar1) ! returns [2, 4, -1]
res2 = LBOUND (ar1, DIM= 3) ! returns -1
res3 = LBOUND (vec1) ! returns [1]
END
```

**See Also**

UBOUND
**LCOBOUND**

**Inquiry Intrinsic Function (Generic):** Returns the lower cobounds of a coarray.

**Syntax**

```fortran
result = LCOBOUND (coarray [,dim [, kind]])
```

- `coarray` *(Input)* Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.
- `dim` *(Input; optional)* Must be an integer scalar with a value in the range 1 <= dim <= n, where n is the corank of `coarray`. The corresponding actual argument must not be an optional dummy argument.
- `kind` *(Input; optional)* Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter is that of default integer type. The result is scalar if `dim` is present; otherwise, the result is an array of rank one and size n, where n is the corank of `coarray`.

The result depends on whether `dim` is specified:

- If `dim` is specified, LCOBOUND (COARRAY, DIM) has a value equal to the lower cobound for cosubscript `dim` of `coarray`.
- If `dim` is not specified, LCOBOUND (COARRAY) has a value whose ith element is equal to LCOBOUND (COARRAY, i), for i = 1, 2, . . . , n, where n is the corank of `coarray`.

**Example**

If B is allocated by the statement `ALLOCATE (B [2:3, 8:*])`, then LCOBOUND (B) is [2, 8] and LCOBOUND (B, DIM=2) is 8.

**LCWRQQ**

**Portability Subroutine:** Sets the value of the floating-point processor control word.

**Module**

```fortran
USE IFPORT
```

**Syntax**

```fortran
CALL LCWRQQ (controlword)
```

- `controlword` *(Input)* INTEGER(2). Floating-point processor control word.

**Example**

```fortran
USE IFPORT
INTEGER(2) control
CALL SCWRQQ(control) ! get control word
! Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC) ! Clear
```
! control word with inverse of rounding control mask
control = control .OR. FPCW$UP  ! Set control word to round up
CALL LCWRQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END

See Also
SETCONTROLFPQQ

LEADZ

Elemental Intrinsic Function (Specific): Returns the number of leading zero bits in an integer.

Syntax
result = LEADZ (i)

i (Input) Must be of type integer or logical.

Results
The result type is default integer. The result value is the number of leading zeros in the binary representation of the integer i.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
Consider the following:

INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
    TYPE *, LEADZ(TWO**J)  ! Prints 64 down to 23 (leading zeros)
ENDO
END

LEN

Inquiry Intrinsic Function (Generic): Returns the length of a character expression.

Syntax
result = LEN (string [, kind])

string (Input) Must be of type character; it can be scalar or array valued. (It can be an array of strings.)

kind (Input; optional) Must be a scalar integer constant expression.

Results
The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.
The result has a value equal to the number of characters in string (if it is scalar) or in an element of string (if it is array valued).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEN ¹</td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following example:

```
CHARACTER (15) C (50)
CHARACTER (25) D
```

LEN (C) has the value 15, and LEN (D) has the value 25.

The following shows another example:

```
CHARACTER (11) STR (100)
INTEGER I

I = LEN (STR)  ! returns 11
I = LEN ('A phrase with 5 trailing blanks.^^^^^')  ! returns 37
```

**See Also**
LEN_TRIM
Declaration Statements for Character Types
Character Data Type

**LEN_TRIM**

*Elemental Intrinsic Function (Generic):* Returns the length of the character argument without counting trailing blank characters.

**Syntax**

```plaintext
result = LEN_TRIM (string [, kind])
```

- `string`  
  (Input) Must be of type character.
- `kind`  
  (Input; optional) Must be a scalar integer constant expression.

**Results**

The result is a scalar of type integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters remaining after any trailing blanks in string are removed. If the argument contains only blank characters, the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

LEN_TRIM (' C D ') has the value 4.
LEN_TRIM (' ') has the value 0.
The following shows another example:

```fortran
INTEGER LEN1
LEN1 = LEN_TRIM (' GOOD DAY ') ! returns 9
LEN1 = LEN_TRIM (' ')          ! returns 0
```

**See Also**
LEN
LNBLNK

**LGE**

**Elemental Intrinsic Function (Generic):**
Determines if a string is lexically greater than or equal to another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LGE is equivalent to the (.GE.) operator.

**Syntax**

```fortran
result = LGE (string_a,string_b)
```

- `string_a` (Input) Must be of type character.
- `string_b` (Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if `string_a` follows `string_b` in the ASCII collating sequence; otherwise, the result is false.

**Specific Name** | **Argument Type** | **Result Type**
--- | --- | ---
LGE | CHARACTER | LOGICAL(4)

1 This specific function cannot be passed as an actual argument.
2 The setting of compiler options specifying integer size can affect this function.

**Example**

LGE ( 'ONE', 'SIX' ) has the value false.

LGE ( 'TWO', 'THREE' ) has the value true.

The following shows another example:

```fortran
LOGICAL L
L = LGE('ABC','ABD')       ! returns .FALSE.
L = LGE ('AB', 'AAAAAAAB') ! returns .TRUE.
```

**See Also**
LGT
LLE
LLT
ASCII and Key Code Charts
**LGT**

**Elemental Intrinsic Function (Generic):**
Determines whether a string is lexically greater than another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LGT is equivalent to the > (.GT.) operator.

**Syntax**

\[
\text{result} = \text{LGT} \left( \text{string\_a}, \text{string\_b} \right)
\]

**string\_a**  
(Input) Must be of type character.

**string\_b**  
(Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if \( \text{string\_a} \) follows \( \text{string\_b} \) in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGT (^{1,2})</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

\(^{1}\)This specific function cannot be passed as an actual argument.

\(^{2}\)The setting of compiler options specifying integer size can affect this function.

**Example**

LGT ( 'TWO', 'THREE' ) has the value true.

LGT ( 'ONE', 'FOUR' ) has the value true.

The following shows another example:

```fortran
LOGICAL L
L = LGT('ABC', 'ABC')  ! returns .FALSE.
L = LGT('ABC', 'AABC') ! returns .TRUE.
```

**LINEAR Clause**

**Parallel Directive Clause:** Specifies that all variables in a list are private to a SIMD lane and that they have a linear relationship within the iteration space of a loop.

**Syntax**

It takes one of the following forms:
In Construct Directive !$OMP SIMD:
LINEAR (var-list[; linear-step])

In Declarative Directive !$OMP DECLARE SIMD:
LINEAR (linear-list[; linear-step])

var-list
Is a comma-separated list of one or more integer variables. Each list item must comply with PRIVATE clause semantics.

For each iteration of a scalar loop, the value of each var is incremented by linear-step. For each iteration of a vector loop, the value of each var is incremented by linear-step times the vector length for the loop.

linear-step
Is a compile-time positive, integer, scalar constant expression. If linear-step is not specified, it is assumed to be 1.

linear-list
Takes one of the following forms:
- list
- modifier (list)

list
Is a comma-separated list of one or more dummy arguments of the procedure that will be invoked concurrently on each SIMD lane. Each list item must comply with PRIVATE clause semantics.

If modifier is not specified or it is VAL or UVAL, each list item must be a scalar of type integer. If modifier is REF, each list item must be a scalar of intrinsic type.

modifier
Is one of the following:
- REF
  Specifies that the storage location of each list item on each lane corresponds to an array at the storage location upon entry to the function indexed by the logical number of the lane times linear-step.
  The referenced values passed into the routine (which forms a vector for calculations) are located sequentially, like in an array, with the distance between elements equal to step.
  This modifier can be used only for dummy arguments passed by reference.
- VAL
  Specifies that the value of each list item on each lane corresponds to the value of the list item upon entry to the function plus the logical number of the lane times linear-step.
  On each iteration of the loop from which the routine is called, the value of the parameter can be calculated as (value_on_previous_iteration + step).
- UVAL
  Similar to VAL but each invocation uses the same storage location for each SIMD lane. This storage location is updated with the final value of the logically last lane. It differs from VAL as follows:
• For VAL, a vector of addresses (references) is passed to the vector variant of the routine.
• For UVAL, only one address (reference) is passed, which may improve performance.

This modifier can be used only for dummy arguments passed by reference.

If modifier is not specified or it is VAL or UVAL, the value of each list item on each lane corresponds to the value of the list item upon entry to the function plus the logical number of the lane times linear-step.

You can only use REF or VAL if the list item is a dummy argument without the Fortran Standard VALUE attribute.

If more than one linear-step is specified for a var, a compile-time error occurs. Multiple LINEAR clauses can be used to specify different values for linear-step. The linear-step expression must be invariant (must not be changed) during the execution of the associated construct. Multiple LINEAR clauses are merged as a union.

The value corresponding to the sequentially last iteration of the associated loops is assigned to the original list item.

A list item in a LINEAR clause cannot appear in any other data scope attribute clause, in another LINEAR clause, or more than once in list. For a list of data scope attribute clauses, see the first table in Clauses Used in Multiple OpenMP* Fortran Directives.

In the sequentially last iteration, any list item with the ALLOCATABLE attribute must have an allocation status of allocated upon exit from that iteration.

If a list item is a dummy argument without the Fortran Standard VALUE attribute and the REF modifier is not specified, then a read of the list item must be executed before any writes to the list item.

The following cannot appear in a LINEAR clause:
• Variables that have the POINTER attribute
• Cray* pointers

The LINEAR (REF) clause is very important because Fortran passes dummy arguments by reference. By default, the compiler places consecutive addresses in a vector register, which leads to an inefficient gather of the addresses.

In the following example, LINEAR (REF (X)) tells the compiler that the 4 addresses for the dummy argument X are consecutive, so the code only needs to dereference X once and then copy consecutive values to a vector register.

```
subroutine test_linear(x, y)
  !$omp declare simd (test_linear) linear(ref(x, y)) ! arguments by reference
  real(8),intent(in)  ::= x
  real(8),intent(out) ::= y
  y = 1. + sin(x)**3
end subroutine test_linear

! procedure that calls test_linear
interface
  ! test_linear needs an explicit interface
...!
  do j = 1,n
    call test_linear(a(j), b(j)) ! loop vectorized via qopenmp-simd
  enddo
...!
```
Example

Consider the following:

```fortran
! universal but slowest definition; it matches the use of func in loops 1, 2, and 3:
 !$OMP DECLARE SIMD
!
! matches the use of func in loop 1:
 !$OMP DECLARE SIMD LINEAR(in1) LINEAR(REF(in2)) UNIFORM(mul)
!
! matches the use of func in loops 2 and 3:
 !$OMP DECLARE SIMD LINEAR(REF(in2))
!
! matches the use of func in loop 2:
 !$OMP DECLARE SIMD LINEAR(REF(in2)) LINEAR(mul)
!
! matches the use of func in loop 3:
 !$OMP DECLARE SIMD LINEAR(VAL(in2:2))

function func(in1, in2, mul)
  integral in1
  integral in2
  integral mul
  ...
  integral a, k
  integral b(100)
  integral c(100)
  integral ndx(100)
  ...
end function func

The following are the loop examples referenced above.

!loop 1
 !$OMP SIMD
 DO i=1,100
  c(i) = func(a + i, b(i), mul) ! the value of the 1st parameter is changed linearly,
    ! the 2nd parameter reference is changed linearly,
    ! the 3rd parameter is not changed
 END DO
!
!loop 2
 !$OMP SIMD
 DO i=1,100
  c(i) = func(b(ndx(i)), b(i), i + 1 ! the value of the 1st parameter is unpredictable,
    ! the 2nd reference is changed linearly,
    ! the 3rd parameter is changed linearly
 END DO
!
!loop 3
 !$OMP SIMD
 DO i=1,100
  k = i * 2                       ! during vectorization, private variables are
    ! transformed into arrays: k -> k_vec(simdlen)
  c(i) = func(b(ndx(i)), k, b(i)) ! the value of the 1st parameter is unpredictable,
    ! for the 2nd parameter both value and reference
    ! to its location can be considered linear,
    ! the value for the 3rd parameter is unpredictable
    ! the $OMP DECLARE SIMD LINEAR(VAL(in2:2)) will
    ! be chosen from the two matching variants)
 END DO
```
LINETO, LINETO_W (W*S)

**Graphics Function:** Draws a line from the current graphics position up to and including the end point.

**Module**

USE IFQWIN

**Syntax**

```
result = LINETO (x, y)
result = LINETO_W (wx, wy)
```

- **x, y** (Input) INTEGER(2). Viewport coordinates of end point.
- **wx, wy** (Input) REAL(8). Window coordinates of end point.

**Results**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0.

The line is drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

If no error occurs, LINETO sets the current graphics position to the viewport point \((x, y)\), and LINETO_W sets the current graphics position to the window point \((wx, wy)\).

If you use FLOODFILLRGB to fill in a closed figure drawn with LINETO, the figure must be drawn with a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**NOTE**

The LINETO routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the LineTo routine by including the IFWIN module, you need to specify the routine name as MSFWIN$LineTo.

**Example**

This program draws the figure shown below.

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) xy

CALL MOVETO(INT2(80), INT2(50), xy)
status = LINETO(INT2(240), INT2(150))
status = LINETO(INT2(240), INT2(50))
END
```
LINETOAR (W*S)

**Graphics Function:** Draws a line between each \(x,y\) point in the from-array to each corresponding \(x,y\) point in the to-array.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{LINETOAR} (\text{loc}(fx), \text{loc}(fy), \text{loc}(tx) \text{ loc}(ty), \text{cnt})
\]

- \(fx\) (Input) INTEGER(2). From \(x\) viewport coordinate array.
- \(fy\) (Input) INTEGER(2). From \(y\) viewport coordinate array.
- \(tx\) (Input) INTEGER(2). To \(x\) viewport coordinate array.
- \(ty\) (Input) INTEGER(2). To \(y\) viewport coordinate array.
- \(cnt\) (Input) INTEGER(4). Length of each coordinate array; all should be the same size.

**Results**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

**Example**

```fortran
! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3),fy(3),tx(3),ty(3),result
integer(4) cnt, i
! load the points
do i = 1,3
```

SETWRITEMODE

LINETOAREX (W*S)

**Graphics Function:** Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. Each line is drawn with the specified graphics color and line style.

**Module**
USE IFQWIN

**Syntax**

```plaintext
result = LINETOAREX (loc(fx), loc(fy), loc(tx) loc(ty), loc(C), loc(S), cnt)
```

- **fx** (Input) INTEGER(2). From x viewport coordinate array.
- **fy** (Input) INTEGER(2). From y viewport coordinate array.
- **tx** (Input) INTEGER(2). To x viewport coordinate array.
- **ty** (Input) INTEGER(2). To y viewport coordinate array.
- **C** (Input) INTEGER(4). Color array.
- **S** (Input) INTEGER(4). Style array.
- **cnt** (Input) INTEGER(4). Length of each coordinate array; also the length of the color array and style array. All of the arrays should be the same size.

**Results**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the specified graphics colors and line styles, and with the current write mode. The current write mode is set with SETWRITEMODE.

If the color has the Z'80000000' bit set, the color is an RGB color; otherwise, the color is a palette color.
The styles are as follows from wingdi.h:

<table>
<thead>
<tr>
<th>Style</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOLID</td>
<td>0</td>
</tr>
<tr>
<td>DASH</td>
<td>1</td>
</tr>
<tr>
<td>DOT</td>
<td>2</td>
</tr>
<tr>
<td>DASHDOT</td>
<td>3</td>
</tr>
<tr>
<td>DASHDOTDOT</td>
<td>4</td>
</tr>
<tr>
<td>NULL</td>
<td>5</td>
</tr>
</tbody>
</table>

Example

```fortran
! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3), fy(3), tx(3), ty(3), result
integer(4) C(3), S(3), cnt, i, color

color = #000000FF

! load the points
do i = 1, 3
  S(i) = 0  ! all lines solid
  C(i) = IOR(Z'80000000', color)
  color = color*256 ! pick another of RGB
  if(IAND(color, Z'00FFFFFF').eq.0) color = Z'000000FF'
  ! from here
  fx(i) = 20*i
  fy(i) = 10
  ! to there
  tx(i) = 20*i
  ty(i) = 60
end do

! draw the lines all at once
! 3 vertical lines in upper left corner, Red, Green, and Blue
result = LINETOAREX(loc(fx), loc(fy), loc(tx), loc(ty), loc(C), loc(S), 3)
end
```

LLE

**Elemental Intrinsic Function (Generic):**
Determines whether a string is lexically less than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LLE is equivalent to the (.LE.) operator.

**Syntax**

```
result = LLE (string_a, string_b)
```

*string_a* (Input) Must be of type character.
string_b

(Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if string_a precedes string_b in the ASCII collating sequence; otherwise, the result is false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLE</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

1This specific function cannot be passed as an actual argument.

2The setting of compiler options specifying integer size can affect this function.

Example

LLE ( 'TWO', 'THREE' ) has the value false.

LLE ( 'ONE', 'FOUR' ) has the value false.

The following shows another example:

```fortran
LOGICAL L
L = LLE('ABC', 'ABC')   ! returns .TRUE.
L = LLE('ABC', 'AABCD') ! returns .FALSE.
```

**LLT**

Elemental Intrinsic Function (Generic):
Determine whether a string is lexically less than another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LLT is equivalent to the < ( .LT. ) operator.

Syntax

```fortran
result = LLT (string_a, string_b)
```

string_a (Input) Must be of type character.

string_b (Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if string_a precedes string_b in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLT ¹,²</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

¹This specific function cannot be passed as an actual argument.
²The setting of compiler options specifying integer size can affect this function.

**Example**

LLT ( 'ONE', 'SIX' ) has the value true.

LLT ( 'ONE', 'FOUR' ) has the value false.

The following shows another example:

```
LOGICAL L
L = LLT ( 'ABC', 'ABC' ) ! returns .FALSE.
L = LLT ( 'AAXYZ', 'ABCDE' ) ! returns .TRUE.
```

**LNBLNK**

*Portability Function:* Locates the position of the last nonblank character in a string.

**Module**

USE IFPORT

**Syntax**

```
result = LNBLNK ( string )
```

*(Input) Character*(*). String to be searched. Cannot be an array.

**Results**

The result type is INTEGER(4). The result is the index of the last nonblank character in string.

LNBLNK is very similar to the intrinsic function LEN_TRIM, except that string cannot be an array.

**Example**

```
USE IFPORT
integer(4) p
p = LNBLNK(' GOOD DAY ') ! returns 9
p = LNBLNK(' ') ! returns 0
```

**See Also**

LEN_TRIM
LOADIMAGE, LOADIMAGE_W (W*S)

**Graphics Functions:** Read an image from a Windows bitmap file and display it at a specified location.

**Module**
USE IFQWIN

**Syntax**

```fortran
result = LOADIMAGE (filename, xcoord, ycoord)
result = LOADIMAGE_W (filename, wxcoord, wycoord)
```

- `filename` *(Input)* Character*(*). Path of the bitmap file.
- `xcoord, ycoord` *(Input)* INTEGER(4). Viewport coordinates for upper-left corner of image display.
- `wxcoord, wycoord` *(Input)* REAL(8). Window coordinates for upper-left corner of image display.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The image is displayed with the colors in the bitmap file. If the color palette in the bitmap file is different from the current system palette, the current palette is discarded and the bitmap’s palette is loaded.

LOADIMAGE specifies the screen placement of the image in viewport coordinates. LOADIMAGE_W specifies the screen placement of the image in window coordinates.

**See Also**
SAVEIMAGE, SAVEIMAGE_W

**LOC**

**Inquiry Intrinsic Function (Generic):** Returns the internal address of a storage item. This function cannot be passed as an actual argument.

**Syntax**

```fortran
result = LOC (x)
```

- `x` *(Input)* Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the `%LOC` built-in function.
Example
The Fortran standard provides the C_LOC intrinsic module function as an alternative to the non-standard LOC. For more information, see the descriptions of C_LOC, C_FUNLOC, C_F_POINTER and C_F_PROCPOINTER.

! Example of using the LOC intrinsic
integer :: array(2) = [10,20]
integer :: t
pointer (p,t) ! Integer pointer extension
! p is pointer, t is pointee (target)
! This declares p as an address-sized integer
p = loc(array(1)) ! Address of array(1)
print *, t ! Prints 10
p = loc(array(2)) ! Address of array(2)
print *, t ! Prints 20

%LOC
Built-in Function: Computes the internal address of a storage item.

Syntax
result = %LOC (a)

a                  (Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Description
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the LOC intrinsic function.

LOCK and UNLOCK
Statements: A LOCK statement causes a lock variable to become locked by an image. An UNLOCK statement causes the lock variable to become unlocked. They take the following forms:

Syntax
LOCK (lock-var [, ACQUIRED_LOCK=log-var] [, STAT=stat-var] [, ERRMSG=err-var])
UNLOCK (lock-var [, STAT=stat-var] [, ERRMSG=err-var])

lock-var Is a scalar variable of type LOCK_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.
log-var Is a scalar logical variable.
stat-var Is a scalar integer variable in which the status of the synchronization is stored.
err-var

Is a scalar default character variable in which explanatory text is stored if an error occurs.

ACQUIRED_LOCK=, STAT=, and ERRMSG= can appear in any order, but only once in a LOCK statement.
STAT= and ERRMSG= can appear in either order, but only once in an UNLOCK statement.

**Description**

A lock variable is unlocked if its value is equal to that of the structure constructor LOCK_TYPE( ). If it has any other value, it is locked.

A lock variable is locked by an image if it was locked by execution of a LOCK statement on that image and has not been subsequently unlocked by execution of an UNLOCK statement on the same image.

When a LOCK statement is specified without an ACQUIRED_LOCK= specifier, it causes the lock variable to become locked by that image. If the lock variable is already locked by another image, that LOCK statement causes the lock variable to become defined after the other image causes the lock variable to become unlocked.

If the lock variable is unlocked, successful execution of a LOCK statement with an ACQUIRED_LOCK= specifier causes the lock variable to become locked by that image and the log-var to become defined with the value TRUE. If the lock variable is already locked by a different image, successful execution of a LOCK statement with an ACQUIRED_LOCK= specifier leaves the lock variable unchanged and causes the log-var to become defined with the value FALSE.

During the execution of the program, the value of a lock variable changes through a sequence of locked and unlocked states when LOCK and UNLOCK statements are executed. If a lock variable becomes unlocked by execution of an UNLOCK statement on image M and next becomes locked by execution of a LOCK statement on image T, the segments preceding the UNLOCK statement on image M precede the segments following the LOCK statement on image T. Execution of a LOCK statement that does not cause the lock variable to become locked does not affect segment ordering.

An error condition occurs in the following cases:
- If the lock variable in a LOCK statement is already locked by the executing image
- If the lock variable in an UNLOCK statement is not already locked by the executing image

If an error condition occurs during execution of a LOCK or UNLOCK statement, the value of the lock variable is not changed and the value of the ACQUIRED_LOCK variable, if any, is not changed.

**Example**

The following example shows the use of LOCK and UNLOCK statements to manage a work queue:

```fortran
USE, INTRINSIC :: ISO_FORTRAN_ENV

TYPE(Task) :: work_queue(50)* ! List of tasks on queue to perform
INTEGER :: work_queue_size*
TYPE(LOCK_TYPE) :: work_queue_lock* ! Lock to manage the work queue

TYPE(Task) :: current_task
INTEGER :: my_image
my_image = THIS_IMAGE()
DO
  ! Process the next task in the work queue
  LOCK (work_queue_lock) ! Start of new segment A
  ! Segment A is ordered with respect to segment B
  ! executed by image my_image-1 below because of lock exclusion
  IF (work_queue_size>0) THEN
```
! Get the next job from the queue
    current_task = work_queue(work_queue_size)
    work_queue_size = work_queue_size-1
END IF
UNLOCK (work_queue_lock) ! Segment ends

... ! Process the task

! Add a new task on the neighboring queue:
LOCK(work_queue_lock[my_image+1])      ! Starts segment B
! Segment B is ordered with respect to segment A
! executed by image my_image+1 above because of lock exclusion
IF (work_queue_size[my_image+1]<SIZE(work_queue)) THEN
    work_queue_size[my_image+1] = work_queue_size[ti+1]+1
    work_queue(work_queue_size[my_image+1])[my_image+1] = current_task
END IF
UNLOCK (work_queue_lock[my_image+1]) ! Ends segment B
END DO

LOG

Elemental Intrinsic Function (Generic): Returns the natural logarithm of the argument.

Syntax

result = LOG (x)

x         (Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

Results

The result type and kind are the same as x. The result value is approximately equal to \( \log_e x \).

If the arguments are complex, the result is the principal value with imaginary part \( \alpha \) in the range \( -\pi \leq \alpha \leq \pi \).

If the real part of \( x < 0 \) and the imaginary part of \( x \) is a positive real zero, the imaginary part of the result is \( -\pi \).

If the real part of \( x < 0 \) and the imaginary part of \( x \) is a negative real zero, the imaginary part of the result is \( \pi \).

<table>
<thead>

</tbody>
</table>
Specific Name | Argument Type | Result Type
---|---|---
CDLOG\(^3,4\) | COMPLEX(8) | COMPLEX(8)
CQLOG | COMPLEX(16) | COMPLEX(16)

1This function is treated like LOG.
2The setting of compiler options specifying real size can affect ALOG, LOG, and CLOG.
3This function can also be specified as ZLOG.
4The setting of compiler options specifying double size can affect CDLOG.

**Example**

LOG (8.0) has the value 2.079442.

LOG (25.0) has the value 3.218876.

The following shows another example:

```fortran
REAL r
r = LOG(10.0)  ! returns 2.302585
```

**See Also**

EXP

LOG10

---

**LOG_GAMMA**

*Elemental Intrinsic Function (Generic):* Returns the logarithm of the absolute value of the gamma function of the argument.

**Syntax**

```
result = LOG_GAMMA (x)
```

\(x\) (Input) Must be of type real. It must not be zero or a negative integer.

**Results**

The result type and kind are the same as \(x\).

The result has a value equal to a processor-dependent approximation to the natural logarithm of the absolute value of the gamma function of \(x\).

**Example**

LOG_GAMMA (3.0) has the approximate value 0.693.

---

**LOG10**

*Elemental Intrinsic Function (Generic):* Returns the common logarithm of the argument.

**Syntax**

```
result = LOG10 (x)
```
\( x \)  
(Input) Must be of type real or complex. If \( x \) is real, its value must be greater than zero. If \( x \) is complex, its value must not be zero.

**Results**

The result type and kind are the same as \( x \). The result value is approximately equal to \( \log_{10} x \).

1This function is treated like LOG10.  
2The setting of compiler options specifying real size can affect ALOG10, CLOG10, and LOG10.  
3The setting of compiler options specifying double size can affect DLOG10 and CDLOG10.

**Example**

LOG10 (8.0) has the value 0.9030900.  
LOG10 (15.0) has the value 1.176091.  

The following shows another example:

```fortran
REAL r  
r = LOG10(10.0)  ! returns 1.0
```

**See Also**

LOG

LOGICAL Function

*Elemental Intrinsic Function (Generic):* Converts the logical value of the argument to a logical value with different kind parameters.

**Syntax**

```
result = LOGICAL (l[,kind])
```

\( l \)  
(Input) Must be of type logical.  

\( kind \)  
(Input; optional) Must be a scalar integer constant expression.

**Results**

The result is of type logical. If \( kind \) is present, the kind parameter is that specified by \( kind \); otherwise, the kind parameter is that of default logical. The result value is that of \( l \).  

The setting of compiler options specifying integer size can affect this function.
**Example**

LOGICAL (L .OR. .NOT. L) has the value true and is of type default logical regardless of the kind parameter of logical variable L.

LOGICAL (.FALSE., 2) has the value false, with the parameter of kind 2.

**See Also**
CMPLX
INT
REAL
Logical Data Types

**LOGICAL Statement**

*Statement:* Specifies the LOGICAL data type.

**Syntax**

LOGICAL
LOGICAL ([KIND=] n)
LOGICAL* n

n Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

**Example**

```fortran
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (2), SAVE :: doit, dont=.FALSE.
LOGICAL switch

! An equivalent declaration is:
LOGICAL flag1, flag2
LOGICAL (2) doit, dont=.FALSE.
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

**See Also**
Logical Data Types
Logical Constants
Data Types, Constants, and Variables

**LONG**

*Portability Function:* Converts an INTEGER(2) argument to INTEGER(4) type.

**Module**

USE IFPORT

**Syntax**

```fortran
result = LONG (int2)
```
**int2**

(Input) INTEGER(2). Value to be converted.

**Results**

The result type is INTEGER(4). The result is the value of *int2* with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to *int2*.

**See Also**

INT
KIND

**LOOP COUNT**

*General Compiler Directive:* Specifies the iterations (typical trip count) for a DO loop.

**Syntax**

!DIR$ LOOP COUNT (*n1*, *n2*)

!DIR$ LOOP COUNT = *n1*, *n2*

!DIR$ LOOP COUNT qualifier(*n*), qualifier(*n*)

!DIR$ LOOP COUNT qualifier=*$n*$, qualifier=*n*

*n1*, *n2*  
Is a non-negative integer constant. It indicates that the next DO loop will iterate *n1*, *n2*, or some other number of times.

qualifier  
Is one or more of the following:

- **MAX** - specifies the maximum loop trip count.
- **MIN** - specifies the minimum loop trip count.
- **AVG** - specifies the average loop trip count.

The value of the loop count affects heuristics used in software pipelining, vectorization, and loop-transformations.

**Example**

Consider the following:

```fortran
!DIR$ LOOP COUNT (10000)
do i =1,m
  b(i) = a(i) +1 ! This is likely to enable the loop to get software-pipelined
endo
```

Note that you can specify more than one LOOP COUNT directive for a DO loop. For example, the following directives are valid:

```fortran
!DIR$ LOOP COUNT (10, 20, 30)
!DIR$ LOOP COUNT MAX=100, MIN=3, AVG=17
DO
...
```

**See Also**

*General Compiler Directives*

**Syntax Rules for Compiler Directives**

**Rules for General Directives that Affect DO Loops**

**Rules for Loop Directives that Affect Array Assignment Statements**
**LSHIFT**

**Elemental Intrinsic Function (Generic):** Shifts the bits in an integer left by a specified number of positions. This is the same as specifying ISHFT with a positive shift.

**See Also**
See ISHFT.

---

**LSTAT**

**Portability Function:** Returns detailed information about a file.

**Module**
USE IFPORT

**Syntax**

```fortran
result = LSTAT (name, statb)
```

- **name** (Input) Character*(*). Name of the file to examine.
- **statb** (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See STAT for the possible values returned in `statb`.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see IERRNO).

LSTAT returns detailed information about the file named in *name*.

On Linux* and macOS* systems, if the file denoted by *name* is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function.

INQUIRE also provides information about file properties.

**Example**

```fortran
USE IFPORT
INTEGER(4) info_array(12), istatus
character*20 file_name
print *, "Enter name of file to examine: ", file_name
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
   print *, info_array
else
   print *, 'Error ', istatus
end if
```

**See Also**
INQUIRE
GETFILEINFOQQ
STAT
LTIME

*Portability Subroutine:* Returns the components of the local time zone time in a nine-element array.

**Module**

USE IFPORT

**Syntax**

CALL LTIME (time, array)

- **time** (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.
- **array** (Output) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from time.

The elements of array are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>array(1)</td>
<td>Seconds (0 - 59)</td>
</tr>
<tr>
<td>array(2)</td>

**Caution**

This subroutine is not year-2000 compliant, use DATE_AND_TIME instead.

On Linux* and macOS*, time can be a negative number returning the time before 00:00:00 Greenwich mean time, January 1, 1970. On Windows*, time can not be negative, in which case all 9 elements of array are set to -1. On all operating systems, if there is a system error in getting the local time, all 9 elements of array are set to -1.

**Example**

```
USE IFPORT
INTEGER(4) input_time, time_array(9)
! find number of seconds since 1/1/70
input_time=TIME()
```
CALL LTIME (input_time, time_array)
PRINT *, time_array

DATE_AND_TIME

M to N

MAKEDIRQQ

Portability Function: Creates a new directory with a specified name.

Module
USE IFPORT

Syntax
result = MAKEDIRQQ (dirname)

dirname (Input) Character*(*). Name of directory to be created.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or backslash (\) as valid delimiters.

If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:

- ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- ERR$EXIST - The directory already exists.
- ERR$NOENT - The file or path specified was not found.

Example
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ ('mynedir')
IF (result) THEN
    WRITE (*,*) 'New subdirectory successfully created'
ELSE
    WRITE (*,*) 'Failed to create subdirectory'
END IF
END

See Also
DELDIRQQ
CHANGEDIRQQ
GETLASTERRORQQ
**MALLOC**

*Elemental Intrinsic Function (Generic): Allocates a block of memory. This is a generic function that has no specific function associated with it. It must not be passed as an actual argument.*

**Syntax**

\[
\text{result} = \text{MALLOC} \ (\text{size})
\]

- **result** (Output) Must be of type integer. This value is the size (in bytes) of memory to be allocated.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the starting address of the allocated memory. The memory allocated can be freed by using the FREE intrinsic function.

**Example**

```
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
```

**MAP Clause**

*Clause for TARGET Directives: Maps a variable from the data environment of the current task to the data environment of the device associated with the construct. This clause only applies to the TARGET directives, which are only available and when targeting Intel® Xeon Phi™ products.*

**Syntax**

\[
\text{MAP} \ (\text{[map-type-modifier[,]]} \ \text{map-type :} \ \text{list})
\]

- **map-type-modifier**
  - **ALWAYS**
    - Specifies that initialization should always occur for the list items.

- **map-type**
  - **ALLOC**
    - On entry to the outermost device region, each new corresponding list item has an undefined initial value.

  - **FROM**
    - On exit from the device region, the value of the corresponding list item is assigned to each original list item.

    - This is ignored for nested regions unless **map-type-modifier** ALWAYS is specified.
TO

On entry to the device region, each new corresponding list item is initialized with the value of the original list item.

This is ignored for nested regions unless map-type-modifier ALWAYS is specified.

TOFROM

On entry to the device region, each new corresponding list item is initialized with the value of the original list item. On exit from the device region, the value of the corresponding list item is assigned to each original list item.

This is ignored for nested regions unless map-type-modifier ALWAYS is specified.

DELETE

On exit from the device region, if the corresponding list item is present on the device, it is then deleted from the device.

RELEASE

On exit from the outermost device region, the corresponding list item is deleted from the device.

If a map-type is not specified, the default is TOFROM.

The map initialization and assignment are done as if by intrinsic assignment, that is, through bitwise copy.

list

Is the name of one or more variables, array sections, or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /).

If a list item is an array section, it must specify contiguous storage.

A list item can appear in at most one of the TO, FROM, or TOFROM clauses. If a list item appears in an ALLOC clause, it cannot appear on a TO or TOFROM clause.

On entry to an outermost target region where this clause is used, for each original list item, a new corresponding list item is created on the device. On exit from the outermost target region, if the corresponding list item is present on the device, it is then deleted from the device.

At least one MAP clause must appear in a directive that allows the clause.

THREADPRIVATE variables cannot appear in a MAP clause.

For the TARGET ENTER DATA directive, map-type must be either TO or ALLOC.

For the TARGET EXIT DATA directive, map-type must be FROM, RELEASE, or DELETE.

For the TARGET and TARGET DATA directives, map-type must be TO, FROM, TOFROM, or ALLOC.

For the TARGET UPDATE directive, map-type must be TO or FROM.

If original and corresponding list items share storage, data races can result when intervening synchronization between tasks does not occur. If variables that share storage are mapped, it causes unspecified behavior.

Any variables within a TARGET MAP region that are not specified in a MAP clause are treated as shared variables within the region.

A list item must not contain any components that have the ALLOCATABLE attribute.
If the allocation status of a list item with the ALLOCATABLE attribute is unallocated upon entry to a target region, the list item must be unallocated upon exit from the region.

If the allocation status of a list item with the ALLOCATABLE attribute is allocated upon entry to a target region, the allocation status of the corresponding list item must not be changed and must not be reshaped in the region.

If an array section of an allocatable array is mapped and the size of the section is smaller than that of the whole array, the target region must not have any reference to the whole array.

See Also
TARGET directive clause DEFAULTMAP

MAP and END MAP
Statement: Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration.

Example

```fortran
UNION
  MAP
    CHARACTER*20 string
  END MAP
  MAP
    INTEGER*2 number(10)
  END MAP
END UNION

UNION
  MAP
    RECORD /Cartesian/ xcoord, ycoord
  END MAP
  MAP
    RECORD /Polar/ length, angle
  END MAP
END UNION
```

See Also
See STRUCTURE.

MASKL
Elemental Intrinsic Function (Generic): Returns a left-justified mask.

Syntax

```
result = MASKL (i[,kind])
```

- `i` (Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits `s` of the model integer defined for bit manipulation contexts.

- `kind` (Input; optional) Must be a scalar integer constant expression.
**Results**

The result type is integer. If \( kind \) is present, the kind parameter of the result is that specified by \( kind \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its leftmost I bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKL (3) has the value SHIFTL (7, BIT_SIZE (0) - 3).

**See Also**

MASKR

**MASKR**

*Elemental Intrinsic Function (Generic): Returns a right-justified mask.*

**Syntax**

\[
\text{result} = \text{MASKR} \ (i[,kind])
\]

- \( i \) (Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits \( s \) of the model integer defined for bit manipulation contexts.
- \( kind \) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If \( kind \) is present, the kind parameter of the result is that specified by \( kind \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its rightmost I bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKR (3) has the value 7.

**See Also**

MASKL

**MASTER**

*OpenMP* Fortran Compiler Directive: Specifies a block of code to be executed by the master thread of the team.

**Syntax**

\[
!$\text{OMP MASTER}
\begin{align*}
\text{block} \\
!$\text{OMP END MASTER}
\end{align*}
\]
block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for a MAS construct is the current team. A master region binds to the innermost enclosing parallel region.

When the MASTER directive is specified, the other threads in the team skip the enclosed block (section) of code and continue execution. There is no implied barrier, either on entry to or exit from the master section.

Example

The following example forces the master thread to execute the routines OUTPUT and INPUT:

```
!$OMP PARALLEL DEFAULT(SHARED)
  CALL WORK(X)
!$OMP MASTER
  CALL OUTPUT(X)
  CALL INPUT(Y)
!$OMP END MASTER
  CALL WORK(Y)
!$OMP END PARALLEL
```

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

MATMUL

Transformational Intrinsic Function (Generic):

Performs matrix multiplication of numeric or logical matrices.

Syntax

```
result = MATMUL (matrix_a, matrix_b)
```

*matrix_a*:*  
(Input) Must be an array of rank one or two. It must be of numeric (integer, real, or complex) or logical type.

*matrix_b*:  
(Input) Must be an array of rank one or two. It must be of numeric type if *matrix_a* is of numeric type or logical type if *matrix_a* is logical type.

At least one argument must be of rank two. The size of the first (or only) dimension of *matrix_b* must equal the size of the last (or only) dimension of *matrix_a*.

Results

The result is an array whose type depends on the data type of the arguments, according to the rules described in Data Type of Numeric Expressions. The rank and shape of the result depends on the rank and shapes of the arguments, as follows:

- If *matrix_a* has shape \((n, m)\) and *matrix_b* has shape \((m, k)\), the result is a rank-two array with shape \((n, k)\).
- If *matrix_a* has shape \((m)\) and *matrix_b* has shape \((m, k)\), the result is a rank-one array with shape \((k)\).
- If *matrix_a* has shape \((n, m)\) and *matrix_b* has shape \((m)\), the result is a rank-one array with shape \((n)\).
If the arguments are of numeric type, element \((i,j)\) of the result has the value \(\text{SUM}((\text{row }i \text{ of } \text{matrix}_a) \times (\text{column }j \text{ of } \text{matrix}_b))\). If the arguments are of logical type, element \((i,j)\) of the result has the value \(\text{ANY}((\text{row }i \text{ of } \text{matrix}_a) \text{ .AND. } (\text{column }j \text{ of } \text{matrix}_b))\).

**Example**

A is matrix

\[
\begin{bmatrix}
2 & 3 & 4 \\
3 & 4 & 5
\end{bmatrix}
\]

B is matrix

\[
\begin{bmatrix}
2 & 3 \\
3 & 4 \\
4 & 5
\end{bmatrix}
\]

X is vector \((1, 2)\), and Y is vector \((1, 2, 3)\).

The result of `MATMUL (A, B)` is the matrix-matrix product \(AB\) with the value

\[
\begin{bmatrix}
29 & 38 \\
38 & 50
\end{bmatrix}
\]

The result of `MATMUL (X, A)` is the vector-matrix product \(XA\) with the value \((8, 11, 14)\).

The result of `MATMUL (A, Y)` is the matrix-vector product \(AY\) with the value \((20, 26)\).

The following shows another example:

```fortran
INTEGER a(2,3), b(3,2), c(2), d(3), e(2,2), f(3), g(2)
a = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! a is
! 1 3 5
! 2 4 6
b = RESHAPE((/1, 2, 3, 4, 5, 6/), (/3, 2/))
! b is
! 1 4
! 2 5
! 3 6
c = (/1, 2/)      ! c is \([1, 2]\)
d = (/1, 2, 3/)   ! d is \([1, 2, 3]\)
e = MATMUL(a, b)    ! returns 22 49
!      28 64
f = MATMUL(c,a)   ! returns [5 11 17]
g = MATMUL(a,d)   ! returns [22 28]
WRITE(*,*) e, f, g
END
```

**See Also**

TRANSPOSE
PRODUCT

**MAX**

*Elemental Intrinsic Function (Generic):* Returns the maximum value of the arguments.

**Syntax**

\[
\text{result} = \text{MAX} \ (a_1, a_2[,a_3]...)
\]
a1, a2, a3  

(Input) All must have the same type (integer, real, or character) and kind parameters.

Results

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MAX0, AMAX1, DMAX1, QMAX1, IMAX0, JMAX0, and KMAX0, the result type is the same as the arguments. For MAX1, IMAX1, JMAX1, and KMAX1, the result type is integer. For AMAX0, AIMAX0, AJMAX0, and AKMAX0, the result type is real. The value of the result is that of the largest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

2Or JMAX0.

3Or AMAX0. AMAX0 is the same as REAL (MAX).

4In Standard Fortran, AMAX0 and MAX1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

5Or JMAX1. MAX1 is the same as INT(MAX).

6The setting of compiler options specifying integer size can affect MAX1.

7The setting of compiler options specifying real size can affect AMAX1.

Example

MAX (2.0, -8.0, 6.0) has the value 6.0.

MAX (14, 32, -50) has the value 32.
The following shows another example:

```plaintext
INTEGER m1, m2
REAL r1, r2
m1 = MAX(5, 6, 7)           ! returns 7
m2 = MAX1(5.7, 3.2, -8.3)   ! returns 5
r1 = AMAX0(5, 6, 7)         ! returns 7.0
r2 = AMAX1(6.4, -12.2, 4.9) ! returns 6.4
```

MAXVAL
MIN

**MAXEXPONENT**

*Inquiry Intrinsic Function (Generic):* Returns the maximum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```plaintext
result = MAXEXPONENT (x)
```

*x*  
(Input) Must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. The result has the value $e_{\text{max}}$, as defined in *Model for Real Data*.

**Example**

```plaintext
REAL(4) x
INTEGER i
i = MAXEXPONENT(x)    ! returns 128.
```

See Also

MINEXPONENT

**MAXLOC**

*Transformational Intrinsic Function (Generic):* Returns the location of the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

**Syntax**

```plaintext
result = MAXLOC (array, dim [, mask, kind, back])
result = MAXLOC (array [, mask, kind, back])
```

*array*  
(Input) Must be an array of type integer, real, or character.

*dim*  
(Input) Must be a scalar integer with a value in the range 1 to $n$, where $n$ is the rank of *array*.

*mask*  
(Input; optional) Must be a logical array that is conformable with *array*. 
kind  (Input; optional) Must be a scalar integer constant expression.
back  (Input; optional) Must be a scalar of type logical.

Results
The result is an array of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if dim is omitted:
• The array result has rank one and a size equal to the rank of array.
• If MAXLOC(array) is specified, the elements in the array result form the subscript of the location of the element with the maximum value in array.
  The i-th subscript returned lies in the range 1 to e_i, where e_i is the extent of the i-th dimension of array.
• If MAXLOC(array, MASK=mask) is specified, the elements in the array result form the subscript of the location of the element with the maximum value corresponding to the condition specified by mask.

The following rules apply if dim is specified:
• The array result has a rank that is one less than array, and shape (d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n), where (d_1, d_2,...d_n) is the shape of array.
• If array has rank one, MAXLOC(array, dim [, mask]) is a scalar and has a value equal to the first element of MAXLOC( array [, MASK = mask]). Otherwise, the value of element (s_1, s_2,...s_{dim-1}, s_{dim+1},...s_n) of MAXLOC( array, dim [, mask]) is equal to MAXLOC( array(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n) [, MASK = mask(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n)]).

If only one element has the maximum value, that element’s subscripts are returned. Otherwise, if more than one element has the maximum value and back is absent or present with the value .FALSE., the element whose subscripts are returned is the first such element, taken in array element order. If back is present with the value .TRUE., the element whose subscripts are returned is the last such element, taken in array element order.

If array has size zero, or every element of mask has the value .FALSE., the value of the result is controlled by compiler option assume [no]old_maxminloc, which can set the value of the result to either 1 or 0.

If array is of type character, the comparison is done using the ASCII collating sequence.
The setting of compiler options specifying integer size can affect this function.

Example
The value of MAXLOC((/3, 7, 4, 7/)) is (2), which is the subscript of the location of the first occurrence of the maximum value in the rank-one array.

A is the array

```
[  4    0    4    2 ]
[  3    1   -2    6 ]
[ -1   -4    5    5 ].
```

MAXLOC (A, MASK=A .LT. 5) has the value (1, 1) because these are the subscripts of the location of the first maximum value (4) that is less than 5.

MAXLOC (A, DIM=1) has the value (1, 2, 3, 2). 1 is the subscript of the location of the first maximum value (4) in column 1; 2 is the subscript of the location of the first maximum value (1) in column 2; and so forth.

MAXLOC (A, DIM=2) has the value (1, 4, 3). 1 is the subscript of the location of the first maximum value in row 1; 4 is the subscript of the location of the first maximum value in row 2; and so forth.
MAXLOC (A, DIM=2, BACK=.TRUE.) has the value (3, 4, 4). 3 is the subscript of the location of the last maximum value in row 1; 4 is the subscript of the location of the last maximum value in row 2; and so forth.

The following shows another example:

```fortran
INTEGER i, maxl(1), max
INTEGER array(3, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/7, 9, -1, -2, 5, 0, 3, 6, 9/), (/3, 3/))
! array is  7 -2 3
!           9  5 6
!          -1  0 9
i = SIZE(SHAPE(array))   ! Get number of dimensions
! in array
ALLOCATE ( AR1(i))       ! Allocate AR1 to number
! of dimensions in array
AR1 = MAXLOC (array, MASK = array .LT. 7) ! Get
! the location (subscripts) of
! largest element less than 7
! in array
!
! MASK = array .LT. 7 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is less than 7,
! and .FALSE. if it is not. This mask causes MAXLOC to
! return the index of the element in array with the
! greatest value less than 7.
!
! array is  7 -2 3 and MASK=array .LT. 7 is F T T
! 9 5 6 F T T
! -1 0 9 T F F
! and AR1 = MAXLOC(array, MASK = array .LT. 7) returns
! (2, 3), the location of the element with value 6

maxl = MAXLOC((/1, 4, 3, 4/))    ! returns 2, the first
! occurrence of maximum
```

FINDLOC

MAXVAL

Transformational Intrinsic Function (Generic):
Returns the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

```
result = MAXVAL (array[,dim] [,mask])
```
array  (Input) Must be an array of type integer, real, or character.
dim   (Input; optional) Must be a scalar integer expression with a value in
       the range 1 to n, where n is the rank of array.
mask  (Input; optional) Must be a logical array that is conformable with
       array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is omitted or array has rank one.

The following rules apply if dim is omitted:
• If MAXVAL( array) is specified, the result has a value equal to the maximum value of all the elements in
  array.
• If MAXVAL( array, MASK= mask) is specified, the result has a value equal to the maximum value of the
  elements in array corresponding to the condition specified by mask.

The following rules apply if dim is specified:
• An array result has a rank that is one less than array, and shape (d1, d2,...,d_dim-1, d_dim+1, ..., dn), where
  (d1, d2,...,dn) is the shape of array.
• If array has rank one, MAXVAL( array, dim[, mask]) has a value equal to that of MAXVAL( array[, MASK =
  mask]). Otherwise, the value of element (s1, s2, ..., s_dim-1, s_dim+1, ..., sn) of MAXVAL( array, dim, [, mask])
  is equal to MAXVAL( array(s1, s2, ..., s_dim-1, :, s_dim+1, ..., sn) [,MASK = mask(s1, s2, ..., s_dim-1, :,
  s_dim+1, ..., sn)].

If array has size zero or if there are no true elements in mask, the result (if dim is omitted), or each element
in the result array (if dim is specified), has the value of the negative number of the largest magnitude
supported by the processor for numbers of the type and kind parameters of array.

If array is of type character, the comparison is done using the ASCII collating sequence.

Example
The value of MAXVAL ((/2, 3, 4/)) is 4 because that is the maximum value in the rank-one array.
MAXVAL (B, MASK=B .LT. 0.0) finds the maximum value of the negative elements of B.
C is the array

\[
\begin{pmatrix}
2 & 3 & 4 \\
5 & 6 & 7
\end{pmatrix}
\]

MAXVAL (C, DIM=1) has the value (5, 6, 7). 5 is the maximum value in column 1; 6 is the maximum value in
column 2; and so forth.

MAXVAL (C, DIM=2) has the value (4, 7). 4 is the maximum value in row 1 and 7 is the maximum value in
row 2.

The following shows another example:

```
INTEGER array(2,3), i(2), max
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
! array is  1 5 3
!        4 2 6
i = SHAPE(array) ! i = [2 3]
ALLOCATE (AR1(i(2))) ! dimension AR1 to the number of
! elements in dimension 2
! (a column) of array
```
ALLOCATE (AR2(i(1))) ! dimension AR2 to the number of
! elements in dimension 1
! (a row) of array
max = MAXVAL(array, MASK = array .LT. 4) ! returns 3
AR1 = MAXVAL(array, DIM = 1) ! returns [ 4 5 6 ]
AR2 = MAXVAL(array, DIM = 2) ! returns [ 5 6 ]
END

**MBCharLen (W*S)**

**NLS Function:** Returns the length, in bytes, of the
first character in a multibyte-character string.

**Module**
USE IFNLS

**Syntax**
result = MBCharLen (string)

*string* (Input) Character*(*)*. String containing the character whose length is
to be determined. Can contain multibyte characters.

**Results**
The result type is INTEGER(4). The result is the number of bytes in the first character contained in *string*. The function returns 0 if *string* has no characters (is length 0).

MBCharLen does not test for multibyte character validity.

**MBConvertMBToUnicode (W*S)**

**NLS Function:** Converts a multibyte-character string
from the current codepage to a Unicode string.

**Module**
USE IFNLS

**Syntax**
result = MBConvertMBToUnicode (mbstr, unicodestr[,flags])

*mbstr* (Input) Character*(*)*. Multibyte codepage string to be converted.
unicodestr

(Output) INTEGER(2). Array of integers that is the translation of the input string into Unicode.

flags

(Input; optional) INTEGER(4). If specified, modifies the string conversion. If flags is omitted, the value NLS$Precomposed is used. Available values (defined in IFNLS.F90) are:

- NLS$Precomposed - Use precomposed characters always. (default)
- NLS$Composite - Use composite wide characters always.
- NLS$UseGlyphChars - Use glyph characters instead of control characters.
- NLS$ErrorOnInvalidChars - Returns -1 if an invalid input character is encountered.

The flags NLS$Precomposed and NLS$Composite are mutually exclusive. You can combine NLS$UseGlyphChars with either NLS$Precomposed or NLS$Composite using an inclusive OR (IOR or OR).

Results

The result type is INTEGER(4). If no error occurs, the result is the number of bytes written to uncodestr (bytes are counted, not characters), or the number of bytes required to hold the output string if uncodestr has zero size. If the uncodestr array is bigger than needed to hold the translation, the extra elements are set to space characters. If uncodestr has zero size, the function returns the number of bytes required to hold the translation and nothing is written to uncodestr.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficentBuffer - The uncodestr argument is too small, but not zero size so that the needed number of bytes would be returned.
- NLS$ErrorInvalidFlags - The flags argument has an illegal value.
- NLS$ErrorInvalidCharacter - A character with no Unicode translation was encountered in mbstr. This error can occur only if the NLS$InvalidCharsError flag was used in flags.

NOTE

By default, or if flags is set to NLS$Precomposed, the function MBConvertMBToUnicode attempts to translate the multibyte codepage string to a precomposed Unicode string. If a precomposed form does not exist, the function attempts to translate the codepage string to a composite form.

See Also

MBConvertUnicodeToMB

MBConvertUnicodeToMB (W*S)

NLS Function: Converts a Unicode string to a multibyte-character string from the current codepage.

Module

USE IFNLS

Syntax

result = MBConvertUnicodeToMB (unicodestr, mbstr[,flags])
**unicodestr**

(Input) INTEGER(2). Array of integers holding the Unicode string to be translated.

**mbstr**

(Output) Character*(*). Translation of Unicode string into multibyte character string from the current codepage.

**flags**

(Input; optional) INTEGER(4). If specified, argument to modify the string conversion. If *flags* is omitted, no extra checking of the conversion takes place. Available values (defined in `IFNLS.F90`) are:

- NLS$CompositeCheck - Convert composite characters to precomposed.
- NLS$SepChars - Generate separate characters.
- NLS$DiscardDns - Discard nonspace characters.
- NLS$DefaultChars - Replace exceptions with default character.

The last three flags (NLS$SepChars, NLS$DiscardDns, and NLS$DefaultChars) are mutually exclusive and can be used only if NLS$CompositeCheck is set, in which case one (and only one) of them is combined with NLS$CompositeCheck using an inclusive OR (IOR or OR). These flags determine what translation to make when there is no precomposed mapping for a base character/nonspace character combination in the Unicode wide character string. The default (IOR(NLS$CompositeCheck, NLS$SepChars)) is to generate separate characters.

**Results**

The result type is INTEGER(4). If no error occurs, returns the number of bytes written to *mbstr* (bytes are counted, not characters), or the number of bytes required to hold the output string if *mbstr* has zero length. If *mbstr* is longer than the translation, it is blank-padded. If *mbstr* is zero length, the function returns the number of bytes required to hold the translation and nothing is written to *mbstr*.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficientBuffer - The *mbstr* argument is too small, but not zero length so that the needed number of bytes is returned.
- NLS$ErrorInvalidFlags - The *flags* argument has an illegal value.

MBConvertMBToUnicode

**MBCurMax (W*S)**

**NLS Function:** Returns the longest possible multibyte character length, in bytes, for the current codepage.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBCurMax( )
```

**Results**

The result type is INTEGER(4). The result is the longest possible multibyte character, in bytes, for the current codepage.
The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**See Also**
MBCharLen

### MBINCHARQQ (W*S)

**NLS Function:** Performs the same function as INCHARQQ except that it can read a single multibyte character at once, and it returns the number of bytes read as well as the character.

**Module**
USE IFNLS

**Syntax**

```
result = MBINCHARQQ (string)
```

*string* (Output) CHARACTER(MBLenMax). String containing the read characters, padded with blanks up to the length MBLenMax. The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**Results**

The result type is INTEGER(4). The result is the number of characters read.

**See Also**
INCHARQQ
MBCurMax
MBCharLen
MBLead

### MBINDEX (W*S)

**NLS Function:** Performs the same function as INDEX except that the strings manipulated can contain multibyte characters.

**Module**
USE IFNLS

**Syntax**

```
result = MBINDEX (string, substring [, back])
```

*string* (Input) CHARACTER(*). String to be searched for the presence of *substring*. Can contain multibyte characters.

*substring* (Input) CHARACTER(*). Substring whose position within *string* is to be determined. Can contain multibyte characters.
(Input; optional) LOGICAL(4). If specified, determines direction of the search. If \textit{back} is .FALSE. or is omitted, the search starts at the beginning of \textit{string} and moves toward the end. If \textit{back} is .TRUE., the search starts end of \textit{string} and moves toward the beginning.

\section*{Results}

The result type is INTEGER(4). If \textit{back} is omitted or is .FALSE., it returns the leftmost position in \textit{string} that contains the start of \textit{substring}. If \textit{back} is .TRUE., it returns the rightmost position in \textit{string} that contains the start of \textit{substring}. If \textit{string} does not contain \textit{substring}, it returns 0. If \textit{substring} occurs more than once, it returns the starting position of the first occurrence ("first" is determined by the presence and value of \textit{back}).

The position returned is a byte index, not a character index because of the confounding case of multibyte characters. As an example, if a substring which is a single multi-byte character matches the second multibyte character in a string consisting of two two-byte multi-byte characters the position is 3, not 2.

INDEX
MBSCAN
MBVERIFY

\section*{MBJISToJMS, MBJMSToJIS (W*S)}

\textbf{NLS Functions: Converts Japan Industry Standard (JIS) characters to Microsoft Kanji (JMS) characters, or converts JMS characters to JIS characters.}

\section*{Module}

USE IFNLS

\section*{Syntax}

\begin{verbatim}
result = MBJISToJMS (char)
result = MBJMSToJIS (char)
\end{verbatim}

\textit{char} (Input) CHARACTER(2). JIS or JMS character to be converted.

A JIS character is converted only if the lead and trail bytes are in the hexadecimal range 21 through 7E.

A JMS character is converted only if the lead byte is in the hexadecimal range 81 through 9F or E0 through FC, and the trail byte is in the hexadecimal range 40 through 7E or 80 through FC.

\section*{Results}

The result type is character with length 2. MBJISToJMS returns a Microsoft Kanji (Shift JIS or JMS) character. MBJMSToJIS returns a Japan Industry Standard (JIS) character.

Only computers with Japanese installed as one of the available languages can use the MBJISToJMS and MBJMSToJIS conversion functions.

NLSSetLocale
**MBLead (W*S)**

**NLS Function:** Determines whether a given character is the lead (first) byte of a multibyte character sequence.

**Module**

USE IFNLS

**Syntax**

```
result = MBLead (char)
```

- **char** (Input) CHARACTER(1). Character to be tested for lead status.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if `char` is the first character of a multibyte character sequence; otherwise, .FALSE..

MBLead only works stepping forward through a whole multibyte character string. For example:

```fortran
DO i = 1, LEN(str)  ! LEN returns the number of bytes, not the number of characters in str
  WRITE(*, 100) MBLead (str(i:i))
END DO
100   FORMAT (L2, \)
```

MBLead is passed only one character at a time and must start on a lead byte and step through a string to establish context for the character. MBLead does not correctly identify a nonlead byte if it is passed only the second byte of a multibyte character because the status of lead byte or trail byte depends on context.

The function MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context. So, MBStrLead can be much slower than MBLead (up to \( n \) times slower, where \( n \) is the length of the string).

**MBLen (W*S)**

**NLS Function:** Returns the number of characters in a multibyte-character string, including trailing blanks.

**Module**

USE IFNLS

**Syntax**

```
result = MBLen (string)
```

- **string** (Input) CHARACTER*(*) (1). String whose characters are to be counted. Can contain multibyte characters.

**Results**

The result type is INTEGER(4). The result is the number of characters in `string`.

---

Intel® Fortran Compiler 19.0 Developer Guide and Reference
MBLen recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

See Also
MBLen_Trim
MBStrLead

**MBLen_Trim (W*S)**

_NLS Function:_ Returns the number of characters in a multibyte-character string, not including trailing blanks.

**Module**
USE IFNLS

**Syntax**
```
result = MBLen_Trim (string)
```

```
string  (Input) Character*(*). String whose characters are to be counted. Can contain multibyte characters.
```

**Results**
The result type is INTEGER(4). The result is the number of characters in string minus any trailing blanks (blanks are bytes containing character 32 (hex 20) in the ASCII collating sequence).

MBLen_Trim recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

**MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE (W*S)**

_NLS Functions:_ Perform the same functions as LGE, LGT, LLE, LLT and the logical operators .EQ. and .NE. except that the strings being compared can include multibyte characters, and optional flags can modify the comparison.

**Module**
USE IFNLS

**Syntax**
```
result = MBLGE (string_a,string_b, [ flags])
```

```
result = MBLGT (string_a,string_b, [ flags])
```

```
result = MBLLE (string_a,string_b, [ flags])
```

```
result = MBLLT (string_a,string_b, [ flags])
```

```
result = MBLEQ (string_a,string_b, [ flags])
```

```
result = MBLNE (string_a,string_b, [ flags])
```

Language Reference
**string_a, string_b**

(Input) Character*(*). Strings to be compared. Can contain multibyte characters.

**flags**

(Input; optional) INTEGER(4). If specified, determines which character traits to use or ignore when comparing strings. You can combine several flags using an inclusive OR (IOR or OR). There are no illegal combinations of flags, and the functions may be used without flags, in which case all flag options are turned off. The available values (defined in IFNLS.F90) are:

- NLS$MB_IgnoreCase - Ignore case.
- NLS$MB_IgnoreNonspace - Ignore nonspacing characters (this flag removes Japanese accent characters if they exist).
- NLS$MB_IgnoreSymbols - Ignore symbols.
- NLS$MB_IgnoreKanaType - Do not differentiate between Japanese Hiragana and Katakana characters (corresponding Hiragana and Katakana characters will compare as equal).
- NLS$MB_IgnoreWidth - Do not differentiate between a single-byte character and the same character as a double byte.
- NLS$MB_StringSort - Sort all symbols at the beginning, including the apostrophe and hyphen (see the Note below).

**Results**

The result type is LOGICAL(4). Comparisons are made using the current locale, not the current codepage. The codepage used is the default for the language/country combination of the current locale.

The results of these functions are as follows:

- MBLGE returns .TRUE. if the strings are equal or string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLGT returns .TRUE. if string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLLE returns .TRUE. if the strings are equal or string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLLT returns .TRUE. if string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLEQ returns .TRUE. if the strings are equal in the collating sequence; otherwise, .FALSE..
- MBLNE returns .TRUE. if the strings are not equal in the collating sequence; otherwise, .FALSE..

If the two strings are of different lengths, they are compared up to the length of the shortest one. If they are equal to that point, then the return value indicates that the longer string is greater.

If flags is invalid, the functions return .FALSE..

If the strings supplied contain Arabic Kashidas, the Kashidas are ignored during the comparison. Therefore, if the two strings are identical except for Kashidas within the strings, the functions return a value indicating they are "equal" in the collation sense, though not necessarily identical.

**NOTE**

When not using the NLS$MB_StringSort flag, the hyphen and apostrophe are special symbols and are treated differently than others. This is to ensure that words like coop and co-op stay together within a list. All symbols, except the hyphen and apostrophe, sort before any other alphanumeric character. If you specify the NLS$MB_StringSort flag, hyphen and apostrophe sort at the beginning also.

LGE
LGT
**MBNext (W*S)**

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately following the given position in a multibyte-character string.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBNext (string, position)
```

**string**

(Input) Character*(*). String to be searched for the first lead byte or single-byte character after the current position. Can contain multibyte characters.

**position**

(Input) INTEGER(4). Position in `string` to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of a trail (second) byte of a multibyte character.

**Results**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in `string` immediately following the position given in `position`, or 0 if no following first byte is found in `string`.

**See Also**

MBPrev

**MBPrev (W*S)**

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately preceding the given string position in a multibyte-character string.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBPrev (string, position)
```

**string**

(Input) Character*(*). String to be searched for the first lead byte or single-byte character before the current position. Can contain multibyte characters.

**position**

(Input) INTEGER(4). Position in `string` to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of the trail (second) byte of a multibyte character.

**Results**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in `string` immediately preceding the position given in `position`, or 0 if no preceding first byte is found in `string`. 
See Also
MBNext

MBSCAN (W*S)

**NLS Function**: Performs the same function as SCAN except that the strings manipulated can contain multibyte characters.

**Module**
USE IFNLS

**Syntax**

```fortran
result = MBSCAN (string, set[, back])
```

- `string` (Input) Character*(*) String to be searched for the presence of any character in `set`.
- `set` (Input) Character*(*) Characters to search for.
- `back` (Input; optional) LOGICAL(4). If specified, determines direction of the search. If `back` is .FALSE. or is omitted, the search starts at the beginning of `string` and moves toward the end. If `back` is .TRUE., the search starts end of `string` and moves toward the beginning.

**Results**
The result type is INTEGER(4). If `back` is .FALSE. or is omitted, it returns the position of the leftmost character in `string` that is in `set`. If `back` is .TRUE., it returns the rightmost character in `string` that is in `set`. If no characters in `string` are in `set`, it returns 0.

**See Also**
SCAN
MBINDEX
MBVERIFY

MBStrLead (W*S)

**NLS Function**: Performs a context-sensitive test to determine whether a given character byte in a string is a multibyte-character lead byte.

**Module**
USE IFNLS

**Syntax**

```fortran
result = MBStrLead (string, position)
```

- `string` (Input) Character*(*) String containing the character byte to be tested for lead status.
- `position` (Input) INTEGER(4). Position in `string` of the character byte in the string to be tested.
Results
The result type is LOGICAL(4). The result is .TRUE. if the character byte in position of string is a lead byte; otherwise, .FALSE..

MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context.

MBLead is passed only one character at a time and must start on a lead byte and step through a string one character at a time to establish context for the character. So, MBStrLead can be much slower than MBLead (up to $n$ times slower, where $n$ is the length of the string).

See Also
MBLead

MBVERIFY (W*S)
NLS Function: Performs the same function as VERIFY except that the strings manipulated can contain multibyte characters.

Module
USE IFNLS

Syntax
result = MBVERIFY (string, set[, back])

string (Input) Character*(*) . String to be searched for presence of any character not in set.

set (Input) Character*(*) . Set of characters tested to verify that it includes all the characters in string.

back (Input; optional) LOGICAL(4) . If specified, determines direction of the search. If back is .FALSE. or is omitted, the search starts at the beginning of string and moves toward the end. If back is .TRUE., the search starts end of string and moves toward the beginning.

Results
The result type is INTEGER(4). If back is .FALSE. or is omitted, it returns the position of the leftmost character in string that is not in set. If back is .TRUE., it returns the rightmost character in string that is not in set. If all the characters in string are in set, it returns 0.

MCLOCK
Inquiry Intrinsic Function (Specific): Returns time accounting for a program.

Syntax
result = MCLOCK( )
Results
The result type is INTEGER(4). The result is the sum (in units of milliseconds) of the current process's user time and the user and system time of all its child processes.

MEMKIND

General Compiler Directive: Enables High Band Width (HBW) memory or non-HBW memory allocation for the lexically next ALLOCATE statement. This directive only applies to Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing) and it is only available for Linux* systems.

Syntax
!DIR$ MEMKIND : memory[, ALIGN:n ]

memory

Specifies the requested memory kind. It must be one of the following:

- HBW
  Enables High Band Width memory allocation for arrays in the lexically next ALLOCATE statement
- DDR
  Enables non-HBW memory (Double Data Rate Random Access Memory) allocation for arrays in the lexically next ALLOCATE statement

n
Is a positive integer constant expression. Its value must be a positive power of 2, that is, 1, 2, 4, 8, 16, etc, between 1 and 2097152 = 2**21 = 2MB on Linux*. It specifies the requested memory alignment in bytes for this allocation.

This directive must be placed lexically immediately before an ALLOCATE statement (intervening comments and blank lines are allowed; statements and other directives are not allowed). The MEMKIND specified in this directive overrides any ATTRIBUTE MEMKIND that is associated with the object being allocated.

You can inquire about the memory allocation space of a variable using the FOR_GET_MEMKIND intrinsic function.

The following rules apply to deallocation of a variable:

- If the variable has the ALLOCATABLE attribute, when it is deallocated the variable is reset to the MEMKIND setting in the current scope. That is, if the variable was explicitly declared with MEMKIND in the called routine (whether it’s local, host-associated or use-associated) then that MEMKIND setting is restored at the time of deallocation.
  If the variable is a dummy argument and it is given the MEMKIND attribute in the called routine, the variable retains that MEMKIND setting on deallocation; otherwise, the variable is given MEMKIND setting DDR on deallocation.
- If the variable has the POINTER attribute, the MEMKIND setting for the variable always reverts to DDR on deallocation.

The MEMKIND setting for a variable can be affected by statements other than ALLOCATE and DEALLOCATE:

- MEMKIND and MOVE_ALLOC
  Consider the statement:

MOVE_ALLOC (FROM, TO)
The definition of MOVE_ALLOC says that TO gets deallocated, then TO points to FROM’s data, finally FROM is marked deallocated. The MEMKIND setting of FROM is copied to TO, and then the MEMKIND setting of FROM is changed according to the deallocation rules above.

- **MEMKIND and ALLOCATE(SOURCE=) or ALLOCATE(MOLD=)**

  If the ALLOCATE statement contains either a SOURCE= or a MOLD= clause, the MEMKIND setting of the source (or mold) is not significant. The new object being allocated takes its MEMKIND setting either from a directive preceding this ALLOCATE statement or from the MEMKIND ATTRIBUTE, if any, of the object being allocated.

- **MEMKIND and reallocation of the left-hand side of an assignment**

  The allocatable object on the left-hand side of an assignment will have the same MEMKIND setting as it had before it was reallocated.

**Example**

In the following example, various allocations and deallocations show how MEMKIND is handled.

```fortran
USE IFCORE
REAL, ALLOCATABLE :: R(:)
!DIR$ ATTRIBUTES MEMKIND:HBW :: R
ALLOCATE(R(100))
PRINT *, FOR_GET_MEMKIND(R) ! prints 1 for HBW
CALL DEALLOCME(R) ! MEMKIND of R was changed by DEALLOCME
PRINT *, FOR_GET_MEMKIND(R) ! prints 0 for DDR
CALL REALLOCME_HBW(R) ! MEMKIND of R is still HBW
print *, for_get_memkind(r) ! prints 1 for HBW
!DIR$ MEMKIND:DDR, ALIGN:32
ALLOCATE(R(1000)) ! Allocated in DDR, 32-byte aligned
PRINT *, FOR_GET_MEMKIND(R) ! prints 0 for DDR
DEALLOCATE(R) ! MEMKIND reverted to HBW, as declared
PRINT *, FOR_GET_MEMKIND(R) ! prints 1 for HBW
CALL REALLOCME(R) ! MEMKIND of R is HBW at entrance
PRINT *, for_get_memkind(r) ! prints 1 for HBW
CONTAINS
    SUBROUTINE DEALLOCME(X)
    REAL, ALLOCATABLE :: X(:)
    DEALLOCATE (X) ! No attribute on the dummy; revert to DDR
    END SUBROUTINE DEALLOCME

    SUBROUTINE REALLOCME(X)
    REAL, ALLOCATABLE :: X(:)
    ALLOCATE(X(100)) ! Use MEMKIND from the actual argument
    END SUBROUTINE REALLOCME

    SUBROUTINE REALLOCME_HBW(X)
    REAL, ALLOCATABLE :: X(:)
    !DIR$ ATTRIBUTES MEMKIND:HBW :: X
    ALLOCATE(X(100)) ! Use MEMKIND specified on dummy argument
    END SUBROUTINE REALLOCME
```

1719
In the following example, allocations and deallocations of pointers are simpler; their MEMKIND always reverts to DDR:

```fortran
REAL, POINTER :: PR(:)       ! MEMKIND always starts as DDR
print *, for_get_memkind(pr) ! prints 0 for DDR
!DIR$ MEMKIND:HBW
ALLOCATE(PR(100))            ! Allocate in HBW memory
PRINT *, FOR_GET_MEMKIND(PR) ! prints 1 for HBW
DEALLOCATE(PR)               ! Resets MEMKIND to DDR
PRINT *, FOR_GET_MEMKIND(PR) ! prints 0 for DDR
ALLOCATE(PR(55))             ! Allocated in DDR
PRINT *, FOR_GET_MEMKIND(PR) ! prints 0 for DDR
END
```

**MERGE**

*Elemental Intrinsic Function (Generic):* Selects between two values or between corresponding elements in two arrays, according to the condition specified by a logical mask.

**Syntax**

```
result = MERGE (tsource, fsource, mask)
```

- `tsource` (Input) May be of any data type.
- `fsource` (Input) Must be of the same type and type parameters as `tsource`.
- `mask` (Input) Must be of type logical.

**Results**

The result type and kind are the same as `tsource`. The value of `mask` determines whether the result value is taken from `tsource` (if `mask` is true) or `fsource` (if `mask` is false).

**Example**

For `MERGE (1.0, 0.0, R < 0)`, `R = -3` has the value 1.0, and `R = 7` has the value 0.0.

TSOURCE is the array

```
[ 1 3 5 ]
[ 2 4 6 ],
```
MERGE is the array

\[
\begin{bmatrix}
8 & 9 & 0 \\
1 & 2 & 3
\end{bmatrix}
\]

and MASK is the array

\[
\begin{bmatrix}
F & T & T \\
T & T & F
\end{bmatrix}
\]

MERGE (TSOURCE, FSOURCE, MASK) produces the result:

\[
\begin{bmatrix}
8 & 3 & 5 \\
2 & 4 & 3
\end{bmatrix}
\]

The following shows another example:

```fortran
INTEGER tsource(2, 3), fsource(2, 3), AR1 (2, 3)
LOGICAL mask(2, 3)
tsource = RESHAPE((/1, 4, 2, 5, 3, 6/), (/2, 3/))
fsource = RESHAPE((/7, 0, 8, -1, 9, -2/), (/2, 3/))
mask = RESHAPE((/.TRUE., .FALSE., .FALSE., .TRUE., .TRUE., .FALSE./), (/2,3/))
! tsource is  1 2 3 , fsource is  7  8  9 , mask is  T F T
!             4 5 6               0 -1 -2            F T F
AR1 = MERGE(tsource, fsource, mask) ! returns  1 8  3
!          0 5 -2
END```

**MERGE_BITS**

**Elemental Intrinsic Function (Generic):** Merges bits by using a mask.

**Syntax**

```
result = MERGE_BITS (i,j,mask)
```

- **i** (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
- **j** (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
- **mask** (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer they must have the same kind type parameter. They cannot both be binary, octal, or hexadecimal literal constants.

If *mask* is of type integer, it must have the same kind type parameter as each other argument of type integer.

**Results**

The result type and kind are the same as *i* if *i* is of type integer; otherwise, the result type and kind are the same as *j*.

If any argument is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to the type and kind parameter of the result. The result has the value of IOR (IAND (*i*, *mask*), IAND (*j*, NOT (*mask*))).
Example
MERGE_BITS (13, 18, 22) has the value 4.

**MERGEABLE Clause**

*Parallel Directive Clause: Specifies that the implementation may generate a merged task.*

**Syntax**

MERGEABLE

When the generated task is an undeferred task or an included task, it specifies that the implementation may instead generate a merged task.

When the MERGEABLE clause is present on a TASKLOOP construct, each generated task is a mergeable task.

**MESSAGE**

*General Compiler Directive: Specifies a character string to be sent to the standard output device during the first compiler pass; this aids debugging.*

**Syntax**

!DIR$ MESSAGE:string

string

Is a character constant specifying a message.

**Example**

!DIR$ MESSAGE:'Compiling Sound Speed Equations'

**See Also**

General Compiler Directives
Syntax Rules for Compiler Directives

**MESSAGEBOXQQ (W*S)**

*QuickWin Function: Displays a message box in a QuickWin window.*

**Module**

USE IFQWIN

**Syntax**

result = MESSAGEBOXQQ (msg,caption,mtype)

msg

caption

(Input) INTEGER(4). Symbolic constant that determines the objects (buttons and icons) and properties of the message box. You can combine several constants (defined in IFQWIN.F90) using an inclusive OR (IOR or OR). The symbolic constants and their associated objects or properties are as follows:

- MB$ABORTRETRYIGNORE - The Abort, Retry, and Ignore buttons.
- MB$DEFBUTTON1 - The first button is the default.
- MB$DEFBUTTON2 - The second button is the default.
- MB$DEFBUTTON3 - The third button is the default.
- MB$ICONASTERISK, MB$ICONINFORMATION - Lowercase i in blue circle icon.
- MB$ICONEXCLAMATION - The exclamation-mark icon.
- MB$ICONHAND, MB$ICONSTOP - The stop-sign icon.
- MB$ICONQUESTION - The question-mark icon.
- MB$OK - The OK button.
- MB$OKCANCEL - The OK and Cancel buttons.
- MB$RETRYCANCEL - The Retry and Cancel buttons.
- MB$SYSTEMMODAL - Box is system-modal: all applications are suspended until the user responds.
- MB$YESNO - The Yes and No buttons.
- MB$YESNOCANCEL - The Yes, No, and Cancel buttons.

Results

The result type is INTEGER(4). The result is zero if memory is not sufficient for displaying the message box. Otherwise, the result is one of the following values, indicating the user's response to the message box:

- MB$IDABORT - The Abort button was pressed.
- MB$IDCANCEL - The Cancel button was pressed.
- MB$IDIGNORE - The Ignore button was pressed.
- MB$IDNO - The No button was pressed.
- MB$IDOK - The OK button was pressed.
- MB$IDRETRY - The Retry button was pressed.
- MB$IDYES - The Yes button was pressed.

Example

```fortran
! Build as QuickWin app
USE IFQWIN
message = MESSAGEBOXQQ('Do you want to continue?'C, &
'Matrix'C, &
MB$ICONQUESTION.OR.MB$YESNO.OR.MB$DEFBUTTON1)
END
```

SETMESSAGEQQ

MIN

Elemental Intrinsic Function (Generic): Returns the minimum value of the arguments.

Syntax

```fortran
result = MIN (a1,a2[,a3...])
```
INPUT) All must have the same type (integer, real, or character) and kind parameters.

Results

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MIN0, AMIN1, QMIN1, IMIN0, JMIN0, and KMIN0, the result type is the same as the arguments. For MIN1, IMIN1, JMIN1, and KMIN1, the result type is integer. For AMIN0, AIMIN0, AJMIN0, and AKMIN0, the result type is real. The value of the result is that of the smallest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

</tbody>
</table>

1These specific functions cannot be passed as actual arguments.
2Or JMIN0.
3Or AIMIN0.AMIN0 is the same as REAL (MIN).
4In Standard Fortran, AMIN0 and MIN1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.
5Or JMIN1.MIN1 is the same as INT (MIN).
6The setting of compiler options specifying integer size can affect MIN1.
7The setting of compiler options specifying real size can affect AMIN1.

Example

MIN (2.0, -8.0, 6.0) has the value -8.0.
MIN (14, 32, -50) has the value -50.
The following shows another example:

```
INTEGER m1, m2
REAL r1, r2
m1 = MIN (5, 6, 7)           ! returns 5
m2 = MIN1 (-5.7, 1.23, -3.8) ! returns -5
r1 = AMIN0 (-5, -6, -7)      ! returns -7.0
r2 = AMIN1(-5.7, 1.23, -3.8) ! returns -5.7
```

MAX

MINEXPONENT

**Inquiry Intrinsic Function (Generic):**

Returns the minimum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```
result = MINEXPONENT (x)
```

- `x` (Input) must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. The result has the value $e_{\min}$ as defined in Model for Real Data.

**Example**

If X is of type REAL(4), MINEXPONENT (X) has the value -125.

The following shows another example:

```
REAL(8) r1  ! DOUBLE PRECISION REAL
INTEGER i
i = MINEXPONENT (r1) ! returns -1021.
```

See Also

MAXEXPONENT

MINLOC

**Transformational Intrinsic Function (Generic):**

Returns the location of the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

**Syntax**

```
result = MINLOC (array, dim [, mask, kind, back])
result = MINLOC (array [, mask, kind, back])
```

- `array` (Input) Must be an array of type integer, real, or character.
- `dim` (Input) Must be a scalar integer with a value in the range 1 to $n$, where $n$ is the rank of `array`. 
mask  (Input; optional) Must be a logical array that is conformable with array.

kind  (Input; optional) Must be a scalar integer constant expression.

back  (Input; optional) Must be a scalar of type logical.

Results

The result is an array of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if dim is omitted:

• The array result has rank one and a size equal to the rank of array.

If MINLOC(array) is specified, the elements in the array result form the subscript of the location of the element with the minimum value in array.

The ith subscript returned lies in the range 1 to ei, where ei is the extent of the ith dimension of array.

• If MINLOC(array, MASK= mask) is specified, the elements in the array result form the subscript of the location of the element with the minimum value corresponding to the condition specified by mask.

The following rules apply if dim is specified:

• The array result has a rank that is one less than array, and shape (d1, d2,...d_dim1-1, d_dim1+1,...d_n), where (d1, d2,...d_n) is the shape of array.

• If array has rank one, MINLOC( array, dim [, mask]) is a scalar and has a value equal to the first element of MINLOC( array [,MASK = mask]). Otherwise, the value of element (s1, s2,...s_dim1-1, s_dim1+1,...s_n) of MINLOC( array, dim [, mask]) is equal to MINLOC( array(s1, s2,...s_dim1-1, ::, s_dim1+1,...s_n) [, MASK = mask(s1, s2,...s_dim1-1, ::, s_dim1+1,...s_n)]).

If only one element has the minimum value, that element’s subscripts are returned. Otherwise, if more than one element has the minimum value and back is absent or present with the value .FALSE., the element whose subscripts are returned is the first such element, taken in array element order. If back is present with the value .TRUE., the element whose subscripts are returned is the last such element, taken in array element order.

If array has size zero, or every element of mask has the value .FALSE., the value of the result is controlled by compiler option assume [no]old_maxminloc, which can set the value of the result to either 1 or 0.

If array is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

Example

The value of MINLOC ((/3, 1, 4, 1/)) is (2), which is the subscript of the location of the first occurrence of the minimum value in the rank-one array.

A is the array

\[
\begin{bmatrix}
4 & 0 & 0 & 2 \\
3 & -6 & -2 & 6 \\
-1 & -4 & 5 & -4 \\
\end{bmatrix}
\]

MINLOC(A, MASK=A .GT. -5) has the value (3, 2) because these are the subscripts of the location of the first minimum value (-4) that is greater than -5.

MINLOC(A, DIM=1) has the value (3, 2, 2, 3). 3 is the subscript of the location of the first minimum value (-1) in column 1; 3 is the subscript of the location of the first minimum value (-6) in column 2; and so forth.

MINLOC(A, DIM=2) has the value (2, 2, 2). 2 is the subscript of the location of the first minimum value (0) in row 1; 2 is the subscript of the location of the first minimum value (-6) in row 2; and so forth.
MINLOC (A, DIM=2, BACK=.TRUE.) has the value (3, 2, 4). 3 is the subscript of the location of the last minimum value (0) in row 1; 2 is the subscript of the location of the last minimum value (-6) in row 2; and so forth.

The following shows another example:

```fortran
INTEGER i, minl(1)
INTEGER array(2, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/-7, 1, -2, -9, 5, 0/),(/2, 3/))
!   array is   -7 -2 5
!           1 -9 0
i = SIZE(SHAPE(array))  ! Get the number of dimensions
!   in array
ALLOCATE (AR1 (i))      ! Allocate AR1 to number
!   of dimensions in array
AR1 = MINLOC (array, MASK = array .GT. -5)   ! Get the
!   location (subscripts) of
!   smallest element greater
!   than -5 in array
!
! MASK = array .GT. -5 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is greater than
! -5, and .FALSE. if it is not. This mask causes MINLOC
! to return the index of the element in array with the
! smallest value greater than -5.
!
! array is   -7 -2 5 and MASK= array .GT. -5 is  F T T
!           1 -9 0                             T F T
! and AR1 = MINLOC(array, MASK = array .GT. -5) returns
! (1, 2), the location of the element with value -2

minl = MINLOC((/-7,2,-7,5/))   ! returns 1, first
       ! occurrence of minimum
END
```

MAXLOC
MINVAL
MAXVAL
FINDLOC

**MINVAL**

*Transformational Intrinsic Function (Generic):*

*Returns the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.*

**Syntax**

\[
\text{result} = \text{MINVAL} (\text{array}, [\text{dim}], [\text{mask}])
\]

`array`  
(Input) Must be an array of type integer, real, or character.
**dim**

(Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.

**mask**

(Input; optional) Must be a logical array that is conformable with array.

### Results

The result is an array or a scalar of the same data type as array.

The result is a scalar if dim is omitted or array has rank one.

The following rules apply if dim is omitted:

- If MINVAL(array) is specified, the result has a value equal to the minimum value of all the elements in array.
- If MINVAL(array, MASK=mask) is specified, the result has a value equal to the minimum value of the elements in array corresponding to the condition specified by mask.

The following rules apply if dim is specified:

- An array result has a rank that is one less than array, and shape (d1, d2, ..., ddim-1, ddim+1, ..., dn), where (d1, d2, ..., dn) is the shape of array.
- If array has rank one, MINVAL(array, dim[, mask]) has a value equal to that of MINVAL(array[,MASK=mask]). Otherwise, the value of element (s1, s2, ..., sdim-1, sdim+1, ..., sn) of MINVAL(array, dim[, mask]) is equal to MINVAL(array(s1, s2, ..., sdim-1, :, sdim+1, ..., sn)[,MASK=mask(s1, s2, ..., sdim-1, :, sdim+1, ..., sn)]).

If array has size zero or if there are no true elements in mask, the result (if dim is omitted), or each element in the result array (if dim is specified), has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind parameters of array.

If array is of type character, the comparison is done using the ASCII collating sequence.

### Example

The value of MINVAL((/2, 3, 4/)) is 2 because that is the minimum value in the rank-one array.

The value of MINVAL(B, MASK=B .GT. 0.0) finds the minimum value of the positive elements of B.

C is the array

```
[ 2  3  4 ]
[ 5  6  7 ].
```

MINVAL (C, DIM=1) has the value (2, 3, 4). 2 is the minimum value in column 1; 3 is the minimum value in column 2; and so forth.

MINVAL (C, DIM=2) has the value (2, 5). 2 is the minimum value in row 1 and 5 is the minimum value in row 2.

The following shows another example:

```fortran
INTEGER array(2, 3), i(2), minv
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
! array is 1 5 3
! 4 2 6
i = SHAPE(array) ! i = [2 3]
ALLOCATE(AR1(i(2))) ! dimension AR1 to number of
! elements in dimension 2
! (a column) of array.
ALLOCATE(AR2(i(1))) ! dimension AR2 to number of
! elements in dimension 1
```

MINLOC
MAXLOC

**MM_PREFETCH**

_Intrinsic Subroutine (Generic):_ Prefetches data from the specified address on one memory cache line. _Intrinsic subroutines cannot be passed as actual arguments._

**Syntax**

```fortran
CALL MM_PREFETCH (address[, hint] [, fault] [, exclusive])
```

- **address** (Input) Is the name of a scalar or array; it can be of any type or rank. It specifies the address of the data on the cache line to prefetch.

- **hint** (Input; optional) Is an optional default integer constant with one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Prefetch Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FOR_K_PREFETCH_T0</td>
<td>Prefetches into the L1 cache (and the L2 and the L3 cache). Use this for integer data.</td>
</tr>
<tr>
<td>1</td>
<td>FOR_K_PREFETCH_T1</td>
<td>Prefetches into the L2 cache (and the L3 cache); floating-point data is used from the L2 cache, not the L1 cache. Use this for real data.</td>
</tr>
<tr>
<td>2</td>
<td>FOR_K_PREFETCH_T2</td>
<td>Prefetches into the L2 cache (and the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line frequently.</td>
</tr>
<tr>
<td>Value</td>
<td>Prefetch Constant</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>3</td>
<td>FOR_K_PREFETCH_N TA</td>
<td>Prefetches into the L2 cache (but not the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line.</td>
</tr>
</tbody>
</table>

The preceding constants are defined in file fordef.for on Windows* systems and file fordef.f on Linux* and macOS* systems.

If hint is omitted, 0 is assumed.

**fault**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, page faults are allowed to occur, if necessary; if .FALSE. is specified, page faults are not allowed to occur. If fault is omitted, .FALSE. is assumed. This argument is currently ignored.

**exclusive**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, you get exclusive ownership of the cache line because you intend to assign to it; if .FALSE. is specified, there is no exclusive ownership. If exclusive is omitted, .FALSE. is assumed. This argument is currently ignored.

**Example**

```fortran
subroutine spread_lf (a, b)
PARAMETER (n = 1025)

real*8 a(n,n), b(n,n), c(n)
do j = 1,n
do i = 1,100
   a(i, j) = b(i-1, j) + b(i+1, j)
call mm_prefetch (a(i+20, j), 1)
call mm_prefetch (b(i+21, j), 1)
endo
dendo
print *, a(2, 567)
stop
end
```

**MOD**

**Elemental Intrinsic Function (Generic):** Returns the remainder when the first argument is divided by the second argument.

**Syntax**

```fortran
result = MOD (a, p)
```

*a*  
(Input) Must be of type integer or real.
(Input) Must have the same type and kind parameters as `a`. It must not have a value of zero.

**Results**

The result type and kind are the same as `a`. If `p` is not equal to zero, the value of the result is \( a - \text{INT}(a/p) \times p \). If `p` is equal to zero, the result is undefined.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMOD</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IMOD(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>MOD (^2)</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KMOD</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
<tr>
<td>AMOD (^3)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DMOD (^{3,4})</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QMOD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\) Or \text{HMOD}.

\(^2\) Or \text{JMOD}.

\(^3\) The setting of compiler options specifying real size can affect AMOD and DMOD.

\(^4\) The setting of compiler options specifying double size can affect DMOD.

**Example**

MOD (7, 3) has the value 1.
MOD (9, -6) has the value 3.
MOD (-9, 6) has the value -3.

The following shows more examples:

```plaintext
INTEGER I
REAL R
R = MOD(9.0, 2.0) ! returns 1.0
I = MOD(18, 5)   ! returns 3
I = MOD(-18, 5)  ! returns -3
I = MOD(8, 5)    ! returns 3
I = MOD(-8, 5)   ! returns -3
I = MOD(8,-5)    ! returns 3
I = MOD(-8,-5)   ! returns -3
```

**See Also**

MODULO

**MODIFYMENUFLAGSQQ (W*S)**

*QuickWin Function:* Modifies a menu item’s state.

**Module**

USE IFQWIN
Syntax

result = MODIFYMENUFLAGSQQ (menuID, itemID, flag)

menuID  
(Input) INTEGER(4). Identifies the menu containing the item whose state is to be modified, starting with 1 as the leftmost menu.

itemID  
(Input) INTEGER(4). Identifies the menu item whose state is to be modified, starting with 0 as the top item.

flags  
(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:

- $MENUGRAYED - Disables and grays out the menu item.
- $MENUDISABLED - Disables but does not gray out the menu item.
- $MENUENABLED - Enables the menu item.
- $MENUSEPARATOR - Draws a separator bar.
- $MENUCHECKED - Puts a check by the menu item.
- $MENUUNCHECKED - Removes the check by the menu item.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

Example

USE IFQWIN
LOGICAL(4) result
CHARACTER(20) str
! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu' C
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Gray out and disable the first two menu items in the first (FILE) menu
result = MODIFYMENUFLAGSQQ (1, 1, $MENUGRAYED)
result = MODIFYMENUFLAGSQQ (1, 2, $MENUGRAYED)
END

MODIFYMENUSTRINGQQ

MODIFYMENUROUTINEQQ (W*S)

QuickWin Function: Changes a menu item’s callback routine.

Module

USE IFQWIN
Syntax

result = MODIFYMENUROUTINEQQ (menuIdD, itemID, routine)

menuID

(Input) INTEGER(4). Identifies the menu that contains the item whose callback routine is to be changed, starting with 1 as the leftmost menu.

itemID

(Input) INTEGER(4). Identifies the menu item whose callback routine is to be changed, starting with 0 as the top item.

routine

(Input) EXTERNAL. Callback subroutine called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- WINPRINT - Prints the program.
- WINSAVE - Saves the program.
- WINEXIT - Terminates the program.
- WINSELECTTEXT - Selects text from the current window.
- WINSELECTGRAPHICS - Selects graphics from the current window.
- WINSELECTALL - Selects the entire contents of the current window.
- WININPUT - Brings to the top the child window requesting input and makes it the current window.
- WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
- WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WINCLEARPASTE - Clears the paste buffer.
- WINSIZETOFIT - Sizes output to fit window.
- WINFULLSCREEN - Displays output in full screen.
- WINSTATE - Toggles between pause and resume states of text output.
- WINCASCADE - Cascades active windows.
- WINTILE - Tiles active windows.
- WINARRANGE - Arranges icons.
- WINSTATUS - Enables a status bar.
- WININDEX - Displays the index for QuickWin help.
- WINUSING - Displays information on how to use Help.
- WINABOUT - Displays information about the current QuickWin application.
- NUL - No callback routine.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

APPENDMENUQQ
DELETEMENUQQ
INSERTMENUQQ
MODIFYMENUFALGSQQ
MODIFYMENUSRINGQQ
**MODIFYMENUSTRINGQQ (W*S)**

*QuickWin Function:* Changes a menu item's text string.

## Module

USE IFQWIN

## Syntax

```
result = MODIFYMENUSTRINGQQ (menuID, itemID, text)
```

- **menuID**
  - (Input) INTEGER(4). Identifies the menu containing the item whose text string is to be changed, starting with 1 as the leftmost item.

- **itemID**
  - (Input) INTEGER(4). Identifies the menu item whose text string is to be changed, starting with 0 as the top menu item.

- **text**
  - (Input) Character(*). Menu item name. Must be a null-terminated C string. For example, words of text'C.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can add access keys in your text strings by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, use "P&rint"C as text.

## Example

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
! Append item to the bottom of the first (FILE) menu
str = 'Add to File Menu'C
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Change the name of the first item in the first menu
str = 'Browse'C
result = MODIFYMENUSTRINGQQ (1, 1, str)
END
```

## MODULE

*Statement:* Marks the beginning of a module program unit, which contains specifications and definitions that can be used by one or more program units.
Syntax

MODULE name
  [specification-part]
[CONTAINS
  [module-subprogram
  [module-subprogram]... ] ]
END[ MODULE [name]]

name

specification-part

Is the name of the module.

Is one or more specification statements, except for the following:

- ENTRY
- FORMAT
- AUTOMATIC (or its equivalent attribute)
- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- Statement functions

An automatic object must not appear in a specification statement.

module-subprogram

Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

A module subprogram can contain internal procedures.

Description

If a name follows the END statement, it must be the same as the name specified in the MODULE statement.

The module name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A module is host to any module procedures it contains, and entities in the module are accessible to the module procedures through host association.

A module must not reference itself (either directly or indirectly).

You can use the PRIVATE attribute to restrict access to procedures or variables within a module.

Although ENTRY statements, FORMAT statements, and statement functions are not allowed in the specification part of a module, they are allowed in the specification part of a module subprogram.

The following rules also apply to modules:

- The specification part of a module must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
- A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the specification-part of a module includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Any executable statements in a module can only be specified in a module subprogram.

A module can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.
A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.

**Example**

The following example shows a simple module that can be used to provide global data:

```fortran
MODULE MOD_A
    INTEGER :: B, C
    REAL E(25,5)
END MODULE MOD_A
...
SUBROUTINE SUB_Z
    USE MOD_A               ! Makes scalar variables B and C, and array E available to this subroutine
    ...
END SUBROUTINE SUB_Z
```

The following example shows a module procedure:

```fortran
MODULE RESULTS
...
CONTAINS
    FUNCTION MOD_RESULTS(X,Y)  ! A module procedure
    ...
    END FUNCTION MOD_RESULTS
END MODULE RESULTS
```

The following example shows a module containing a derived type:

```fortran
MODULE EMPLOYEE_DATA
    TYPE EMPLOYEE
        INTEGER ID
        CHARACTER(LEN=40) NAME
    END TYPE
END MODULE
```

The following example shows a module containing an interface block:

```fortran
MODULE ARRAY_CALCULATOR
    INTERFACE
        FUNCTION CALC_AVERAGE(D)
            REAL :: CALC_AVERAGE
            REAL, INTENT(IN) :: D(:)
        END FUNCTION
    END INTERFACE
END MODULE ARRAY_CALCULATOR
```

The following example shows a derived-type definition that is public with components that are private:

```fortran
MODULE MATTER
    TYPE ELEMENTS
        PRIVATE
        INTEGER C, D
    END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

This design allows you to change components of a type without affecting other program units that use the module.
If a derived type is needed in more than one program unit, the definition should be placed in a module and accessed by a USE statement whenever it is needed, as follows:

```fortran
MODULE STUDENTS
  TYPE STUDENT_RECORD
    ...
  END TYPE
CONTAINS
  SUBROUTINE COURSE_GRADE(...) TYPE(STUDENT_RECORD) NAME
    ...
  END SUBROUTINE
END MODULE STUDENTS
...

PROGRAM SENIOR_CLASS
  USE STUDENTS
  TYPE(STUDENT_RECORD) NAME ID
  ...
END PROGRAM
```

Program SENIOR_CLASS has access to type STUDENT_RECORD, because it uses module STUDENTS. Module procedure COURSE_GRADE also has access to type STUDENT_RECORD, because the derived-type definition appears in its host.

**MODULE FUNCTION**

*Statement:* Indicates a separate module procedure.

**Example**

```fortran
submodule (M) A contains
  real module function foo (arg) result(res)
    type(tt), intent(in) :: arg
    res = arg%r
  end function foo
end submodule A
```

See Also
- Separate Module Procedures

**MODULE PROCEDURE**

*Statement:* Identifies module procedures in an interface block that specifies a generic name.
Example

!A program that changes non-default integers and reals
! into default integers and reals
PROGRAM CHANGE_KIND
USE Module1
integer(2) in
integer indef
indef = DEFAULT(in)
END PROGRAM

! procedures sub1 and sub2 defined as follows:
MODULE Module1
INTERFACE DEFAULT
MODULE PROCEDURE Sub1, Sub2
END INTERFACE
CONTAINS
  FUNCTION Sub1(y)
      REAL(8) y
      sub1 = REAL(y)
  END FUNCTION
  FUNCTION Sub2(z)
      INTEGER Sub2
      INTEGER(2) z
      sub2 = INT(z)
  END FUNCTION
END MODULE

Separate Module Procedures

MODULO

Elemental Intrinsic Function (Generic): Returns the modulo of the arguments.

Syntax

result = MODULO (a,p)
\( a \)  
(Input) Must be of type integer or real.

\( p \)  
(Input) Must have the same type and kind parameters as \( a \). It must not have a value of zero.

**Results**

The result type is the same as \( a \). The result value depends on the type of \( a \), as follows:

- If \( a \) is of type integer and \( p \) is not equal to zero, the value of the result is \( a - \text{FLOOR}(\text{REAL}(a) / \text{REAL}(p)) \times p \), that is, the result has a value such that \( a = q \times p + \text{result} \) where \( q \) is an integer. The following also applies:
  - If \( p > 0 \), then \( 0 \leq \text{result} < p \)
  - If \( p < 0 \), then \( p < \text{result} \leq 0 \)
- If \( a \) is of type real and \( p \) is not equal to zero, the value of the result is \( a - \text{FLOOR}(a / p) \times p \).

If \( p \) is equal to zero (regardless of the type of \( a \)), the result is undefined.

**Example**

\[
\begin{align*}
\text{MODULO} (7, 3) & \text{ has the value 1.} \\
\text{MODULO} (9, -6) & \text{ has the value -3.} \\
\text{MODULO} (-9, 6) & \text{ has the value 3.}
\end{align*}
\]

The following shows more examples:

<table>
<thead>
<tr>
<th>INTEGER I</th>
<th>REAL R</th>
</tr>
</thead>
<tbody>
<tr>
<td>I = MODULO(8, 5)</td>
<td>returns 3</td>
</tr>
<tr>
<td>I = MODULO(-8, 5)</td>
<td>returns 2</td>
</tr>
<tr>
<td>I = MODULO(8, -5)</td>
<td>returns -2</td>
</tr>
<tr>
<td>I = MODULO(-8, -5)</td>
<td>returns -3</td>
</tr>
<tr>
<td>R = MODULO(7.285, 2.35)</td>
<td>returns 0.2350001</td>
</tr>
<tr>
<td>R = MODULO(7.285, -2.35)</td>
<td>returns -2.115</td>
</tr>
</tbody>
</table>

MOD

**MOVE_ALLOC**

*Intrinsic Subroutine (Generic):* Moves an allocation from one allocatable object to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

\[
\text{CALL MOVE_ALLOC} (\text{from}, \text{to})
\]

\( \text{from} \)  
(Input; output) Can be of any type, type parameters, corank, and rank; it must be allocatable.

\( \text{to} \)  
(Output) Must be type compatible with \( \text{from} \) and have the same rank and corank; it must be allocatable. \( \text{to} \) must be polymorphic if \( \text{from} \) is polymorphic. Each nondeferred type parameter of the declared type of \( \text{to} \) must have the same value as the corresponding type parameter of the declared type of \( \text{from} \). For more information about type compatibility, see the description in \text{CLASS}.  

1739
If \( to \) is currently allocated, it is deallocated. If \( from \) is allocated, \( to \) becomes allocated with the same type, type parameters, array bounds, and values as \( from \). Lastly, \( from \) is deallocated.

If \( to \) has the TARGET attribute, any pointer associated with \( from \) at the time of the call to MOVE_ALLOC becomes correspondingly associated with \( to \). If \( to \) does not have the TARGET attribute, the pointer association status of any pointer associated with \( from \) on entry becomes undefined.

During execution of MOVE_ALLOC, the internal descriptor contents are copied from \( from \) to \( to \), so that the storage pointed to by \( to \) is the storage that \( from \) used to point to.

Typically, MOVE_ALLOC is used to provide an efficient way to reallocate a variable to a larger size without copying the data twice.

**Example**

The following shows an example of how to increase the allocated size of \( X \) and keep the old values with only one copy of the old values. Using only assignment, a temporary variable named \( Y \) will be allocated and \( X \) assigned to \( Y \). Then \( X \) will be deallocated and reallocated to be twice the size; then \( Y \) will be assigned to the first half of \( X \). Finally, the temporary \( Y \) is deallocated.

```fortran
! This program uses MOVE_ALLOC to make an allocated array \( X \) bigger and
! keep the old values of \( X \) in the variable \( X \). Only one copy of the old values
! of \( X \) is needed.
integer :: I, N = 2
real, allocatable :: X(:,), Y(:)
allocate (X(N), Y(2*N)) ! \( Y \) is twice as big as \( X \)
X = /(I(I=1,N)/) ! put "old values" into \( X \)
Y = -1 ! put different "old values" into \( Y \)
print *, ' allocated of \( X \) is ', allocated (X)
print *, ' allocated of \( Y \) is ', allocated (Y)
print *, ' old \( X \) is ', X
print *, ' old \( Y \) is ', Y
Y (1:N) = X ! copy all of \( X \) into the first half of \( Y \)
! this is the only copying of values required
print *, ' new \( Y \) is ', Y
call move_alloc (Y, X) ! \( X \) is now twice as big as it was, \( Y \) is
! deallocated, the values were not copied from \( Y \) to \( X \)
print *, ' allocated of \( X \) is ', allocated (X)
print *, ' allocated of \( Y \) is ', allocated (Y)
print *, ' new \( X \) is ', X
end
```

The following shows the output for the above example:

<table>
<thead>
<tr>
<th>allocated of ( X ) is</th>
<th>( T )</th>
</tr>
</thead>
<tbody>
<tr>
<td>allocated of ( Y ) is</td>
<td>( T )</td>
</tr>
<tr>
<td>old ( X ) is</td>
<td>1.000000</td>
</tr>
<tr>
<td>old ( Y ) is</td>
<td>-1.000000</td>
</tr>
<tr>
<td>new ( Y ) is</td>
<td>1.000000</td>
</tr>
<tr>
<td>allocated of ( X ) is</td>
<td>( T )</td>
</tr>
<tr>
<td>allocated of ( Y ) is</td>
<td>( F )</td>
</tr>
<tr>
<td>new ( X ) is</td>
<td>1.000000</td>
</tr>
</tbody>
</table>

**MOVETO, MOVETO_W (W*S)**

*Graphics Subroutines: Move the current graphics position to a specified point. No drawing occurs.*
Module
USE IFQWIN

Syntax
CALL MOVETO (x, y, s)
CALL MOVETO_W (wx, wy, ws)

x, y

s

(Input) INTEGER(2). Viewport coordinates of the new graphics position.

(Output) Derived type xycoord. Viewport coordinates of the previous graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord  ! x coordinate
  INTEGER(2) ycoord  ! y coordinate
END TYPE xycoord
```

wx, wy

ws

(Input) REAL(8). Window coordinates of the new graphics position.

(Output) Derived type wxycoord. Viewport coordinates of the previous graphics position. The derived type wxycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE wxycoord
  DOUBLE PRECISION WX, WY
  STRUCTURE/WXYCOORD/
    DOUBLE PRECISION WX
    DOUBLE PRECISION WY
END STRUCTURE
END TYPE wxycoord
```

MOVETO sets the current graphics position to the viewport coordinate (x, y). MOVETO_W sets the current graphics position to the window coordinate (wx, wy).

MOVETO and MOVETO_W assign the coordinates of the previous position to s.

Example

```fortran
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
INTEGER(4) result
TYPE (xycoord) xy
RESULT = SETCOLORRGB(Z'FF0000') ! blue
x = 60
! Draw a series of lines DO y = 50, 92, 3
  CALL MOVETO(x, y, xy)
  status = LINETO(INT2(x + 20), y)
END DO
END
```

GETCURRENTPOSITION
LINETO
OUTGTEXT
**MVBITS**

**Elemental Intrinsic Subroutine (Generic):** Copies a sequence of bits (a bit field) from one location to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL MVBITS (from, frompos, len, to, topos)
```

- **from** (Input) Integer. Can be of any integer type. It represents the location from which a bit field is transferred.
- **frompos** (Input) Can be of any integer type; it must not be negative. It identifies the first bit position in the field transferred from `from`. `frompos + len` must be less than or equal to `BIT_SIZE(from)`.
- **len** (Input) Can be of any integer type; it must not be negative. It identifies the length of the field transferred from `from`.
- **to** (Input; output) Can be of any integer type, but must have the same kind parameter as `from`. It represents the location to which a bit field is transferred. `to` is set by copying the sequence of bits of length `len`, starting at position `frompos` of `from` to position `topos` of `to`. No other bits of `to` are altered.
- **topos** (Input) Can be of any integer type; it must not be negative. It identifies the starting position (within `to`) for the bits being transferred. `topos + len` must be less than or equal to `BIT_SIZE(to)`.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

You can also use the following specific routines:

<table>
<thead>
<tr>
<th>Subroutine</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMVBITS</td>
<td>Arguments <code>from</code> and <code>to</code> must be INTEGER(1).</td>
</tr>
<tr>
<td>HMVBITS</td>
<td>Arguments <code>from</code> and <code>to</code> must be INTEGER(2).</td>
</tr>
<tr>
<td>IMVBITS</td>
<td>Arguments <code>from</code> and <code>to</code> must be INTEGER(2).</td>
</tr>
<tr>
<td>JMVBITS</td>
<td>Arguments <code>from</code> and <code>to</code> must be INTEGER(4).</td>
</tr>
<tr>
<td>KMVBITS</td>
<td>Arguments <code>from</code> and <code>to</code> must be INTEGER(8).</td>
</tr>
</tbody>
</table>

**Example**

If `TO` has the initial value of 6, its value after a call to `MVBITS(7, 2, TO, 0)` is 5.

The following shows another example:

```fortran
INTEGER(1) :: from = 13  ! 00001101
INTEGER(1) :: to = 6     ! 00000110
CALL MVBITS(from, 2, 2, to, 0) ! returns to = 00000111
END
```

**See Also**

- BIT_SIZE
- IBCLR
**NAMELIST**

**Statement:** Associates a name with a list of variables. This group name can be referenced in some input/output operations.

**Syntax**

\[
\text{NAMELIST} \ /\text{group}\ /\text{var-list}[[,] /\text{group}/\text{var-list}]... \\
\text{group} \\
\text{var-list}
\]

- **group** is the name of the group.
- **var-list** is a list of variables (separated by commas) that are to be associated with the preceding group name. The variables can be of any data type.

**Description**

The namelist group name is used by namelist I/O statements instead of an I/O list. The unique group name identifies a list whose entities can be modified or transferred.

A variable can appear in more than one namelist group.

Each variable in var-list must be accessed by use or host association, or it must have its type, type parameters, and shape explicitly or implicitly specified in the same scoping unit. If the variable is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

You cannot specify an assumed-size array in a namelist group.

Only the variables specified in the namelist can be read or written in namelist I/O. It is not necessary for the input records in a namelist input statement to define every variable in the associated namelist.

The order of variables in the namelist controls the order in which the values appear on namelist output. Input of namelist values can be in any order.

If the group name has the PUBLIC attribute, no item in the variable list can have the PRIVATE attribute.

The group name can be specified in more than one NAMELIST statement in a scoping unit. The variable list following each successive appearance of the group name is treated as a continuation of the list for that group name.

**Example**

In the following example, D and E are added to the variables A, B, and C for group name LIST:

```
NAMELIST /LIST/ A, B, C
NAMELIST /LIST/ D, E
```

In the following example, two group names are defined:

```
CHARACTER*30 NAME(25)
NAMELIST /INPUT/ NAME, GRADE, DATE /OUTPUT/ TOTAL, NAME
```

Group name INPUT contains variables NAME, GRADE, and DATE. Group name OUTPUT contains variables TOTAL and NAME.
The following shows another example:

```
NAMELIST /example/ i1, l1, r4, r8, z8, z16, c1, c10, iarray
! The corresponding input statements could be:
&example
i1  = 11
l1  = .TRUE.
r4  = 24.0
r8  = 28.0d0
z8  = (38.0, 0.0)
z16 = (316.0d0, 0.0d0)
c1  = 'A'
c10 = 'abcdefghij'
iarray(8) = 41, 42, 43
/
```

A sample program, NAMELIST.F90, is included in the `<install-dir>/samples` subdirectory.

**NARGS**

*Inquiry Intrinsic Function (Specific):* Returns the total number of command-line arguments, including the command. This function cannot be passed as an actual argument.

**Syntax**

```
result = NARGS()
```

**Results**

The result type is INTEGER(4). The result is the number of command-line arguments, including the command. For example, NARGS returns 4 for the command-line invocation of `PROG1 -g -c -a`.

**Example**

```
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END

! MYPROG.F90 responds to command switches -r, -c, ! and/or -d
INTEGER(4) count, num, i, status
CHARACTER(80) buf
REAL r1 / 0.0 /
COMPLEX c1 / (0.0,0.0) /
REAL(8) d1 / 0.0 /

num = 5
count = NARGS()
DO i = 1, count-1
   CALL GETARG(i, buf, status)
```
IF (status .lt. 0) THEN
  WRITE (*,*) 'GETARG error - exiting'
  EXIT
END IF
IF (buf(2:status) .EQ.'r') THEN
  r1 = REAL(num)
  WRITE (*,*) 'r1 = ',r1
ELSE IF (buf(2:status) .EQ.'c') THEN
  c1 = CMPLX(num)
  WRITE (*,*) 'c1 = ', c1
ELSE IF (buf(2:status) .EQ.'d') THEN
  dl = DBLE(num)
  WRITE (*,*) 'dl = ', dl
ELSE
  WRITE(*,*) 'Invalid command switch: ', buf (1:status)
END IF
END DO
END

NEAREST

**Elemental Intrinsic Function (Generic): Returns the nearest different number (representable on the processor) in a given direction.**

**Syntax**

\[
\text{result} = \text{NEAREST} \ (x, \ s)
\]

\(x\) \hspace{1cm} \text{(Input) Must be of type real.}

\(s\) \hspace{1cm} \text{(Input) Must be of type real and nonzero.}

**Results**

The result type and kind are the same as \(x\). The result has a value equal to the machine representable number that is different from and nearest to \(x\), in the direction of the infinity with the same sign as \(s\).

**Example**

If 3.0 and 2.0 are REAL(4) values, NEAREST (3.0, 2.0) has the value \(3 + 2^{-22}\), which equals approximately 3.0000002. (For more information on the model for REAL(4), see Model for Real Data.

The following shows another example:

```
REAL(4) r1
REAL(8) r2, result
r1 = 3.0
result = NEAREST (r1, -2.0)
WRITE(*,*) result ! writes 2.999999761581421
```

! When finding nearest to REAL(8), can’t see

```fortran
! the difference unless output in HEX
r2 = 111502.07D0
result = NEAREST(r2, 2.0)
WRITE('(*,1x,Z16)') result  ! writes 40FB38E11EB851ED
result = NEAREST(r2, -2.0)
WRITE('(*,1x,Z16)') result  ! writes 40FB38E11EB851EB
END
```

EPSILON

NEW_LINE

**Inquiry Intrinsic Function (Generic):** Returns a new line character.

Syntax

```fortran
result = NEW_LINE(a)
```

a

(Input) Must be of type default character. It may be a scalar or an array.

Results

The result is a character scalar of length one with the same kind type parameter as a.

The result value is the ASCII newline character ACHAR(10).

NINT

**Elemental Intrinsic Function (Generic):** Returns the nearest integer to the argument.

Syntax

```fortran
result = NINT (a [,kind])
```

a

(Input) Must be of type real.

kind

(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If a is greater than zero, NINT(a) has the value INT(a + 0.5); if a is less than or equal to zero, NINT(a) has the value INT(a - 0.5).

</table>

¹Or JNINT.
²The setting of compiler options specifying integer size can affect NINT, IDNINT, and IQNINT.
³Or JIDNNT. For compatibility with older versions of Fortran, IDNINT can also be specified as a generic function.
⁴Or JIQNNT. For compatibility with older versions of Fortran, IQNINT can also be specified as a generic function.

**Example**

NINT (3.879) has the value 4.
NINT (-2.789) has the value -3.

The following shows another example:

```fortran
INTEGER(4) i1, i2
i1 = NINT(2.783) ! returns 3
i2 = IDNINT(-2.783D0) ! returns -3
```

**NLSEnumCodepages (W*S)**

*NLS Function:* Returns an array containing the codepages supported by the system, with each array element describing one valid codepage.

**Module**

USE IFNLS

**Syntax**

```fortran
ptr=> NLSEnumCodepages( )
```

**Results**

The result is a pointer to an array of codepages, with each element describing one supported codepage.

**NOTE**

After use, the pointer returned by NLSEnumCodepages should be deallocated with the DEALLOCATE statement.
See Also
NLSEnumLocales
DEALLOCATE

NLSEnumLocales (W*S)

**NLS Function:** Returns an array containing the language and country combinations supported by the system, in which each array element describes one valid combination.

**Module**
USE IFNLS

**Syntax**

```fortran
ptr => NLSEnumLocales()
```

**Results**
The result is a pointer to an array of locales, in which each array element describes one supported language and country combination. Each element has the following structure:

```fortran
TYPE NLS$EnumLocale
  CHARACTER*(NLS$MaxLanguageLen)  Language
  CHARACTER*(NLS$MaxCountryLen)   Country
  INTEGER(4)                      DefaultWindowsCodepage
  INTEGER(4)                      DefaultConsoleCodepage
END TYPE
```

If the application is a Windows or QuickWin application, NLS$DefaultWindowsCodepage is the codepage used by default for the given language and country combination. If the application is a console application, NLS$DefaultConsoleCodepage is the codepage used by default for the given language and country combination.

**NOTE**
After use, the pointer returned by NLSEnumLocales should be deallocated with the DEALLOCATE statement.

See Also
NLSEnumCodepages
DEALLOCATE

NLSFormatCurrency (W*S)

**NLS Function:** Returns a correctly formatted currency string for the current locale.

**Module**
USE IFNLS

**Syntax**

```fortran
result = NLSFormatCurrency(outstr, instr[, flags])
```
(Output) Character*(*). String containing the correctly formatted currency for the current locale. If outstr is longer than the formatted currency, it is blank-padded.

(int) Character*(*). Number string to be formatted. Can contain only the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

flags (Input; optional) INTEGER(4). If specified, modifies the currency conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:
- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides

Results

The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:
- NLS$ErrorInsufficientBuffer - outstr buffer is too small
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorInvalidInput - instr has an illegal value

Example

USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatCurrency(str, "1.23")
print *, str ! prints $1.23
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints $1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatCurrency(str, "1.23")
print *, str ! prints 1 Pts
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints 1.000.001 Pts

NLSFormatNumber
NLSFormatDate
NLSFormatTime

NLSFormatDate (W*S)

**NLS Function:** Returns a correctly formatted string containing the date for the current locale.

Module

USE IFNLS

Syntax

result = NLSFormatDate (outstr [, intime] [, flags])
The Intel® Fortran Compiler 19.0 Developer Guide and Reference

**outstr**
(Output) Character*(*) String containing the correctly formatted date for the current locale. If *outstr* is longer than the formatted date, it is blank-padded.

**intime**
(Input; optional) INTEGER(4). If specified, date to be formatted for the current locale. Must be an integer date such as the packed time created with PACKTIMEQQ. If you omit *intime*, the current system date is formatted and returned in *outstr*.

**flags**
(Input; optional) INTEGER(4). If specified, modifies the date conversion. If you omit *flags*, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:
- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
- NLS$UseAltCalendar - Use the locale’s alternate calendar
- NLS$LongDate - Use local long date format
- NLS$ShortDate - Use local short date format

**Results**
The result type is INTEGER(4). The result is the number of characters written to *outstr* (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:
- NLS$ErrorInsufficientBuffer - *outstr* buffer is too small
- NLS$ErrorInvalidFlags - *flags* has an illegal value
- NLS$ErrorInvalidInput - *intime* has an illegal value

**Example**

```fortran
USE IFNLS
INTEGER(4) i
CHARACTER(40) str
i = NLSFORMATDATE(str, FLAGS=NLS$NORMAL) ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$USEALTCALENDAR) ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$LONGDATE) ! Sunday, August 1, 2010
i = NLSFORMATDATE(str, FLAGS=NLS$SHORTDATE) ! 8/1/10
END
```

**See Also**

NLSFormatTime
NLSFormatCurrency
NLSFormatNumber

**NLSFormatNumber (W*S)**

**NLS Function:** Returns a correctly formatted number string for the current locale.

**Module**

USE IFNLS

**Syntax**

```
result = NLSFormatNumber (outstr, instr [, flags])
```
**outstr**

(Output) Character*(*) String containing the correctly formatted number for the current locale. If `outstr` is longer than the formatted number, it is padded with blanks.

**instr**

(Input) Character*(*) Number string to be formatted. Can only contain the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

**flags**

(Input; optional) INTEGER(4). If specified, modifies the number conversion. If you omit `flags`, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- **NLS$Normal** - No special formatting
- **NLS$NoUserOverride** - Do not use user overrides

**Results**

The result type is INTEGER(4). The result is the number of characters written to `outstr` (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- **NLS$ErrorInsufficentBuffer** - `outstr` buffer is too small
- **NLS$ErrorInvalidFlags** - `flags` has an illegal value
- **NLS$ErrorInvalidInput** - `instr` has an illegal value

**Example**

```fortran
USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatNumber(str, "1.23")
print *, str ! prints 1.23
i = NLSFormatNumber(str, "1000000.99")
print *, str ! prints 1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatNumber(str, "1.23")
print *, str ! prints 1,23
i = NLSFormatNumber(str, "1000000.99")
print *, str ! prints 1,000,000.99
END
```

**See Also**

NLSFormatTime
NLSFormatCurrency
NLSFormatDate

**NLSFormatTime (W*S)**

**NLS Function:** Returns a correctly formatted string containing the time for the current locale.

**Module**

USE IFNLS

**Syntax**

```fortran
result = NLSFormatTime (outstr [, intime] [, flags])
```
**outstr**

(Output) Character*. String containing the correctly formatted time for the current locale. If `outstr` is longer than the formatted time, it is blank-padded.

**intime**

(Input; optional) INTEGER(4). If specified, time to be formatted for the current locale. Must be an integer time such as the packed time created with PACKTIMEQQ. If you omit `intime`, the current system time is formatted and returned in `outstr`.

**flags**

(Input; optional) INTEGER(4). If specified, modifies the time conversion. If you omit `flags`, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
- NLS$NoMinutesOrSeconds - Do not return minutes or seconds
- NLS$NoSeconds - Do not return seconds
- NLS$NoTimeMarker - Do not add a time marker string
- NLS$Force24HourFormat - Return string in 24 hour format

**Results**

The result type is INTEGER(4). The result is the number of characters written to `outstr` (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - `outstr` buffer is too small
- NLS$ErrorInvalidFlags - `flags` has an illegal value
- NLS$ErrorInvalidInput - `intime` has an illegal value

**Example**

```fortran
USE IFNLS
INTEGER(4) i
CHARACTER(20) str
i = NLSFORMATTIME(str, FLAGS=NLS$NORMAL)  ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOMINUTESORSECONDS)  ! 11 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOTIMEMARKER)  ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=IOR(NLS$FORCE24HOURFORMAT, &
                       NLS$NOSECONDS))  ! 23:38 PM
END
```

**See Also**

NLSFormatCurrency
NLSFormatDate
NLSFormatNumber

**NLSGetEnvironmentCodepage (W*S)**

**NLS Function:** Returns the codepage number for the system (Window) codepage or the console codepage.

**Module**

USE IFNLS

**Syntax**

```fortran
result = NLSGetEnvironmentCodepage (flags)
```
flags

(Input) INTEGER(4). Tells the function which codepage number to return. Available values (defined in IFNLS.F90) are:

- NLS$ConsoleEnvironmentCodepage - Gets the codepage for the console
- NLS$WindowsEnvironmentCodepage - Gets the current Windows codepage

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, it returns one of the following error codes:

- NLS$ErrorInvalidFlags - flags has an illegal value.
- NLS$ErrorNoConsole - There is no console associated with the given application. So, operations with the console codepage are not possible.

See Also

NLSGetEnvironmentCodepage

NLSGetLocale (W*S)

NLS Subroutine: Returns the current language, country, or codepage.

Module

USE IFNLS

Syntax

CALL NLSGetLocale ([language] [,country] [,codepage])

language (Output; optional) Character(*). Current language.
country (Output; optional) Character(*). Current country.
codepage (Output; optional) INTEGER(4). Current codepage.

NLSGetLocale returns a valid codepage in codepage. It does not return one of the NLS$... symbolic constants that can be used with NLSSetLocale.

Example

USE IFNLS
CHARACTER(50) cntry, lang
INTEGER(4) code
CALL NLSGetLocale (lang, cntry, code)  ! get all three
CALL NLSGetLocale (CODEPAGE = code)  ! get the codepage
CALL NLSGetLocale (COUNTRY = cntry, CODEPAGE =code) ! get country
                ! and codepage

See Also

NLSSetLocale

NLSGetLocaleInfo (W*S)

NLS Function: Returns information about the current locale.
Module
USE IFNLS

Syntax
result = NLSGetLocaleInfo (type, outstr)

**type**  
(Input) INTEGER(4). NLS parameter requested. A list of parameter names is provided in NLS LocaleInfo Parameters.

**outstr**  
(Output) Character*(*). Parameter setting for the current locale. All parameter settings placed in outstr are character strings, even numbers. If a parameter setting is numeric, the ASCII representation of the number is used. If the requested parameter is a date or time string, an explanation of how to interpret the format in outstr is provided in NLS Date and Time Format.

Results
The result type is INTEGER(4). The result is the number of characters written to outstr if successful, or if outstr has 0 length, the number of characters required to hold the requested information. Otherwise, the result is one of the following error codes (defined in IFNLS.F90):

- NLS$ErrorInvalidInput - type has an illegal value.
- NLS$ErrorInsufficientBuffer - The outstr buffer was too small, but was not 0 (so that the needed size would be returned).

The NLS$LI parameters are used for the argument type and select the locale information returned by NLSGetLocaleInfo in outstr. You can perform an inclusive OR with NLS$NoUserOverride and any NLS$LI parameter. This causes NLSGetLocaleInfo to bypass any user overrides and always return the system default value.

The following table lists and describes the NLS$LI parameters in alphabetical order.

### NLS LocaleInfo Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NLS$LI_ICALENDARTYPE</td>
<td>Specifies which type of calendar is currently being used:</td>
</tr>
<tr>
<td></td>
<td>1 - Gregorian (as in United States)</td>
</tr>
<tr>
<td></td>
<td>2 - Gregorian (English strings always)</td>
</tr>
<tr>
<td></td>
<td>3 - Era: Year of the Emperor (Japan)</td>
</tr>
<tr>
<td></td>
<td>4 - Era: Year of the Republic of China</td>
</tr>
<tr>
<td></td>
<td>5 - Tangun Era (Korea)</td>
</tr>
<tr>
<td>NLS$LI_ICENTURY</td>
<td>Specifies whether to use full 4-digit century for the short date only:</td>
</tr>
<tr>
<td></td>
<td>0 - Two-digit year</td>
</tr>
<tr>
<td></td>
<td>1 - Full century</td>
</tr>
<tr>
<td>NLS$LI_ICOUNTRY</td>
<td>The country code, based on international phone codes, also referred to as IBM country codes.</td>
</tr>
<tr>
<td>NLS$LI_ICURRDIGITS</td>
<td>Number of decimal digits for the local monetary format.</td>
</tr>
<tr>
<td>NLS$LI_ICURRENCY</td>
<td>Determines how positive currency is represented:</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLS$LI_IDATE</td>
<td>Short Date format ordering:</td>
</tr>
<tr>
<td></td>
<td>0 - Month-Day-Year</td>
</tr>
<tr>
<td></td>
<td>1 - Day-Month-Year</td>
</tr>
<tr>
<td></td>
<td>2 - Year-Month-Day</td>
</tr>
<tr>
<td>NLS$LI_IDAYLZERO</td>
<td>Specifies whether to use leading zeros in day fields for the short date only:</td>
</tr>
<tr>
<td></td>
<td>0 - Use no leading zeros</td>
</tr>
<tr>
<td></td>
<td>1 - Use leading zeros</td>
</tr>
<tr>
<td>NLS$LI_IDEFAULTANSCODEPAGE</td>
<td>ANSI code page associated with this locale.</td>
</tr>
<tr>
<td>NLS$LI_IDEFAULTCOUNTRY</td>
<td>Country code for the principal country in this locale. This is provided so that partially specified locales can be completed with default values.</td>
</tr>
<tr>
<td>NLS$LI_IDEFAULTLANGUAGE</td>
<td>Language ID for the principal language spoken in this locale. This is provided so that partially specified locales can be completed with default values.</td>
</tr>
<tr>
<td>NLS$LI_IDEFAULTOEMCODEPAGE</td>
<td>OEM code page associated with the locale.</td>
</tr>
<tr>
<td>NLS$LI_IDIGITS</td>
<td>The number of decimal digits.</td>
</tr>
<tr>
<td>NLS$LI_IFIRSTDAYOFWEEK</td>
<td>Specifies which day is considered first in a week:</td>
</tr>
<tr>
<td></td>
<td>0 - SDAYNAME1</td>
</tr>
<tr>
<td></td>
<td>1 - SDAYNAME2</td>
</tr>
<tr>
<td></td>
<td>2 - SDAYNAME3</td>
</tr>
<tr>
<td></td>
<td>3 - SDAYNAME4</td>
</tr>
<tr>
<td></td>
<td>4 - SDAYNAME5</td>
</tr>
<tr>
<td></td>
<td>5 - SDAYNAME6</td>
</tr>
<tr>
<td></td>
<td>6 - SDAYNAME7</td>
</tr>
<tr>
<td>NLS$LI_IFIRSTWEEKOFYEAR</td>
<td>Specifies which week of the year is considered first:</td>
</tr>
<tr>
<td></td>
<td>0 - Week containing 1/1</td>
</tr>
<tr>
<td></td>
<td>1 - First full week following 1/1</td>
</tr>
<tr>
<td></td>
<td>2 - First week containing at least 4 days</td>
</tr>
<tr>
<td>NLS$LI_IINTLCURRDIGITS</td>
<td>Number of decimal digits for the international monetary format.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLS$LI_ILANGUAGE</td>
<td>An ID indicating the language.</td>

<tr>
<td>NLS$LI_ILDATE</td>
<td>Long Date format ordering:</td>
</tr>
<tr>
<td></td>
<td>0 - Month-Day-Year</td>
</tr>
<tr>
<td></td>
<td>1 - Day-Month-Year</td>
</tr>
<tr>
<td></td>
<td>2 - Year-Month-Day</td>
</tr>
<tr>
<td>NLS$LI_ILZERO</td>
<td>Determines whether to use leading zeros in decimal fields:</td>
</tr>
<tr>
<td></td>
<td>0 - Use no leading zeros</td>
</tr>
<tr>
<td></td>
<td>1 - Use leading zeros</td>
</tr>
<tr>
<td>NLS$LI_IMEASURE</td>
<td>This value is 0 if the metric system (S.I.) is used and 1 for the U.S. system of measurements.</td>
</tr>
<tr>
<td>NLS$LI.IMONLZERO</td>
<td>Specifies whether to use leading zeros in month fields for the short date only:</td>
</tr>
<tr>
<td></td>
<td>0 - Use no leading zeros</td>
</tr>
<tr>
<td></td>
<td>1 - Use leading zeros</td>
</tr>
<tr>
<td>NLS$LI_INEGCURR</td>
<td>Determines how negative currency is represented:</td>
</tr>
<tr>
<td></td>
<td>0 ($1.1)</td>
</tr>
<tr>
<td></td>
<td>1 -$1.1</td>
</tr>
<tr>
<td></td>
<td>2 $-1.1</td>
</tr>
<tr>
<td></td>
<td>3 $1.1-</td>
</tr>
<tr>
<td></td>
<td>4 (1.1$)</td>

<td></td>
<td>13 1.1- $ (space before $)</td>
</tr>
<tr>
<td></td>
<td>14 ($ 1.1) (space after $)</td>
</tr>
<tr>
<td></td>
<td>15 (1.1 $) (space before $)</td>
</tr>
<tr>
<td>NLS$LI_INEGNUMBER</td>
<td>Determines how negative numbers are represented:</td>
</tr>
<tr>
<td></td>
<td>0 - Puts negative numbers in parentheses: (1.1)</td>
</tr>
<tr>
<td></td>
<td>1 - Puts a minus sign in front: -1.1</td>
</tr>
<tr>
<td></td>
<td>2 - Puts a minus sign followed by a space in front: - 1.1</td>
</tr>
<tr>
<td></td>
<td>3 - Puts a minus sign after: 1.1-</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLS$LI_INEGSEPBYSPACE</td>
<td>1 if the monetary symbol is separated by a space from a negative amount; otherwise, 0.</td>
</tr>
<tr>
<td>NLS$LI_INEGSIGNPOSN</td>
<td>Determines the formatting index for negative values. Same values as for NLS$LI_IPOSSIGNPOSN.</td>
</tr>
<tr>
<td>NLS$LI_INEGSYMPRECEDES</td>
<td>1 if the monetary symbol precedes, 0 if it follows a negative amount.</td>
</tr>
<tr>
<td>NLS$LI_IOPTIONALCALENDAR</td>
<td>Specifies which additional calendar types are valid and available for this locale. This can be a null separated list of all valid optional calendars:</td>
</tr>
<tr>
<td></td>
<td>0 - No additional types valid</td>
</tr>
<tr>
<td></td>
<td>1 - Gregorian (localized)</td>
</tr>
<tr>
<td></td>
<td>2 - Gregorian (English strings always)</td>
</tr>
<tr>
<td></td>
<td>3 - Era: Year of the Emperor (Japan)</td>
</tr>
<tr>
<td></td>
<td>4 - Era: Year of the Republic of China</td>
</tr>
<tr>
<td></td>
<td>5 - Tangun Era (Korea)</td>
</tr>
<tr>
<td>NLS$LI_IPOSSEPBYSPACE</td>
<td>1 if the monetary symbol is separated by a space from a positive amount; otherwise, 0.</td>
</tr>
<tr>
<td>NLS$LI_IPOSSIGNPOSN</td>
<td>Determines the formatting index for positive values:</td>
</tr>
<tr>
<td></td>
<td>0 - Parenthesis surround the amount and the monetary symbol</td>
</tr>
<tr>
<td></td>
<td>1 - The sign string precedes the amount and the monetary symbol</td>
</tr>
<tr>
<td></td>
<td>2 - The sign string follows the amount and the monetary symbol</td>
</tr>
<tr>
<td></td>
<td>3 - The sign string immediately precedes the monetary symbol</td>
</tr>
<tr>
<td></td>
<td>4 - The sign string immediately follows the monetary symbol</td>
</tr>
<tr>
<td>NLS$LI_IPOSSYMPRECEDES</td>
<td>1 if the monetary symbol precedes, 0 if it follows a positive amount.</td>
</tr>
<tr>
<td>NLS$LI_ITIME</td>
<td>Time format:</td>
</tr>
<tr>
<td></td>
<td>0 - Use 12-hour format</td>
</tr>
<tr>
<td></td>
<td>1 - Use 24-hour format</td>
</tr>
<tr>
<td>NLS$LI_ITLZERO</td>
<td>Determines whether to use leading zeros in time fields:</td>
</tr>
<tr>
<td></td>
<td>0 - Use no leading zeros</td>
</tr>
<tr>
<td></td>
<td>1 - Use leading zeros for hours</td>
</tr>
<tr>
<td>NLS$LI_S1159</td>
<td>String for the AM designator.</td>
</tr>
<tr>
<td>NLS$LI_S2359</td>
<td>String for the PM designator.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLS$LI_SABBREVCTRYYNAME</td>
<td>The abbreviated name of the country as per ISO Standard 3166.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVDAYNAME1 -</td>
<td>Native abbreviated name for each day of the week. 1 = Mon, 2 = Tue, etc.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVDAYNAME7</td>
<td></td>
</tr>
<tr>
<td>NLS$LI_SABBREVLANGNAME</td>
<td>The abbreviated name of the language, created by taking the 2-letter language abbreviation as found in ISO Standard 639 and adding a third letter as appropriate to indicate the sublanguage.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVMONTHNAME1 -</td>
<td>Native abbreviated name for each month. 1 = Jan, 2 = Feb, etc. 13 = the 13th month, if it exists in the locale.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVMONTHNAME13</td>
<td></td>
</tr>
<tr>
<td>NLS$LI_SCOUNTRY</td>
<td>The full localized name of the country.</td>
</tr>
<tr>
<td>NLS$LI_SCURRENCY</td>
<td>The string used as the local monetary symbol. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SDATE</td>
<td>Character(s) for the date separator. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SDAYNAME1 -</td>
<td>Native name for each day of the week. 1 = Monday, 2 = Tuesday, etc.</td>
</tr>
<tr>
<td>NLS$LI_SDAYNAME7</td>
<td></td>
</tr>
<tr>
<td>NLS$LI_SDECIMAL</td>
<td>The character(s) used as decimal separator. This is restricted such that it cannot be set to digits 0 - 9.</td>
</tr>
<tr>
<td>NLS$LI_SENGCOUNTRY</td>
<td>The full English name of the country. This will always be restricted to characters that map into the ASCII 127 character subset.</td>
</tr>
<tr>
<td>NLS$LI_SENGLANGUAGE</td>
<td>The full English name of the language from the ISO Standard 639. This will always be restricted to characters that map into the ASCII 127 character subset.</td>
</tr>
<tr>
<td>NLS$LI_SGROUPING</td>
<td>Sizes for each group of digits to the left of the decimal. An explicit size is needed for each group; sizes are separated by semicolons. If the last value is 0 the preceding value is repeated. To group thousands, specify &quot;3;0&quot;.</td>
</tr>
<tr>
<td>NLS$LI_SINTLSYMBOL</td>
<td>Three characters of the International monetary symbol specified in ISO 4217 &quot;Codes for the Representation of Currencies and Funds&quot;, followed by the character separating this string from the amount.</td>
</tr>
<tr>
<td>NLS$LI_SLANGUAGE</td>
<td>The full localized name of the language.</td>
</tr>
<tr>
<td>NLS$LI_SLIST</td>
<td>Character(s) used to separate list items, for example, comma in many locales.</td>
</tr>
<tr>
<td>NLS$LI_SLONGDATE</td>
<td>Long Date formatting string for this locale. The string returned may contain a string within single quotes (’ ’). Any characters within single quotes should be left as is. The d, M and y should have the day, month, and year substituted, respectively.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLS$LI_SMONDECIMALSEP</td>
<td>The character(s) used as monetary decimal separator. This is restricted such that it cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SMONGROUPING</td>
<td>Sizes for each group of monetary digits to the left of the decimal. If the last value is 0, the preceding value is repeated. To group thousands, specify &quot;3;0&quot;.</td>
</tr>
<tr>
<td>NLS$LI_SMONTHNAME1 - NLS$LI_SMONTHNAME13</td>
<td>Native name for each month. 1 = January, 2 = February, etc. 13 = the 13th month, if it exists in the locale.</td>
</tr>
<tr>
<td>NLS$LI_SMONTHOUSANDSEP</td>
<td>The character(s) used as monetary separator between groups of digits left of the decimal. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SNATIVECTRYNAME</td>
<td>The native name of the country.</td>
</tr>
<tr>
<td>NLS$LI_SNATIVEDIGITS</td>
<td>The ten characters that are the native equivalent to the ASCII 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SNATIVELANGNAME</td>
<td>The native name of the language.</td>
</tr>
<tr>
<td>NLS$LI_SNEGATIVESIGN</td>
<td>String value for the negative sign. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SPOSITIVESIGN</td>
<td>String value for the positive sign. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_SSHORTDATE</td>
<td>Short Date formatting string for this locale. The d, M and y should have the day, month, and year substituted, respectively. See NLS Date and Time Format for explanations of the valid strings.</td>
</tr>
<tr>
<td>NLS$LI_STHOUSAND</td>
<td>The character(s) used as separator between groups of digits left of the decimal. This is restricted such that it cannot be set to digits 0 - 9.</td>
</tr>
<tr>
<td>NLS$LI_STIME</td>
<td>Character(s) for the time separator. Cannot be set to digits 0-9.</td>
</tr>
<tr>
<td>NLS$LI_STIMEFORMAT</td>
<td>Time formatting string. See NLS Date and Time Format for explanations of the valid strings.</td>
</tr>
</tbody>
</table>

When NLSGetLocaleInfo ( type, outstr ) returns information about the date and time formats of the current locale, the value returned in outstr can be interpreted according to the following tables. Any text returned within a date and time string that is enclosed within single quotes should be left in the string in its exact form; that is, do not change the text or the location within the string.

**Day**

The day can be displayed in one of four formats using the letter "d". The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Day of the month as digits without leading zeros for single-digit days</td>
</tr>
<tr>
<td>dd</td>
<td>Day of the month as digits with leading zeros for single-digit days</td>
</tr>
<tr>
<td>ddd</td>
<td>Day of the week as a three-letter abbreviation (SABBREVDAYNAME)</td>
</tr>
<tr>
<td>ddddd</td>
<td>Day of the week as its full name (SDAYNAME)</td>
</tr>
</tbody>
</table>

**Month**

...
The month can be displayed in one of four formats using the letter "M". The uppercase "M" distinguishes months from minutes. The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Month as digits without leading zeros for single-digit months</td>
</tr>
<tr>
<td>MM</td>
<td>Month as digits with leading zeros for single-digit months</td>
</tr>
<tr>
<td>MMM</td>
<td>Month as a three-letter abbreviation (SABBREVMONTHNAME)</td>
</tr>
<tr>
<td>MMMM</td>
<td>Month as its full name (SMONTHNAME)</td>
</tr>
</tbody>
</table>

**Year**

The year can be displayed in one of three formats using the letter "y". The following table shows the three variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>Year represented by only the last digit</td>
</tr>
<tr>
<td>yy</td>
<td>Year represented by only the last two digits</td>
</tr>
<tr>
<td>yyyy</td>
<td>Year represented by the full 4 digits</td>
</tr>
</tbody>
</table>

**Period/Era**

The period/era string is displayed in a single format using the letters "gg".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gg</td>
<td>Period/Era string</td>
</tr>
</tbody>
</table>

**Time**

The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker. The following table shows the numerous variations of the time format. Lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The lowercase "m" distinguishes minutes from months.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>Hours without leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>hh</td>
<td>Hours with leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>H</td>
<td>Hours without leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>HH</td>
<td>Hours with leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>m</td>
<td>Minutes without leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>mm</td>
<td>Minutes with leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>s</td>
<td>Seconds without leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>ss</td>
<td>Seconds with leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>t</td>
<td>One-character time marker string</td>
</tr>
<tr>
<td>tt</td>
<td>Multicharacter time marker string</td>
</tr>
</tbody>
</table>

**Example**

```fortran
USE IFNLS
INTEGER(4) strlen
CHARACTER(40) str
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
```
print *, str ! prints Monday if language is English
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints Tuesday if language is English

NLSSetEnvironmentCodepage (W*S)

NLS Function: Sets the codepage for the current console. The specified codepage affects the current console program and any other programs launched from the same console. It does not affect other open consoles or any consoles opened later.

Module
USE IFNLS

Syntax
result = NLSSetEnvironmentCodepage (codepage,flags)

codepage (Input) INTEGER(4). Number of the codepage to set as the console codepage.

flags (Input) INTEGER(4). Must be set to NLS$ConsoleEnvironmentCodepage.

Results
The result type is INTEGER(4). The result is zero if successful. Otherwise, returns one of the following error codes defined in IFNLS.F90:

- NLS$ErrorInvalidCodepage - codepage is invalid or not installed on the system
- NLS$ErrorInvalidFlags - flags is not valid
- NLS$ErrorNoConsole - There is no console associated with the given applicatio. So operations, with the console codepage are not possible

The flags argument must be a NLS$ConsoleEnvironmentCodepage; it cannot be a NLS$WindowsEnvironmentCodepage. NLSSetEnvironmentCodepage does not affect the Windows* codepage.

See Also
NLSSetEnvironmentCodepage

NLSSetLocale (W*S)

NLS Function: Sets the current language, country, or codepage.

Module
USE IFNLS

Syntax
result = NLSSetLocale (language[,country] [,codepage])
language  (Input) Character*(*).. One of the languages supported by the Windows* NLS APIs.

country  (Input; optional) Character*(*).. If specified, characterizes the language further. If omitted, the default country for the language is set.

codepage  (Input; optional) INTEGER(4). If specified, codepage to use for all character-oriented NLS functions. Can be any valid supported codepage or one of the following predefined values defined in IFNLS.F90:

- NLS$CurrentCodepage - The codepage is not changed. Only the language and country settings are altered by the function.
- NLS$ConsoleEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for console programs.
- NLS$ConsoleLanguageCodepage - The codepage is changed to the default console codepage for the language and country combination specified.
- NLS$WindowsEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for Windows programs.
- NLS$WindowsLanguageCodepage - The codepage is changed to the default Windows codepage for the language and country combination specified.

If you omit codepage, it defaults to NLS$WindowsLanguageCodepage. At program startup, NLS$WindowsEnvironmentCodepage is used to set the codepage.

Results
The result type is INTEGER(4). The result is zero if successful. Otherwise, one of the following error codes (defined in IFNLS.F90) may be returned:

- NLS$ErrorInvalidLanguage - language is invalid or not supported
- NLS$ErrorInvalidCountry - country is invalid or is not valid with the language specified
- NLS$ErrorInvalidCodepage - codepage is invalid or not installed on the system

NOTE
NLSSetLocale works on installed locales only. Many locales are supported, but they must be installed through the system Control Panel/International menu.

When doing mixed-language programming with Fortran and C, calling NLSSetLocale with a codepage other than the default environment Windows codepage causes the codepage in the C run-time library to change by calling C's setmbcp( ) routine with the new codepage. Conversely, changing the C run-time library codepage does not change the codepage in the Fortran NLS library.

Calling NLSSetLocale has no effect on the locale used by C programs. The locale set with C's setlocale( ) routine is independent of NLSSetLocale.

Calling NLSSetLocale with the default environment console codepage, NLS$ConsoleEnvironmentCodepage, causes an implicit call to the Windows API SetFileApisToOEM( ). Calling NLSSetLocale with any other codepage causes a call to SetFileApisToANSI( ).

NLSGetLocale

**NOFREEFORM**

*Statement:* Specifies that source code is in fixed-form format.

For more information, see FREEFORM and NOFREEFORM.

**NOFUSION**

*General Compiler Directive:* Prevents a loop from fusing with adjacent loops.

**Syntax**

```
!DIR$ NOFUSION
```

The NOFUSION directive lets you fine tune your program on a loop-by-loop basis.

This directive should be placed immediately before the DO statement of the loop that should not be fused.

**Example**

Consider the following example that demonstrates use of the NOFUSION directive:

```fortran
subroutine sub (b,a,n)
  real a(n), b(n)
  do i=1,n
    a(i) = a(i) + b(i)
  enddo
  !DIR$ NOFUSION
  do i=1,n
    a(i) = a(i) + 1
  enddo
end
```

The following shows the same example, but it uses Standard Fortran array assignments, which allow implicit arrays:

```fortran
subroutine sub (b,a,n)
  real a(n), b(n)
  a = a + b
  !DIR$ NOFUSION
  a = a + 1
end
```

**See Also**

General Compiler Directives

Syntax Rules for Compiler Directives

Rules for General Directives that Affect DO Loops

Rules for Loop Directives that Affect Array Assignment Statements

**NON_RECURSIVE**

*Keyword:* Specifies that a subroutine or function does not call itself directly or indirectly.

For more information, see RECURSIVE and NON_RECURSIVE.
**NOOPTIMIZE**

*Statement:* Disables optimizations.

For more information, see OPTIMIZE and NOOPTIMIZE.

**NOPREFETCH**

*Statement:* Disables data prefetching.

For more information, see PREFETCH and NOPREFETCH.

**NORM2**

*Transformational Intrinsic Function (Generic):* Returns the $L_2$ norm of an array.

**Syntax**

\[
\text{result} = \text{NORM2} \ (x [, \ dim])
\]

- \(x\) (Input) Must be a real array.
- \(dim\) (Input; optional) Must be a scalar integer with a value in the range $1 \leq dim \leq n$, where \(n\) is the rank of \(x\).

**Results**

The result is of the same type and kind parameters as \(x\).

The result is a scalar if \(dim\) is omitted; otherwise, the result has rank \(n - 1\) and shape \([d_1, d_2, ... , d_{dim-1}, d_{dim+1}, ... , d_n]\), where \(n\) is the rank of \(x\) and \([d_1, d_2, ... , d_n]\) is the shape of \(x\).

The result of NORM2 \((x)\) has a value equal to a processor-dependent approximation to the generalized $L_2$ norm of \(x\), which is the square root of the sum of the squares of the elements of \(x\).

The result of NORM2 \((x, \ DIM=dim)\) has a value equal to that of NORM2 \((x)\) if \(x\) has rank one.

Otherwise, the value of element \((s_1, s_2, ... , s_{dim-1}, s_{dim+1}, ... , s_n)\) of the result is equal to NORM2 \((x (s_1, s_2, ... , s_{dim-1}, :, s_{dim+1}, ... , s_n))\).

It is recommended that the processor compute the result without undue overflow or underflow.

**Example**

The value of NORM2 \(([3.0, 4.0])\) is 5.0 (approximately).

If \(X\) has the value:

\[
\begin{bmatrix}
1.0 & 2.0 \\
3.0 & 4.0
\end{bmatrix}
\]

then the value of NORM2 \((X, \ DIM=1)\) is approximately \([3.162, 4.472]\) and the value of NORM2 \((X, \ DIM=2)\) is approximately \([2.236, 5.0]\).

**NOSTRICT**

*Statement:* Enables language features not found in the language standard specified on the command line.

For more information, see STRICT and NOSTRICT.
NOT

*Elemental Intrinsic Function (Generic): Returns the logical complement of the argument.*

**Syntax**

\[
\text{result} = \text{NOT}(i)
\]

\(i\) (Input) Must be of type integer.

**Results**

The result type and kind are the same as \(i\). The result value is obtained by complementing \(i\) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>(i)</th>
<th>(\text{NOT}(i))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BNOT</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>INOT(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JNOT</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KNOT</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or HNOT.

**Example**

If \(I\) has a value equal to 10101010 (base 2), \(\text{NOT}(I)\) has the value 01010101 (base 2).

The following shows another example:

\[
\begin{align*}
\text{INTEGER}(2) & \quad i(2), \quad j(2) \\
i & = (\langle 4, 132 \rangle) \quad ! \quad i(1) = 0000000000000100 \\
\text{NOT}(i) & \quad \text{returns } (-5,-133) \quad ! \quad j(1) = 1111111111111011 \\
n & = \langle 4, 132 \rangle \quad ! \quad j(2) = 1111111111111101
\end{align*}
\]

NOUNROLL
Statement: Disables the unrolling of a DO loop.
For more information, see UNROLL and NOUNROLL.

NOUNROLL_AND_JAM
Statement: Hints to the compiler to disable loop unrolling and jamming.
For more information, see UNROLL_AND_JAM and NOUNROLL_AND_JAM.

NOVECTOR
Statement: Disables vectorization of a DO loop.
For more information, see VECTOR and NOVECTOR.

NOWAIT Clause
Parallel Directive Clause: Specifies that threads may resume execution before the execution of the region completes.

Syntax
NOWAIT

When you specify this clause, it removes the synchronization barrier implied at the end of the region. Note that NOWAIT can also be specified as a keyword in several directives. At most one NOWAIT clause or keyword can appear in a directive that allows the clause or keyword.

NULL
Transformational Intrinsic Function (Generic): Initializes a pointer as disassociated when it is declared.

Syntax
result = NULL ([ mold])

mold (Optional) Must be a pointer; it can be of any type. Its pointer association status can be associated, disassociated, or undefined. If its status is associated, the target does not have to be defined with a value.

Results
The result type and kind are the same as mold, if present; otherwise, it is determined as follows:

<table>
<thead>
<tr>
<th>If NULL ( ) Appears...</th>
<th>Type is Determined From...</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the right side of pointer assignment</td>
<td>The pointer on the left side</td>
</tr>
<tr>
<td>As initialization for an object in a declaration</td>
<td>The object</td>
</tr>
</tbody>
</table>
If NULL ( ) Appears... The result is a pointer with disassociated association status.

<table>
<thead>
<tr>
<th>If NULL ( ) Appears...</th>
<th>Type is Determined From...</th>
</tr>
</thead>
<tbody>
<tr>
<td>As default initialization for a component</td>
<td>The component</td>
</tr>
<tr>
<td>In a structure constructor</td>
<td>The corresponding component</td>
</tr>
<tr>
<td>As an actual argument</td>
<td>The corresponding dummy argument</td>
</tr>
<tr>
<td>In a DATA statement</td>
<td>The corresponding pointer object</td>
</tr>
</tbody>
</table>

Caution
If you use module IFWIN or IFWINTY, you will have a name conflict if you use the NULL intrinsic. To avoid this problem, rename the integer parameter constant NULL to something else; for example:

```
USE IFWIN, NULL0 => NULL
```

This example lets you use both NULL0 and NULL( ) in the same program unit with no conflict.

Example
Consider the following:

```
INTEGER, POINTER :: POINT1 => NULL( )
```

This statement defines the initial association status of POINT1 to be disassociated.

NULLIFY
Statement: Disassociates a pointer from a target.

Syntax
NULLIFY (pointer-object[, pointer-object]...)

```
pointer-object          Is a structure component or the name of a variable; it must be a
                          pointer (have the POINTER attribute).
```

Description
The initial association status of a pointer is undefined. You can use NULLIFY to initialize an undefined pointer, giving it disassociated status. Then the pointer can be tested using the intrinsic function ASSOCIATED.

Example
The following is an example of the NULLIFY statement:

```
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR_A(:), PTR_B(:)
PTR_A => TAR
PTR_B => TAR
...
NULLIFY(PTR_A)
```

After these statements are executed, PTR_A will have disassociated status, while PTR_B will continue to be associated with variable TAR.
The following shows another example:

```fortran
! POINTER2.F90  Pointing at a Pointer and Target
!DIR$ FIXEDFORMLINESIZE:80

REAL, POINTER :: arrow1 (:)
REAL, POINTER :: arrow2 (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:)

ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1

arrow2 => arrow1
IF (ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow2

NULLIFY (arrow2)
IF (.NOT.ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is not pointed.'
WRITE (*,'( 1x,a,7f8.0)') 'pointer',arrow1
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

END
```

**NUM_IMAGES**

*Transformational Intrinsic Function (Generic):*

*Returns the number of images.*

**Syntax**

```fortran
result = NUM_IMAGES()
```

**Results**

The result type is default integer. The result is the number of images.

You can specify a compiler option or environment variable to modify the number of images. If both are specified, the environment variable setting overrides the compiler option setting.

A compiler option must be specified to enable coarrays. If it is not specified and you use this intrinsic function, an error occurs.
Example

In the following example, image 1 is used to read data. The other images then copy the data:

```fortran
REAL :: R[*]
IF (THIS_IMAGE()==1) THEN
   READ (?,*) R
   DO I = 2, NUM_IMAGES()
      R[I] = R
   END DO
END IF
SYNC ALL
```

O to P

OBJCOMMENT

**General Compiler Directive:** Specifies a library search path in an object file.

**Syntax**

```
!DIR$ OBJCOMMENT LIB: library
```

*library* is a character constant specifying the name and, if necessary, the path of the library that the linker is to search.

The linker searches for the library named in OBJCOMMENT as if you named it on the command line, that is, before default library searches. You can place multiple library search directives in the same source file. Each search directive appears in the object file in the order it is encountered in the source file.

If the OBJCOMMENT directive appears in the scope of a module, any program unit that uses the module also contains the directive, just as if the OBJCOMMENT directive appeared in the source file using the module.

If you want to have the OBJCOMMENT directive in a module, but do not want it in the program units that use the module, place the directive outside the module that is used.

Example

```fortran
! MOD1.F90
MODULE a
!DIR$ OBJCOMMENT LIB: "opengl32.lib"
END MODULE a

! MOD2.F90
!DIR$ OBJCOMMENT LIB: "graftools.lib"
MODULE b
!
END MODULE b

! USER.F90
PROGRAM go
   USE a  ! library search contained in MODULE a
   ! included here
   USE b  ! library search not included
END
```
OFFLOAD

**OFFLOAD Compiler Directive:** Enables statements to execute on the target. This directive only applies when targeting Intel® Xeon Phi™ products. This directive is deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.

Syntax

```
!DIR$ [OMP] OFFLOAD clause[[,] clause...]  
```

```plaintext
clause  
```

Can be any of the following:

- **TARGET** *(target-name [::target-number]*)
  
  An optional *clause*. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.

  Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

- **SIGNAL** *(tag)*
  
  An optional *clause*. Include it to enable the CPU to continue execution after initiating the OFFLOAD.

  If this clause is used, the computation performed by the offload and any data transfers occur concurrently with the CPU execution of the code after the directive.

  If this clause is not used, then the entire offload and associated data transfers are executed synchronously: the CPU will not continue execution past the directive until the computation performed by the offload has completed.

  SIGNAL is device specific; if you use this clause, you must specify a *target-number* >=0 in the TARGET clause.

- **WAIT** *(tag [, tag, ...]*)
  
  An optional *clause*. Include it to specify a wait for completion of a previously initiated asynchronous data transfer or asynchronous computation.

  WAIT is device specific; if you use this clause, you must specify a *target-number* >=0 in the TARGET clause.

- **MANDATORY**
  
  An optional *clause*. Include it to specify that execution on the processor is required. Execution on the CPU is not allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message.
You cannot specify both MANDATORY and OPTIONAL since they are opposites.

If OPTIONAL is not specified for this directive and it is not specified in option \([q \text{ or } Q]\)offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **OPTIONAL**

  An optional clause. Include it to specify that execution on the processor is requested but not required. Execution on the CPU is allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program is executed on the CPU, not the TARGET.

  You cannot specify both MANDATORY and OPTIONAL since they are opposites.

  If OPTIONAL is not specified for this directive and it is not specified in option \([q \text{ or } Q]\)offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **STATUS (var)**

  An optional clause. Include it to determine the status of the execution of an offloading construct. When used with the OPTIONAL or MANDATORY clause, the STATUS clause also lets you modify the action to take upon failure.

  var is of derived type offload_status defined in mic_lib.mod. This status variable can be queried for details about the offload. The module mic_lib.mod is provided and contains the following definitions:

  ```fortran
  use, intrinsic :: iso_c_binding
  enum , bind (C)
  enumerator :: OFFLOAD_SUCCESS         = 0
  enumerator :: OFFLOAD_DISABLED        = 1  ! offload is disabled
  enumerator :: OFFLOAD_UNAVAILABLE     = 2  ! card is not available
  enumerator :: OFFLOAD_OUT_OF_MEMORY   = 3  ! not enough memory on device
  enumerator :: OFFLOAD_PROCESS_DIED    = 4  ! target process has died
  enumerator :: OFFLOAD_ERROR           = 5  ! unspecified error
  end enum

  type, bind (C) :: offload_status
  integer(kind=c_int) :: result        = OFFLOAD_DISABLED   ! result, see enum above
  integer(kind=c_int) :: device_number = -1  ! device number
  integer(kind=c_int) :: data_sent     = 0  ! number of bytes sent to the target
  integer(kind=c_int) :: data_received = 0  ! number of bytes received by host
  end type offload_status
  ```
When you specify STATUS with the MANDATORY clause, and the
offload cannot be performed, the construct is not automatically
executed on the host. The program continues execution. You
should examine var for the cause of the offload failure and take
appropriate action. Note that if no STATUS clause is specified, then
the program is terminated.

When you specify STATUS with the OPTIONAL clause, and the
offload cannot be performed, the construct is executed on the host
processor. You can examine the var in the STATUS clause to
determine the cause of the offload failure.

- offload-parameter [[,] offload-parameter]
  One or more data movement clauses (see below).

The following arguments are used in the above clause items:

  target-name
  Is an identifier that represents the target. The only allowable target
  name is MIC.

  target-number
  (Required for SIGNAL and WAIT) Is an integer expression whose value
  is interpreted as shown in the following table.

  When target-number is specified, the implicit MANDATORY offload is
  overridden and execution on the CPU is allowed when either the
  OPTIONAL clause is also specified or optional is also specified in the
  [Q]offload option.

  -1
  This value specifies execution on the processor. The runtime
  system chooses the specific processor. Execution on the CPU
  is not allowed.

  If the correct target hardware needed to run the offloaded
code is not available on the system, the program fails with
an error message. Execution on the CPU is allowed when the
OPTIONAL clause is also specified or optional is also specified in option

  [q or Q]offload.

  This value is not allowed if you
specify the SIGNAL or WAIT
clause.

  >= 0
  A value greater than or equal to
zero specifies execution on a
specific processor. The number
of the specific processor is
determined as follows:

  processor = MOD (target-
  number, number_of_copros)
If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option [q or Q]offload.

< -1 These values are reserved.

If you don't specify the target-number argument, the runtime system executes the code on the processor, and if multiple processors are available, on which processor. If no processor is available, the program fails with an error message.

For example, in a system with 4 processors:

- Specifying 2 or 6 tells the runtime systems to use processor 2 for the transfer, because both MOD(2,4) and MOD(6,4) equal 2.
- Specifying 1000 tells the runtime systems to use processor 0 for the transfer, because MOD(1000,4) = 0.

**NOTE**
Leaving data values on the processor from one execution of offloaded code to another is called "data persistence". In a system with multiple processors, you need to specify a target-number to reliably use data persistence. When you use ALLOC_IF or FREE_IF to implement data persistence on the processor, but do not specify a target-number, the runtime system randomly chooses a processor, so the chosen processor could be one on which the data is not available.

**if-specifier**
Is a Boolean expression.

If the expression evaluates to true, then the program attempts to offload the statement. If the specified target processor is absent from the system or not available at that time because it is fully loaded, then the offloaded code executes on the CPU.

If the expression evaluates to false, then the offloaded code executes on the CPU and none of the other OFFLOAD clauses have any effect.

**tag**
Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.

When used with SIGNAL, tag is an integer value associated with an asynchronous computation or an asynchronous data transfer. tag can be used in subsequent WAIT clauses in other OFFLOAD, OFFLOAD_TRANSFER, or OFFLOAD_WAIT directives.
When used with \texttt{WAIT}, \textit{tag} is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same \textit{tag} that you specified in the \texttt{SIGNAL} clause that started the asynchronous computation or data transfer with the \texttt{OFFLOAD} or \texttt{OFFLOAD\_TRANSFER} directive.

\textbf{offload-parameter}

Can be any of the following data movement clauses:

\begin{itemize}
\item \texttt{IN ( identifier[, identifier...] [: modifier[,] modifier...] )}
\item \texttt{OUT ( identifier[, identifier...] [: modifier[,] modifier...] )}
\item \texttt{INOUT ( identifier[, identifier...] [: modifier[,] modifier...] )}
\item \texttt{NOCOPY ( identifier[, identifier...] [: modifier[,] modifier...] )}
\end{itemize}

When a program runs in a heterogeneous environment, program variables are copied back and forth between the CPU and the target. The \textit{offload-parameter} is a specification for controlling the direction in which variables are copied, and for pointers, the amount of data that is copied.

The data selected for transfer is a combination of variables implicitly transferred because they are lexically referenced within offload constructs, and variables explicitly listed in an \textit{offload-parameter}.

\begin{itemize}
\item \textbf{IN} This indicates that the variable is strictly an input to the target region and it is copied from the CPU to the processor. Its value is not copied back from the processor to the CPU after the region completes.
\item \textbf{OUT} This indicates that the variable is strictly an output of the target region. The host CPU does not copy the variable to the target processor. It is copied from the processor to the CPU.
\item \textbf{INOUT} This indicates that the variable is both copied from the CPU to the target processor and back from the processor to the CPU.
\item \textbf{NOCOPY} This indicates that the variable should not be copied.
\end{itemize}

A variable whose value is reused from the last target execution or a variable that is used entirely within the offloaded code section can be named in a NOCOPY clause to avoid any copying.

If the NOCOPY clause is being used to retain values across offload instances (data persistence), then currently values of non-scalar variables
with automatic storage allocation (stack variables) are not preserved across offload instances. However, all statically allocated variables are preserved, and non-scalar variables with automatic allocation are also preserved across offload instances.

If the NOCOPY clause is being used merely to suppress data transfer between the CPU and the target, then variables of all memory allocation types are supported.

A variable that is a derived type, or components of that variable, can appear in different clauses of the same directive.

An IN or OUT `element-count-expr` expression (see description below within `modifier`) is evaluated at a point in the program before the statement or clause in which it is used.

An array variable whose size is known from its declaration is copied in its entirety. If a subset of an array is to be processed, use the name of the starting element of the subset and the `element-count-expr` to transfer the array subset.

Because a data pointer variable not listed in an IN clause is uninitialized within the offload region, it must be assigned a value on the target before it can be referenced.

**identifier**

Is a variable, a subscripted variable, an array slice, or a component reference. The variable or the component reference may have the ALLOCATABLE or POINTER attribute. An array slice may be contiguous or non-contiguous.

**modifier**

Is one of the following:

- **LENGTH (element-count-expr)**

  where `element-count-expr` is an integer expression, computed at runtime. Use it with:

  - Integer pointer variables (not Fortran 90 POINTERs)

    Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host CPU and the target. Instead, objects that an integer pointer points to are copied to or from the target, and the value of the pointer variable is recreated. By default, a single element is copied.

    Use `element-count-expr` to specify how many elements pointed to should be considered as data. If the expression value is zero or negative, the program fails with an error message.
• Arrays (including assumed-size)
  
  element-count-expr specifies a number of elements copied between the CPU and target.

A Fortran array variable can be one of four major types: explicit-shape, assumed-shape, deferred-shape and assumed-size. The runtime descriptor for the first three types makes that array variable’s size known at compile time or at runtime. The last dimension of an assumed-size array is the length of its variable.

By default, the compiler copies explicit-shape, assumed-shape and deferred-shape arrays in their entirety. They do not need an element-count-expr. However, you can use an optional element-count-expr to specify the total number of elements to copy, which limits the number of elements copied back and forth in the last dimension of the array.

You must specify an assumed-size array with an element-count-expr specification, because the compiler does not know the total size of the array. The value of the element-count-expr is the total number of elements of the array to be copied.

• ALLOC_IF (condition) | FREE_IF (condition)

where condition is a Boolean expression.

The ALLOC_IF modifier specifies a Boolean condition that controls whether the allocatable variables in the IN clause will be allocated a new block of memory on the target when the offload is executed on the target. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused (data persistence). You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a FREE_IF(.FALSE.) clause on an earlier offload.

The FREE_IF modifier specifies a Boolean condition that controls whether to deallocate the memory allocated for the allocatable variables in an IN clause. If the expression evaluates to true, the memory pointed to by each variable listed in the clause is deallocated. If the condition evaluates to false, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

The following are the default settings for ALLOC_IF and FREE_IF:

<table>
<thead>
<tr>
<th></th>
<th>ALLOC_IF</th>
<th>FREE_IF</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>INOUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>

For more information, see Managing Memory Allocation for Pointer Variables.

- **ALIGN** *(expression)*

  where the value of *expression* should be a power of two.

  This modifier applies to pointer variables and requests the specified minimum alignment for pointer data allocated on the target.

- **ALLOC** *(array-subscript-list)*

  where *array-subscript-list* is a list of array section triplets that specifies a set of elements of an array that need allocation. The *array-subscript-list* takes the following form:

  \[
  \text{start-element : end-element [ : stride] [ , start-element : end-element [ : stride] ]...}
  \]

  This modifier can only be used in IN and OUT clauses and only one *identifier* must be listed in the clause. A one to one correspondence is established between the *identifier* in the IN or OUT clause and the base variable that will be allocated with *array-subscript-list* dimensions.

  When ALLOC is specified, the allocation on the target is the same shape as *array-subscript-list*. The variable being transferred or allocated must be the same variable used in the ALLOC modifier (*identifier* or *into-identifier*). Only unit strides are allowed in *array-subscript-list*. When *array-subscript-list* has rank greater than one, the second and subsequent subscript triplet must specify all elements at that dimension. Therefore, *array-subscript-list* must describe an array that is simply contiguous. (See CONTIGUOUS.)

  Data is transferred into that portion of the array specified by the IN or OUT clauses. Therefore, memory allocation and the data transfer can use separate array slice references.

  When the lower bound of the first dimension of *array-subscript-list* in the ALLOC is greater than the lower bound of the first dimension of *identifier*, then the memory allocation begins with that element. The memory below the lower bound is unallocated and should not be referenced by the program. This allows a smaller section of the array to be transferred to the target without requiring that the entire array be allocated.

  For more information, see Allocating Memory for Parts of Arrays.

- **INTO** *(into-identifier)*

  where *into-identifier* is a variable, a subscripted variable, an array slice, or a component reference with the same form, rank, dimensions, and kind type parameters as the *identifier* in the clause.

  This modifier can only be used in IN and OUT clauses and only one *identifier* must be listed in the clause. When INTO is specified, data can be transferred from one variable on the CPU to another on the target, and vice versa. This establishes a one to one correspondence between a single source variable and a single destination variable.
You can specify ALLOC, ALLOC_IF, and FREE_IF modifiers along with the INTO modifier.

When INTO is used in an IN clause, data is copied from the CPU object identifier to the target object into-identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the into-identifier in the INTO clause.

When INTO is used in an OUT clause, data is copied from the target object into-identifier to the CPU object identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the identifier in the OUT expression.

When this modifier is used, the source expression generates a stream of elements to be copied into the memory range specified by the INTO expression.

If overlap occurs between the source and destination variables, it causes undefined behavior (although with disjoint memories it will work as expected). No ordering can be assumed between transfers from different IN or OUT clauses.

For more information, see Moving Data from One Variable to Another.

The OFFLOAD directive both transfers data and offloads computation.
The OMP is optional in the syntax. When it is present, the next line, other than a comment, must be an OpenMP* PARALLEL, PARALLEL SECTIONS, or PARALLEL DO directive. Otherwise the compiler issues an error.
When OMP is not present in the syntax, the OFFLOAD directive must be followed by one of the following or the compiler issues an error:

- An OpenMP* PARALLEL, PARALLEL SECTIONS, or PARALLEL DO directive
  This specifies remote execution of that top-level OpenMP* construct.
- A CALL statement
  This specifies remote execution of that single procedure call.
- An assignment statement where the right side only executes a function
  This specifies remote execution of that single function invocation.

You can choose whether to offload a statement based on runtime conditions, such as the size of a data set. The IF (if-specifier) clause lets you specify the condition.

The SIGNAL and WAIT clauses refer to a specific target device, so you must specify target-number in the TARGET clause. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

If the if-specifier evaluates to false and a SIGNAL (tag) clause is used in the directive, then the SIGNAL is undefined and any WAIT on this SIGNAL has undefined behavior.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.
For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.

In the data movement clauses (IN, OUT, INOUT, and NOCOPY) and the modifiers ALLOC and INTO, you can specify an array slice of any rank. For an assumed-size dummy array, you can specify the following syntax, interchangeably:

- var:length(k), where k is a scalar integer expression computed at runtime representing the number of elements of var to be moved.
- var(section-subscript-list), where section-subscript-list is a comma-separated list of subscript triplets of the form [ subscript ] : [ subscript ] [ : stride ]

**NOTE**
Do not use the __MIC__ preprocessor symbol inside a statement following an OMP OFFLOAD directive. However, you can use it in a subprogram called from the directive.

Conceptually, this is the sequence of events when a statement marked for offload is encountered:

1. If there is no IF clause, go to step 3.
2. On the host, evaluate the IF expression. If it evaluates to true, go to step 3. Otherwise, execute the region on the host and go to step 17.
3. Attempt to acquire the target. If successful, go to step 4. Otherwise:
   - If there is no MANDATORY clause, execute the region on the host and go to step 17.
   - If there is a STATUS clause, set the var to indicate the error and go to step 17.
   - Otherwise, terminate the program with an appropriate error message.
4. On the host, compute all ALLOC_IF, FREE_IF, and element-count-expr expressions used in IN and OUT clauses.
5. On the host, gather all variable values that are inputs to the offload.
6. Send the input values from the host to the target.
7. On the target, allocate memory for variable-length OUT variables.
8. On the target, copy input values into corresponding target variables.
9. On the target, execute the offloaded region.
10. On the target, compute all element-count-expr expressions used in OUT clauses.
11. On the target, gather all variable values that are outputs of the offload.
12. Send output values back from the target to the host.
13. On the host, copy values received into corresponding host variables.
14. If no error occurred on the target, go to step 17.
15. If there is a STATUS clause, set the var to indicate the error and go to step 17.
16. Otherwise, terminate the program with an appropriate error message.
17. Continue processing the program on the host.

**Example**

The following example demonstrates offloading a CALL statement or assignment statement. Note that !DIR$ OFFLOAD TARGET (MIC) prefixes the statement designated for offload.

```plaintext
! Offload call of routine calc
!DIR$ OFFLOAD TARGET(MIC)
CALL calc(...)  

! Offload call of function recalc
!DIR$ OFFLOAD TARGET(MIC)
X = recalc(...)  
```
The following example demonstrates using the OFFLOAD directive in conjunction with the OpenMP* PARALLEL directive to specify remote execution of the OpenMP construct.

```fortran
! Offload OpenMP parallel construct
!$omp offload target(mic)
!$omp parallel
... !$omp end parallel
```

The following example demonstrates how to use a variable-length array to specify a number of elements copied between the CPU and target.

```fortran
subroutine sample (Z,N,M)
integer, intent(in)  :: N,M
real, dimension (N,*) :: Z
... !dir$ omp offload target(mic) in (Z:length(N*M))
... end subroutine sample
```

The following example shows various forms of identifier and use of the ALLOC and INTO modifiers in IN clauses:

```fortran
subroutine foo
real a(1000,500), b(1000,500), c(2000, 20)
real, pointer :: p(:)
p => c(1:20:2)
!dir$ offload target(mic) in ( a : into (b) )
... !dir$ offload target(mic) in ( c(i:j:k,1:m:n) ) ! k and n must be strides of 1
... !dir$ offload target(mic) in ( p(1:20) : alloc (p(1:100)) )
... end
```

The following example demonstrates using the OFFLOAD directive, as well as directives OFFLOAD_TRANSFER and OFFLOAD_WAIT.

```fortran
! Sample use of OFFLOAD, OFFLOAD_TRANSFER, and OFFLOAD_WAIT

module M
    integer, parameter :: iter = 10
    integer, parameter :: count = 25000

    !dir$ options /offload_attribute_target=mic
    real,    allocatable :: in1(:), in2(:), out1(:), out2(:)
    !dir$ end options

    integer              :: sin1, sin2, sout1, sout2
contains
    !dir$ attributes offload:mic :: compute
    subroutine compute(x, y)
```

1780
real, allocatable :: x(:,), y(:)
integer :: i

!dir$ omp parallel do num_threads(96) private(i)
do i = 1, count
  y(i) = x(i) * x(i)
end do
end subroutine compute

subroutine do_async_in()

integer :: i

! prime loop with initial in1 transfer to target
!dir$ offload_transfer target(mic:0) signal(sin1) &
in( in1 : alloc_if(.false.) free_if(.false.) )
do i = 1, iter
  if (mod(i,2) == 0) then
    ! initiate another in1 data transfer to target, skip if last iteration
    !dir$ offload_transfer target(mic:0) if(i /= iter) signal(sin1) &
in( in1 : alloc_if(.false.) free_if(.false.) )
    ! wait for in2 transfer to complete, then offload computation
    !dir$ offload target(mic:0) wait(sin2) &
    nocopy(in2) &
    out( out2 : alloc_if(.false.) free_if(.false.) )
call compute(in2, out2);
    ! use out2 results on host
    call use_result(out2);
  else
    ! initiate another in2 data transfer to target, skip if last iteration
    !dir$ offload_transfer target(mic:0) if(i /= iter) signal(sin2) &
in( in2 : alloc_if(.false.) free_if(.false.) )
    ! wait for in1 transfer to complete, then offload computation
    !dir$ offload target(mic:0) wait(sin1) &
    nocopy( in1 ) &
    out( out1 : alloc_if(.false.) free_if(.false.) )
call compute(in1, out1);
    ! use out1 results on host
    call use_result(out1)
  endif
enddo
end subroutine do_async_in

subroutine do_async_out()

integer :: i

do i = 1, (iter + 1)
   if ( mod(i,2) == 0 ) then
      if ( i < (iter + 1)) then
         ! offload computation, leave results on target
         !dir$ offload target(mic:0) &
         !   in( in2 : alloc_if(.false.) free_if(.false.) ) &
         !      nocopy( out2 )
         call compute(in2, out2)
         ! transfer out2 results (asynchronously) back to host
         !dir$ offload_transfer target(mic:0) signal(sout2) &
         !      out( out2 : alloc_if(.false.) free_if(.false.) )
         endif
      ! wait for out1 results on host
      !dir$ offload_wait target(mic:0) wait(sout1)
      ! use out1 results on host
      call use_result(out1);
   else
      if (i < (iter + 1)) then
         ! offload computation, leave results on target
         !dir$ offload target(mic:0) &
         !   in( in1 : alloc_if(.false.) free_if(.false.) ) &
         !      nocopy( out1 )
         call compute(in1, out1)
         ! transfer out1 results (asynchronously) back to host
         !dir$ offload_transfer target(mic:0) signal(sout1) &
         !      out( out1 : alloc_if(.false.) free_if(.false.) )
         endif
      if (i > 1) then
         ! wait for out2 results on host
         !dir$ offload_wait target(mic:0) wait(sout2)
         ! use out2 results on host
         call use_result(out2)
      endif
   endif
endif
enddo

end subroutine do_async_out

subroutine do_sync()
    integer :: i
    do i = 1, iter
        ! transfer data to host, compute, and return results synchronously
        !dir$ offload target(mic:0) &
        ! in( in1 : alloc_if(.false.) free_if(.false.) ) &
        ! out( out1 : alloc_if(.false.) free_if(.false.) )
        call compute(in1, out1)

        ! use out1 results on host
        call use_result(out1)
    enddo
end subroutine do_sync

subroutine use_result(x)
    ! use results from offload computations on host
    real, allocatable :: x(:)
    print*, "USE_RESULT *****************"
end subroutine use_result

end module M

program main
    use M
    integer :: i
    allocate ( in1(count), in2(count), out1(count), out2(count) )

    !dir$ omp parallel do num_threads(96) private(i)
    do i = 1, count
        in1(i) = REAL(i)
        in2(i) = REAL(i)
    enddo

    ! Initialize signal variables to unique values
    ! allocate memory on target only
    !dir$ offload_transfer target(mic:0) &
The following example demonstrates the tag argument:

```
module mmod
!
real :: x (1000) = 1.1
real :: y(1000) = 2.2
end module mmod

program mmain
!
! compile with symbol name "doGLOB" defined to use a global tag
! compile with symbol name "doGLOB" undefined to use a local tag
!
use mmod
!
integer :: ktag = 2
call f (ktag)
call g (ktag)
print *, (y (j),j=1,1000,100) ! print every 100th element == 5.1
end program mmain

subroutine f (kktag)
!
!
!copy X to MIC, signal when done
!
!copy X to MIC, signal when done
!
end subroutine f
```
subroutine g (kktag)
use mmmod
integer :: kktag

#ifdef doGLOB
!dir$ offload begin target (mic:0) wait (gtag) OUT (y) ! wait for offload_transfer in f to copy x
#else
!dir$ offload begin target (mic:0) wait (kktag) OUT (y) ! wait for offload_transfer in f to copy x
#endif

y = x + 4                   ! y is all 5.1s
!
!dir$ end offload
end subroutine g

The following examples demonstrate using the STATUS clause.

Example 1
use mic_lib
type (offload_status) :: stat
!dir$ offload target (mic:1) status (stat)
... ! code to be offloaded to the processor
!dir$ end offload
if (stat%result .ne. OFFLOAD_SUCCESS) then
... ! handle the error condition
end if

Example 2
use mic_lib
type (offload_status) :: stat
real :: p (20), q (20)
integer :: my_mic

!dir$ offload_transfer target (mic), status (stat), in (p, q)
if (stat%result == OFFLOAD_OUT_OF_MEMORY) then
    ! memory could not be allocated
    ...
else
    ! data has been transferred, can continue using processor
    my_mic = stat%device_number
    !dir$ offload target (mic:my_mic), status (stat)
    ...
end if

OFFLOAD BEGIN and END OFFLOAD

OFFLOAD Compiler Directives: Enable a group of statements to execute on the target. These directives only apply when targeting Intel® Xeon Phi™ products. These directives are deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.

Syntax

```
!DIR$ OFFLOAD BEGIN clause[ [, ] clause...] block
!DIR$ END OFFLOAD
```

clause Can be any of the clauses accepted by the OFFLOAD directive with identical meanings and restrictions.

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

These directives provide the same functionality as the OFFLOAD directive, except that they let you offload a block of code that includes any number of Fortran statements, including DO, CALL and any assignments, but not OpenMP* directives.

The OFFLOAD BEGIN directive must be paired with a closing END OFFLOAD directive.

Example

In the following example, the DO loop is designated for offloading.

```
subroutine sample()
    ... !DIR$ OFFLOAD BEGIN TARGET(MIC)
        do i = 1, n
            a(i) = b(i) ** 2.0
        enddo
    !DIR$ END OFFLOAD
    ... end subroutine sample
```

See OFFLOAD for further examples.

OFFLOAD_TRANSFER

OFFLOAD Compiler Directive: Initiates asynchronous data transfer, or initiates and completes synchronous data transfer. The action performed depends on the whether SIGNAL is specified. This directive only applies when targeting Intel® Xeon Phi™ products.
products. This directive is deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.

Syntax

!DIR$ OFFLOAD_TRANSFER clause[, clause...]

clause

Can be any of the following:

• TARGET (target-name [::target-number])

• IF (if-specifier)

An optional clause. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.

Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

• SIGNAL (tag)

An optional clause. Include it to enable asynchronous data transfer, meaning that data transfers are initiated, and the CPU can continue executing after initiating the OFFLOAD_TRANSFER. When you don’t include it, data transfer is synchronous.

SIGNAL is device specific; if you use this clause, you must specify a target-number >=0 in the TARGET clause.

• WAIT (tag [, tag, ...])

An optional clause. Include it to specify a wait for completion of a previously initiated asynchronous data transfer or asynchronous computation.

WAIT is device specific; if you use this clause, you must specify a target-number >=0 in the TARGET clause.

• MANDATORY

An optional clause. Include it to specify that execution on the processor is required. Execution on the CPU is not allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message.

You cannot specify both MANDATORY and OPTIONAL since they are opposites.

If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

• OPTIONAL

An optional clause. Include it to specify that execution on the processor is requested but not required. Execution on the CPU is allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program is executed on the CPU, not the TARGET.

You cannot specify both MANDATORY and OPTIONAL since they are opposites.
If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **STATUS (var)**

  An optional clause. Include it to determine the status of the execution of an offloading construct. When used with the OPTIONAL or MANDATORY clause, the STATUS clause also lets you modify the action to take upon failure.

  var is of derived type offload_status defined in mic_lib.mod. This status variable can be queried for details about the offload. The module mic_lib.mod is provided and contains the following definitions:

  ```fortran
  use, intrinsic :: iso_c_binding
  
  enum , bind (C) 
  enumerator :: OFFLOAD_SUCCESS         = 0
  enumerator :: OFFLOAD_DISABLED        = 1  ! offload is disabled
  enumerator :: OFFLOAD_UNAVAILABLE     = 2  ! card is not available
  enumerator :: OFFLOAD_OUT_OF_MEMORY   = 3  ! not enough memory on device
  enumerator :: OFFLOAD_PROCESS_DIED    = 4  ! target process has died
  enumerator :: OFFLOAD_ERROR           = 5  ! unspecified error
  end enum
  
  type, bind (C) :: offload_status
  integer(kind=c_int) ::  result        = OFFLOAD_DISABLED   ! result, see enum above
  integer(kind=c_int) ::  device_number = -1  ! device number
  integer(kind=c_int) ::  data_sent     =  0  ! number of bytes sent to the target
  integer(kind=c_int) ::  data_received =  0  ! number of bytes received by host
  end type offload_status
  ```

  When you specify STATUS with the MANDATORY clause, and the offload cannot be performed, the construct is not automatically executed on the host. The program continues execution. You should examine var for the cause of the offload failure and take appropriate action. Note that if no STATUS clause is specified, then the program is terminated.

  When you specify STATUS with the OPTIONAL clause, and the offload cannot be performed, the construct is executed on the host processor. You can examine the var in the STATUS clause to determine the cause of the offload failure.

- **offload-parameter [[,] offload-parameter]**

  One or more data movement clauses (see below).

The following arguments are used in the above clause items:
target-name

Is an identifier that represents the target. The only allowable target name is MIC.

target-number

(Required for SIGNAL and WAIT) Is an integer expression whose value is interpreted as shown in the following table.

When target-number is specified, the implicit MANDATORY offload is overridden and execution on the CPU is allowed when either the OPTIONAL clause is also specified or optional is also specified in option [q or Q]offload.

-1

This value specifies execution on the processor. The runtime system chooses the specific processor. Execution on the CPU is not allowed.

If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option [q or Q]offload.

This value is not allowed if you specify the SIGNAL or WAIT clause.

>= 0

A value greater than or equal to zero specifies execution on a specific processor. The number of the specific processor is determined as follows:

\[ \text{processor} = \text{MOD} (\text{target-number}, \text{number_of_coprocs}) \]

If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option [q or Q]offload.

< -1

These values are reserved.

If you don’t specify the target-number argument, the runtime system executes the code on the processor, and if multiple processors are available, on which processor. If no processor is available, the program fails with an error message.
For example, in a system with 4 processors:

- Specifying 2 or 6 tells the runtime systems to use processor 2 for the transfer, because both \( \text{MOD}(2,4) \) and \( \text{MOD}(6,4) \) equal 2.
- Specifying 1000 tells the runtime systems to use processor 0 for the transfer, because \( \text{MOD}(1000,4) = 0 \).

\[ \text{if-specifier} \]

Is a Boolean expression.

If the expression evaluates to true, then the data transfer specified by the directive occurs. If the specified target processor is absent from the system or not available at that time because it is fully loaded, then no action is taken.

If the expression evaluates to false, then no action is taken and none of the other offload clauses have any effect.

\[ \text{tag} \]

Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.

When used with \text{SIGNAL}, \text{tag} is an integer value associated with an asynchronous computation or an asynchronous data transfer. \text{tag} can be used in subsequent \text{WAIT} clauses in other \text{OFFLOAD}, \text{OFFLOAD_TRANSFER}, or \text{OFFLOAD_WAIT} directives.

When used with \text{WAIT}, \text{tag} is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same \text{tag} that you specified in the \text{SIGNAL} clause that started the asynchronous computation or data transfer with the \text{OFFLOAD} or \text{OFFLOAD_TRANSFER} directive.

\[ \text{offload-parameter} \]

Can be any of the following data movement clauses:

- \( \text{IN ( identifier[, identifier...] [: modifier][, modifier... ] ] } \)
- \( \text{OUT ( identifier[, identifier...] [: modifier][, modifier... ] ] } \)
- \( \text{NOCOPY ( identifier[, identifier...] [: modifier][, modifier... ] ] } \)

When a program runs in a heterogeneous environment, program variables are copied back and forth between the CPU and the target. The \text{offload-parameter} is a specification for controlling the direction in which variables are copied, and for pointers, the amount of data that is copied.

<table>
<thead>
<tr>
<th>IN</th>
<th>OUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>This indicates that the variable is strictly an input to the target region and it is copied from the CPU to the processor. Its value is not copied back from the processor to the CPU after the region completes.</td>
<td>This indicates that the variable is strictly an output of the target region. The host CPU does not copy the variable to the target processor. It is copied from the processor to the CPU.</td>
</tr>
</tbody>
</table>
This indicates that the variable should not be copied. A variable whose value is reused from the last target execution or one that is used entirely within the offloaded code section may be named in a NOCOPY clause to avoid any copying.

A variable that is a derived type, or components of that variable, can appear in different clauses of the same directive.

Memory is allocated on the processor for the variable.

This clause is required. It must not contain both an IN clause and an OUT clause.

An IN or OUT element-count-expr expression (see description below within modifier) is evaluated at a point in the program before the statement or clause in which it is used.

An array variable whose size is known from its declaration is copied in its entirety. If a subset of an array is to be processed, use the name of the starting element of the subset and the element-count-expr to transfer the array subset.

identifier

Is a variable, a subscripted variable, an array slice, or a component reference. The variable or the component reference may have the ALLOCATABLE or POINTER attribute. An array slice may be contiguous or non-contiguous.

modifier

Is one of the following:

- LENGTH (element-count-expr)

  where element-count-expr is an integer expression, computed at runtime. Use it with:

  - Integer pointer variables (not Fortran 90 POINTERs)

    Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host CPU and the target. Instead, objects that an integer pointer points to are copied to or from the target, and the value of the pointer variable is recreated. By default, a single element is copied.

    Use element-count-expr to specify how many elements pointed to should be considered as data. If the expression value is zero or negative, the program fails with an error message.

  - Arrays (including assumed-size)

    element-count-expr specifies a number of elements copied between the CPU and target.
A Fortran array variable can be one of four major types: explicit-shape, assumed-shape, deferred-shape and assumed-size. The runtime descriptor for the first three types makes that array variable's size known at compile time or at runtime. The last dimension of an assumed-size array is the length of its variable.

By default, the compiler copies explicit-shape, assumed-shape and deferred-shape arrays in their entirety. They do not need an `element-count-expr`. However, you can use an optional `element-count-expr` to specify the total number of elements to copy, which limits the number of elements copied back and forth in the last dimension of the array.

You must specify an assumed-size array with an `element-count-expr` specification, because the compiler does not know the total size of the array. The value of the `element-count-expr` is the total number of elements of the array to be copied.

- `ALLOC_IF ( condition ) | FREE_IF ( condition )`

where `condition` is a Boolean expression.

The ALLOC_IF modifier specifies a Boolean condition that controls whether the allocatable variables in the IN clause will be allocated a new block of memory on the target when the offload is executed on the target. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused. You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a FREE_IF(.FALSE.) clause on an earlier offload.

The FREE_IF modifier specifies a Boolean condition that controls whether to deallocate the memory allocated for the allocatable variables in an IN clause. If the expression evaluates to true, the memory pointed to by each variable listed in the clause is deallocated. If the condition evaluates to false, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

The following are the default settings for ALLOC_IF and FREE_IF:

<table>
<thead>
<tr>
<th></th>
<th>ALLOC_IF</th>
<th>FREE_IF</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>INOUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>OUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>NOCOPY</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

For more information, see Managing Memory Allocation for Pointer Variables.

- `ALIGN ( expression )`

where the value of `expression` should be a power of two.
This modifier applies to pointer variables and requests the specified minimum alignment for pointer data allocated on the target.

- **ALLOC** \((\text{array-subscript-list})\)

  where \(\text{array-subscript-list}\) is a list of array section triplets that specifies a set of elements of an array that need allocation. The \(\text{array-subscript-list}\) takes the following form:

  \[
  \text{start-element} : \text{end-element} \ [ : \text{stride}] \ , \text{start-element} : \text{end-element} \ [ : \text{stride}] \ ...
  \]

  This modifier can only be used in IN and OUT clauses and only one \(\text{identifier}\) must be listed in the clause. A one to one correspondence is established between the \(\text{identifier}\) in the IN or OUT clause and the base variable that will be allocated with \(\text{array-subscript-list}\) dimensions.

  When ALLOC is specified, the allocation on the target is the same shape as \(\text{array-subscript-list}\). The variable being transferred or allocated must be the same variable used in the ALLOC modifier (\(\text{identifier}\) or \(\text{into-identifier}\)). Only unit strides are allowed in \(\text{array-subscript-list}\). When \(\text{array-subscript-list}\) has rank greater than one, the second and subsequent subscript triplet must specify all elements at that dimension. Therefore, \(\text{array-subscript-list}\) must describe an array that is simply contiguous. (See CONTIGUOUS.)

  Data is transferred into that portion of the array specified by the IN or OUT clauses. Therefore, memory allocation and the data transfer can use separate array slice references.

  When the lower bound of the first dimension of \(\text{array-subscript-list}\) in the ALLOC is greater than the lower bound of the first dimension of \(\text{identifier}\), then the memory allocation begins with that element. The memory below the lower bound is unallocated and should not be referenced by the program. This allows a smaller section of the array to be transferred to the target without requiring that the entire array be allocated.

  For more information, see Allocating Memory for Parts of Arrays.

- **INTO** \((\text{into-identifier})\)

  where \(\text{into-identifier}\) is a variable, a subscripted variable, an array slice, or a component reference with the same form, rank, dimensions, and kind type parameters as the \(\text{identifier}\) in the clause.

  This modifier can only be used in IN and OUT clauses and only one \(\text{identifier}\) must be listed in the clause. When INTO is specified, data can be transferred from one variable on the CPU to another on the target, and vice versa. This establishes a one to one correspondence between a single source variable and a single destination variable.

  You can specify ALLOC, ALLOC_IF, and FREE_IF modifiers along with the INTO modifier.

  When INTO is used in an IN clause, data is copied from the CPU object \(\text{identifier}\) to the target object \(\text{into-identifier}\). If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the \(\text{into-identifier}\) in the INTO clause.
When INTO is used in an OUT clause, data is copied from the target object into-identifier to the CPU object identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the identifier in the OUT expression.

When this modifier is used, the source expression generates a stream of elements to be copied into the memory range specified by the INTO expression.

If overlap occurs between the source and destination variables, it causes undefined behavior (although with disjoint memories it will work as expected). No ordering can be assumed between transfers from different IN or OUT clauses.

For more information, see Moving Data from One Variable to Another.

This directive initiates asynchronous data transfer if SIGNAL is specified. If SIGNAL is not specified, it initiates and completes synchronous data transfer.

You can choose whether to offload a statement based on runtime conditions, such as the size of a data set. The IF (if-specifier) clause lets you specify the condition.

Use SIGNAL (tag) to start the asynchronous computation.

The SIGNAL and WAIT clauses refer to a specific target device, so you must specify target-number in the TARGET clause. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

If the if-specifier evaluates to false and a SIGNAL (tag) clause is used in the directive, then the SIGNAL is undefined and any WAIT on this SIGNAL has undefined behavior.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.

See Example 2 in the OFFLOAD Examples section for an example showing how to use offload_status to identify the target-number value when using -1, or when target-number is not specified.

For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.

In the data movement clauses (IN, OUT, INOUT, and NOCOPY) and the modifiers ALLOC and INTO, you can specify an array slice of any rank. For an assumed-size dummy array, you can specify the following syntax, interchangeably:

- var:length(k), where k is a scalar integer expression computed at runtime representing the number of elements of var to be moved.
- var(section-subscript-list), where section-subscript-list is a comma-separated list of subscript triplets of the form [ subscript ] : [ subscript ] [ : stride ]

Example

See the examples in OFFLOAD.
OFFLOAD_WAIT

**OFFLOAD Compiler Directive**: Specifies a wait for a previously initiated asynchronous activity. This directive only applies when targeting Intel® Xeon Phi™ products. This directive is deprecated. For similar functionality, you can use the OpenMP Fortran TARGET directives.

**Syntax**

```plaintext
!DIR$ OFFLOAD_WAIT clause[ [, ] clause ...]
```

*clause* can be any of the following:

- **TARGET** *(target-name : target-number)*
  - An optional *clause*. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.

- **IF** *(if-specifier)*
  - Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

- **WAIT** *(tag [, tag, ...])*  
  - A required *clause*. It specifies a wait until a previously initiated asynchronous data transfer or asynchronous computation is completed.

- **STATUS** *(var)*  
  - An optional *clause*. Include it to determine the status of the execution of an offloading construct.

*var* is of derived type *offload_status* defined in *mic_lib.mod*. This status variable can be queried for details about the offload. The module *mic_lib.mod* is provided and contains the following definitions:

```plaintext
use, intrinsic :: iso_c_binding

enum, bind (C)  
enumerator :: OFFLOAD_SUCCESS = 0  
enumerator :: OFFLOAD_DISABLED = 1 ! offload is
```

OFFLOAD

OFFLOAD_WAIT

About Asynchronous Data Transfer

About Asynchronous Computation

Writing Target-Specific Code Using a Directive

Dealing with Multiple Processors in a System

Subscript Triplets
disabled
enumerator :: OFFLOAD_UNAVAILABLE = 2  ! card is not available
enumerator :: OFFLOAD_OUT_OF_MEMORY = 3  ! not enough memory on device
enumerator :: OFFLOAD_PROCESS_DIED = 4  ! target process has died
enumerator :: OFFLOAD_ERROR = 5  ! unspecified error
end enum

type, bind (C) :: offload_status
  integer(kind=c_int) :: result        = OFFLOAD_DISABLED  ! result, see enum above
  integer(kind=c_int) :: device_number = -1  ! device number
  integer(kind=c_int) :: data_sent     = 0  ! number of bytes sent to the target
  integer(kind=c_int) :: data_received = 0  ! number of bytes received by host
end type offload_status

The following arguments are used in the above clause items:

target-name
Is an identifier that represents the target. The only allowable target name is MIC.

target-number
Is a required integer expression whose value is interpreted as follows:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;= 0</td>
<td>A value greater than or equal to zero specifies execution on a specific processor. The number of the specific processor is determined as follows: processor = MOD (target-number, number_of_copros)</td>
</tr>
<tr>
<td>&lt;= -1</td>
<td>These values are reserved.</td>
</tr>
</tbody>
</table>

For example, in a system with 4 processors:

- Specifying 2 or 6 tells the runtime systems to use processor 2 for the transfer, because both MOD(2,4) and MOD(6,4) equal 2.
- Specifying 1000 tells the runtime systems to use processor 0 for the transfer, because MOD(1000,4) = 0.

if-specifier
Is a Boolean expression.

If the expression evaluates to true, then execution waits for the completion of a previously initiated asynchronous data transfer or asynchronous computation. If the specified target processor is absent from the system or not available at that time because it is fully loaded, then no action is taken.

If the expression evaluates to false, then no action is taken and none of the other offload clauses have any effect.

tag
Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.
When used with WAIT, tag is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same tag that you specified in the SIGNAL clause that started the asynchronous computation or data transfer with the OFFLOAD or OFFLOAD_TRANSFER directive.

The OFFLOAD_WAIT directive specifies a wait for the completion of a previously initiated asynchronous data transfer performed by the OFFLOAD_TRANSFER directive, or an asynchronous computation and return data transfer, if any, performed by the OFFLOAD directive.

The WAIT clause refers to a specific target device, so you must specify target-number in the TARGET clause.

The signal associated with tag is cleared following completion of the previously initiated asynchronous data transfer or asynchronous computation. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.

For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.

**OPEN**

**Statement:** Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.

**Syntax**

OPEN ([UNIT=] io-unit[, FILE= name] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i- var], slist)

*io-unit*

Is an external unit specifier.

*name*

Is a character or numeric expression specifying the name of the file to be connected. For more information, see FILE Specifier.
label
Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

msg-var
Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

i-var
Is a scalar integer variable that is defined as a positive integer (the number of the error message) if an error occurs, a negative integer if an end-of-file record is encountered, and zero if no error occurs. For more information, see I/O Status Specifier.

slist
Is one or more of the following OPEN specifiers in the form specifier=value or specifier (each specifier can appear only once):

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Value</th>
<th>Specifier</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>DECIMAL, NAME</td>
<td>ROUND</td>
<td></td>
</tr>
<tr>
<td>ACTION</td>
<td>DEFAULTFILE, NEWUNIT</td>
<td>SHARE</td>
<td></td>
</tr>
<tr>
<td>ASSOCIATEVARIABLE</td>
<td>DELIM</td>
<td>NOSHARED</td>
<td>SHARED</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>DISPOSE, ORGANIZATIONAL</td>
<td>SIGN</td>
<td></td>
</tr>
<tr>
<td>BLANK</td>
<td>ENCODING, PAD</td>
<td>STATUS</td>
<td></td>
</tr>
<tr>
<td>BLOCKSIZE</td>
<td>FILE, POSITION</td>
<td>TITLE</td>
<td></td>
</tr>
<tr>
<td>BUFFERCOUNT</td>
<td>FORM, READONLY</td>
<td>TYPE</td>
<td></td>
</tr>
<tr>
<td>BUFFERED</td>
<td>IOFOCUS, RECL</td>
<td>USEROPEN</td>
<td></td>
</tr>
<tr>
<td>CARRIAGECONTROL</td>
<td>MAXREC</td>
<td>RECORDSIZE</td>
<td></td>
</tr>
<tr>
<td>CONVERT</td>
<td>MODE, RECORDTYPE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The OPEN specifiers and their acceptable values are summarized in the OPEN Statement Overview.

The control specifiers that can be specified in an OPEN statement are discussed in I/O Control List in the Language Reference.

Description
The control specifiers ([UNIT=] *io-unit*, ERR= *label*, and IOSTAT= *i-var*) and OPEN specifiers can appear anywhere within the parentheses following OPEN. However, if the UNIT specifier is omitted, the *io-unit* must appear first in the list.

If you specify BLANK=, DECIMAL=, PAD=, ROUND=, or SIGN=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS=’YES’.

Specifier values that are scalar numeric expressions can be any integer or real expression. The value of the expression is converted to integer data type before it is used in the OPEN statement.

If the NEWUNIT= specifier does not appear, an *io-unit* must be specified. If the keyword UNIT= is omitted, the *io-unit* must be first in the control list.

If the NEWUNIT= specifier appears, an *io-unit* must not be specified.
If the NEWUNIT= specifier appears, either the FILE= specifier or the STATUS=SCRATCH specifier must also appear.

Only one unit at a time can be connected to a file, but multiple OPENs can be performed on the same unit. If an OPEN statement is executed for a unit that already exists, the following occurs:

- If FILE is not specified, or FILE specifies the same file name that appeared in a previous OPEN statement, the current file remains connected.
  
  If the file names are the same, the values for the BLANK, CARRIAGECONTROL, CONVERT, DELIM, DISPOSE, ERR, IOSTAT, and PAD specifiers can be changed. Other OPEN specifier values cannot be changed, and the file position is unaffected.
- If FILE specifies a different file name, the previous file is closed and the new file is connected to the unit.

The ERR and IOSTAT specifiers from any previously executed OPEN statement have no effect on any currently executing OPEN statement. If an error occurs, no file is opened or created.

Secondary operating system messages do not display when IOSTAT is specified. To display these messages, remove IOSTAT or use a platform-specific method.

**Example**

You can specify character values at run time by substituting a character expression for a specifier value in the OPEN statement. The character value can contain trailing blanks but not leading or embedded blanks; for example:

```fortran
CHARACTER*6 FINAL / ' '/
...
IF (expr) FINAL = 'DELETE'
OPEN (UNIT=1, STATUS='NEW', DISP=FINAL)
```

The following statement creates a new sequential formatted file on unit 1 with the default file name fort.1:

```fortran
OPEN (UNIT=1, STATUS='NEW', ERR=100)
```

The following example opens the existing file /usr/users/someone/test.dat:

```fortran
OPEN (unit=10, DEFAULTFILE='/usr/users/someone/', FILE='test.dat',
     FORM='FORMATTED', STATUS='OLD')
```

The following example opens a new file:

```fortran
! Prompt user for a filename and read it:
CHARACTER*64 filename
WRITE (*, '(A)') ' enter file to create: '
READ (*, '(A)') filename
! Open the file for formatted sequential access as unit 7.
! Note that the specified access need not have been specified,
! since it is the default (as is "formatted").
OPEN (7, FILE = filename, ACCESS = 'SEQUENTIAL', STATUS = 'NEW')
```

The following example opens an existing file called DATA3.TXT:

```fortran
! Open a file created by an editor, "DATA3.TXT", as unit 3:
OPEN (3, FILE = 'DATA3.TXT')
```

OPEN Statement Overview
**OPTIONAL**

**Statement and Attribute:** Permits dummy arguments to be omitted in a procedure reference.

**Syntax**

The OPTIONAL attribute can be specified in a type declaration statement or an OPTIONAL statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
type,[att-ls,] OPTIONAL [, att-ls] :: d-arg[, d-arg]...
```

**Statement:**

```fortran
OPTIONAL [::] d-arg[, d-arg] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `d-arg` Is the name of a dummy argument.

**Description**

The OPTIONAL attribute can only appear in the scoping unit of a subprogram or an interface body, and can only be specified for dummy arguments. It cannot be specified for arguments that are passed by value.

A dummy argument is "present" if it is associated with an actual argument that is itself present. A dummy argument that is not optional must be present. You can use the PRESENT intrinsic function to determine whether an optional dummy argument is associated with an actual argument.

To call a procedure that has an optional argument, you must use an explicit interface.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

**Example**

The following example shows a type declaration statement specifying the OPTIONAL attribute:

```fortran
SUBROUTINE TEST(A)
REAL, OPTIONAL, DIMENSION(-10:2) :: A
END SUBROUTINE
```

The following is an example of the OPTIONAL statement:

```fortran
SUBROUTINE TEST(A, B, L, X)
  OPTIONAL :: B
  INTEGER A, B, L, X
  IF (PRESENT(B)) THEN        ! Printing of B is conditional
    PRINT *, A, B, L, X       ! on its presence
  ELSE
    PRINT *, A, L, X
  ENDIF
END SUBROUTINE
```

The following is an example of the OPTIONAL statement:

```fortran
INTERFACE
  SUBROUTINE TEST(ONE, TWO, THREE, FOUR)
END SUBROUTINE
```
INTEGER ONE, TWO, THREE, FOUR
OPTIONAL :: TWO
END SUBROUTINE
END INTERFACE

INTEGER I, J, K, L
I = 1
J = 2
K = 3
L = 4

CALL TEST(I, J, K, L)          ! Prints: 1 2 3 4
CALL TEST(I, THREE=K, FOUR=L) ! Prints: 1 3 4
END

Note that in the second call to subroutine TEST, the second positional (optional) argument is omitted. In this case, all following arguments must be keyword arguments.

The following shows another example:

SUBROUTINE ADD (a,b,c,d)
  REAL              a, b, d
  REAL, OPTIONAL :: c
  IF (PRESENT(c)) THEN
    d = a + b + c + d
  ELSE
    d = a + b + d
  END IF
END SUBROUTINE

Consider the following:

SUBROUTINE EX (a, b, c)
  REAL, OPTIONAL :: b,c
END SUBROUTINE

This subroutine can be called with any of the following statements:

CALL EX (x, y, z)   !All 3 arguments are passed.
CALL EX (x)         !Only the first argument is passed.
CALL EX (x, c=z=z)  !The first optional argument is omitted.

Note that you cannot use a series of commas to indicate omitted optional arguments, as in the following example:

CALL EX (x,,z)   !Invalid statement.

This results in a compile-time error.

OPTIMIZE and NOOPTIMIZE

General Compiler Directive: Enables or disables optimizations for the program unit.
**Syntax**

```fortran
!DIR$ OPTIMIZE(: n)
!DIR$ NOOPTIMIZE

n
```

Is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options O0, O1, O2, and O3. If n is omitted, the default is 2, which corresponds to option O2.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to -O0 (Linux* and macOS*) and /Od (Windows*).

The procedure is compiled with an optimization level equal to the smaller of n and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with compiler option O3, this procedure is compiled at O0 while the rest of the program is compiled at O3.

**See Also**

Syntax Rules for Compiler Directives
O compiler option

**OPTIONS Directive**

**General Compiler Directive:** Affects data alignment and warnings about data alignment. Also controls whether a target attribute is assigned to a section of program declarations.

**Syntax**

```fortran
!DIR$ OPTIONS option[option]
...
!DIR$ END OPTIONS
```

Is one (or more) of the following:

- `/OFFLOAD_ATTRIBUTE_TARGET=target-name`
  - Controls whether a target attribute is assigned to a section of program declarations. The declarations can contain interface definitions and variable declarations. This option enables statements to execute on the target.
  - Currently, the only supported value for target-name is mic.
This option is useful for properly declaring variables and function names used in offloaded code within the subprogram in which the directive appears. You cannot use it for offloading a complete routine. This setting is deprecated.

/WARN=[NO]ALIGNMENT Controls whether warnings are issued by the compiler for data that is not naturally aligned. By default, you receive compiler messages when misaligned data is encountered (/WARN=ALIGNMENT).

/[NO]ALIGN[= p] Controls alignment of fields in record structures and data items in common blocks. The fields and data items can be naturally aligned (for performance reasons) or they can be packed together on arbitrary byte boundaries.

p Is a specifier with one of the following forms:

[class=]rule
(class= rule, ...)
ALL
NONE

class Is one of the following keywords:

- COMMONS: For common blocks
- RECORDS: For records
- STRUCTURES: A synonym for RECORDS

rule Is one of the following keywords:

- PAC Packs fields in records or data items in common blocks on arbitrary
- KED
NATURALLY

Naturally aligns fields in records and data items in common blocks on up to 64-bit boundaries (inconsistent with the Standard Fortran).

This keyword causes the compiler to naturally align all data in a common block, including INTEGER(KIND=8), REAL(KIND=8), and all COMPLEX data.

STANDARD

Naturally aligns data items in common blocks on up to 32-bit boundaries (consistent with...
the Standard Fortran).

This keyword only applies to common blocks; so, you can specify / ALIGN=C OMMONS =STANDARD, but you cannot specify / ALIGN=S TANDARD.

**ALL** Is the same as specifying OPTIONS / ALIGN, OPTIONS / ALIGN=NATURAL, and OPTIONS / ALIGN=(RECORD S=NATURAL,COMMONS=NATURAL).

**NONE** Is the same as specifying OPTIONS / NOALIGN, OPTIONS / ALIGN=PACKED, and OPTIONS / ALIGN=(RECORD S=PACKED,COMMONS=PACKED).

The OPTIONS (and accompanying END OPTIONS) directives must come after OPTIONS, SUBROUTINE, FUNCTION, and BLOCK DATA statements (if any) in the program unit, and before the executable part of the program unit.

The OPTIONS directive supersedes the compiler option align and the compiler option [q or Q]offload-attribute-target.
For performance reasons, Intel® Fortran aligns local data items on natural boundaries. However, EQUIVALENCE, COMMON, RECORD, and STRUCTURE data declaration statements can force misaligned data. If /WARN=NOALIGNMENT is specified, warnings will not be issued if misaligned data is encountered.

**NOTE**

Misaligned data significantly increases the time it takes to execute a program. As the number of misaligned fields encountered increases, so does the time needed to complete program execution. Specifying /ALIGN (or compiler option align) minimizes misaligned data.

If you want aligned data in common blocks, do one of the following:

- Specify OPTIONS /ALIGN=COMMONS=STANDARD for data items up to 32 bits in length.
- Specify OPTIONS /ALIGN=COMMONS=NATURAL for data items up to 64 bits in length.
- Place source data declarations within the common block in descending size order, so that each data item is naturally aligned.

If you want packed, unaligned data in a record structure, do one of the following:

- Specify OPTIONS /ALIGN=RECORDS=PACKED.
- Place source data declarations in the record structure so that the data is naturally aligned.

**Example**

```fortran
! directives can be nested up to 100 levels
!DIR$ OPTIONS /ALIGN=PACKED    ! Start of Group A
declarations
!DIR$ OPTIONS /ALIGN=RECO=NATU  ! Start of nested Group B
more declarations
!DIR$ END OPTIONS             ! End of Group B
still more declarations
!DIR$ END OPTIONS             ! End of Group A
```

The OPTIONS specification for Group B only applies to RECORDS; common blocks within Group B will be PACKED. This is because COMMONS retains the previous setting (in this case, from the Group A specification).

In the following example that applies only when targeting Intel® Xeon Phi™ products, the target attribute is passed to function h and real variables a and b.

```fortran
SUBROUTINE f(x)
REAL x
INTERFACE
  SUBROUTINE g(y)
    REAL y
  END SUBROUTINE g
END INTERFACE
!DIR$ OPTIONS /OFFLOAD_ATTRIBUTE_TARGET=mic
INTERFACE
  FUNCTION h (z)
    REAL z
  END FUNCTION h
END INTERFACE
REAL a, b
!DIR$ END OPTIONS
...
END SUBROUTINE f
```
The following example demonstrates incorrect usage of the `mic` setting.

```
!DIR$ OPTIONS /OFFLOAD_ATTRIBUTE_TARGET=mic
SUBROUTINE INVALID()
...
END SUBROUTINE INVALID
!DIR$ END OPTIONS
```

**See Also**
General Compiler Directives
Syntax Rules for Compiler Directives
align compiler option
qoffload-attribute-target, Qoffload-attribute-target  compiler option

**OPTIONS Statement**

**Statement:** Overrides or confirms the compiler options in effect for a program unit.

**Syntax**
```
OPTIONS option[option...]  
```

- `option` is one of the following:
  - `/ASSUME = [NO]UNDERSCORE`
  - `/CHECK = ALL [NO]BOUNDS NONE`
  - `/NOCHECK`
  - `/CONVERT = BIG_ENDIAN CRAY FDX FGX IBM LITTLE_ENDIAN NATIVE VAXD VAXG /
  - `[NO]EXTEND_SOURCE`
  - `[NO]F77`
  - `[NO]I4`
  - `/[NO]RECURSIVE`

Note that an option must always be preceded by a slash `/`. Some OPTIONS statement options are equivalent to compiler options.
The OPTIONS statement must be the first statement in a program unit, preceding the PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

OPTIONS statement options override compiler options, but only until the end of the program unit for which they are defined. If you want to override compiler options in another program unit, you must specify the OPTIONS statement before that program unit.

**Example**

The following are valid OPTIONS statements:

```fortran
OPTIONS /CHECK=ALL/F77
OPTIONS /I4
```

**See Also**

OPEN Statement CONVERT Method
OPTIONS Statement Method

For details on compiler options, see your Compiler Options reference

**OR**

*Elemental Intrinsic Function (Generic): Performs a bitwise inclusive OR on its arguments.*

See IOR.

**Example**

```fortran
INTEGER i
i = OR(3, 10) ! returns 11
```

**ORDERED**

*OpenMP* Fortran Compiler Directive: Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations, or, as a stand-alone directive, it specifies cross-iteration dependences in a doacross loop nest.

**Syntax**

It takes one of the following forms:

**Form 1:**

```fortran
!$OMP ORDERED [clause [[,] clause ]]
   block
!$OMP END ORDERED
```

**Form 2:**

```fortran
!$OMP ORDERED clause [[,] clause ]...
```

**Form 1 clause**

Is an optional clause. It can be one of the following:

- **SIMD [keyword [, keyword]...]**
  Applies an ordered region inside a SIMD loop. Possible values are:
  - **MONOTONIC (list [ : linear-step ] )**
The list is a comma-separated list of one or more integer scalar variables. The linear-step is a positive, integer, scalar constant expression. The linear-step expression must be invariant (it must not be changed) during the execution of the associated construct. If linear-step is omitted, a default value of 1 is used.

Multiple MONOTONIC keywords may appear; they are merged into a single MONOTONIC list. You cannot specify multiple MONOTONIC keywords with different linear-steps for the same variable.

Each list item may have the POINTER attribute but not the ALLOCATABLE attribute. Each list item must comply with PRIVATE clause semantics.

• OVERLAP (expr)

The expr is an integer expression. It specifies a block of code that has to be executed in scalar mode for overlapping loop index values and in parallel for different loop index values within the SIMD loop.

The OVERLAP keyword can appear no more than once in an ORDERED directive.

• THREADS

Applies an ordered region inside a PARALLEL DO loop. If no clause is specified, the directive behaves as if THREADS was specified.

At most one THREADS clause can appear in an ORDERED construct. At most one SIMD clause can appear in an ORDERED construct.

Form 2 clause

Is one of the following:

• DEPEND (SOURCE)
• DEPEND (SINK : vec)

At most one DEPEND (SOURCE) clause can appear on an ORDERED construct.

Either DEPEND (SINK : vec) clauses or DEPEND (SOURCE) clauses can appear in an ORDERED construct, but not both.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for an ORDERED construct is the current team. An ordered region binds to the innermost enclosing loop region or the innermost enclosing SIMD region if the SIMD clause is present.

A doacross loop nest is a loop nest that has cross-iteration dependences. An iteration is dependent on one or more lexicographically earlier iterations. The ORDERED clause parameter on a loop directive identifies the loops associated with the doacross loop nest.

An ORDERED directive with no clause or with the THREADS clause specified can appear only in the dynamic extent of a DO or PARALLEL DO directive. The DO directive to which the ordered section binds must have the ORDERED clause specified.

An iteration of a loop using a DO directive must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.
One thread is allowed in an ordered section at a time. Threads are allowed to enter in the order of the loop iterations. No thread can enter an ordered section until it can be guaranteed that all previous iterations have completed or will never execute an ordered section. This sequentializes and orders code within ordered sections while allowing code outside the section to run in parallel.

Ordered sections that bind to different DO directives are independent of each other.

If the SIMD clause is specified, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

You can only specify the SIMD clause ($OMP ORDERED SIMD) within an !$OMP SIMD loop or an !$OMP DECLARE SIMD procedure.

When a thread executing any subsequent iteration encounters an ORDERED construct with one or more DEPEND (SINK : vec) clauses, it waits until its dependences on all valid iterations specified by the DEPEND clauses are satisfied before it completes execution of the ORDERED region. A specific dependence is satisfied when a thread executing the corresponding iteration encounters an ORDERED construct with a DEPEND (SOURCE) clause.

For MONOTONIC (list : linear-step), the following rules apply:

- The value of the new list item on each iteration of the associated SIMD loop corresponds to the value of the original list item before entering the associated loop, plus the number of the iterations for which the conditional update happens prior to the current iteration, times linear-step.
- The value corresponding to the sequentially last iteration of the associated loop is assigned to the original list item.
- A list item must not be used in statements that lexically precede the ORDERED SIMD to which it is bound, that is, in the region from the OMP SIMD to the OMP ORDERED SIMD. A list item must not be modified outside the ORDERED SIMD to which it is bound, that is, in the region from the OMP END ORDERED to the OMP END SIMD.

Example

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
END DO
...
SUBROUTINE WORK(K)
!$OMP ORDERED
   WRITE(*,*) K
!$OMP END ORDERED
!$OMP END SIMD
```

Ordered SIMD sections are useful for resolving cross-iteration data dependencies in otherwise data-parallel computations. For example, it may handle histogram updates such the following:

```fortran
!$OMP SIMD
DO I=0,N
   AMOUNT = COMPUTE_AMOUNT(I)
   CLUSTER = COMPUTE_CLUSTER(I)  ! Multiple I’s may belong to the same cluster within SIMD chunk
   !$OMP ORDERED SIMD
   TOTALS(CLUSTER) = TOTALS(CLUSTER) + AMOUNT  ! Requires ordering to process multiple updates to the same cluster
   !$OMP END ORDERED SIMD
END DO
```

Intel® Fortran Compiler 19.0 Developer Guide and Reference
The MONOTONIC keyword on the OMP ORDERED SIMD directive specifies that the body of a loop must be executed in the natural order of the loop iterations. In the following example, the block of code in the OMP ORDERED SIMD is executed in the ascending, monotonic order of the loop index I:

```fortran
COUNT = 0
!$OMP SIMD
DO I = 1, N
   IF (COND(I)) THEN
      !$OMP ORDERED SIMD MONOTONIC (COUNT:1)
      A(COUNT) = A(COUNT) + B(I)
      COUNT = COUNT + 1
      B(I) = C(COUNT)
   END IF
END DO
!$OMP END SIMD
```

In the following example, the OVERLAP keyword specifies that the block of code after the OMP ORDERED SIMD directive may contain overlap between the loop iterations:

```fortran
!$OMP SIMD
DO I = 1, N
   INX = INDEX(I)
   !$OMP ORDERED SIMD OVERLAP (INX)
   A(INX) = A(INX) + B(I)
END DO
!$OMP END SIMD
```

**OUTGTEXT (W*S)**

*Graphics Subroutine:* In graphics mode, sends a string of text to the screen, including any trailing blanks.

**Module**

USE IFQWIN

**Syntax**

```fortran
CALL OUTGTEXT (text)
```

`text` (Input) Character*(*) String to be displayed.

Text output begins at the current graphics position, using the current font set with SETFONT and the current color set with SETCOLORRGB or SETCOLOR. No formatting is provided. After it outputs the text, OUTGTEXT updates the current graphics position.

Before you call OUTGTEXT, you must call the INITIALIZEFONTS function.

Because OUTGTEXT is a graphics function, the color of text is affected by the SETCOLORRGB function, not by SETTEXTCOLORRGB.
Example

```fortran
! build as a QuickWin App.
USE IFQWIN
INTEGER(2) result
INTEGER(4) i
TYPE (xycoord) xys

result = INITIALIZEFONTS()
result = SETFONT('t''Arial''h18w10pvib')
do i=1,6
   CALL MOVETO(INT2(0),INT2(30*(i-1)),xys)
   grstat=SETCOLOR(INT2(i))
   CALL OUTGTEXT('This should be ')
   SELECT CASE (i)
      CASE (1)
         CALL OUTGTEXT('Blue')
      CASE (2)
         CALL OUTGTEXT('Green')
      CASE (3)
         CALL OUTGTEXT('Cyan')
      CASE (4)
         CALL OUTGTEXT('Red')
      CASE (5)
         CALL OUTGTEXT('Magenta')
      CASE (6)
         CALL OUTGTEXT('Orange')
   END SELECT
endo do
END
```

**OUTTEXT (W*S)**

*Graphics Subroutine:* In text or graphics mode, sends a string of text to the screen, including any trailing blanks.

Module
USE IFQWIN

Syntax
CALL OUTTEXT (text)

*text* (Input) Character*(*) String to be displayed.

Text output begins at the current text position in the color set with SETTEXTCOLORRGB or SETTEXTCOLOR. No formatting is provided. After it outputs the text, OUTTEXT updates the current text position.
To output text using special fonts, you must use the OUTGTEXT subroutine.

**Example**

```fortran
USE IFQWIN
INTEGER(2) oldcolor
TYPE (rccoord) rc

CALL CLEARSCREEN($GCLEARSCREEN)
CALL SETTEXTPOSITION (INT2(1), INT2(5), rc)
oldcolor = SETTEXTCOLOR(INT2(4))
CALL OUTTEXT ('Hello, everyone')
END
```

**PACK Directive**

*General Compiler Directive: Specifies the memory alignment of derived-type items (and record structure items).*

**Syntax**

```fortran
!DIR$ PACK[: {1 | 2 | 4 | 8} ]
```

Items of derived types, unions, and structures are aligned in memory on the smaller of two sizes: the size of the type of the item, or the current alignment setting. The current alignment setting can be 1, 2, 4, or 8 bytes. The default initial setting is 8 bytes (unless compiler option vms or align rec n bytes is specified). By reducing the alignment setting, you can pack variables closer together in memory.

The PACK directive lets you control the packing of derived-type or record structure items inside your program by overriding the current memory alignment setting.

For example, if PACK:1 is specified, all variables begin at the next available byte, whether odd or even. Although this slightly increases access time, no memory space is wasted. If PACK:4 is specified, INTEGER(1), LOGICAL(1), and all character variables begin at the next available byte, whether odd or even. INTEGER(2) and LOGICAL(2) begin on the next even byte; all other variables begin on 4-byte boundaries.

If the PACK directive is specified without a number, packing reverts to the compiler option setting (if any), or the default setting of 8.

The directive can appear anywhere in a program before the derived-type definition or record structure definition. It cannot appear inside a derived-type definition or record structure definition.

**Example**

```fortran
! Use 4-byte packing for this derived type
! Note PACK is used outside of the derived type definition
!DIR$ PACK:4
TYPE pair
  INTEGER a, b
END TYPE
! revert to default or compiler option
!DIR$ PACK
```
PACK Function

Transformational Intrinsic Function (Generic):
Takes elements from an array and packs them into a
rank-one array under the control of a mask.

Syntax

\[
\text{result} = \text{PACK} \left( \text{array}, \text{mask[,vector]} \right)
\]

- **array** (Input) Must be an array. It may be of any data type.
- **mask** (Input) Must be of type logical and conformable with array. It determines which elements are taken from array.
- **vector** (Input; optional) Must be a rank-one array with the same type and type parameters as array. Its size must be at least \( t \), where \( t \) is the number of true elements in mask. If mask is a scalar with value true, vector must have at least as many elements as there are in array. Elements in vector are used to fill out the result array if there are not enough elements selected by mask.

Results

The result is a rank-one array with the same type and kind parameters as array. If vector is present, the size of the result is that of vector. Otherwise, the size of the result is the number of true elements in mask, or the number of elements in array (if mask is a scalar with value true).

Elements in array are processed in array element order to form the result array. Element \( i \) of the result is the element of array that corresponds to the \( i \)th true element of mask. If vector is present and has more elements than there are true values in mask, any result elements that are empty (because they were not true according to mask) are set to the corresponding values in vector.

Example

N is the array

\[
\begin{bmatrix}
0 & 8 & 0 \\
0 & 0 & 0 \\
7 & 0 & 0 \\
\end{bmatrix}
\]

PACK \((N, \text{MASK}=N \neq 0, \text{VECTOR}=(1, 3, 5, 9, 11, 13))\) produces the result \((7, 8, 5, 9, 11, 13)\).

PACK \((N, \text{MASK}=N \neq 0)\) produces the result \((7, 8)\).
The following shows another example:

```fortran
INTEGER array(2, 3), vec1(2), vec2(5)
LOGICAL mask (2, 3)
array = RESHAPE((/7, 0, 0, -5, 0, 0/), (/2, 3/))
mask = array .NE. 0
! array is  7  0 0 and mask is T F F
!            0 -5 0               F T F
VEC1 = PACK(array, mask)      ! returns ( 7, -5 )
VEC2 = PACK(array, array .GT. 0, VECTOR= (/1,2,3,4,5/))
! returns ( 7, 2, 3, 4, 5 )
```

UNPACK

PACKTIMEQQ

*Portability Subroutine: Packs time and date values.*

Module
USE IFPORT

Syntax
CALL PACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

- `timedate` (Output) INTEGER(4). Packed time and date information.
- `iyr` (Input) INTEGER(2). Year (xxxxAD).
- `imon` (Input) INTEGER(2). Month (1 - 12).
- `iday` (Input) INTEGER(2). Day (1 - 31)
- `ihr` (Input) INTEGER(2). Hour (0 - 23)
- `imin` (Input) INTEGER(2). Minute (0 - 59)
- `isec` (Input) INTEGER(2). Second (0 - 59)

The input values are interpreted as being in the time zone set on the local computer and following the daylight savings rules for that time zone.

The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

Example

```fortran
USE IFPORT
INTEGER(2) year, month, day, hour, minute, second, &
hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour, &
minute, second)
END
```

UNPACKTIMEQQ
PARALLEL Directive (OpenMP* API)

OpenMP* Fortran Compiler Directive: Defines a parallel region.

Syntax

```fortran
!$OMP PARALLEL [clause[,] clause] ... ]
   block
!$OMP END PARALLEL
```

clause

Is one or more of the following:

- COPYIN (list)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- FIRSTPRIVATE (list)
- IF ([PARALLEL:] scalar-logical-expression)
- NUM_THREADS ( scalar_integer_expression )
  Specifies the number of threads to be used in a parallel region. The `scalar_integer_expression` must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive.
- PRIVATE (list)
- PROC_BIND (MASTER | CLOSE | SPREAD)
  Specifies a method for mapping the threads in the team to the "places" in the current partition.
  Once a thread is assigned to a place, the OpenMP* implementation should not move it to another place.
  MASTER instructs the execution environment to assign every thread in the team to the same place as the master thread.
  CLOSE instructs the execution environment to assign the threads to places close to the place of the parent thread.
  SPREAD creates a sparse distribution for a team of T threads among the P places of the parent's place partition.
  For CLOSE and SPREAD, the threads with the smallest numbers are assigned starting with the place of the master thread. For CLOSE, threads are packed into consecutive places within the parent's partition. For SPREAD, the partition of the master thread is subdivided and threads in the team are assigned round-robin to those subpartitions.
  Only a single PROC_BIND clause can appear in the directive.
- REDUCTION (reduction-identifier : list)
- SHARED (list)

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).
The PARALLEL and END PARALLEL directive pair must appear in the same routine in the executable section of
the code.

The END PARALLEL directive denotes the end of the parallel region. There is an implied barrier at this point.
Only the master thread of the team continues execution at the end of a parallel region.

The number of threads in the team can be controlled by the NUM_THREADS clause, the environment variable
OMP_NUM_THREADS, or by calling the run-time library routine OMP_SET_NUM_THREADS from a serial
portion of the program.

NUM_THREADS supersedes the OMP_SET_NUM_THREADS routine, which supersedes the
OMP_NUM_THREADS environment variable. Subsequent parallel regions, however, are not affected unless
they have their own NUM_THREADS clauses.

Once specified, the number of threads in the team remains constant for the duration of that parallel region.
If the dynamic threads mechanism is enabled by an environment variable or a library routine, then the
number of threads requested by the NUM_THREADS clause is the maximum number to use in the parallel
region.

The code contained within the dynamic extent of the parallel region is executed on each thread, and the code
path can be different for different threads.

If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes
the master of that new team. By default, nested parallel regions are always serialized and executed by a
team of one thread.

**Example**

You can use the PARALLEL directive in coarse-grain parallel programs. In the following example, each thread
in the parallel region decides what part of the global array X upon which to work based on the thread
number:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,NPOINTS)
   IAM = OMP_GET_THREAD_NUM( )
   NP = OMP_GET_NUM_THREADS( )
   IPOINTS = NPOINTS/NP
   CALL SUBDOMAIN(X,IAM,IPOINTS)
!$OMP END PARALLEL
```

Assuming you previously used the environment variable OMP_NUM_THREADS to set the number of threads
to six, you can change the number of threads between parallel regions as follows:

```fortran
CALL OMP_SET_NUM_THREADS(3)
!$OMP PARALLEL
   ...
!$OMP END PARALLEL
CALL OMP_SET_NUM_THREADS(4)
!$OMP PARALLEL DO
   ...
!$OMP END PARALLEL DO
```

**See Also**

PARALLEL DO
SHARED Clause
Parallel Processing Model for information about Binding Sets
PARALLEL and NOPARALLEL Loop Directives

General Compiler Directives: PARALLEL facilitates auto-parallelization by assisting the compiler’s dependence analysis of the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.

Syntax

!DIR$ PARALLEL [clause[, clause] ... ]

!DIR$ NOPARALLEL

clause

Is one or more of the following:

- ALWAYS [ASSERT]
- FIRSTPRIVATE (list)
  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different iterations are initialized to the value the variable had upon entering the parallel loop.
- LASTPRIVATE (list)
  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel loop is exited, each variable has the value that resulted from the sequentially last iteration of the parallel loop.
- NUM_THREADS (scalar_integer_expression)
  Specifies the number of threads to be used to parallelize the immediately following DO loop. The scalar_integer_expression must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive. Once specified, the number of threads used remains constant for the duration of that parallelized DO loop.
- PRIVATE (list)
  Declares specified variables to be private to each thread in a team. The declared variables become private to a task.

list

Is one or more items in the form: var [:expr].... Each list item must be separated by a comma.

var

Is a scalar or array variable. The following rules apply:

- Assumed-size arrays cannot appear in a PRIVATE clause.
- A variable that is part of another variable (for example, as an array or structure element) cannot appear in a PRIVATE clause.
- A variable that appears in a PRIVATE clause must either be definable, or an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
- Variables that appear in namelist statements, in variable format expressions, and in expressions for statement function definitions, cannot appear in a PRIVATE clause.
Is an integer expression denoting the number of array elements to privatize. When \( expr \) is specified, \( var \) must be an array or a pointer variable. The following rules also apply:

- If \( var \) is an array, then only its first \( expr \) elements are privatized. If \( expr \) is omitted, the entire array is privatized.
- If \( var \) is a pointer, then the first \( expr \) elements are privatized (element size is provided by the pointer's target type). If \( expr \) is omitted, only the pointer variable itself is privatized.
- Program behavior is undefined if \( expr \) evaluates to a non-positive value, or if it exceeds the array size.

**Example**

```fortran
program main
  parameter (n=100)
  integer x(n), a(n), k
  !DIR$ NOPARALLEL
  do i=1,n
    x(i) = i
  enddo
  !DIR$ PARALLEL LASTPRIVATE (k)
  do i=1,n
    a( x(i) ) = i
    k = x(i)
  enddo
  print *, k ! print 100, the value of x(n)
end
```

**See Also**

- General Compiler Directives
- Syntax Rules for Compiler Directives
- Rules for General Directives that Affect DO Loops
- Rules for Loop Directives that Affect Array Assignment Statements
PARALLEL DO

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single DO directive.

Syntax

```fortran
!$OMP PARALLEL DO [clause[, clause] ... ]
    do-loop
![$OMP END PARALLEL DO]
```

- **do-loop**
  - Can be any of the clauses accepted by the DO or PARALLEL directives.
  - Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
  - You cannot branch out of a DO loop associated with a DO directive.

If the END PARALLEL DO directive is not specified, the PARALLEL DO is assumed to end with the DO loop that immediately follows the PARALLEL DO directive. If used, the END PARALLEL DO directive must appear immediately after the end of the DO loop.

The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a DO directive.

Example

In the following example, the loop iteration variable is private by default and it is not necessary to explicitly declare it. The END PARALLEL DO directive is optional:

```fortran
!$OMP PARALLEL DO
    DO I=1,N
        B(I) = (A(I) + A(I-1)) / 2.0
    END DO
!$OMP END PARALLEL DO
```

The following example shows how to use the REDUCTION clause in a PARALLEL DO directive:

```fortran
!$OMP PARALLEL DO DEFAULT(PRIVATE) REDUCTION(+: A,B)
    DO I=1,N
        CALL WORK(ALOCAL,BLOCAL)
        A = A + ALOCAL
        B = B + BLOCAL
    END DO
!$OMP END PARALLEL DO
```

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Specifies a PARALLEL construct that contains one DO SIMD construct and no other statement.
**Syntax**

```fortran
!$OMP PARALLEL DO SIMD [clause[{}, clause] ... ]
  do-loop
  [!$OMP END PARALLEL DO SIMD]

clause

Can be any of the clauses accepted by the PARALLEL, DO, or SIMD directives.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END PARALLEL DO SIMD directive is not specified, an END PARALLEL DO SIMD directive is assumed at the end of do-loop.

You cannot specify NOWAIT in a PARALLEL DO SIMD directive.

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

### PARALLEL SECTIONS

*OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.

**Syntax**

```fortran
!$OMP PARALLEL SECTIONS [clause[{}, clause] ... ]
  [!$OMP SECTION]
    block
  [!$OMP SECTION
    block]...
!$OMP END PARALLEL SECTIONS

clause

Can be any of the clauses accepted by the PARALLEL or SECTIONS directives.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
The last section ends at the END PARALLEL SECTIONS directive.

**Example**

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```fortran
!$OMP PARALLEL SECTIONS
!$OMP SECTION
  CALL XAXIS
!$OMP SECTION
  CALL YAXIS
!$OMP SECTION
  CALL ZAXIS
!$OMP END PARALLEL SECTIONS
```

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

---

**PARALLEL WORKSHARE**

*OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.

**Syntax**

```
!$OMP PARALLEL WORKSHARE [clause[, clause] ... ]
  block
!$OMP END PARALLEL WORKSHARE
```

- **clause**
  - Can be any of the clauses accepted by the *PARALLEL* directive.

- **block**
  - Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

---

**PARAMETER**

*Statement and Attribute*: Defines a named constant.

**Syntax**

The PARAMETER attribute can be specified in a type declaration statement or a PARAMETER statement, and takes one of the following forms:

**Type Declaration Statement**:

```
type, [att-ls] PARAMETER [, att-ls] :: c =expr[, c = expr] ...
```

**Statement**:

```
PARAMETER [( ]c = expr[, c = expr] ... [ ] )
```

- **type**
  - Is a data type specifier.
att-ls          Is an optional list of attribute specifiers.
c          Is the name of the constant.
expr          Is a constant expression. It can be of any data type.

Description
The type, type parameters, and shape of the named constant are determined in one of the following ways:

- By an explicit type declaration statement in the same scoping unit.
- By the implicit typing rules in effect for the scoping unit. If the named constant is implicitly typed, it can
  appear in a subsequent type declaration only if that declaration confirms the implicit typing.

For example, consider the following statement:

```fortran
PARAMETER (MU=1.23)
```

According to implicit typing, MU is of integer type, so MU=1. For MU to equal 1.23, it should previously be
declared REAL in a type declaration or be declared in an IMPLICIT statement.

A named array constant defined by a PARAMETER statement must have its rank specified in a previous
specification statement.

A named constant must not appear in a format specification or as the character count for Hollerith constants.
For compilation purposes, writing the name is the same as writing the value.

If the named constant is used as the length specifier in a CHARACTER declaration, it must be enclosed in
parentheses.

The name of a constant cannot appear as part of another constant, although it can appear as either the real
or imaginary part of a complex constant.

You can only use the named constant within the scoping unit containing the defining PARAMETER statement.

Any named constant that appears in the constant expression must have been defined previously in the same
type declaration statement (or in a previous type declaration statement or PARAMETER statement), or made
accessible by use or host association.

An entity with the PARAMETER attribute must not be a variable, a coarray, or a procedure.

Omission of the parentheses in a PARAMETER statement is an extension controlled by compiler option
altparam. In this form, the type of the name is taken from the form of the constant rather than from implicit
or explicit typing of the name.

Example
The following example shows a type declaration statement specifying the PARAMETER attribute:

```fortran
REAL, PARAMETER :: C = 2.9979251, Y = (4.1 / 3.0)
```

The following is an example of the PARAMETER statement:

```fortran
REAL(4) PI, PIOV2
REAL(8) DPI, DPIOV2
LOGICAL FLAG
CHARACTER(*) LONGNAME
PARAMETER (PI=3.1415927, DPI=3.141592653589793238D0)
PARAMETER (PIOV2=PI/2, DPIOV2=DPI/2)
PARAMETER (FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS')
```
The following shows implicit-shape arrays declared using a PARAMETER attribute and PARAMETER statements:

```
INTEGER, PARAMETER :: R(*) = [1,2,3]
REAL :: M (2:*, -1:*)
PARAMETER (M = RESHAPE ([R,R], [3,2]))
```

The following shows other examples:

```
! implicit integer type
PARAMETER (nblocks = 10)
!
! implicit real type
IMPLICIT REAL (L-M)
PARAMETER (loads = 10.0, mass = 32.2)
!
! typed by PARAMETER statement
! Requires compiler option
PARAMETER mass = 47.3, pi = 3.14159
PARAMETER bigone = 'This constant is larger than forty characters'
!
! PARAMETER in attribute syntax
REAL, PARAMETER :: mass=47.3, pi=3.14159, loads=10.0, mass=32.2
```

altparam compiler option

**PARITY**

*Transformational Intrinsic Function (Generic):* Reduces an array by using an exclusive OR (.NEQV.) operation.

**Syntax**

```
result = PARITY (mask[, dim])
```

*mask* (Input) Must be an array of type logical.

*dim* (Input; optional) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of *mask*. The corresponding actual argument must not be an optional dummy argument.

**Results**

The result has the same type and kind parameters as *mask*. It is scalar if *dim* does not appear; otherwise, the result has rank n - 1 and shape [d1, d2, ..., dim-1, dim+1, ..., dn] where [d1, d2, ..., dn] is the shape of *mask*.

The result of PARITY(*mask*) has the value .TRUE. if an odd number of the elements of *mask* are true; otherwise, .FALSE..
If \( \text{mask} \) has rank one, \( \text{PARITY}(\text{mask}, \dim) \) is equal to \( \text{PARITY}(\text{mask}) \). Otherwise, the value of element \( (s_1, s_2, \ldots, s_{\dim-1}, s_{\dim+1}, \ldots, s_n) \) of \( \text{PARITY}(\text{mask}, \dim) \) is equal to \( \text{PARITY}(\text{mask} (s_1, s_2, \ldots, s_{\dim-1}, :, s_{\dim+1}, \ldots, s_n)) \).

**Example**

If \( A \) is the array

\[
\begin{bmatrix}
T & F & T \\
T & T & F
\end{bmatrix}
\]

and \( T \) has the value \( .\text{TRUE.} \) and \( F \) has the value \( .\text{FALSE.} \), then

\( \text{PARITY}(A, \dim=1) \) has the value \([F, T, T]\) and \( \text{PARITY}(A, \dim=2) \) has the value \([F, F]\).

**PASSDIRKEYSQQ (W*S)**

*QuickWin Function:* Determines the behavior of direction and page keys in a QuickWin application.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{PASSDIRKEYSQQ}(\text{val})
\]

(Input) \( \text{INTEGER}(4) \) or \( \text{LOGICAL}(4) \).

A value of \( .\text{TRUE.} \) causes direction and page keys to be input as normal characters (the PassDirKeys flag is turned on). A value of \( .\text{FALSE.} \) causes direction and page keys to be used for scrolling.

The following constants, defined in IFQWIN.F90, can be used as integer arguments:

- \( \text{PASS\_DIR\_FALSE} \) - Turns off any special handling of direction keys. They are not passed to the program by GETCHARQQ.
- \( \text{PASS\_DIR\_TRUE} \) - Turns on special handling of direction keys. That is, they are passed to the program by GETCHARQQ.
- \( \text{PASS\_DIR\_INSDEL} \) - INSERT and DELETE are also passed to the program by GETCHARQQ.
- \( \text{PASS\_DIR\_CNTRL} \) - Only needed for a QuickWin application, but harmless if used with a Standard Graphics application that already passes CTRL+C.

This value allows CTRL+C to be passed to a QuickWin program by GETCHARQQ if the following is true: the program must have removed the File menu EXIT item by using DELETEMENUQQ.

This value also passes direction keys and INSERT and DELETE.

**Results**

The return value indicates the previous setting of the PassDirKeys flag.

The return data type is the same as the data type of \( \text{val} \); that is, either \( \text{INTEGER}(4) \) or \( \text{LOGICAL}(4) \).

When the PassDirKeys flag is turned on, the mouse must be used for scrolling since the direction and page keys are treated as normal input characters.
The PASSDIRKEYSQQ function is meant to be used primarily with the GETCHARQQ and INCHARQQ functions. Do not use normal input statements (such as READ) with the PassDirKeys flag turned on, unless your program is prepared to interpret direction and page keys.

Example

```fortran
use IFQWIN

logical*4 res
character*1 ch, ch1

Print */,*"Type X to exit, S to scroll, D to pass Direction keys"

123 continue
ch = getcharqq()
! check for escapes
! 0x00 0x?? is a function key
! 0xEE 0x?? is a direction key
if (ichar(ch) .eq. 0) then
    ch1 = getcharqq()
    print */,*"Function key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
    goto 123
else if (ichar(ch) .eq. 224) then
    ch1 = getcharqq()
    print */,*"Direction key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
    goto 123
else
    print *,ichar(ch)," ",ch

if(ch .eq. 'S') then
    res = passdirkeysqq(.false.)
    print */,*"Entering Scroll mode ",res
endif

if(ch .eq. 'D') then
    res = passdirkeysqq(.true.)
    print */,*"Entering Direction keys mode ",res
endif

if(ch .ne. 'X') go to 123
endif
end
```

The following example uses an integer constant as an argument to PASSDIRKEYSQQ:
Program to illustrate how to get almost every character from the keyboard in QuickWin or Standard Graphics mode.

Comment out the deletemenu line for Standard Graphics mode.

If you are doing a standard graphics application, control C will come in as a Z'03' without further effort.

In a QuickWin application, The File menu Exit item must be deleted, and PassDirKeysQQ called with PASS_DIR_CNTRLC to get control C.

```fortran
use IFQWIN
integer(4) status
character*1 key1, key2, ch1
write(*,*) 'Initializing'

!-----don't do this for a Standard Grapics application
! remove File menu Exit item.
status = deletemenuqq(1,3) ! stop QuickWin from getting control C

!-----set up to pass all keys to window including control c.
status  = passdirkeysqq(PASS_DIR_CNTRLC)

! read and print characters

10 key1 = getcharqq()

!-----first check for control+c
if(ichar(key1) .eq. 3) then
  write(*,*) 'Control C Received'
  write(*,*) "Really want to quit?"
  write(*,*) "Type Y <cr> to exit, or any other char <cr> to continue."
  read(*,*) ch1
  if(ch1.eq."y" .or. ch1.eq."Y") goto 30
  goto 10
endif

if(ichar(key1).eq.0) then ! function key?
  key2 = getcharqq()
  write(*,15) ichar(key1),ichar(key2),key2
else
  if(ichar(key1).eq.224) then ! direction key?
    key2 = getcharqq()
    write(*,16) ichar(key1),ichar(key2),key2
  else
    write(*,20) key1,ichar(key1) ! normal key
    goto 10
  endif

endif
```

Language Reference

1827
PAUSE

**Statement:** Temporarily suspends program execution and lets you execute operating system commands during the suspension. The PAUSE statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

```fortran
PAUSE [pause-code]
```

`pause-code` (Optional) Is an optional message. It can be either of the following:

- A scalar character constant of type default character.
- A string of up to six digits; leading zeros are ignored. (Standard Fortran limits digits to five.)

If you specify `pause-code`, the PAUSE statement displays the specified message and then displays the default prompt.

If you do not specify `pause-code`, the system displays the following default message:

```
FORTRAN PAUSE
```

The following prompt is then displayed:

- On Windows* systems:
  ```
  Fortran Pause - Enter command<CR> or <CR> to continue.
  ```
- On Linux* and macOS* systems:
  ```
  PAUSE prompt>
  ```

For alternate methods of pausing while reading from and writing to a device, see `READ` and `WRITE`.

**Effect on Windows* Systems**

The program waits for input on stdin. If you enter a blank line, execution resumes at the next executable statement.

Anything else is treated as a DOS command and is executed by a system( ) call. The program loops, letting you execute multiple DOS commands, until a blank line is entered. Execution then resumes at the next executable statement.

**Effect on Linux* and macOS* Systems**

The effect of PAUSE differs depending on whether the program is a foreground or background process, as follows:

- If a program is a foreground process, the program is suspended until you enter the CONTINUE command. Execution then resumes at the next executable statement.
Any other command terminates execution.

- If a program is a background process, the behavior depends on stdin, as follows:
  - If stdin is redirected from a file, the system displays the following (after the pause code and prompt):

    
    To continue from background, execute 'kill -15 n'
    
    In this message, n is the process id of the program.
  - If stdin is not redirected from a file, the program becomes a suspended background job, and you must specify fg to bring the job into the foreground. You can then enter a command to resume or terminate processing.

**Example**

The following examples show valid PAUSE statements:

```
PAUSE 701
PAUSE 'ERROUSE RESULT DETECTED'
```

The following shows another example:

```
CHARACTER*24 filename
PAUSE 'Enter DIR to see available files or press RETURN' &
&' if you already know filename.'
READ('*','(A)') filename
OPEN(1,FİLE=filename)
... 
```

**PEEKCHARQQ**

*Run-Time Function:* Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.

**Module**

USE IFCORE

**Syntax**

```
result = PEEKCHARQQ( )
```

**Results**

The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..

To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ to .FALSE..

**Example**

```
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
```
WRITE(*,*) 'Press any key'
pushed = PEEKCHARQ ( )
END DO
END

PERERROR

Run-Time Subroutine: Sends a message to the standard error stream, preceded by a specified string, for the last detected error.

Module
USE IFQCORE

Syntax
CALL PERERROR (string)

string (Input) Character*(*). Message to precede the standard error message.

The string sent is the same as that given by GERROR.

Example
USE IFQCORE
character*24 errtext
errtext = 'In my opinion, '
      . . .
! any error message generated by errtext is preceded by 'In my opinion, '
Call PERERROR (errtext)

GERROR
IERRNO

PIE, PIE_W (W*S)

Module
USE IFQWIN

Syntax
result = PIE (i,x1,y1,x2,y2,x3,y3,x4,y4)
result = PIE_W (i, wx1, wy1, wx2, wy2, wx3, y3,wx4, wy4)
i
(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90:
  • $GFILLINTERIOR - Fills the figure using the current color and fill mask.
  • $GBORDER - Does not fill the figure.

x1, y1
(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2
(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

x3, y3
(Input) INTEGER(2). Viewport coordinates of start vector.

x4, y4
(Input) INTEGER(2). Viewport coordinates of end vector.

wx1, wy1
(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2
(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

wx3, wy3
(Input) REAL(8). Window coordinates of start vector.

wx4, wy4
(Input) REAL(8). Window coordinates of end vector.

Results
The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the pie is clipped or partially out of bounds, the pie is considered successfully drawn and the return is 1. If the pie is drawn completely out of bounds, the return is 0.

The border of the pie wedge is drawn in the current color set by SETCOLORRGB.

The PIE function uses the viewport-coordinate system. The center of the arc is the center of the bounding rectangle, which is specified by the viewport-coordinate points (x1, y1) and (x2, y2). The arc starts where it intersects an imaginary line extending from the center of the arc through (x3, y3). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (x4, y4).

The PIE_W function uses the window-coordinate system. The center of the arc is the center of the bounding rectangle specified by the window-coordinate points (wx1, wy1) and (wx2, wy2). The arc starts where it intersects an imaginary line extending from the center of the arc through (wx3, wy3). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (wx4, wy4).

The fill flag option $GFILLINTERIOR is equivalent to a subsequent call to FLOODFILLRGB using the center of the pie as the starting point and the current graphics color (set by SETCOLORRGB) as the fill color. If you want a fill color different from the boundary color, you cannot use the $GFILLINTERIOR option. Instead, after you have drawn the pie wedge, change the current color with SETCOLORRGB and then call FLOODFILLRGB. You must supply FLOODFILLRGB with an interior point in the figure you want to fill. You can get this point for the last drawn pie or arc by calling GETARCINFO.

If you fill the pie with FLOODFILLRGB, the pie must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.
NOTE
The PIE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Pie routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Pie.

Example

```fortran
! build as Graphics App.
USE IFQWIN
INTEGER(2) status, dummy
INTEGER(2) x1, y1, x2, y2, x3, y3, x4, y4
x1 = 80; y1 = 50
x2 = 180; y2 = 150
x3 = 110; y3 = 80
x4 = 90; y4 = 180

status = SETCOLOR(INT2(4))
dummy = PIE( $GFILLINTERIOR, x1, y1, x2, y2, &
               x3, y3, x4, y4)
END
```

This figure shows the coordinates used to define PIE and PIE_W:

POINTER - Fortran

**Statement and Attribute:** Specifies that an object or a procedure is a pointer (a dynamic variable). A pointer does not contain data, but points to a scalar or array variable where data is stored. A pointer has no initial storage set aside for it; memory storage is created for the pointer as a program runs.
Syntax
The POINTER attribute can be specified in a type declaration statement or a POINTER statement, and takes one of the following forms:

Type Declaration Statement:

\[
\text{type}, [\text{att-ls},] \text{POINTER} [, \text{att-ls}] :: \text{ptr}(\text{d-spec})[ , \text{ptr}(\text{d-spec})] ... \\
\]

Statement:

\[
\text{POINTER} [::] \text{ptr}(\text{d-spec})[ , \text{ptr}(\text{d-spec})] ... \\
\]

- \text{type-spec} \quad \text{Is a data type specifier.}
- \text{att-ls} \quad \text{Is an optional list of attribute specifiers.}
- \text{ptr} \quad \text{Is the name of the pointer. The pointer cannot be declared with the INTENT or PARAMETER attributes.}
- \text{d-spec} \quad \text{(Optional) Is a deferred-shape specification (\text{:: [: :]} ...). Each colon represents a dimension of the array.}

Description
No storage space is created for a data pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target.

Each pointer has an association status, which tells whether the pointer is currently associated with a target object. When a pointer is initially declared, its status is undefined. You can use the ASSOCIATED intrinsic function to find the association status of a pointer if the pointer's association status is defined.

Entities with the POINTER attribute can be associated with different data objects or procedures during execution of a program.

A data pointer must not be referenced or defined unless it is pointer associated with a target object that can be referenced or defined. A procedure pointer must not be referenced unless it is pointer associated with a target procedure.

If the data pointer is an array, and it is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

A pointer cannot be specified in an EQUIVALENCE or NAMELIST statement. A pointer in a DATA statement can only be associated with NULL().

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

An entity with the POINTER attribute must not have the ALLOCATABLE, INTRINSIC, or TARGET attribute, and it must not be a coarray.

Fortran pointers are not the same as integer pointers. For more information, see the POINTER - Integer statement.

Example
The following example shows type declaration statements specifying the POINTER attribute:

```
TYPE(SYSTEM), POINTER :: CURRENT, LAST
REAL, DIMENSION(:,,:), POINTER :: I, J, REVERSE
```

The following is an example of the POINTER statement:

```
TYPE(SYSTEM) :: TODAYS
POINTER :: TODAYS, A(:,:)
```
The following shows another example:

```fortran
REAL, POINTER :: arrow (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:,:)

! The following statement associates the pointer with an unused ! block of memory.
ALLOCATE (arrow (1:8), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(/1x,a)') 'ARROW allocated'
arrow = 5.
WRITE (*,'(1x,8f8.0/)') arrow
ALLOCATE (bullseye (1:8,3), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'*) 'BULLSEYE allocated'
bullseye = 1.
bullseye (1:8:2,2) = 10.
WRITE (*,'(1x,8f8.0)') bullseye

! The following association breaks the association with the first ! target, which being unnamed and unassociated with other pointers, ! becomes lost. ARROW acquires a new shape.
arrow => bullseye (2:7,2)
WRITE (*,'(/1x,a)') 'ARROW is repointed & resized, all the 5s are lost'
WRITE (*,'(1x,8f8.0/)') arrow

NULLIFY (arrow)
IF (.NOT.ASSOCIATED(arrow)) WRITE (*,'(/a/)') ' ARROW is not pointed'

DEALLOCATE (bullseye, STAT = ierr)
IF (ierr.eq.0) WRITE (*,'*) 'Deallocation successful.'
END
```

POINTER - Integer

**Statement:** Establishes pairs of objects and pointers, in which each pointer contains the address of its paired object. This statement is different from the Fortran POINTER statement.
Syntax

POINTER (pointer,pointee) [, (pointer,pointee)] . . .

pointer
Is a variable whose value is used as the address of the pointee.

pointee
Is a variable; it can be an array name or array specification. It can also be a procedure named in an EXTERNAL statement or in a specific (non-generic) procedure interface block.

The following are pointer rules and behavior:

- Two pointers can have the same value, so pointer aliasing is allowed.
- When used directly, a pointer is treated like an integer variable. On IA-32 architecture, a pointer occupies one numeric storage unit, so it is a 32-bit quantity (INTEGER(4)). On Intel® 64 architecture, a pointer occupies two numeric storage units, so it is a 64-bit quantity (INTEGER(8)).
- A pointer cannot be a pointee.
- A pointer cannot appear in an ASSIGN statement and cannot have the following attributes:
  
  | ALLOCATABLE | INTRINSIC | POINTER |
  | EXTERNAL    | PARAMETER | TARGET  |

  A pointer can appear in a DATA statement with integer literals only.

- Integers can be converted to pointers, so you can point to absolute memory locations.
- A pointer variable cannot be declared to have any other data type.
- You can give values to pointers by doing the following:
  
  - Retrieve addresses by using the LOC intrinsic function (or the %LOC built-in function)
  - Allocate storage for an object by using the MALLOC intrinsic function (or by using malloc(3f) on Linux* and macOS* systems)

  For example:

<table>
<thead>
<tr>
<th>Using %LOC:</th>
<th>Using MALLOC:</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I(10)</td>
<td>INTEGER I(10)</td>
</tr>
<tr>
<td>INTEGER I(10) /10*10/</td>
<td>POINTER (P,I)</td>
</tr>
<tr>
<td>POINTER (P,I)</td>
<td>P = MALLOC(40)</td>
</tr>
<tr>
<td>P = %LOC(I1)</td>
<td>I = 10</td>
</tr>
<tr>
<td>I(2) = I(2) + 1</td>
<td>I(2) = I(2) + 1</td>
</tr>
</tbody>
</table>

- The value in a pointer is used as the pointee’s base address.

The following are pointee rules and behavior:

- A pointee is not allocated any storage. References to a pointee look to the current contents of its associated pointer to find the pointee’s base address.
- A pointee cannot be data-initialized or have a record structure that contains data-initialized fields.
- A pointee can appear in only one integer POINTER statement.
- A pointee array can have fixed, adjustable, or assumed dimensions.
- A pointee cannot appear in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement, and it cannot have the following attributes:

  | ALLOCATABLE | OPTIONAL | SAVE |
  | AUTOMATIC   | PARAMETER | STATIC |
  | INTENT     | POINTER  |

- A pointee cannot be:
• A dummy argument
• A function return value
• A record field or an array element
• Zero-sized
• An automatic object
• The name of a generic interface block
• If a pointee is of derived type, it must be of sequence type.

**Example**

```fortran
POINTER (p, k)
INTEGER j(2)

! This has the same effect as j(1) = 0, j(2) = 5
p = LOC(j)
k = 0
p = p + SIZEOF(k) ! 4 for 4-byte integer
k = 5
```

**POLYBEZIER, POLYBEZIER_W (W*S)**

*Graphics Functions*: Draw one or more Bezier curves.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = POLYBEZIER (lppoints,cpoints)
result = POLYBEZIER_W (lppoints,cpoints)
```

**lppoints**

(Input) Derived type xycoord. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
INTEGER(2) xcoord
INTEGER(2) ycoord
END TYPE xycoord
```

**cpoints**

(Input) INTEGER(2). Number of points in lppoints.

**Results**

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point must be given for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, cpoints should contain 4 for one curve, 7 for 2 curves, 10 for 3 curves, and so forth.
POLYBEZIER does not use or change the current graphics position.

Example

Program Bezier
use IFQWIN

END PROGRAM BEZIER

See Also
POLYBEZIERTO, POLYBEZIERTO_W
POLYBEZIERTO, POLYBEZIERTO_W (W*S)

Graphics Functions: Draw one or more Bezier curves.

Module
USE IFQWIN

Syntax

result = POLYBEZIERTO (lppoints,cpoints)
result = POLYBEZIERTO_W (lppoints,cpoints)

lppoints
(Input) Derived type xycoord. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

cpoints
(Input) INTEGER(2). Number of points in ppoints or lppoints.

Results

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point is the current graphics position as set by MOVETO for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, cpoints should contain 3 for one curve, 6 for 2 curves, 9 for 3 curves, and so forth.

POLYBEZIERTO moves the current graphics position to the ending point of the last curve drawn.

Example

See the example in POLYBEZIER, POLYBEZIER_W (W*S).

See Also

MOVETO, MOVETO_W

POLYGON, POLYGON_W (W*S)

Graphics Functions: Draw a polygon using the current graphics color, logical write mode, and line style.

Module
USE IFQWIN

Syntax

result = POLYGON (control,lppoints,cpoints)
result = POLYGON_W (control,lppoints,cpoints)
control

(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90:

- $GFILLINTERIOR - Draws a solid polygon using the current color and fill mask.
- $GBORDER - Draws the border of a polygon using the current color and line style.

lppoints

(Input) Derived type xycoord. Array of derived types defining the polygon vertices in viewport coordinates. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

cpoints

(Input) INTEGER(2). Number of polygon vertices.

Results

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

The border of the polygon is drawn in the current graphics color, logical write mode, and line style, set with SETCOLORRGB, SETWRITEMODE, and SETLINESTYLE, respectively. The POLYGON routine uses the viewport-coordinate system (expressed in xycoord derived types), and the POLYGON_W routine uses real-valued window coordinates (expressed in xycoord types).

The argument lppoints is an array whose elements are xycoord derived types. Each element specifies one of the polygon’s vertices. The argument cpoints is the number of elements (the number of vertices) in the lppoints array.

Note that POLYGON draws between the vertices in their order in the array. Therefore, when drawing outlines, skeletal figures, or any other figure that is not filled, you need to be careful about the order of the vertices. If you don’t want lines between some vertices, you may need to repeat vertices to make the drawing backtrack and go to another vertex to avoid drawing across your figure. Also, POLYGON draws a line from the last specified vertex back to the first vertex.

If you fill the polygon using FLOODFILLRGB, the polygon must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**NOTE**

The POLYGON routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Polygon routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Polygon.

Example

```fortran
! Build as a Graphics App.

! Draw a skeletal box
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) poly(12)

! Set up box vertices in order they will be drawn, &
! repeating some to avoid unwanted lines across box

POLYLINEQQ (W*S)

Graphics Function: Draws a line between each successive x, y point in a given array.

Module
USE IFQWIN

Syntax
result = POLYLINEQQ (points, cnt)
points

(Input) An array of DF_POINT objects. The derived type DF_POINT is defined in IFQWIN.F90 as:

```
type DF_POINT
  sequence
  integer(4) x
  integer(4) y
end type DF_POINT
```

cnt

(Input) INTEGER(4). Number of elements in the points array.

Results

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, zero.

POLYLINEQQ uses the viewport-coordinate system.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

The current graphics position is not used or changed as it is in the LINETO function.

Example

```
! Build for QuickWin or Standard Graphics
USE IFQWIN
TYPE(DF_POINT) points(12)
integer(4) result
integer(4) cnt, i

! load the points
do i = 1,12,2
  points(i).x =20*i
  points(i).y =10
  points(i+1).x =20*i
  points(i+1).y =60
end do

! A sawtooth pattern will appear in the upper left corner
result = POLYLINEQQ(points, 12)
end
```

POPCNT

Elemental Intrinsic Function (Generic): Returns the number of 1 bits in the integer argument.

Syntax

```
result = POPCNT (i)
```

i

(Input) Must be of type integer or logical.
Results
The result type and kind are the same as \( i \). The result value is the number of 1 bits in the binary representation of the integer \( i \).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
If the value of \( I \) is B'0...00011010110', the value of POPCNT(\( I \)) is 5.

POPPAR

**Elemental Intrinsic Function (Generic):** Returns the parity of the integer argument.

Syntax
\[
\text{result} = \text{POPPAR}(i)
\]

\( i \) (Input) Must be of type integer or logical.

Results
The result type and kind are the same as \( i \). The result value is 1 if there are an odd number of 1 bits in the binary representation of the integer \( I \). The result value is zero if there are an even number.

POPPAR(\( i \)) is the same as \( 1 \text{ .AND. POPCNT}(i) \).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
If the value of \( I \) is B'0...00011010110', the value of POPPAR(\( I \)) is 1.

PRECISION

**Inquiry Intrinsic Function (Generic):** Returns the decimal precision in the model representing real numbers with the same kind parameter as the argument.

Syntax
\[
\text{result} = \text{PRECISION}(x)
\]

\( x \) (Input) Must be of type real or complex; it can be scalar or array valued.

Results
The result is a scalar of type default integer. The result has the value \( \text{INT}((\text{DIGITS}(x) - 1) * \text{LOG10}(\text{RADIX}(x))) \). If \( \text{RADIX}(x) \) is an integral power of 10, 1 is added to the result.

Example
If \( X \) is a REAL(4) value, PRECISION(\( X \)) has the value 6. The value 6 is derived from \( \text{INT}((24-1) * \text{LOG10}(2.)) = \text{INT}(6.92...) \). For more information on the model for REAL(4), see Model for Real Data.
PREFETCH and NOPREFETCH

General Compiler Directives: PREFETCH hints to the compiler to prefetch data into closer levels of cache. Prefetching data can minimize the effects of memory latency. NOPREFETCH disables data prefetching. These directives give fine-level control to the programmer to influence the prefetches generated by the compiler.

Syntax

!DIR$ PREFETCH [var1[: hint1[: distance1]] [\text{,} var2[: hint2[: distance2]]...]

!DIR$ PREFETCH *: hint[: distance]

!DIR$ NOPREFETCH [var1[,var2...]]

\text{var} Is an optional memory reference.

\text{hint} Is an optional integer constant expression with the integer value 0, 1, 2, or 3. These are the same as the defined values FOR_K_PREFETCH_T0, FOR_K_PREFETCH_T1, FOR_K_PREFETCH_T2, or FOR_K_PREFETCH_NTA for \text{hint} in the intrinsic subroutine \text{MM_PREFETCH}. To use this argument, you must also specify \text{var}.

\text{distance} Is an optional integer constant expression with a value greater than 0. It indicates the number of (possibly vectorized) loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify \text{var} and \text{hint}.

To use these directives, compiler option \text{[q or Q]opt-prefetch} must be set. Note that this option is turned on by default if the compiler general optimization level is O2 or higher.

This directive affects the DO loop it precedes.

If you specify PREFETCH *, the \text{hint} and optional \text{distance} are used to prefetch all array accesses in the DO loop.

If you specify NOPREFETCH with no arguments, the following occurs:

- All arrays accessed in the DO loop will NOT be preetched.
- It negates all other PREFETCH directives for the following DO loop.

If a loop includes expression \text{A(j)}, placing \text{!DIR$ PREFETCH A:0:d} in front of the loop instructs the compiler to insert a vprefetch0 instruction for \text{A} within the loop that is \text{d} iterations ahead.

The PREFETCH directive takes precedence over the \text{[q or Q]opt-prefetch-distance} options.

The variables in a NOPREFETCH or PREFETCH directive take precedence over PREFETCH *.

A NOPREFETCH directive with no arguments negates all other PREFETCH directives for the following DO loop.

Example

\begin{verbatim}
! Issue no prefetches for A1
! Issue vector prefetch from L2 and higher caches for B with a distance
! of 16 vectorized iterations ahead
! Issue vector prefetch from L1 and higher caches for B with a distance
! of 4 vectorized iterations ahead
!DIR$ NOPREFETCH A1
\end{verbatim}
In the following example, array A will be prefetched with hint 0 and distance 5, arrays B and C will be prefetched with hint 1 and distance 10, and array D will not be prefetched:

```
!DIR$ PREFETCH *:1:10
!DIR$ PREFETCH A:0:5
!DIR$ NOPREFETCH D
DO J = 1, N
   A (J) = B (J) + C (J) + D (J)
END DO
```

O compiler option
qopt-prefetch-distance, Qopt-prefetch-distance compiler option

PRESENT

**Inquiry Intrinsic Function (Generic):** Returns whether or not an optional dummy argument is present, that is, whether it has an associated actual argument.

Syntax

```
result = PRESENT (a)
```

a

(Input) Must be an argument of the current procedure and must have the OPTIONAL attribute. An explicit interface for the current procedure must be visible to its caller; for more information, see Procedure Interfaces.

Results

The result is a scalar of type default logical. The result is .TRUE. if a is present; otherwise, the result is .FALSE..

Example

Consider the following:

```
MODULE MYMOD
CONTAINS
SUBROUTINE CHECK (X, Y)
   REAL X, Z
   REAL, OPTIONAL :: Y
   ...
   IF (PRESENT (Y)) THEN
      Z = Y
   ELSE
      Z = X * 2
END IF
END SUBROUTINE CHECK
END MODULE MYMOD
```
USE MYMOD
CALL CHECK (15.0, 12.0) ! Causes Z to be set to 12.0
CALL CHECK (15.0) ! Causes Z to be set to 30.0

The following shows another example:

CALL who( 1, 2 ) ! prints "A present" "B present"
CALL who( 1 ) ! prints "A present"
CALL who( b = 2 ) ! prints "B present"
CALL who( ) ! prints nothing

CONTAINS
SUBROUTINE who( a, b )
  INTEGER(4), OPTIONAL :: a, b
  IF (PRESENT(a)) PRINT *, 'A present'
  IF (PRESENT(b)) PRINT *, 'B present'
END SUBROUTINE who
END

See Also
OPTIONAL
Optional Arguments

PRINT

*Statement: Displays output on the screen. TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.*

Syntax

The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using environment variable FOR_PRINT.

A PRINT statement takes one of the following forms:

Formatted:

PRINT form[, io-list]

Formatted - List-Directed:

PRINT *[, io-list]

Formatted - Namelist:

PRINT nml
  form
  io-list
  *
  nml

Is the nonkeyword form of a format specifier (no FMT=).

Is an I/O list.

Is the format specifier indicating list-directed formatting.

Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.
Example

In the following example, one record (containing four fields of data) is printed to the implicit output device:

```
CHARACTER*16 NAME, JOB
PRINT 400, NAME, JOB
  FORMAT ('NAME=', A, 'JOB=', A)
```

The following shows another example:

```
!  The following statements are equivalent:
  PRINT   '(A11)', 'Abbottsford'
  WRITE(*, '(A11)') 'Abbottsford'
  TYPE    '(A11)', 'Abbottsford'
```

See Also

File Operation I/O Statements
PRINT as a value in CLOSE

PRIORITY

**Parallel Directive Clause:** Specifies that the generated tasks have the indicated priority for execution.

**Syntax**

```
PRIORITY (priority-value)
```

**priority-value**

Provides a hint for the priority of task execution order. *priority-value* must evaluate to a non-negative scalar integer value.

Among all tasks ready to be executed, higher priority tasks (those with a higher numerical value of *priority-value*) are recommended to execute before lower priority tasks. A program that relies on task execution order being determined by this *priority-value* may have unspecified behavior.

At most one PRIORITY clause can appear in the directive.

If this clause is not specified, tasks generated by the construct have a task priority of zero (the default).

PRIVATE Clause

**Parallel Directive Clause:** Declares one or more variables to be private to each thread in a team.

**Syntax**

```
PRIVATE (list)
```

**list**

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

This clause allows each thread to have its own copy of the variable and makes it a local variable to the thread.
The following occurs when variables are declared in a PRIVATE clause:

- A new object of the same type is declared once for each thread in the team (or for each implicit task in a region) and it is used by each thread (or task) inside the scope of the directive construct instead of the original variable. The new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
- Variables defined as PRIVATE are undefined for each thread upon entering the construct and the corresponding shared variable is undefined when the parallel construct is exited. Within a parallel, worksharing, or task region, the initial status of a private pointer is undefined.

The value and allocation status of the original variable will change only in the following cases:

- If it is accessed and modified by means of a pointer
- If it is accessed in the region but outside of the construct
- As a side effect of directives or clauses
- If accessed and modified via construct association.

If a variable has the ALLOCATABLE attribute, the following rules apply:

- If the variable is not currently allocated, the new list item will have an initial state of "unallocated".
- If the variable is allocated, the new list item will have an initial state of allocated with the same array bounds.

A variable that appears in a PRIVATE clause may be storage-associated with other variables when the PRIVATE clause is encountered by constructs such as EQUIVALENCE or COMMON. If A is a variable appearing in a PRIVATE clause and B is a variable that is storage-associated with A, then the following applies:

- The contents, allocation, and association status of B are undefined on entry to the parallel or task region.
- Any definition of A, or any definition of its allocation or association status, causes the contents, allocation, and association status of B to become undefined.
- Any definition of B, or any definition of its allocation or association status, causes the contents, allocation, and association status of A to become undefined.
- A list item that appears in a private clause can be a selector in an ASSOCIATE construct. If the ASSOCIATE construct association is established before entry to a parallel region, the association between the associate name and the original PRIVATE list item will be retained in the parallel region.

The following are restrictions for the PRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that appears in a PRIVATE clause must either be definable or it must be an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
- Assumed-size arrays must not appear in a PRIVATE clause.
- A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a PRIVATE clause. This restriction does not apply to the FIRSTPRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

Variables in a list can appear in other clauses as follows:

- Variables that appear in a PRIVATE, FIRSTPRIVATE, or REDUCTION clause in a parallel construct can also appear in a PRIVATE clause in an enclosed parallel, task, or worksharing construct.
- Variables that appear in a PRIVATE or FIRSTPRIVATE clause in a task construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.
- Variables that appear in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clause in a worksharing construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.
**NOTE**
Variables that are used as counters for explicit or implicit DO loops or FORALL commands, or common blocks that are specified to be THREADPRIVATE become automatically private to each thread, even though they are not explicitly included inside a PRIVATE clause at the beginning of the scope of the parallel region.

**Example**
Consider the following:

```
!$OMP PARALLEL PRIVATE(A, B)
```

In this simple case, each thread will have its own copy of variables A and B. The variables can have different values in each thread because the variables are local to the thread.

**See Also**
FIRSTPRIVATE clause
LASTPRIVATE clause

**PRIVATE Statement**

*Statement and Attribute:* Specifies that entities in a module can be accessed only within the module itself.

**Syntax**
The PRIVATE attribute can be specified in a type declaration statement or a PRIVATE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls,] PRIVATE [, att-ls] :: entity[, entity] ...
```

**Statement:**

```
PRIVATE [[:]] entity[, entity] ...]
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `entity` Is one of the following:
  - A variable name
  - A procedure name
  - A derived type name
  - A named constant
  - A namelist group name
  - An OpenMP* reduction-identifier

In statement form, an entity can also be one of the following:

- A module name
- A generic name
- A defined operator
- A defined assignment
- A defined I/O generic specification

**Description**
The PRIVATE attribute can only appear in the scoping unit of a module.
Only one PRIVATE statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by USE association whose names do not appear in a PUBLIC statement.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PRIVATE statement, the module name must have appeared in a USE statement within the same scoping unit.

A PRIVATE attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies the derived-type definition is not accessible outside the module or the module's descendants.

A PRIVATE statement without an entity-list can appear in the component-definition part of a derived-type definition, specifying the default accessibility of all components as PRIVATE. A PRIVATE statement with no entity-list can appear in the type-bound-procedure-part of a derived-type definition specifying the default accessibility of all type-bound procedures of that type as PRIVATE. In such cases, the default accessibility of components and type-bound procedures can be overridden by explicitly declaring a component or type-bound procedure PUBLIC.

A PRIVATE attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is not accessible outside the module or its descendants.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility. Entities with PUBLIC accessibility can be accessed from outside the module by means of a USE statement.

If a derived type is declared PRIVATE in a module, its components are also PRIVATE. The derived type and its components are accessible to any subprograms within the defining module and the module's descendants through host association, but they are not accessible from outside the module.

If the derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module through use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the definition.

**Example**

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```
The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
    REAL ALL_B
    PUBLIC ALL_B
    TYPE RESTRICTED_DATA
        REAL LOCAL_C(50)
    END TYPE RESTRICTED_DATA
    PRIVATE RESTRICTED_DATA
END MODULE
```

The following derived-type declaration statement indicates that the type is restricted to the module:

```fortran
TYPE, PRIVATE :: DATA
...
END TYPE DATA
```

The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
    TYPE ELEMENTS
        PRIVATE
        INTEGER C, D
    END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```fortran
!LENGTH in module VECTRLEN calculates the length of a 2-D vector.
!The module contains both private and public procedures
MODULE VECTRLEN
    PRIVATE SQUARE
    PUBLIC LENGTH
    CONTAINS
    SUBROUTINE LENGTH(x,y,z)
        REAL,INTENT(IN) x,y
        REAL,INTENT(OUT) z
        CALL SQUARE(x,y)
        z = SQRT(x + y)
        RETURN
    END SUBROUTINE
    SUBROUTINE SQUARE(x1,y1)
        REAL x1,y1
        x1 = x1**2
        y1 = y1**2
        RETURN
    END SUBROUTINE
END MODULE
```

PROCEDURE

Statement: Declares procedure pointers, dummy procedures, and external procedures.

Syntax

PROCEDURE (\[proc-interface]\) \[\[, proc-attr-spec\]\]... ::] proc-decl-list

proc-interface (Optional) Is the name of an interface, an intrinsic type specifier, or a derived-type TYPE statement.

If an interface name is specified, it must be the name of an abstract interface, a procedure that has an explicit interface, or a procedure pointer. It must have been previously declared and it cannot be the same as a keyword that specifies an intrinsic type.

If proc-interface is a type specifier, the declared procedures or procedure pointers are functions that have implicit interfaces and the specified result type. If a type is specified for an external function, its function definition must specify the same result type and type parameters.

proc-attr-spec (Optional) Is one of the following attributes:

- PUBLIC
- PRIVATE
- BIND (C [ , NAME = init-expr])
  This is also called a language-binding-spec. The init-expr is a scalar character constant expression of default character kind. If NAME= is specified, there can only be one proc-decl item, which cannot have the POINTER attribute or be a dummy procedure.
- INTENT(INOUT)
- OPTIONAL
- POINTER
- PROTECTED
- SAVE

Each proc-attr-spec gives the corresponding attribute to all procedures declared in that statement.

If a procedure entity has the INTENT attribute or SAVE attribute, it must also have the POINTER attribute.

proc-decl-list Is one or more of the following:

procedure-name => null-init

where null-init is a reference to intrinsic function NULL with no arguments. If => null-init appears, the procedure must have the POINTER attribute.

Description

A PROCEDURE statement declares procedure pointers, dummy procedures, and external procedures. It specifies the EXTERNAL attribute for all entities in the proc-decl-list.

You cannot use the PROCEDURE statement to identify a BLOCK DATA subprogram.
If null-init appears, it specifies that the initial association status of the corresponding procedure entity is disassociated. It also implies the SAVE attribute.

You can also declare procedures by using an EXTERNAL statement or a procedure component definition statement.

If the BIND attribute is specified for a procedure, each dummy argument must be:

- An interoperable procedure or a variable that is interoperable
- Assumed shape
- Assumed rank
- Assumed type
- Of assumed-character length or has the ALLOCATABLE or POINTER attribute

If the BIND attribute is specified for a function, the function result must be an interoperable scalar variable.

A Fortran procedure is interoperable if it has the BIND attribute; that is, if its interface is specified with a language-binding-spec.

The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a procedure that has a BIND attribute.

A dummy argument of a procedure that has a BIND attribute must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that has a BIND attribute must be of interoperable type or assumed type.

When a procedure whose interface has the BIND attribute is called, any actual argument corresponding to a dummy argument with the ALLOCATABLE or POINTER attribute is passed by C descriptor. Similarly, if a Fortran procedure with a BIND attribute has such dummy arguments, they are received by C descriptor.

**Example**

Consider the following:

```fortran
PROCEDURE (NAME_TEMP) :: NAME37
```

The above declares NAME37 to be a procedure with an identical interface to that of NAME_TEMP.

The following are equivalent:

```fortran
PROCEDURE (INTEGER) X
INTEGER, EXTERNAL :: X
```

Consider the following:

```fortran
ABSTRACT INTERFACE
  FUNCTION SIM_FUNC (X)
    REAL, INTENT (IN) :: X
    REAL :: SIM_FUNC
  END FUNCTION SIM_FUNC
END INTERFACE

INTERFACE
  SUBROUTINE SUB2 (X)
    REAL, INTENT (IN) :: X
  END SUBROUTINE SUB2
END INTERFACE
```

The following shows external and dummy procedures with explicit interfaces:

```fortran
PROCEDURE (SIM_FUNC) :: VMAC, KAPPA
PROCEDURE (SUB2) :: FRINGLES
```
The following shows procedure pointers with an explicit interface, one initialized to NULL():

```fortran
PROCEDURE (SIM_FUNC), POINTER :: P1, R1 => NULL()
PROCEDURE (SIM_FUNC), POINTER :: KAPPA_POINTER
```

The following shows a derived type with a procedure pointer component:

```fortran
TYPE MEMO_TYPE
  PROCEDURE (SIM_FUNC), POINTER :: COMPONENT
END TYPE MEMO_TYPE
```

The following shows a variable of the above type:

```fortran
TYPE (MEMO_TYPE) :: STRUCTA
```

The following shows an external or dummy function with an implicit interface:

```fortran
PROCEDURE (INTEGER) :: PHIL0
```

**PROCESSOR Clause**

*Parallel Directive Clause*: Tells the compiler to create a vector version of the routine for the specified processor. When running on a processor that does not match "cpuid", a scalar version will be invoked multiple times based on vector length.

**Syntax**

```fortran
PROCESSOR (cpuid)
```

*cpuid* is one of the following:

- `ato` Intel Atom® processors with Supplemental Streaming SIMD Extensions 3 (SSSE3)
- `m` Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)
- `ms` Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) with MOVBE instructions enabled
- `be` This is a synonym for `core_5th_gen_avx`
- `adw`
Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture processors with Intel® Streaming SIMD Extensions 4.1 (Intel® SSE4.1)

Intel® Core™2 Duo processors and Intel® Xeon® processors with Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)

2nd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX)

3rd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX) including the RDRND instruction

4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction

4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)

5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions

5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry
Instruction Extensions (ADX) instructions, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)

Intel® Core™ processors with support for Advanced Encryption Standard (AES) instructions and carry-less multiplication instruction

Intel® Core™ i7 processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) instructions

Other Intel processors for IA-32 or Intel® 64 architecture or compatible processors not provided by Intel Corporation

This is a synonym for core_4th_gen_avx.

This is a synonym for mic_avx512.

The Intel® Xeon Phi™ product family code name Knights Mill.

Intel® Many Integrated Core Architecture (Intel® MIC Architecture)

2nd generation Intel® Xeon Phi™ processor family with support for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, Intel® AVX-512 Exponential and Reciprocal instructions, Intel® AVX-512 Prefetch instructions for Intel® processors, and Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions.

This setting is only available on Intel® 64 architecture targeting the Intel® Xeon Phi™ product family x200 (formerly code name Knights Landing)

Intel® Pentium® processor

Intel® Pentium® 4 processor
Intel® Pentium® 4 processor with Intel® Streaming SIMD Extensions 3 (Intel® SSE3) instructions, Intel® Core™ Duo processors, Intel® Core™ Solo processors

Intel® Pentium® II processors

Intel® Pentium® III processors

Intel® Pentium® III processors with no XMM registers

Intel® Pentium® M processors

Intel® Pentium® processors with MMX™ technology

Intel® Pentium® Pro processors

Intel® microarchitecture code name Skylake. This keyword targets the Client CPU without support for Intel® AVX-512 instructions.

Intel® microarchitecture code name Skylake. This keyword targets the Server CPU with support for Intel® AVX-512 instructions.

The vector version of the routine that is created by the compiler is not affected by processor options specified on the command line.

Multiple PROCESSOR clauses cause a syntax error.

ATTRIBUTES VECTOR

PRODUCT

*Transformational Intrinsic Function (Generic):*

Returns the product of all the elements in an entire array or in a specified dimension of an array.

**Syntax**

\[
\text{result} = \text{PRODUCT} (\text{array}[,,\text{dim}] [,\text{mask}])
\]

- **array**  
  (Input) Must be an array of type integer, real, or complex.

- **dim**  
  (Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \(\text{array}\).

- **mask**  
  (Input; optional) Must be of type logical and conformable with \(\text{array}\).

**Results**

The result is an array or a scalar of the same data type as \(\text{array}\).

The result is a scalar if \(\text{dim}\) is omitted or \(\text{array}\) has rank one.

The following rules apply if \(\text{dim}\) is omitted:

- If PRODUCT(\(\text{array}\)) is specified, the result is the product of all elements of \(\text{array}\). If \(\text{array}\) has size zero, the result is 1.
- If PRODUCT(\(\text{array}\), MASK= \(\text{mask}\)) is specified, the result is the product of all elements of \(\text{array}\) corresponding to true elements of \(\text{mask}\). If \(\text{array}\) has size zero, or every element of \(\text{mask}\) has the value .FALSE., the result is 1.

The following rules apply if \(\text{dim}\) is specified:

- If \(\text{array}\) has rank one, the value is the same as PRODUCT(\(\text{array}[,,\text{dim}]= \text{mask}\)).
- An array result has a rank that is one less than \(\text{array}\), and shape \((d_1, d_2, ..., d_{\text{dim}-1}, d_{\text{dim}+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of \(\text{array}\).
- The value of element \((s_1, s_2, ..., s_{\text{dim}-1}, ::, s_{\text{dim}+1}, ..., s_n)\) of PRODUCT(\(\text{array}, \text{dim}[,, \text{mask}]\)) is equal to PRODUCT(\(\text{array}(s_1, s_2, ..., s_{\text{dim}-1}, ::, s_{\text{dim}+1}, ..., s_n) [,\text{MASK}= \text{mask}(s_1, s_2, ..., s_{\text{dim}-1}, ::, s_{\text{dim}+1}, ..., s_n)]\)).

**Example**

PRODUCT ((/2, 3, 4/)) returns the value 24 (the product of 2 \(\times\) 3 \(\times\) 4). PRODUCT ((/2, 3, 4/), DIM=1) returns the same result.

PRODUCT (C, MASK=C .LT. 0.0) returns the product of the negative elements of C.

A is the array

\[
\begin{bmatrix}
1 & 4 & 7 \\
2 & 3 & 5
\end{bmatrix}
\]

PRODUCT (A, DIM=1) returns the value (2, 12, 35), which is the product of all elements in each column. 2 is the product of 1 \(\times\) 2 in column 1. 12 is the product of 4 \(\times\) 3 in column 2, and so forth.

PRODUCT (A, DIM=2) returns the value (28, 30), which is the product of all elements in each row. 28 is the product of 1 \(\times\) 4 \(\times\) 7 in row 1. 30 is the product of 2 \(\times\) 3 \(\times\) 5 in row 2.

If \(\text{array}\) has shape (2, 2), \(\text{mask}\) is omitted, and \(\text{dim}\) is 1, the result is an array result with shape (2, 2) whose elements have the following values.
<table>
<thead>
<tr>
<th>Resultant array element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>result(1, 1)</td>
<td>array(1, 1, 1) * array(2, 1, 1)</td>
</tr>
<tr>
<td>result(2, 1)</td>
<td>array(1, 2, 1) * array(2, 2, 1)</td>
</tr>
<tr>
<td>result(1, 2)</td>
<td>array(1, 1, 2) * array(2, 1, 2)</td>
</tr>
<tr>
<td>result(2, 2)</td>
<td>array(1, 2, 2) * array(2, 2, 2)</td>
</tr>
</tbody>
</table>

The following shows another example:

```
INTEGER array (2, 3)
INTEGER AR1(3), AR2(2)
array = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2,3/))
! array is  1 2 3
!           4 5 6
AR1 = PRODUCT(array, DIM = 1) ! returns [ 4 10 18 ]
AR2 = PRODUCT(array, MASK = array .LT. 6, DIM = 2)
! returns [ 6 20 ]
END
```

See Also
SUM

PROGRAM

Statement: Identifies the program unit as a main program and gives it a name.

Syntax

```
[PROGRAM name]
  [specification-part]
  [execution-part]
[CONTAINS
  internal-subprogram-part]
END[PROGRAM [name]]
```

name

Is the name of the program.

specification-part

Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

execution-part

Is one or more executable constructs or statements, except for ENTRY or RETURN statements.

internal-subprogram-part

Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.
Description

The PROGRAM statement is optional. Within a program unit, a PROGRAM statement can be preceded only by comment lines or an OPTIONS statement.

The END statement is the only required part of a program. If a name follows the END statement, it must be the same as the name specified in the PROGRAM statement.

The program name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A main program must not reference itself (either directly or indirectly).

Example

The following is an example of a main program:

```fortran
PROGRAM TEST
  INTEGER C, D, E(20,20) ! Specification part
  CALL SUB_1            ! Executable part
  ...
CONTAINS
  SUBROUTINE SUB_1      ! Internal subprogram
  ...
END SUBROUTINE SUB_1
END PROGRAM TEST
```

The following shows another example:

```fortran
PROGRAM MyProg
  PRINT *, 'hello world'
END
```

PROTECTED

Statement and Attribute: Specifies limitations on the use of module entities.

Syntax

The PROTECTED attribute can be specified in a type declaration statement or a PROTECTED statement, and takes one of the following forms:

Type Declaration Statement:

```
type, [att-ls, ] PROTECTED [, att-ls] :: entity[, entity] ...
```

Statement:

```
PROTECTED [::]entity[, entity] ...
```

<table>
<thead>
<tr>
<th>type</th>
<th>Is a data type specifier.</th>
</tr>
</thead>
<tbody>
<tr>
<td>att-ls</td>
<td>Is an optional list of attribute specifiers.</td>
</tr>
<tr>
<td>entity</td>
<td>Is the name of an entity in a module.</td>
</tr>
</tbody>
</table>

The PROTECTED attribute can only appear in the specification part of a module.

The PROTECTED attribute can only be specified for a procedure pointer or named variable that is not in a common block.

A non-pointer object that has the PROTECTED attribute and is accessed by use association can not appear in a variable definition or as the target in a pointer assignment statement.
A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as any of the following:

- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
- An object in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following restrictions apply outside of the module in which the entity has been given the PROTECTED attribute:

- A non-pointer entity may not be defined or redefined.
- A pointer entity may not have its association status changed through the pointer.

**Example**

The following example shows a type declaration statement specifying the PROTECTED attribute:

```
INTEGER, PROTECTED :: D, E
```

Consider the following example:

```fortran
MODULE counter_mod
    INTEGER, PROTECTED :: current = 0
    CONTAINS

    INTEGER FUNCTION next()
    current = current + 1    ! current can be modified here
    next = current
    RETURN
    END FUNCTION next

END MODULE counter_mod

PROGRAM test_counter
    USE counter_mod
    PRINT *, next()             ! Prints 1
    current = 42                 ! Error: variable is protected
END PROGRAM test_counter
```

**See Also**

- Modules and Module Procedures
- Type Declarations
- Compatible attributes
- Pointer Assignments

**PSECT**

*General Compiler Directive:* Modifies characteristics of a common block.

**Syntax**

```
!DIR$ PSECT /common-name/ a[,a] ...
```

- `common-name` is the name of the common block. The slashes (/) are required.
- `a` is one of the following:
  - `ALIGN= val` or `ALIGN= keyword`
Specifies minimum alignment for the common block. ALIGN only has an effect when specified on Windows* and Linux* systems.

The val is a constant ranging from 0 through 6 on Windows* systems and 0 through 4 on Linux* systems. The specified number is interpreted as a power of 2. The value of the expression is the alignment in bytes.

The keyword is one of the following:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to val</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>0</td>
</tr>
<tr>
<td>WORD</td>
<td>1</td>
</tr>
<tr>
<td>LONG</td>
<td>2</td>
</tr>
<tr>
<td>QUAD</td>
<td>3</td>
</tr>
<tr>
<td>OCTA</td>
<td>4</td>
</tr>
<tr>
<td>PAGE</td>
<td>On IA-32 architecture: range is 0 through 13 for Windows*; 0 through 12 for Linux*</td>
</tr>
</tbody>
</table>

• [NO]WRT

Determines whether the contents of a common block can be modified during program execution.

If one program unit changes one or more characteristics of a common block, all other units that reference that common block must also change those characteristics in the same way.

The defaults are ALIGN=OCTA and WRT.

General Compiler Directives
Syntax Rules for Compiler Directives

PUBLIC

**Statement and Attribute:** Specifies that entities in a module can be accessed from outside the module by specifying a USE statement.

Syntax

The PUBLIC attribute can be specified in a type declaration statement or a PUBLIC statement, and takes one of the following forms:

**Type Declaration Statement:**

type,[att-ls,] PUBLIC [, att-ls] :: entity [, entity]...

**Statement:**

PUBLIC [[::] entity [, entity] ...]

*type*  
Is a data type specifier.

*att-ls*  
Is an optional list of attribute specifiers.
entity

Is one of the following:
- A variable name
- A procedure name
- A derived type name
- A named constant
- A namelist group name
- An OpenMP* reduction-identifier

In statement form, an entity can also be one of the following:
- A module name
- A generic name
- A defined operator
- A defined assignment
- A defined I/O generic specification

Description

The PUBLIC attribute can only appear in the scoping unit of a module.

Only one PUBLIC statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by use association.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility for all entities in the module and entities accessible from other modules by use association.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PUBLIC statement, the module name must have appeared in a USE statement within the same scoping unit.

A PUBLIC attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies that the derived-type definition is accessible by USE association where the module is used.

A PUBLIC attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is accessible by USE association where the module is used, even if the default accessibility of the components and type-bound procedures of the derived type has been set to PRIVATE in the definition of the derived type.

If a derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module procedure has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:
- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the derived-type definition or in the module's descendants.
Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
  PRIVATE RESTRICTED_DATA
END MODULE
```

The following example shows a PUBLIC type with PRIVATE components:

```
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
      INTEGER C, D
    END TYPE
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```
! LENGTH in module VECTRLEN calculates the length of a 2-D vector.
! The module contains both private and public procedures
MODULE VECTRLEN
  PRIVATE SQUARE
  PUBLIC LENGTH
  CONTAINS
    SUBROUTINE LENGTH(x,y,z)
      REAL, INTENT(IN) x,y
      REAL, INTENT(OUT) z
      CALL SQUARE(x,y)
      z = SQRT(x + y)
    RETURN
    END SUBROUTINE
    SUBROUTINE SQUARE(x1,y1)
      REAL x1,y1
      x1 = x1**2
      y1 = y1**2
    RETURN
    END SUBROUTINE
END MODULE
```

See Also

PRIVATE
MODULE
TYPE
Defining Generic Names for Procedures
USE
PURE

**Keyword:** Asserts that a user-defined procedure has no side effects.

**Description**

This kind of procedure is specified by using the prefix PURE or the prefix ELEMENTAL without the prefix IMPURE in a FUNCTION or SUBROUTINE statement.

A pure procedure has no side effects. It has no effect on the state of the program, except for the following:

- For functions: It returns a value.
- For subroutines: It modifies INTENT(OUT) and INTENT(INOUT) parameters.

The following intrinsic and library procedures are implicitly pure:

- All intrinsic functions
- The elemental intrinsic subroutine MVBITS
- The intrinsic subroutine MOVE_ALLOC

A statement function is pure only if all functions that it references are pure.

Except for procedure arguments and pointer arguments, the following intent must be specified in the specification part of the procedure for all dummy arguments:

- For functions: INTENT(IN) or the VALUE attribute
- For subroutines: any INTENT (IN, OUT, or INOUT) or the VALUE attribute

A local variable declared in a pure procedure (including variables declared in any internal procedure) must not:

- Specify the SAVE attribute
- Be initialized in a type declaration statement or a DATA statement

The following variables have restricted use in pure procedures (and any internal procedures):

- Global variables
- Dummy arguments with INTENT(IN) (or no declared intent)
- Objects that are storage associated with any part of a global variable

They must not be used in any context that does either of the following:

- Causes their value to change. For example, they must not be used as:
  - The left side of an assignment statement or pointer assignment statement
  - An actual argument associated with a dummy argument with INTENT(OUT), INTENT(INOUT), or the POINTER attribute
  - An index variable in a DO or FORALL statement, or an implied-DO clause
  - The variable in an ASSIGN statement
  - An input item in a READ statement
  - An internal file unit in a WRITE statement
  - An object in an ALLOCATE, DEALLOCATE, or NULLIFY statement
  - An IOSTAT or SIZE specifier in an I/O statement, or the STAT specifier in an ALLOCATE or DEALLOCATE statement
- Creates a pointer to that variable. For example, they must not be used as:
  - The target in a pointer assignment statement
• The right side of an assignment to a derived-type variable (including a pointer to a derived type) if the
derived type has a pointer component at any level

A pure procedure must not contain the following:
• Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit
number or *)
• A PAUSE statement
• A STOP statement
• An image control statement
• An OpenMP* directive

A pure procedure can be used in contexts where other procedures are restricted; for example:
• It can be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
• It can be called from a pure procedure. Pure procedures can only call other pure procedures, including
one referenced by means of a defined operator, defined assignment, or finalization.
• It can be passed as an actual argument to a pure procedure.

If a procedure is used in any of these contexts, its interface must be explicit and it must be declared pure in
that interface.

Example

Consider the following:

```fortran
PURE FUNCTION DOUBLE(X)
    REAL, INTENT(IN) :: X
    DOUBLE = 2 * X
END FUNCTION DOUBLE
```

The following shows another example:

```fortran
PURE INTEGER FUNCTION MANDELBROT(X)
    COMPLEX, INTENT(IN) :: X
    INTEGER__:: K
    ! Assume SHARED_DEFS includes the declaration
    ! INTEGER ITOL
    USE SHARED_DEFS

    K = 0
    XTMP = -X
    DO WHILE (ABS(XTMP) < 2.0 .AND. K < ITOL)
        XTMP = XTMP**2 - X
        K = K + 1
    END DO
    MANDELBROT = K
END FUNCTION
```

The following shows the preceding function used in an interface block:

```fortran
INTERFACE
    PURE INTEGER FUNCTION MANDELBROT(X)
        COMPLEX, INTENT(IN) :: X
    END FUNCTION MANDELBROT
END INTERFACE
```
The following shows a FORALL construct calling the MANDELBROT function to update all the elements of an array:

```fortran
FORALL (I = 1:N, J = 1:M)
    A(I,J) = MANDELBROT(COMPLX((I-1)*1.0/(N-1), (J-1)*1.0/(M-1))
END FORALL
```

FUNCTION
SUBROUTINE
FORALL
ELEMENTAL prefix

PUTC

**Portability Function:** Writes a character to Fortran external unit number 6.

**Module**

USE IFPORT

**Syntax**

result = PUTC (char)

**char**

(Input) Character. Character to be written to external unit 6.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

**Example**

```fortran
use IFPORT
integer(4) i4
character*1 char1
do i = 1,26
    char1 = char(123-i)
    i4 = putc(char1)
    if (i4.ne.0) iflag = 1
enddo
```

GETC
WRITE
PRINT
FPUTC

**PUTIMAGE, PUTIMAGE_W (W*S)**

**Graphics Subroutines:** Transfer the image stored in memory to the screen.

**Module**

USE IFQWIN
Syntax

CALL PUTIMAGE (x, y, image, action)

CALL PUTIMAGE_W (wx, wy, image, action)

x, y  (Input) INTEGER(2). Viewport coordinates for upper-left corner of the image when placed on the screen.

wx, wy (Input) REAL(8). Window coordinates for upper-left corner of the image when placed on the screen.

image  (Input) INTEGER(1). Array of single-byte integers. Stored image buffer.

action  (Input) INTEGER(2). Interaction of the stored image with the existing screen image. One of the following symbolic constants defined in IFQWIN.F90:

- $GAND - Forms a new screen display as the logical AND of the stored image and the existing screen display. Points that have the same color in both the existing screen image and the stored image remain the same color, while points that have different colors are joined by a logical AND.
- $GOR - Superimposes the stored image onto the existing screen display. The resulting image is the logical OR of the image.
- $GPRESET - Transfers the data point-by-point onto the screen. Each point has the inverse of the color attribute it had when it was taken from the screen by GETIMAGE, producing a negative image.
- $GPSET - Transfers the data point-by-point onto the screen. Each point has the exact color attribute it had when it was taken from the screen by GETIMAGE.
- $GXOR - Causes points in the existing screen image to be inverted wherever a point exists in the stored image. This behavior is like that of a cursor. If you perform an exclusive OR of an image with the background twice, the background is restored unchanged. This allows you to move an object around without erasing the background. The $GXOR constant is a special mode often used for animation.
- In addition, the following ternary raster operation constants can be used (described in the online documentation for the Windows* API BitBlt):
  - $GSRCCOPY (same as $GPSET)
  - $GSRCPAINT (same as $GOR)
  - $GSRCAND (same as $GAND)
  - $GSRCINVERT (same as $GXOR)
  - $GSRCERASE
  - $GNOTSRCCOPY (same as $GPRESET)
  - $GNOTSRCERASE
  - $GMERGECOPY
  - $GMERGEPAINT
  - $GPATCOPY
  - $GPATPAINT
  - $GPATINVERT
  - $GDSTINVERT
• $GBLACKNESS
• $GWHITENESS

PUTIMAGE places the upper-left corner of the image at the viewport coordinates \((x, y)\). PUTIMAGE\_W places the upper-left corner of the image at the window coordinates \((wx, wy)\).

Example

```fortran
! Build as a Graphics App.
USE IFQWIN
INTEGER(1), ALLOCATABLE :: buffer(:)
INTEGER(2) status, x
INTEGER(4) imsize

status = SETCOLOR(INT2(4))

! draw a circle
status = ELLIPSE($GFILLINTERIOR,INT2(40),INT2(55), &

PXF(type)GET

**POSIX Subroutine:** Gets the value stored in a component (or field) of a structure.

Module
USE IFPOSIX

Syntax

CALL PXF(type)GET \((jhandle, compname, value, ierror)\)
CALL PXF(type)GET \((jhandle, compname, value, ilen, ierror)\) ! syntax when \((type)\) is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALGET</td>
</tr>
</tbody>
</table>
**PXF(type)GET**

**POSIX Subroutine:** Sets the value of a component (or field) of a structure.

### Module

USE IFPOSIX

### Syntax

CALL PXF(type)SET (jhandle, compname, value, ierror)

CALL PXF(type)SET (jhandle, compname, value, ilen, ierror) ! syntax when (type) is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINSET</td>
</tr>
</tbody>
</table>

**jhandle**  
(Input) INTEGER(4). A handle of a structure.

**compname**  
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value**  
(Output) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). Stores the value of the component (or field).

**ilen**  
(Output) INTEGER(4). This argument can only be used when (type) is STR (PXFSTRGET). Stores the length of the returned string.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXF(type)GET subroutines retrieve the value from component (or field) compname of the structure associated with handle jhandle into variable value.

**Example**

See the example in PXFTIMES (which shows PXFINSETGET and PXFIN8GET)

**See Also**

PXF(type)SET
### Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL</td>

<td>PXFREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*(*)</td>
<td>PXFSTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFINT8SET</td>
</tr>
</tbody>
</table>

- **jhandle** *(Input)* INTEGER(4). A handle of a structure.
- **compname** *(Input)* Character. The name of the component (or field) of the structure to write data to.
- **value** *(Input)* A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). The value for the component (or field).
- **ilen** *(Input)* INTEGER(4). This argument can only be used when *(type)* is STR (PXFSTRSET). The length of the string in *value*.
- **ierror** *(Output)* INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### Example

See the example in PXFSTRUCTCREATE (which shows PXFSTRSET)

### See Also

PXF(type)GET

### PXFA(type)GET

**POSIX Subroutine**: Gets the array values stored in a component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFA(type)GET (jhandle, compname, value, ilen, ierror)
```

CALL PXFA(type)GET (jhandle, compname, value, ilen, ilen, ierror) ! syntax when *(type)* is STR

_A placeholder for one of the following values:_

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFAINTGET</td>
</tr>
</tbody>
</table>
### Table: Value Data Type Routine Name

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFAREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFALGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*(*)</td>
<td>PXFASTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFACHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8GET</td>
</tr>
</tbody>
</table>

**jhandle**
(Input) INTEGER(4). A handle of a structure.

**compname**
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value**
(Output) An array, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).

**ialen**
(Input) INTEGER(4). The size of array value.

**ilen**
(Output) INTEGER(4). This argument can only be used when (type) is STR (PXFASTRGET). An array that stores the lengths of elements of array value.

**ierror**
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**See Also**
PXFA(type)SET
PXF(type)GET

**PXFA(type)SET**

**POSIX Subroutine: Sets the value of an array component (or field) of a structure.**

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFA(type)SET (jhandle, compname, value, ialen, ierror)
```

```
CALL PXFA(type)SET (jhandle, compname, value, ialen, ilen, ierror) ! syntax when (type) is STR
```
A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFAINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFAREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFALGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFASTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFACHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8SET</td>
</tr>
</tbody>
</table>

- **jhandle** (Input) INTEGER(4). A handle of a structure.
- **compname** (Input) Character. The name of the component (or field) of the structure to write data to.
- **value** (Input) An array, whose data type depends on the value of **(type)**. See the table above for the data types for each value; for example, if the value for **(type)** is INT, the data type of the array is INTEGER(4). The value for the component (or field).
- **ialen** (Input) INTEGER(4). The size of array **value**.
- **ilen** (Input) INTEGER(4). This argument can only be used when **(type)** is STR (PXFASTRSET). An array that specifies the lengths of elements of array **value**.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFA**(type)**GET subroutines are similar to the PXF**(type)**GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA**(type)**GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**See Also**
PXFA**(type)**GET
PXF**(type)**SET

**PXFACCESS**

**POSIX Subroutine:** Determines the accessibility of a file.

**Module**
USE IFPOSIX

**Syntax**

```call pxfaccess (path, ielen, iemode, ierror)```
**path**  
(Input) Character. The name of the file.

**ilen**  
(Input) INTEGER(4). The length of the path string.

**iamode**  
(Input) INTEGER(4). One or more of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Checks for existence of the file.</td>
</tr>
<tr>
<td>1</td>
<td>Checks for execute permission.</td>
</tr>
<tr>
<td>2</td>
<td>Checks for write access.</td>
</tr>
<tr>
<td>4</td>
<td>Checks for read access.</td>
</tr>
<tr>
<td>6</td>
<td>Checks for read/write access.</td>
</tr>
</tbody>
</table>

1L*X only

**ierror**  
(Output) INTEGER(4). The error status.

If access is permitted, the result value is zero; otherwise, an error code. Possible error codes are:

- -1: A bad parameter was passed.
- ENOENT: The named directory does not exist.
- EACCES: Access requested was denied.

On Windows* systems, if the name given is a directory name, the function only checks for existence. All directories have read/write access on Windows* systems.

**PXFALARM**

**POSIX Subroutine: Schedules an alarm.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFALARM (iseconds, isecleft, ierror)

**iseconds**  
(Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.

**isecleft**  
(Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered.

It is set to zero if there was no previously scheduled alarm signal.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFALARM subroutine arranges for a SIGALRM signal to be delivered to the process in seconds **iseconds**.

On Linux* and macOS* systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

IPXCONST
PXFSIGACTION

**PXFCALLSUBHANDLE**

*POSIX Subroutine:* Calls the associated subroutine.

**Module**
USE IFPOSIX

**Syntax**

```
CALL PXFCALLSUBHANDLE (jhandle2, ival, ierror)
```

- **jhandle2** *(Input)* INTEGER(4). A handle to the subroutine.
- **ival** *(Input)* INTEGER(4). The argument to the subroutine.
- **ierror** *(Output)* INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine. PXFGETSUBHANDLE should be used to obtain a subroutine handle.

**NOTE**
The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

See Also
PXFGETSUBHANDLE

**PXFCFGETISPEED (L*X, M*X)**

*POSIX Subroutine:* Returns the input baud rate from a termios structure.

**Module**
USE IFPOSIX

**Syntax**

```
CALL PXFCFGETISPEED (jtermios, iospeed, ierror)
```

- **jtermios** *(Input)* INTEGER(4). A handle of structure termios.
- **iospeed** *(Output)* INTEGER(4). The returned value of the input baud rate from the structure associated with handle **jtermios**.
- **ierror** *(Output)* INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
NOTE
To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also
PXFSTRUCTCREATE
PXFCFSETISPEED

PXFCFGETOSPEED (L*X, M*X)

POSIX Subroutine: Returns the output baud rate from a termios structure.

Module
USE IFPOSIX

Syntax
CALL PXFCFGETOSPEED (jtermios, iospeed, ierror)

jtermios (Input) INTEGER(4). A handle of structure termios.
iostream (Output) INTEGER(4). The returned value of the output baud rate from the structure associated with handle jtermios.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE
To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also
PXFSTRUCTCREATE
PXFCFSETOSPEED

PXFCFSETISPEED (L*X, M*X)

POSIX Subroutine: Sets the input baud rate in a termios structure.

Module
USE IFPOSIX

Syntax
CALL PXFCFSETISPEED (jtermios, ispeed, ierror)

jtermios (Input) INTEGER(4). A handle of structure termios.
ispeed (Input) INTEGER(4). The value of the input baud rate for the structure associated with handle jtermios.
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**NOTE**
To get a handle for an instance of the *termios* structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

---

**See Also**
PXFSTRUCTCREATE
PXFCFGETISPEED

**PXFCFSETOSPEED** *(L*X, M*X)*

*POSIX Subroutine:* Sets the output baud rate in a *termios* structure.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCFSETOSPEED (jtermios, ispeed, ierror)

*jtermios* (Input) INTEGER(4). A handle of structure *termios*.

*ispeed* (Input) INTEGER(4). The value of the output baud rate for the structure associated with handle *jtermios*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**NOTE**
To get a handle for an instance of the *termios* structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

---

**See Also**
PXFSTRUCTCREATE
PXFCFGETOSPEED

**PXFCHDIR**

*POSIX Subroutine:* Changes the current working directory.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCHDIR (path, ilen, ierror)
**PXFMKDIR**

**POSIX Subroutine:** Changes the path to a directory.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFMKDIR (path, ilen, ierror)

- **path** (Input) Character. The directory to be changed to.
- **ilen** (Input) INTEGER(4). The length of the path string.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

**See Also**
PXFMKDIR

**PXFCHMOD**

**POSIX Subroutine:** Changes the ownership mode of the file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCHMOD (path, ilen, imode, ierror)

- **path** (Input) Character. The path to the file.
- **ilen** (Input) INTEGER(4). The length of the path string.
- **imode** (Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++ Installation in the \include directory under sys\stat.h for the values of **imode**. On Linux* and macOS* systems, use octal file-access mode.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

**NOTE**
On Linux* and macOS* systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

**PXFCHOWN (L*X, M*X)**

**POSIX Subroutine:** Changes the owner and group of a file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCHOWN (path, ilen, iowner, igroup, ierror)

- **path** (Input) Character. The path to the file.
- **ilen** (Input) INTEGER(4). The length of the path string.
**PXFCLEARENV**

**POSIX Subroutine:** Clears the process environment.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCLEARENV (ierror)

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

After a call to PXFCLEARENV, no environment variables are defined.

**PXFCLOSE**

**POSIX Subroutine:** Closes the file associated with the descriptor.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCLOSE (fd, ierror)

*fd*  
(Input) INTEGER(4). A file descriptor.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**See Also**

PXFOPEN

**PXFCLOSEDIR**

**POSIX Subroutine:** Closes the directory stream.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCLOSEDIR (idirid, ierror)
idirid (Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with idirid.

See Also
PXFOPENDIR

PXFCONST

POSIX Subroutine: Returns the value associated with a constant.

Module
USE IFPOSIX

Syntax
CALL PXFCONST (constname, ival, ierror)

constname (Input) Character. The name of one of the following constants:
- STDIN_UNIT
- STDOUT_UNIT
- STDERR_UNIT
- EINVAL
- ENONAME
- ENOHANDLE
- EARRAYLEN
- ENOENT
- ENOTDIR
- EACCES

The constants beginning with E signify various error values for the system variable errno.

ival (Output) INTEGER(4). The returned value of the constant.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, it is set to -1.

For more information on these constants, see your Microsoft® Visual C++ documentation (Windows® systems) or the errno.h file (Linux® and macOS® systems).

See Also
PXFISCONST

PXFCREAT

POSIX Subroutine: Creates a new file or rewrites an existing file.

Module
USE IFPOSIX
Syntax
CALL PXFCREAT (path, ilen, imode, ifildes, ierror)

path (Input) Character. The pathname of the file.
ilen (Input) INTEGER(4). The length of path string.
imode (Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* and macOS* systems, use octal file-access mode.
ifildes (Output) INTEGER(4). The returned file descriptor.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFCTERMID (L*X, M*X)
POSIX Subroutine: Generates a terminal pathname.
Module
USE IFPOSIX
Syntax
CALL PXFCTERMID (s, ilen, ierror)
s (Output) Character. The returned pathname of the terminal.
ilen (Output) INTEGER(4). The length of the returned value in the s string.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
This subroutine returns a string that refers to the current controlling terminal for the current process.

PXFDUP, PXFDUP2
POSIX Subroutine: Duplicates an existing file descriptor.
Module
USE IFPOSIX
Syntax
CALL PXFDUP (ifildes, fid, ierror)
CALL PXFDUP2 (ifildes, ifildes2, ierror)

ifildes (Input) INTEGER(4). The file descriptor to duplicate.
fid (Output) INTEGER(4). The returned new duplicated file descriptor.
ifildes2 (Input) INTEGER(4). The number for the new file descriptor.
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFDUP subroutine creates a second file descriptor for an opened file.

The PXFDUP2 subroutine copies the file descriptor associated with *ifildes*. Integer number *ifildes2* becomes associated with this new file descriptor, but the value of *ifildes2* is not changed.

### PXFE(type)GET

**POSIX Subroutine: Gets the value stored in an array element component (or field) of a structure.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFE(type)GET (jhandle, compname, index, value, ierror)

CALL PXFE(type)GET (jhandle, compname, index, value, ilen, ierror) ! syntax when (type) is STR

**(type)**

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8GET</td>
</tr>
</tbody>
</table>

**jhandle**

(Input) INTEGER(4). A handle of a structure.

**compname**

(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**index**

(Input) INTEGER(4). The index of the array element to get data for.

**value**

(Output) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). Stores the value of the component (or field).

**ilen**

(Output) INTEGER(4). This argument can only be used when *(type)* is STR (PXFESTRGET). Stores the length of the returned string.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFE(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)GET subroutines are used, the array element with index \( index \) is accessed (read from the component or field).

See Also
PXFE(type)SET
PXF(type)GET

**PXFE(type)SET**

**POSIX Subroutine:** Sets the value of an array element component (or field) of a structure.

**Module**
USE IFPOSIX

**Syntax**

CALL PXFE(type)SET (jhandle, compname, index, value, ierror)

CALL PXFE(type)SET (jhandle, compname, index, value, ilen, ierror) ! syntax when (type) is STR

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8SET</td>
</tr>
</tbody>
</table>

\( \text{jhandle} \) (Input) INTEGER(4). A handle of a structure.

\( \text{compname} \) (Input) Character. The name of the component (or field) of the structure to write data to.

\( \text{index} \) (Input) INTEGER(4). The index of the array element to write data to.

\( \text{value} \) (Input) A variable, whose data type depends on the value of \( \text{(type)} \). See the table above for the data types for each value; for example, if the value for \( \text{(type)} \) is INT, the data type is INTEGER(4). The value for the component (or field).

\( \text{ilen} \) (Input) INTEGER(4). This argument can only be used when \( \text{(type)} \) is STR (PXFESTRSET). The length of the string \( \text{value} \).

\( \text{ierror} \) (Output) INTEGER(4). The error status.

If successful, \( \text{ierror} \) is set to zero; otherwise, an error code.
The PXFE(type)SET subroutines are similar to the PXF(type)SET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)SET subroutines are used, the array element with index index is accessed (written to the component or field).

**See Also**
PXFE(type)GET
PXF(type)SET

**PXFEXECV**

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFEXECV (path, lenpath, argv, lenargv, iargc, ierror)

- *path* (Input) Character. The path to the new executable process.
- *lenpath* (Input) INTEGER(4). The length of *path* string.
- *argv* (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
- *lenargv* (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in *argv*.
- *iargc* (Input) INTEGER(4). The number of command-line arguments
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the *argv* array. If execution is successful, no return is made to the calling process.

**See Also**
PXFEXECVE
PXFEXECVP

**PXFEXECVE**

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFEXECVE (path, lenpath, argv, lenargv, iargc, env, lenenv, ienvc, ierror)

- *path* (Input) Character. The path to the new executable process.
lenpath  (Input) INTEGER(4). The length of path string.

argv  (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

lenargv  (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

iargc  (Input) INTEGER(4). The number of command-line arguments.

eenv  (Input) An array of character strings. Contains the environment settings for the new process.

lenenv  (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in env.

ienvc  (Input) INTEGER(4). The number of environment settings in env.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array and environment settings specified in the env array.

See Also
PXFEXECV
PXFEXECVP

PXFEXECVP
POSIX Subroutine: Executes a new process by passing command-line arguments.

Module
USE IFPOSIX

Syntax
CALL PXFEXECVP (file,lenfile,argv,lenargv,iargc,ierror)

file  (Input) Character. The filename of the new executable process.

lenfile  (Input) INTEGER(4). The length of file string.

argv  (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

lenargv  (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

iargc  (Input) INTEGER(4). The number of command-line arguments.

ierror  (Input) Character. The filename of the new executable process.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVP subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. It uses the PATH environment variable to find the file to execute.
PXFEXIT, PXFFASTEXIT

POSIX Subroutine: Exits from a process.

Module

USE IFPOSIX

Syntax

CALL PXFEXIT (istatus)

CALL PXFFASTEXIT (istatus)

istatus (Input) INTEGER(4). The exit value.

The PXFEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions `atexit` and `onexit`, and flushes all file buffers before terminating the process. The `istatus` value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing `atexit` or `onexit`, and without flushing stream buffers.

Example

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *," the child process will be born"
call PXFFORK(ipid, IERROR)
call PXFGETPID(ipid_ret,IERROR)
if(ipid.EQ.0) then
  print *," I am a child process"
  print *," My child's pid is", IPID_RET
call PXFGETPPID(IPID_RET,IERROR)
  print *," The pid of my parent is",IPID_RET
  print *," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
  print *," I am a parent process"
  print *," My parent pid is ", IPID_RET
  print *," I am creating the process with pid", IPID
  print *," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *," The child with pid ", IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
  print *, " The child exited normally"
  istat_ret = IPXFWEXITSTATUS(ISTAT)
  print 10," The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program
```
PXFFCNTL (L*M, M*X)  

**POSIX Subroutine:** Manipulates an open file descriptor.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFCNTL (ifildes, icmd, iargin, iargout, ierror)

- **ifildes** (Input) INTEGER(4). A file descriptor.
- **icmd** (Input) INTEGER(4). Defines an action for the file descriptor.
- **iargin** (Input; output) INTEGER(4). Interpretation of this argument depends on the value of icmd.
- **iargout** (Output) INTEGER(4). Interpretation of this argument depends on the value of icmd.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in *icmd*, can be obtained by using the values of predefined macros in C header *fcntl.h*, or by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_DUPFD</td>
<td>Returns into <em>iargout</em> the lowest available unopened file descriptor greater than or equal to <em>iargin</em>. The new file descriptor refers to the same open file as <em>ifildes</em> and shares any locks. The system flag FD_CLOEXEC for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.</td>
</tr>
<tr>
<td>F_GETFD</td>
<td>Returns into <em>iargout</em> the value of system flag FD_CLOEXEC associated with <em>ifildes</em>. In this case, <em>iargin</em> is ignored.</td>
</tr>
<tr>
<td>F_SETFD</td>
<td>Sets or clears the system flag FD_CLOEXEC for file descriptor <em>ifildes</em>. The PXFEXEC family of functions will close all file descriptors with the FD_CLOEXEC flag set. The value for FD_CLOEXEC is obtained from argument <em>iargin</em>.</td>
</tr>
<tr>
<td>F_GETFL</td>
<td>Returns the file status flags for file descriptor <em>ifildes</em>. Unlike F_GETFD, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for PXFCONST or IPXFCONST, can be returned:</td>
</tr>
<tr>
<td>Constant</td>
<td>Action</td>
</tr>
<tr>
<td>----------</td>
<td>--------</td>
</tr>
<tr>
<td>O_APPEND</td>
<td>Specifies the file is opened in append mode.</td>
</tr>
<tr>
<td>O_NONBLOCK</td>
<td>Specifies when the file is opened, it does not block waiting for data to become available.</td>
</tr>
<tr>
<td>O_RDONLY</td>
<td>Specifies the file is opened for reading only.</td>
</tr>
<tr>
<td>O_RDWR</td>
<td>Specifies the file is opened for both reading and writing.</td>
</tr>
<tr>
<td>O_WRONLY</td>
<td>Specifies the file is opened for writing only.</td>
</tr>
</tbody>
</table>

**F_SETFL**
Sets the file status flags from `iargin` for file descriptor `ifildes`. Only O_APPEND or O_NONBLOCK flags can be modified. In this case, `iargout` is ignored.

**F_GETLK**
Gets information about a lock. Argument `iargin` must be a handle of structure `flock`. This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle `iargin`. If there are no locks in place that would prevent the lock from being locked, field `l_type` in the structure is set to the value of the constant with symbolic name `F_UNLCK`.

**F_SETLK**
Sets or clears a lock. Argument `iargin` must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field `l_type`. If the lock is busy, an error is returned.

**F_SETLKW**
Sets or clears a lock, but causes the process to wait if the lock is busy. Argument `iargin` must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field `l_type`. If the lock is busy, PXFCNTL waits for an unlock.

**NOTE**
To get a handle for an instance of the `flock` structure, use `PXFSTRUCTCREATE` with the string ‘flock’ for the structure name.

**See Also**
PXFSTRUCTCREATE
IPXFCONST
PXFCNST
**PXFFDOPEN**

**POSIX Subroutine: Opens an external unit.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFDOPEN (ifildes, iunit, access, ierror)

*ifildes*  
(Input) INTEGER(4). The file descriptor of the opened file.

*iunit*  
(Input) INTEGER(4). The Fortran logical unit to connect to file descriptor *ifildes*.

*access*  
(Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Possible Values</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NEWLINE'</td>
<td>'YES' or 'NO'</td>
<td>I/O type</td>
<td>'YES'</td>
</tr>
<tr>
<td>'BLANK'</td>
<td>'NULL' or 'ZERO'</td>
<td>Interpretation of blanks</td>
<td>'NULL'</td>
</tr>
<tr>
<td>'STATUS'</td>
<td>'OLD', 'SCRATCH', or 'UNKNOWN'</td>
<td>File status at open</td>
<td>'UNKNOWN'</td>
</tr>
<tr>
<td>'FORM'</td>
<td>'FORMATTED' or 'UNFORMATTED'</td>
<td>Format type</td>
<td>'FORMATTED'</td>
</tr>
</tbody>
</table>

Keywords should be separated from their values by the equals ('=') character; for example:

```
call PXFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN', IERROR)
```

*ierror*  
(Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by *iunit* to a file descriptor *ifildes*. If unit is already connected to a file, the file should be closed before using PXFFDOPEN.

**NOTE**

On Windows* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

**See Also**

PXFPOSIXIO
**PXFFFLUSH**  
**POSIX Subroutine:** Flushes a file directly to disk.

**Module**  
USE IFPOSIX

**Syntax**  
CALL PXFFFLUSH (lunit,ierror)

  - **lunit** (Input) INTEGER(4). A Fortran logical unit.
  - **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
The PXFFFLUSH subroutine writes any buffered output to the file connected to unit **lunit**.

**PXFFGETC**  
**POSIX Subroutine:** Reads a character from a file.

**Module**  
USE IFPOSIX

**Syntax**  
CALL PXFFGETC (lunit,char,ierror)

  - **lunit** (Input) INTEGER(4). A Fortran logical unit.
  - **char** (Input) Character. The character to be read.
  - **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
The PXFFGETC subroutine reads a character from a file connected to unit **lunit**.

**See Also**  
PXFFPUTC

**PXFFILENO**  
**POSIX Subroutine:** Returns the file descriptor associated with a specified unit.

**Module**  
USE IFPOSIX

**Syntax**  
CALL PXFFILENO (lunit,fd,ierror)

  - **lunit** (Input) INTEGER(4). A Fortran logical unit.
  - **fd** (Output) INTEGER(4). The returned file descriptor.
**ierror**

(Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code. Possible error codes are:

- **EINVAL**: `lunit` is not an open unit.
- **EBADF**: `lunit` is not connected with a file descriptor.

The PXFFILENO subroutine returns in `fd` the file descriptor associated with `lunit`.

---

**NOTE**

On Windows* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

---

**NOTE**

The file-descriptor used by POSIX is not the same as the corresponding file handle used by Windows, so it does not have the same value.

---

**See Also**

PXFPOSIXIO

**PXFFORK (L*X, M*X)**

**POSIX Subroutine**: Creates a child process that differs from the parent process only in its PID.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFFORK (ipid, ierror)
```

- **ipid**
  
  (Output) INTEGER(4). The returned PID of the new child process.

- **ierror**

  (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent’s thread of execution, and a zero is returned in the child’s thread of execution. Otherwise, a -1 is returned in the parent’s context and no child process is created.

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierr, ipid_ret, istat_ret
print *, " the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *, " I am a child process"
end if
```

Language Reference

1891
print *," My child's pid is", IPID_RET
call PXGETPPID(IPID_RET,IERROR)
print *," The pid of my parent is",IPID_RET
print *," Now I have exited with code 0xABCD"
call PXEXIT(Z'ABCD')

else
    print *," I am a parent process"
    print *," My parent pid is", IPID_RET
    print *," I am creating the process with pid", IPID
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The pid of my parent is", IPID_RET
    print *," Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The child with pid ", IPID_RET," has exited"
    if( PXFWIFEXITED(ISTAT) ) then
        print *, " The child exited normally"
        istrat_ret = PXFWEXITSTATUS(ISTAT)
        print 10," The low byte of the child exit code is", istrat_ret
    end if
end if

10 FORMAT (A,Z)
end program

IPXWEXITSTATUS

PXFFPATHCONF

POSIX Subroutine: Gets the value for a configuration option of an opened file.

Module
USE IFPOSIX

Syntax
CALL PXFFPATHCONF (ifildes, name, ival, ierror)

ifildes (Input) INTEGER(4). The file descriptor of the opened file.
name (Input) INTEGER(4). The configurable option.
ival (Output) INTEGER(4). The value of the configurable option.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor ifildes.

The configuration option, defined in name, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If ifildes refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>Constant</td>
<td>Action</td>
</tr>
<tr>
<td>--------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_PC_MAX_CANON¹</td>
<td>Returns the maximum length of a formatted input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT¹</td>
<td>Returns the maximum length of an input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in ifildes that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when ifildes is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the file descriptor ifildes must refer to a pipe or FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED¹</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If ifildes refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC¹</td>
<td>Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE¹</td>
<td>Returns nonzero if special character processing can be disabled; the file descriptor ifildes must refer to a terminal.</td>
</tr>
</tbody>
</table>

¹L*X, M*X

On Linux* and macOS* systems, the corresponding macros are defined in <unistd.h>. The values for name can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in <unistd.h>. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>_POSIX_PATH_MAX</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>_POSIX_CHOWN_RESTRICTED</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NO_TRUNC</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
</tbody>
</table>

IPXFCONST
PXFCONST
PXFPATHCONF
**PXFFPUTC**

**POSIX Subroutine:** Writes a character to a file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFPUTC (lunit, char, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **char** (Input) Character. The character to be written.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit **lunit**.

**See Also**

PXFFGETC

**PXFFSEEK**

**POSIX Subroutine:** Modifies a file position.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFSEEK (lunit, ioffset, iwhence, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **ioffset** (Input) INTEGER(4). The number of bytes away from **iwhence** to place the pointer.
- **iwhence** (Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in stdio.h):
  - SEEK_SET = 0 Offset from the beginning of the file.
  - SEEK_CUR = 1 Offset from the current position of the file pointer.
  - SEEK_END = 2 Offset from the end of the file.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code. Possible error codes are:

- EINVAL: No file is connected to **lunit**, **iwhence** is not a proper value, or the resulting offset is invalid.
- ESPIPE: **lunit** is a pipe or FIFO.
- EEND: The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit **lunit**.
PXFFSTAT

**POSIX Subroutine:** Gets a file's status information.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFSTAT (ifildes, jstat, ierror)

*ifildes*  
(Input) INTEGER(4). The file descriptor for an opened file.

*jstat*  
(Input) INTEGER(4). A handle of structure *stat*.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with *ifildes* into the structure associated with handle *jstat*.

**NOTE**
To get a handle for an instance of the *stat* structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

**See Also**
PXFSTRUCTCREATE

PXFFTELL

**POSIX Subroutine:** Returns the relative position in bytes from the beginning of the file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFTELL (lunit, ioffset, ierror)

*lunit*  
(Input) INTEGER(4). A Fortran logical unit.

*ioffset*  
(Output) INTEGER(4). The returned relative position in bytes from the beginning of the file.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFGETARG

**POSIX Subroutine:** Gets the specified command-line argument.
Module
USE IFPOSIX

Syntax
CALL PXFGETARG (argnum, str, istr, ierror)

argnum (Input) INTEGER(4). The number of the command-line argument.
str (Output) Character. The returned string value.
istr (Output) INTEGER(4). The length of the returned string; it is zero if an error occurs.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFGETARG subroutine places the command-line argument with number argnum into character string str. If argnum is equal to zero, the value of the argument returned is the command name of the executable file.

See Also
IPXFARGC

PXFGETC

POSIX Subroutine: Reads a character from standard input unit 5.

Module
USE IFPOSIX

Syntax
CALL PXFGETC (nextcar, ierror)

nextcar (Output) Character. The returned character that was read.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also
PXFPUTC

PXFGETCWD

POSIX Subroutine: Returns the path of the current working directory.

Module
USE IFPOSIX

Syntax
CALL PXFGETCWD (buf, ilen, ierror)
buf (Output) Character. The returned pathname of the current working directory.

ilen (Output) INTEGER(4). The length of the returned pathname.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of buf is insufficient.

**PXGETID (L*X, M*X)**

**POSIX Subroutine:** Gets the effective group ID of the current process.

**Module**
USE IFPOSIX

**Syntax**
CALL PXGETID (i egid,i error)

iegid (Output) INTEGER(4). The returned effective group ID.

ierror (Output) INTEGER(4). The error status.

**Description**
If successful, ierror is set to zero; otherwise, an error code.
The effective ID corresponds to the set ID bit on the file being executed.

**PXGETENV**

**POSIX Subroutine:** Gets the setting of an environment variable.

**Module**
USE IFPOSIX

**Syntax**
CALL PXGETENV (name,lenname,value,lenval,ierror)

name (Input) Character. The name of the environment variable.

lenname (Input) INTEGER(4). The length of name.

value (Output) Character. The returned value of the environment variable.

lenval (Output) INTEGER(4). The returned length of value. If an error occurs, it returns zero.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**See Also**
PXGETENV
PXGETEUID (L*X, M*X)

**POSIX Subroutine:** Gets the effective user ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXGETEUID (ieuid, ierror)
```

- **ieuid** (Output) INTEGER(4). The returned effective user ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

PXGETGID (L*X, M*X)

**POSIX Subroutine:** Gets the real group ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXGETGID (igid, ierror)
```

- **igid** (Output) INTEGER(4). The returned real group ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

**Example**

See the example in PXGETGROUPS

**See Also**

PXFSETGID

PXGETGRGID (L*X, M*X)

**POSIX Subroutine:** Gets group information for the specified GID.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXGETGRGID (jgid, jgroup, ierror)
```

- **jgid** (Output) INTEGER(4). The ID of the group.
- **jgroup** (Output) INTEGER(4). The group name.
- **ierror** (Output) INTEGER(4). The error status.
**PXGETGRGID (L*X, M*X)**

**POSIX Subroutine:** Gets group information for the named group.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGGETGRGID (jgid, jgroup, ierror)

- **jgid** (Input) INTEGER(4). The group ID to retrieve information about.
- **jgroup** (Input) INTEGER(4). A handle of structure group.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is not changed; otherwise, an error code.

The PXGETGRGID subroutine stores the group information from `/etc/group` for the entry that matches the group GID `jgid` in the structure associated with handle `jgroup`.

**NOTE**

To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

**Example**

See the example in PXFGETGROUPS

**See Also**

PXFSTRUCTCREATE

PXFGETGRNAM (L*X, M*X)

**POSIX Subroutine:** Gets group information for the named group.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGGETGRNAM (name, ilen, jgroup, ierror)

- **name** (Input) Character. The name of the group to retrieve information about.
- **ilen** (Input) INTEGER(4). The length of the name string.
- **jgroup** (Input) INTEGER(4). A handle of structure group.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is not changed; otherwise, an error code.

The PXGETGRNAM subroutine stores the group information from `/etc/group` for the entry that matches the group name `name` in the structure associated with handle `jgroup`.

**NOTE**

To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

**See Also**

PXFSTRUCTCREATE
PXFGETGROUPS (L*X, M*X)

POSIX Subroutine: Gets supplementary group IDs.

Module
USE IFPOSIX

Syntax
CALL PXFGETGROUPS (igidsetsize, igrouplist, ngroups, ierror)

igidsetsize (Input) INTEGER(4). The number of elements in the igrouplist array.

igrouplist (Output) INTEGER(4). The array that has the returned supplementary group IDs.

ngroups (Output) INTEGER(4). The total number of supplementary group IDs for the process.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFGETGROUPS subroutine returns, up to size igidsetsize, the supplementary group IDs in array igrouplist. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

Example

program test5
  use ifposix
  implicit none
  integer(4) number_of_groups, ierror, isize, i,igid
  integer(4) , allocatable, dimension(:):: igrouplist
  integer(JHANDLE_SIZE) jgroup

  ! Get total number of groups in system
  ! call PXFGETGROUPS with 0
  call PXFGETGROUPS(0, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) STOP 'Error: first call of PXFGETGROUPS fails'
  print *," The number of groups in system ", number_of_groups

  ! Get Group IDs
  isize = number_of_groups
  ALLOCATE( igrouplist(isize))
  call PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) then
    DEALLOCATE(igrouplist)
    STOP 'Error: first call of PXFGETGROUPS fails'
  end if

  print *," Create an instance for structure 'group' ">
  call PXFSTRUCTCREATE("group",jgroup, ierror)
  if(ierror.NE.0) then
    DEALLOCATE(igrouplist)
    STOP 'Error: PXFSTRUCTCREATE failed to create an instance of group'
  end if
do i=1, number_of_groups

  call PXFSTRUCTFREE(jgroup, ierror)
  print *, 'Error: PXFGETGRGID failed for gid=', igid
  STOP 'Abnormal termination'
end if

call PRINT_GROUP_INFO(jgroup)
DEALLOCATE(igrouplist)
call PXFSTRUCTFREE(jgroup, ierror)
print *, ' Program will normal terminated'
call PXFEXIT(0)
end

PXFGETLOGIN

POSIX Subroutine: Gets the name of the user.

Module

USE IFPOSIX

Syntax

CALL PXFGETLOGIN (s,ilen,ierror)

s (Output) Character. The returned user name.
ilen (Output) INTEGER(4). The length of the string stored in s.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFGETPGRP (L*X, M*X)

POSIX Subroutine: Gets the process group ID of the calling process.
Module
USE IFPOSIX

Syntax
CALL PXFGETPGRP (ipgrp,ierror)

ipgrp (Output) INTEGER(4). The returned process group ID.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Each process group is a member of a session and each process is a member of the session in which its process group is a member.

PXFGETPID

POSIX Subroutine: Gets the process ID of the calling process.

Module
USE IFPOSIX

Syntax
CALL PXFGETPID (ipid,ierror)

ipid (Output) INTEGER(4). The returned process ID.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid", IPID
   print *," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
   print *, " The child exited normally"
   istat_ret = IPXFEXITSTATUS(ISTAT)
   print 10," The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

**PXGETPPID**

**POSIX Subroutine**: Gets the process ID of the parent of the calling process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETPPID (ippid, ierror)

ippid (Output) INTEGER(4). The returned process ID.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
call PXGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid ", IPID
   print *," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
if( PXFWEXITED(ISTAT) ) then
   print *, " The child exited normally"
   istat_ret = IPXFWEXITSTATUS(ISTAT)
   print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program
```

**PXGETPWNAM (L*X, M*X)**

**POSIX Subroutine**: Gets password information for a specified name.
Module
USE IFPOSIX

Syntax
CALL PXFGETPWNAM (name, ilen, jpasswd, ierror)

name (Input) Character. The login name of the user to retrieve information about. For example, a login name might be "jsmith", while the actual name is "John Smith".

ilen (Input) INTEGER(4). The length of the name string.

jpasswd (Input) INTEGER(4). A handle of structure compnam.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is not changed; otherwise, an error code.

The PXFGETPWNAM subroutine stores the user information from /etc/passwd for the entry that matches the user name name in the structure associated with handle jpasswd.

NOTE
To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

See Also
PXFSTRUCTCREATE

PXFGETPWUID (L*X, M*X)

POSIX Subroutine: Gets password information for a specified UID.

Module
USE IFPOSIX

Syntax
CALL PXFGETPWUID (iuid, jpasswd, ierror)

iuid (Input) INTEGER(4). The user ID to retrieve information about.

jpasswd (Output) INTEGER(4). A handle of structure compnam.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFGETPWUID subroutine stores the user information from /etc/passwd for the entry that matches the user ID iuid in the structure associated with handle jpasswd.

NOTE
To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.
See Also

PXFSTRUCTCREATE

PXFGETSUBHANDLE

**POSIX Subroutine:** Returns a handle for a subroutine.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETSUBHANDLE (sub, jhandle1, ierror)

*sub*  
(Input) The Fortran subroutine to get a handle for.

*jhandle1*  
(Output) INTEGER(4). The returned handle for the subroutine.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**NOTE**

The argument *sub* cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

PXFGETUID (L*X, M*X)

**POSIX Subroutine:** Gets the real user ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETUID (iuid, ierror)

*iuid*  
(Output) INTEGER(4). The returned real user ID.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

See Also

PXFSETUID

PXFISATTY (L*X, M*X)

**POSIX Subroutine:** Tests whether a file descriptor is connected to a terminal.
Module
USE IFPOSIX

Syntax
CALL PXFISATTY (ifildes, isatty, ierr)

ifildes        (Input) INTEGER(4). The file descriptor.
isatty         (Output) LOGICAL(4). The returned value.
ierror         (Output) INTEGER(4). The error status.

If successful, ierr is set to zero; otherwise, an error code.
If file descriptor ifildes is open and connected to a terminal, isatty returns .TRUE.; otherwise, .FALSE..

See Also
PXFOPEN

PXFISBLK
POSIX Function: Tests for a block special file.

Module
USE IFPOSIX

Syntax
result = PXFISBLK (m)

m              (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a block special file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFISCHR

PXFISCHR
POSIX Function: Tests for a character file.

Module
USE IFPOSIX

Syntax
result = PXFISCHR (m)

m              (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a character file, the result value is .TRUE.; otherwise, .FALSE..
See Also
PXFISBLK

PXFISCONST

**POSIX Function:** Tests whether a string is a valid constant name.

**Module**
USE IFPOSIX

**Syntax**
```
result = PXFISCONST (s)
```

*s* (Input) Character. The name of the constant to test.

**Results**
The result type is logical. The PXFISCONST function confirms whether the argument is a valid constant name that can be passed to functions PXFCONST and IPXFCONST. It returns .TRUE. only if IPXFCONST will return a valid value for name s.

See Also
IPXFCONST
PXFCONST

PXFISDIR

**POSIX Function:** Tests whether a file is a directory.

**Module**
USE IFPOSIX

**Syntax**
```
result = PXFISDIR (m)
```

*m* (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

**Results**
The result type is logical. If the file is a directory, the result value is .TRUE.; otherwise, .FALSE..

PXFISFIFO

**POSIX Function:** Tests whether a file is a special FIFO file.

**Module**
USE IFPOSIX

**Syntax**
```
result = PXFISFIFO (m)
```
m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical.
The PXFISFIFO function tests whether the file is a special FIFO file created by PXFMKFIFO. If the file is a special FIFO file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFMKFIFO
PXFISREG

PXFISREG
POSIX Function: Tests whether a file is a regular file.

Module
USE IFPOSIX

Syntax
result = PXFISREG (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a regular file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFMKFIFO
PXFISFIFO

PXFKILL
POSIX Subroutine: Sends a signal to a specified process.

Module
USE IFPOSIX

Syntax
CALL PXFKILL (ipid, isig, ierror)

ipid (Input) INTEGER(4). The process to kill. It is determined by one of the following values:

- > 0  Kills the specific process.
- < 0  Kills all processes in the group.
- == 0  Kills all processes in the group except special processes.
Kills all processes.

- **`isig`** (Input) INTEGER(4). The value of the signal to be sent.
- **`ierror`** (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFKILL subroutine sends a signal with value `isig` to a specified process. On Windows* systems, only the `ipid` for the current process can be used.

**PXFLINK (L*X, M*X)**

**POSIX Subroutine:** Creates a link to a file or a directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFLINK (existing, lenexist, new, lennew, ierror)

- **`existing`** (Input) Character. The path to the file or directory that you want to link to.
- **`lenexist`** (Input) INTEGER(4). The length of the `existing` string.
- **`new`** (Input) Character. The name of the new link file.
- **`lennew`** (Input) INTEGER(4). The length of the `new` string.
- **`ierror`** (Output) INTEGER(4). The error status.

If successful, `ierror` is not changed; otherwise, an error code.

The PXFLINK subroutine creates a new link (also known as a hard link) to an existing file or directory.

This new name can be used exactly as the old one for any operation. Both names refer to the same entity (so they have the same permissions and ownership) and it is impossible to tell which name was the "original".

**PXFLOCALTIME**

**POSIX Subroutine:** Converts a given elapsed time in seconds to local time.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFLOCALTIME (isecnds, iatime, ierror)

- **`isecnds`** (Input) INTEGER(4). The elapsed time in seconds since 00:00:00 Greenwich Mean Time, January 1, 1970.
**iatime**

(Output) INTEGER(4). One-dimensional array with 9 elements containing numeric time data. The elements of *iatime* are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>iatime(1)</td>
<td>Seconds (0-59)</td>
</tr>
<tr>
<td>iatime(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>iatime(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>iatime(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>iatime(5)</td>
<td>Month (1-12)</td>
</tr>
<tr>
<td>iatime(6)</td>
<td>Gregorian year (for example, 1990)</td>
</tr>
<tr>
<td>iatime(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>iatime(8)</td>
<td>Day of year (1-366)</td>
</tr>
<tr>
<td>iatime(9)</td>
<td>Daylight savings flag (1 if daylight savings time is in effect; otherwise, 0)</td>
</tr>
</tbody>
</table>

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFLOCALTIME subroutine converts the time (in seconds since epoch) in the *isecnds* argument to the local date and time as described by the array *iatime* above.

**PXFLSEEK**

**POSIX Subroutine:** Positions a file a specified distance in bytes.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFLSEEK (ifildes, ioffset, iwhence, iposition, ierror)

*ifildes*  
(Input) INTEGER(4). A file descriptor.

*ioffset*  
(Input) INTEGER(4). The number of bytes to move.

*iwhence*  
(Input) INTEGER(4). The starting position. The value must be one of the following:

- SEEK_SET = 0  
  Sets the offset to *ioffset* bytes.
- SEEK_CUR = 1  
  Sets the offset to its current location plus *ioffset* bytes.
Sets the offset to the size of the file plus \textit{ioffset} bytes.

\texttt{iposition} (Output) INTEGER(4). The ending position; the resulting offset location as measured in bytes from the beginning of the file.

\texttt{ierror} (Output) INTEGER(4). The error status.

If successful, \texttt{ierror} is set to zero; otherwise, an error code.

The PXFLSEEK subroutine repositions the offset of file descriptor \texttt{ifildes} to the argument \texttt{ioffset} according to the value of argument \texttt{iwhence}.

PXFLSEEK allows the file offset to be set beyond the end of the existing end-of-file. If data is later written at this point, subsequent reads of the data in the gap return bytes of zeros (until data is actually written into the gap).

\textbf{PXFMKDIR}

\textit{POSIX Subroutine: Creates a new directory.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFMKDIR (\texttt{path}, \texttt{ilen}, \texttt{imode}, \texttt{ierror})

\texttt{path} (Input) Character. The path for the new directory.

\texttt{ilen} (Input) INTEGER(4). The length of \texttt{path} string.

\texttt{imode} (L*X only) (Input) INTEGER(4). The mode mask. Octal file-access mode.

\texttt{ierror} (Output) INTEGER(4). The error status.

If successful, \texttt{ierror} is set to zero; otherwise, an error code.

\textbf{See Also}

PXFRMDIR
PXFCHDIR

\textbf{PXFMKFIFO (L*X, M*X)}

\textit{POSIX Subroutine: Creates a new FIFO.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFMKFIFO (\texttt{path}, \texttt{ilen}, \texttt{imode}, \texttt{ierror})

\texttt{path} (Input) Character. The path for the new FIFO.

\texttt{ilen} (Input) INTEGER(4). The length of \texttt{path} string.
**imode**  
(Input) INTEGER(4). The mode mask; specifies the FIFO’s permissions. Octal file-access mode.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFMKFIFO subroutine creates a FIFO special file with name *path*. A FIFO special file is similar to a pipe, except that it is created in a different way. Once a FIFO special file is created, any process can open it for reading or writing in the same way as an ordinary file.

However, the FIFO file has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks it until some other process opens the same FIFO for writing, and vice versa.

**See Also**
PXFSIFIFO

**PXFOPEN**

**POSIX Subroutine: Opens or creates a file.**

**Module**
USE IFPOSIX

**Syntax**
CALL PXFOPEN (path, ilen, iopenflag, imode, ifildes, ierror)

**path** 
(Input) Character. The path of the file to be opened or created.

**ilen** 
(Input) INTEGER(4). The length of *path* string.

**iopenflag** 
(Input) INTEGER(4). The flags for the file. (For possible constant names that can be passed to PXFCONST or IPXFCONST, see below.)

**imode** 
(Input) INTEGER(4). The permissions for a new file. This argument should always be specified when *iopenflag*=*O_CREAT*; otherwise, it is ignored. (For possible permissions, see below.)

**ifildes** 
(Output) INTEGER(4). The returned file descriptor for the opened or created file.

**ierror** 
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

For *iopenflag*, you should specify one of the following constant values:

- **O_RDONLY** (read only)
- **O_WRONLY** (write only)
- **O_RDWR** (read and write)

In addition, you can also specify one of the following constant values by using a bitwise inclusive OR (IOR):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>O_CREAT</strong></td>
<td>Creates a file if the file does not exist.</td>
</tr>
</tbody>
</table>

Intel® Fortran Compiler 19.0 Developer Guide and Reference

1912
<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>O_EXCL</td>
<td>When used with O_CREAT, it causes the open to fail if the file already exists. In this case, a symbolic link exists, regardless of where it points to.</td>
</tr>
<tr>
<td>O_NOCTTY</td>
<td>If path refers to a terminal device, it prevents it from becoming the process's controlling terminal even if the process does not have one.</td>
</tr>
<tr>
<td>O_TRUNC</td>
<td>If the file already exists, it is a regular file, and imode allows writing (its value is O_RDWR or O_WRONLY), it causes the file to be truncated to length 0.</td>
</tr>
<tr>
<td>O_APPEND</td>
<td>Opens the file in append mode. Before each write, the file pointer is positioned at the end of the file, as if with PXFLSEEK.</td>
</tr>
<tr>
<td>O_NONBLOCK (or O_NDELAY)</td>
<td>When possible, opens the file in non-blocking mode. Neither the open nor any subsequent operations on the file descriptor that is returned will cause the calling process to wait. This mode need not have any effect on files other than FIFOs.</td>
</tr>
<tr>
<td>O_SYNC</td>
<td>Opens the file for synchronous I/O. Any writes on the resulting file descriptor will block the calling process until the data has been physically written to the underlying hardware.</td>
</tr>
<tr>
<td>O_NOFOLLOW</td>
<td>If path is a symbolic link, it causes the open to fail.</td>
</tr>
<tr>
<td>O_DIRECTORY</td>
<td>If path is not a directory, it causes the open to fail.</td>
</tr>
<tr>
<td>O_LARGEFILE</td>
<td>On 32-bit systems that support the Large Files System, it allows files whose sizes cannot be represented in 31 bits to be opened.</td>
</tr>
<tr>
<td>O_BINARY</td>
<td>Opens the file in binary (untranslated) mode.</td>
</tr>
<tr>
<td>O_SHORT_LIVED</td>
<td>Creates the file as temporary. If possible, it does not flush to the disk.</td>
</tr>
<tr>
<td>O_TEMPORARY</td>
<td>Creates the file as temporary. The file is deleted when last file handle is closed.</td>
</tr>
<tr>
<td>O_RANDOM</td>
<td>Specifies primarily random access from the disk.</td>
</tr>
<tr>
<td>O_SEQUENTIAL</td>
<td>Specifies primarily sequential access from the disk.</td>
</tr>
<tr>
<td>O_TEXT</td>
<td>Opens the file in text (translated) mode.</td>
</tr>
</tbody>
</table>

1L*X only  
2W*S  
3For more information, see "Text and Binary Modes" in the Visual C++* programmer's guide.
Argument *imode* specifies the permissions to use if a new file is created. The permissions only apply to future accesses of the newly created file. The value for *imode* can be any of the following constant values (which can be obtained by using PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_IRWXU</td>
<td>00700 user (file owner) has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRUSR, S_IREAD</td>
<td>00400 user has read permission.</td>
</tr>
<tr>
<td>S_IWUSR, S_IWRITE</td>
<td>00200 user has write permission.</td>
</tr>
<tr>
<td>S_IXUSR, S_IEXEC</td>
<td>00100 user has execute permission.</td>
</tr>
<tr>
<td>S_IRWXG¹</td>
<td>00070 group has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRGRP¹</td>
<td>00040 group has read permission.</td>
</tr>
<tr>
<td>S_IWGRP¹</td>
<td>00020 group has write permission.</td>
</tr>
<tr>
<td>S_IXGRP¹</td>
<td>00010 group has execute permission.</td>
</tr>
<tr>
<td>S_IRWXO¹</td>
<td>00007 others have read, write and execute permission.</td>
</tr>
<tr>
<td>S_IROTH¹</td>
<td>00004 others have read permission.</td>
</tr>
<tr>
<td>S_IWOTH¹</td>
<td>00002 others have write permission.</td>
</tr>
<tr>
<td>S_IXOTH¹</td>
<td>00001 others have execute permission.</td>
</tr>
</tbody>
</table>

¹L*X only

**Example**

The following call opens a file for writing only and if the file does not exist, it is created:

```fortran
call PXFOPEN( "OPEN.OUT", &
  8, &
  IOR( IPXFCONST(O_WRONLY), IPXFCONST(O_CREAT) ), &
  IOR( IPXFCONST(S_IREAD), IPXFCONST(S_IWRITE) ) )
```

PXFCLOSE
IPXFCONST
PXFCONST

**PXFOPENDIR**

**POSIX Subroutine:** Opens a directory and associates a stream with it.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFOPENDIR (dirname, lendirname, opendirid, ierror)
**dirname**

(Input) Character. The directory name.

**lendirname**

(Input) INTEGER(4). The length of *dirname* string.

**opendirid**

(Output) INTEGER(4). The returned ID for the directory.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

This subroutine opens a directory pointed to by the *dirname* argument and returns the ID of the directory into *opendirid*. After the call, this ID can be used by functions PXFREADDR, PXFREWINDDIR, PXFCLOSEDIR.

**See Also**

PXFCLOSEDIR
PXFREADDR
PXFREADDR

**PXFPATHCONF**

**POSIX Subroutine:** Gets the value for a configuration option of an opened file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPATHCONF (path, ien, name, ival, ierror)

**path**

(Input) Character. The path to the opened file.

**ilen**

(Input) INTEGER(4). The length of *path*.

**name**

(Input) INTEGER(4). The configurable option.

**ival**

(Input) INTEGER(4). The value of the configurable option.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPATHCONF subroutine gets a value for the configuration option named for the opened file with path *path*.

The configuration option, defined in *name*, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If <em>path</em> refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON1</td>
<td>Returns the maximum length of a formatted input line; the <em>path</em> must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT1</td>
<td>Returns the maximum length of an input line; the <em>path</em> must refer to a terminal.</td>
</tr>
<tr>
<td>Constant</td>
<td>Action</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in path that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when path is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the path must refer to a FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If path refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>Returns nonzero if special character processing can be disabled; the path must refer to a terminal.</td>
</tr>
</tbody>
</table>

\(^1\)L*X, M*X

On Linux* and macOS* systems, the corresponding macros are defined in <unistd.h>. The values for name can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in <unistd.h>. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>

PXFFPATHCONF

**PXFPause**

**POSIX Subroutine:** Suspends process execution.

**Module**

USE IFPOSIX
**Syntax**

CALL PXFPAUSE (ierror)

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPAUSE subroutine causes the invoking process (or thread) to sleep until a signal is received that either terminates it or causes it to call a signal-catching function.

**PXFPIPE (L*X, M*X)**

**POSIX Subroutine:** Creates a communications pipe between two processes.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPIPE (ireadfd,iwritefd,ierror)

*ireadfd* (Output) INTEGER(4). The file descriptor for reading.

*iwritefd* (Output) INTEGER(4). The file descriptor for writing.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPIPE subroutine returns a pair of file descriptors, pointing to a pipe inode, and places them into *ireadfd* for reading and into *iwritefd* for writing.

**PXFPOSIXIO**

**POSIX Subroutine:** Sets the current value of the POSIX I/O flag.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPOSIXIO (new,old,ierror)

*new* (Input) INTEGER(4). The new value for the POSIX I/O flag.

*old* (Output) INTEGER(4). The previous value of the POSIX I/O flag.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

This subroutine sets the current value of the Fortran POSIX I/O flag and returns the previous value of the flag. The initial state of the POSIX I/O flag is unspecified.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is 1, the unit is accessed as if the records are newline delimited, even if the file does not contain records that are delimited by a new line character.
If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is zero, a connection to a file descriptor is not assumed and the records in the file are not required to be accessed as if they are newline delimited.

**PXFPUTC**

*POSIX Subroutine: Outputs a character to logical unit 6 (stdout).*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPUTC (ch, ierror)

- **ch** (Input) Character. The character to be written.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

**See Also**

PXFGETC

**PXREAD**

*POSIX Subroutine: Reads from a file.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREAD (ifildes, buf, nbyte, nread, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor of the file to be read from.
- **buf** (Output) Character. The buffer that stores the data read from the file.
- **nbyte** (Input) INTEGER(4). The number of bytes to read.
- **nread** (Output) INTEGER(4). The number of bytes that were read.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The **PXFREAD** subroutine reads *nbyte* bytes from the file specified by *ifildes* into memory in *buf*. The subroutine returns the total number of bytes read into *nread*. If no error occurs, the value of *nread* will equal the value of *nbyte*.

**See Also**

PXFWRITE
**PXFREADDR**

**POSIX Subroutine:** Reads the current directory entry.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREADDR (idirid, jdirent, ierror)

- **idirid** (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
- **jdirent** (Output) INTEGER(4). A handle of structure dirent.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFREADDR subroutine reads the entry of the directory associated with idirid into the structure associated with handle jdirent.

**NOTE**

To get a handle for an instance of the dirent structure, use PXFSTRUCTCREATE with the string 'dirent' for the structure name.

**See Also**

PXFOPENDIR
PXFREWINDDIR

**PXFRENAME**

**POSIX Subroutine:** Changes the name of a file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFRENAME (old, lenold, new, lennew, ierror)

- **old** (Input) Character. The name of the file to be renamed.
- **lenold** (Input) INTEGER(4). The length of old string.
- **new** (Input) Character. The new file name.
- **lennew** (Input) INTEGER(4). The length of new string.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
PXFREWINDDIR

**POSIX Subroutine:** Resets the position of the stream to the beginning of the directory.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFREWINDDIR (idirid, ierror)

- **idirid** (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFRMDIR

**POSIX Subroutine:** Removes a directory.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFRMDIR (path, ilen, ierror)

- **path** (Input) Character. The directory to be removed. It must be empty.
- **ilen** (Input) INTEGER(4). The length of *path* string.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**See Also**
PXFMKDIR
PXFCCHDIR

PXFSETENV

**POSIX Subroutine:** Adds a new environment variable or sets the value of an environment variable.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)

- **name** (Input) Character. The name of the environment variable.
- **lenname** (Input) INTEGER(4). The length of *name*.
new
(Input) Character. The value of the environment variable.

lennew
(Input) INTEGER(4). The length of new.

ioverwrite
(Input) INTEGER(4). A flag indicating whether to change the value of the environment variable if it exists.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

If name does not exist, PXFSETENV adds it with value new.

If name exists, PXFSETENV sets its value to new if ioverwrite is a nonzero number. If ioverwrite is zero, the value of name is not changed.

If lennew is equal to zero, PXFSETENV sets the value of the environment variable to a string equal to new after removing any leading or trailing blanks.

Example

```
program test2
  use ifposix
  character*10 name, new
  integer lenname, lennew, ioverwrite, ierror
  name = "FOR_NEW"
  lenname = 7
  new = "ON"
  lennew = 2
  ioverwrite = 1
  CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
  print *, "name= ", name
  print *, "lenname= ", lenname
  print *, "new= ", lennew
  print *, "lennew= ", lenname
  print *, "ierror= ", ierror
end
```

See Also
PXFGETENV

PXFSETGID (L*X, M*X)

POSIX Subroutine: Sets the effective group ID of the current process.

Module
USE IFPOSIX

Syntax
CALL PXFSETGID (igid, ierror)

igid
(Input) INTEGER(4). The group ID.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
If the caller is the superuser, the real and saved group ID's are also set. This feature allows a program other than root to drop all of its group privileges, do some un-privileged work, and then re-engage the original effective group ID in a secure manner.

**Caution**
If the user is root then special care must be taken. PXFSETGID checks the effective gid of the caller. If it is the superuser, all process-related group ID's are set to gid. After this has occurred, it is impossible for the program to regain root privileges.

See Also
PXFGETGID

**PXFSETPGID (L*X, M*X)**

*POSIX Subroutine: Sets the process group ID.*

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSETPGID (ipid,ipgid,ierror)

  *ipid*  
  (Input) INTEGER(4). The process group ID to change.

  *ipgid*  
  (Input) INTEGER(4). The new process group ID.

  *ierror*  
  (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETPGID subroutine sets the process group ID of the process specified by *ipid* to *ipgid*.

If *ipid* is zero, the process ID of the current process is used. If *ipgid* is zero, the process ID of the process specified by *ipid* is used.

PXFSETPGID can be used to move a process from one process group to another, but both process groups must be part of the same session. In this case, *ipgid* specifies an existing process group to be joined and the session ID of that group must match the session ID of the joining process.

**PXFSETSID (L*X, M*X)**

*POSIX Subroutine: Creates a session and sets the process group ID.*

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSETSID (isid,ierror)

  *isid*  
  (Output) INTEGER(4). The session ID.

**PXFSETUID (L*X, M*X)**

**POSIX Subroutine:** Sets the effective user ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSETUID (iuid, ierror)

- **iuid** (Output) INTEGER(4). The session ID.
- **ierror** (Output) INTEGER(4). The user status.

If successful, **ierror** is set to zero; otherwise, an error code.

If the effective user ID of the caller is root, the real and saved user ID's are also set. This feature allows a program other than root to drop all of its user privileges, do some un-privileged work, and then re-engage the original effective user ID in a secure manner.

**Caution**

If the user is root then special care must be taken. PXFSETUID checks the effective uid of the caller. If it is the superuser, all process-related user ID's are set to uid. After this has occurred, it is impossible for the program to regain root privileges.

**See Also**

PXGETUID

**PXFSIGACTION (L*X, M*X)**

**POSIX Subroutine:** Changes the action associated with a specific signal. It can also be used to examine the action of a signal.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGACTION (isig, jsigact, josigact, ierror)
isig

(Input) INTEGER(4). The signal number whose action should be changed.

jsigact

(Input) INTEGER(4). A handle of structure sigaction. Specifies the new action for signal isig.

josigact

(Output) INTEGER(4). A handle of structure sigaction. Stores the previous action for signal isig.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The signal specified in isig can be any valid signal except SIGKILL and SIGSTOP.

If jsigact is nonzero, the new action for signal isig is installed from the structure associated with handle jsigact. If josigact is nonzero, the previous action of the specified signal is saved in the structure associated with handle josigact where it can be examined.

NOTE
To get a handle for an instance of the sigaction structure, use PXFSTRUCTCREATE with the string 'sigaction' for the structure name.

See Also
PXFSTRUCTCREATE

PXFSIGADDSET (L*X, M*X)

POSIX Subroutine: Adds a signal to the signal set.

Module
USE IFPOSIX

Syntax
CALL PXFSIGADDSET (jsigset, isigno, ierror)

jsigset

(Input) INTEGER(4). A handle of structure sigset. This is the set to add the signal to.

isigno

(Input) INTEGER(4). The signal number to add to the set.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGADDSET subroutine adds signal number isigno to the set of signals associated with handle jsigset. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.
NOTE
To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGDELSSET
PXFSIGACTION

PXFSIGDELSSET (L*X, M*X)

*POSIX Subroutine:* Deletes a signal from the signal set.

Module
USE IFPOSIX

Syntax
CALL PXFSIGDELSSET (jsigset,isigno,ierror)

(jsigset) (Input) INTEGER(4). A handle of structure `sigset`. This is the set to delete the signal from.

(isigno) (Input) INTEGER(4). The signal number to delete from the set.

(ierror) (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFSIGDELSSET subroutine removes signal number `isigno` from the set of signals associated with handle `jsigset`. This set of signals is used by PXFSIGACTION as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows* systems, PXFSIGACTION ignores the field `sa_mask` in structure `sigaction`.

NOTE
To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGADDSET
PXFSIGACTION

PXFSIGEMPTYSET (L*X, M*X)

*POSIX Subroutine:* Empties a signal set.

Module
USE IFPOSIX

Syntax

CALL PXFSIGEMPTYSET (jsigset,isigno,ierror)

(jsigset) (Input) INTEGER(4). A handle of structure `sigset`. This is the set to delete the signal from.

(isigno) (Input) INTEGER(4). The signal number to delete from the set.

(ierror) (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFSIGEMPTYSET subroutine empties the set of signals associated with handle `jsigset`. This set of signals is used by PXFSIGACTION as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows* systems, PXFSIGACTION ignores the field `sa_mask` in structure `sigaction`.

NOTE
To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.
Syntax

CALL PXFSIGEMPTYSET (jsigset,ierror)

jsigset  (Input) INTEGER(4). A handle of structure sigset. This is the set to empty.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, nonzero.

The PXFSIGEMPTYSET subroutine initializes the signal set associated with handle jsigset to empty; all signals are excluded from the set. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGFILLSET
PXFSIGACTION

PXFSIGFILLSET (L*X, M*X)

POSIX Subroutine: Fills a signal set.

Module
USE IFPOSIX

Syntax

CALL PXFSIGFILLSET (jsigset,ierror)

jsigset  (Input) INTEGER(4). A handle of structure sigset. This is the set to fill.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGFILLSET subroutine initializes the signal set associated with handle jsigset to full; all signals are included into the set. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.
See Also
PXFSTRUCTCREATE
PXFSIGEMPTYSET
PXFSIGACTION

PXFSIGISMEMBER (L*X, M*X)

POSIX Subroutine: Tests whether a signal is a member of a signal set.

Module
USE IFPOSIX

Syntax
CALL PXFSIGISMEMBER (jsignset, isigno, ismember, ierror)

- jsignset (Input) INTEGER(4). A handle of structure sigset. This is the set the signal will be tested in.
- isigno (Input) INTEGER(4). The signal number to test for membership.
- ismember (Output) Logical. The returned result.
- ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGISMEMBER subroutine tests whether isigno is a member of the set associated with handle jsignset. If the signal is a member of the set, ismember is set to .TRUE.; otherwise, .FALSE.. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGACTION

PXFSIGPENDING (L*X, M*X)

POSIX Subroutine: Examines pending signals.

Module
USE IFPOSIX

Syntax
CALL PXFSIGPENDING (jsigset, ierror)

See Also
PXFSTRUCTCREATE
PXFSIGACTION
\textit{jsigset} \hspace{1cm} \text{(Input) INTEGER(4). A handle of structure \textit{sigaction}. The signals to examine.}

\textit{ierror} \hspace{1cm} \text{(Output) INTEGER(4). The error status.}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The \texttt{PXFSIGPENDING} subroutine is used to examine pending signals (ones that have been raised while blocked). The signal mask of the pending signals is stored in the signal set associated with handle \textit{jsigset}.

\textbf{PXFSIGPROCMASK (L*X, M*X)}

\textit{POSIX Subroutine: Changes the list of currently blocked signals.}

\textbf{Module}

\texttt{USE IFPOSIX}

\textbf{Syntax}

\texttt{CALL PXFSIGPROCMASK (ihow, jsigset, josigset, ierror)}

\begin{itemize}
  \item \textit{ihow} \hspace{1cm} \text{(Input) INTEGER(4). Defines the action for \textit{jsigset}.}
  \item \textit{jsigset} \hspace{1cm} \text{(Input) INTEGER(4). A handle of structure \textit{sigaction}. The signals to examine.}
  \item \textit{josigset} \hspace{1cm} \text{(Input) INTEGER(4). A handle of structure \textit{sigset}. Stores the previous mask of blocked signals.}
  \item \textit{ierror} \hspace{1cm} \text{(Output) INTEGER(4). The error status.}
\end{itemize}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The argument \textit{ihow} indicates the way in which the set is to be changed, and consists of one of the following constant names:

\begin{center}
\begin{tabular}{ll}
\textbf{Constant} & \textbf{Action} \\
SIG_BLOCK & The resulting set of blocked signals will be the union of the current signal set and the \textit{jsigset} signal set. \\
SIG_UNBLOCK & The resulting set of blocked signals will be the current set of blocked signals with the signals in \textit{jsigset} removed. It is legal to attempt to unblock a signal that is not blocked. \\
SIG_SETMASK & The resulting set of blocked signals will be the \textit{jsigset} signal set. \\
\end{tabular}
\end{center}

\textsuperscript{1}These names can be used in \texttt{PXFCONST} or \texttt{IPXFCONST}.

If \textit{josigset} is non-zero, the previous value of the signal mask is stored in the structure associated with handle \textit{josigset}.

\textbf{See Also}

  \item IPXFCONST
  \item PXFCONST
\end{itemize}

1928
PXFSIGSUSPEND (L*X, M*X)

*POSIX Subroutine:* Suspends the process until a signal is received.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSIGSUSPEND (jsigset, ierror)

`jsigset` (Input) INTEGER(4). A handle of structure sigset. Specifies a set of signals.

`ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

PXFSIGSUSPEND temporarily replaces the signal mask for the process with that given by the structure associated with the `jsigset` handle; it then suspends the process until a signal is received.

PXFSLEEP

*POSIX Subroutine:* Forces the process to sleep.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSLEEP (iseconds, isecleft, ierror)

`iseconds` (Input) INTEGER(4). The number of seconds to sleep.

`isecleft` (Output) INTEGER(4). The number of seconds left to sleep.

`ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFSLEEP subroutine forces the current process to sleep until seconds `iseconds` have elapsed or a signal arrives that cannot be ignored.

PXFSTAT

*POSIX Subroutine:* Gets a file's status information.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFSTAT (path, ilen, jstat, ierror)

`path` (Input) Character. The path to the file.
ilen (Input) INTEGER(4). The length of path string.

jstat (Input) INTEGER(4). A handle of structure stat.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSTAT subroutine puts the status information for the file specified by path into the structure associated with handle jstat.

NOTE
To get a handle for an instance of the stat structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

See Also
PXFSTRUCTCREATE

PXFSTRUCTCOPY
POSIX Subroutine: Copies the contents of one structure to another.

Module
USE IFPOSIX

Syntax
CALL PXFSTRUCTCOPY (structname, jhandle1, jhandle2, ierror)

structname (Input) Character. The name of the structure.

jhandle1 (Input) INTEGER(4). A handle to the structure to be copied.

jhandle2 (Input) INTEGER(4). A handle to the structure that will receive the copy.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Example
See the example in PXFSTRUCTCREATE

PXFSTRUCTCREATE
POSIX Subroutine: Creates an instance of the specified structure.

Module
USE IFPOSIX

Syntax
CALL PXFSTRUCTCREATE (structname, jhandle, ierror)
### structname

_(Input) Character. The name of the structure._

As for any character string, the name must be specified in single or double quotes; for example, the structure `sigaction` would be specified as 'sigaction'. For more information on available structures, see the table below.

### jhandle

_(Output) INTEGER(4). The handle of the newly-created structure._

### ierror

_(Output) INTEGER(4). The error status._

If successful, `ierror` is set to zero; otherwise, an error code.

If your application passes information to the system, you should call one of the PXF(type)SET subroutines. If your application needs to get information from the structure, you should call one of the PXF(type)GET subroutines.

The following table shows:
- The structures that are available in the Fortran POSIX library
- The fields within each structure
- The subroutines you must use to access the structure fields

¹L*X only

As for any character string, you must use single or double quotes when specifying a field name in a PXF(type)GET or PXF(type)SET subroutine. For example, field name sysname (in structure utsname) must be specified as 'sysname'.
Example

```fortran
program test4
  use ifposix
  implicit none
  integer(jhandle_size) jhandle1, jhandle2
  integer(4) ierror, ilen1

  print *, "Create a first instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname", jhandle1, ierror)
  if(ierror.NE.0) STOP 'Error: cannot create structure for jhandle1'

  print *, "Create a second instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname", jhandle2, ierror)
  if(ierror.NE.0) then
    call PXFSTRUCTFREE(jhandle1, ierror)
    STOP 'test failed - cannot create structure for jhandle2'
  end if

  print *, "Fill the structure associated with jhandle1 with arbitrary data"
  call PXFSTRSET(jhandle1, "sysname", "00000000000000", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component sysname for jhandle1')

  call PXFSTRSET(jhandle1, "Nodename", "11111111111111", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component nodename for jhandle1')

  call PXFSTRSET(jhandle1, "RELEASE", "22222222222222", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component release for jhandle1')

  call PXFSTRSET(jhandle1, "VERSION", "33333333333333", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component version for jhandle1')

  call PXFSTRSET(jhandle1, "machine", "44444444444444", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component machine for jhandle1')

  print *, "Fill the structure associated with jhandle2 with arbitrary data"
  call PXFSTRSET(jhandle2, "sysname", "aaaaaaaaa", 7, ierror)
  if(ierror.NE.0) call Error('Error: can't set component sysname for jhandle2')

  call PXFSTRSET(jhandle2, "Nodename", "BBBBBBBBBBBBBBB", 14, ierror)
  if(ierror.NE.0) call Error('Error: can't set component nodename for jhandle2')

  call PXFSTRSET(jhandle2, "RELEASE", "cCCC cc-cccnc", 12, ierror)
  if(ierror.NE.0) call Error('Error: can't set component release for jhandle2')

  call PXFSTRSET(jhandle2, "VERSION", "ddddd", 1, ierror)
  if(ierror.NE.0) call Error('Error: can't set component version for jhandle2')

  call PXFSTRSET(jhandle2, "machine", "eeeeeee", 6, ierror)
  if(ierror.NE.0) call Error('Error: can't set component machine for jhandle2')

  print *, "Print contents of the structure associated with jhandle1"
  call PRINT_UTSNAME(jhandle1)

  print *, "Print contents of the structure associated with jhandle2"
  call PRINT_UTSNAME(jhandle2)

  print *, "Get operating system info into structure associated with jhandle1"
```

call PXFUNAME(jhandle1,ierror)
if(ierr.error.NE.0) call Error('Error: call to PXFUNAME has failed')

print *,"Print contents of the structure associated with jhandle1"
print*," returned from PXFUNAME"
call PRINT_UTSNAME(jhandle1)

print *,"Copy the contents of the structure associated with jhandle1" print *," into the structure associated with jhandle2"
call PXFSTRUCTCOPY("utsname",jhandle1,jhandle2,ierror)
if(ierr.error.NE.0) call Error('Error: can't copy jhandle1 contents into jhandle2')

print *,"Print the contents of the structure associated with jhandle2." print *," It should be the same after copying."
call PRINT_UTSNAME(jhandle2)

print *,"Free memory for instance of structure associated with jhandle1"
call PXFSTRUCTFREE(jhandle1,ierror)
if(ierr.error.NE.0) STOP 'Error: can't free instance of structure for jhandle1'

print *,"Free memory for instance of structure associated with jhandle2"
call PXFSTRUCTFREE(jhandle2,ierror)
if(ierr.error.NE.0) STOP 'Error: can't free instance of structure for jhandle2'

print *,"Program terminated normally"
call PXFEXIT(0)
end

PXFSTRUCTFREE
the example in PXFTIMES

PXFSTRUCTFREE
POSIX Subroutine: Deletes the instance of a structure.

Module
USE IFPOSIX

Syntax
CALL PXFSTRUCTFREE (jhandle,ierror)

jhandle  (Input) INTEGER(4). The handle of a structure.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFSTRUCTFREE subroutine deletes the instance of the structure associated with handle jhandle.

Example
See the example in PXFSTRUCTCREATE, the example in PXFTIMES
PXFSYSCONF

POSIX Subroutine: Gets values for system limits or options.

Module

USE IFPOSIX

Syntax

CALL PXFSYSCONF (name, ival, ierror)

name (Input) INTEGER(4). The system option you want information about.
ival (Output) INTEGER(4). The returned value.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFSYSCONF lets you determine values for system limits or system options at runtime.

The value for name can be any of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SC_ARG_MAX¹</td>
<td>Indicates the maximum length of the arguments to the PXFEXEC family of routines.</td>
</tr>
<tr>
<td>_SC_CHILD_MAX¹</td>
<td>Indicates the number of simultaneous processes per user ID.</td>
</tr>
<tr>
<td>_SC_CLK_TCK</td>
<td>Indicates the number of clock ticks per second.</td>
</tr>
<tr>
<td>_SC_STREAM_MAX²</td>
<td>Indicates the maximum number of streams that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_TZNAME_MAX</td>
<td>Indicates the maximum number of bytes in a timezone name.</td>
</tr>
<tr>
<td>_SC_OPEN_MAX</td>
<td>Indicates the maximum number of files that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_JOB_CONTROL¹</td>
<td>Indicates whether POSIX-style job control is supported.</td>
</tr>
<tr>
<td>_SC_SAVED_IDS¹</td>
<td>Indicates whether a process has a saved set-user-ID and a saved set-group-ID.</td>
</tr>
<tr>
<td>_SC_VERSION¹</td>
<td>Indicates the year and month the POSIX.1 standard was approved in the format YYYYMML; the value 199009L indicates the most recent revision, 1990.</td>
</tr>
<tr>
<td>_SC_BC_BASE_MAX¹</td>
<td>Indicates the maximum obase value accepted by the bc(1) utility.</td>
</tr>
<tr>
<td>_SC_BC_DIM_MAX¹</td>
<td>Indicates the maximum value of elements that bc(1) permits in an array.</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>_SC_BC_SCALE_MAX</code>¹</td>
<td>Indicates the maximum scale value allowed by <code>bc(1)</code>.</td>
</tr>
<tr>
<td><code>_SC_BC_STRING_MAX</code>¹</td>
<td>Indicates the maximum length of a string accepted by <code>bc(1)</code>.</td>
</tr>
<tr>
<td><code>_SC_COLL_WEIGHTS_MAX</code>¹</td>
<td>Indicates the maximum numbers of weights that can be assigned to an entry of the <code>LC_COLLATE</code> order keyword in the locale definition file.</td>
</tr>
<tr>
<td><code>_SC_EXPR_NEST_MAX</code>¹,³</td>
<td>Indicates the maximum number of expressions that can be nested within parentheses by <code>expr(1)</code>.</td>
</tr>
<tr>
<td><code>_SC_LINE_MAX</code>¹</td>
<td>Indicates the maximum length of a utility’s input line length, either from standard input or from a file. This includes the length for a trailing newline.</td>
</tr>
<tr>
<td><code>_SC_RE_DUP_MAX</code>¹</td>
<td>Indicates the maximum number of repeated occurrences of a regular expression when the interval notation <code>{m,n}</code> is used.</td>
</tr>
<tr>
<td><code>_SC_2_VERSION</code>¹</td>
<td>Indicates the version of the POSIX.2 standard; it is in the format YYYYMM.</td>
</tr>
<tr>
<td><code>_SC_2_DEV</code>¹</td>
<td>Indicates whether the POSIX.2 C language development facilities are supported.</td>
</tr>
<tr>
<td><code>_SC_2_FORT_DEV</code>¹</td>
<td>Indicates whether the POSIX.2 FORTRAN language development utilities are supported.</td>
</tr>
<tr>
<td><code>_SC_2_FORT_RUN</code>¹</td>
<td>Indicates whether the POSIX.2 FORTRAN runtime utilities are supported.</td>
</tr>
<tr>
<td><code>_SC_2_LOCALEDEF</code>¹</td>
<td>Indicates whether the POSIX.2 creation of locates via <code>localedef(1)</code> is supported.</td>
</tr>
<tr>
<td><code>_SC_2_SW_DEV</code>¹</td>
<td>Indicates whether the POSIX.2 software development utilities option is supported.</td>
</tr>
<tr>
<td><code>_SC_PAGESIZE</code> (or <code>_SC_PAGE_SIZE</code>)</td>
<td>Indicates the size of a page (in bytes).</td>
</tr>
<tr>
<td><code>_SC_PHYS_PAGES</code>⁴</td>
<td>Indicates the number of pages of physical memory. Note that it is possible for the product of this value and the value of <code>_SC_PAGE_SIZE</code> to overflow.</td>
</tr>
<tr>
<td><code>_SC_AVPHYS_PAGES</code>⁴</td>
<td>Indicates the number of currently available pages of physical memory.</td>
</tr>
</tbody>
</table>

¹L*X only
²The corresponding POSIX macro is `STREAM_MAX`.
³The corresponding POSIX macro is `EXPR_NEST_MAX`.
⁴L*X, W*32

The corresponding macros are defined in `<bits/confname.h>` on Linux* systems; `<unistd.h>` on macOS* systems. The values for argument name can be obtained by using `PXCONST` or `IPXCONST` when passing the string names of predefined macros in the appropriate .h file.

PXFCONST

PXFTCDRAIN (L*X, M*X)

**POSIX Subroutine:** Waits until all output written has been transmitted.

Module
USE IFPOSIX

Syntax
CALL PXFTCDRAIN (ifildes, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFTCFLOW (L*X, M*X)

**POSIX Subroutine:** Suspends the transmission or reception of data.

Module
USE IFPOSIX

Syntax
CALL PXFTCFLOW (ifildes, iaction, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.
iaction  (Input) INTEGER(4). The action to perform.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTCFLOW subroutine suspends or resumes transmission or reception of data from the terminal referred to by ifildes. The action performed depends on the value of iaction, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCOOFF</td>
<td>Output is suspended.</td>
</tr>
<tr>
<td>TCOON</td>
<td>Output is resumed.</td>
</tr>
<tr>
<td>TCIOFF</td>
<td>A STOP character is transmitted. This should cause the terminal to stop transmitting data to the system.</td>
</tr>
</tbody>
</table>
A START character is transmitted. This should cause the terminal to resume transmitting data to the system.

These names can be used in PXFCONST or IPXFCONST.

IPXFCONST
PXFCONST

**PXFTCFLUSH (L*X, M*X)**

**POSIX Subroutine:** Discards terminal input data, output data, or both.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFTCFLUSH (ifildes, iaction, ierror)

1. (Input) INTEGER(4). The file descriptor associated with the terminal.
2. (Input) INTEGER(4). The action to perform.
3. (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The action performed depends on the value of iaction, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant 1</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCIFLUSH</td>
<td>Discards all data that has been received but not read.</td>
</tr>
<tr>
<td>TCOFLUSH</td>
<td>Discards all data that has been written but not transmitted.</td>
</tr>
<tr>
<td>TCIOFLUSH</td>
<td>Discards both data received but not read and data written but not transmitted. (Performs TCIFLUSH and TCOFLUSH actions.)</td>
</tr>
</tbody>
</table>

These names can be used in PXFCONST or IPXFCONST.

**PXFTCGETATTR (L*X, M*X)**

**POSIX Subroutine:** Reads current terminal settings.

**Module**
USE IFPOSIX
**Syntax**

CALL PXFTCGETATTR (ifildes, jtermios, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **jtermios** (Output) INTEGER(4). A handle for structure `termios`. Stores the terminal settings.
- **ierror** (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**NOTE**
To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

**See Also**
- PXFSTRUCTCREATE
- PXFTCSETATTR

**PXFTCGETPGRP (L*X, M*X)**

**POSIX Subroutine:** Gets the foreground process group ID associated with the terminal.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCGETPGRP (ifildes, ipgid, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **ipgid** (Output) INTEGER(4). The returned process group ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**See Also**
- PXFTCSETPGRP

**PXFTCSENDBREAK (L*X, M*X)**

**POSIX Subroutine:** Sends a break to the terminal.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCSENDBREAK (ifildes, iduration, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
iduration  (Input) INTEGER(4). Indicates how long the break should be.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTCSENDBREAK subroutine sends a break (a \0' with a framing error) to the terminal associated with ifildes.

**PXFTCSETATTR (L*X, M*X)**

**POSIX Subroutine: Writes new terminal settings.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCSETATTR (ifildes, ioptacts, jtermios, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.

ioptacts  (Input) INTEGER(4). Specifies when the terminal changes take effect.

jtermios  (Input) INTEGER(4). A handle for structure termios. Contains the new terminal settings.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTCSETATTR subroutine copies all terminal parameters from structure termios into the terminal associated with ifildes. When the terminal settings will change depends on the value of ioptacts, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant ¹</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCSANOW</td>
<td>The changes occur immediately.</td>
</tr>
<tr>
<td>TCSADRAIN</td>
<td>The changes occur after all output written to ifildes has been transmitted.</td>
</tr>
<tr>
<td>TCSAFLUSH</td>
<td>The changes occur after all output written to ifildes has been transmitted, and all input that had been received but not read has been discarded.</td>
</tr>
</tbody>
</table>

¹These names can be used in PXFCONST or IPXFCONST.

**NOTE**

To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

**See Also**

PXFSTRUCTCREATE

PXFTCGETATTR
PXFTCSETPGRP (L*X, M*X)

POSIX Subroutine: Sets the foreground process group ID associated with the terminal.

Module
USE IFPOSIX

Syntax
CALL PXFTCSETPGRP (ifildes, ipgid, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.
ipgid    (Input) INTEGER(4). The foreground process group ID for ifildes.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also
PXFTCGETPGRP

PXFTIME

POSIX Subroutine: Returns the current system time.

Module
USE IFPOSIX

Syntax
CALL PXFTIME (itime, ierror)

itime   (Output) INTEGER(4). The returned system time.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTIME subroutine returns the number of seconds since Epoch (00:00:00 UTC, January 1, 1970).

Example
See the example in PXFTIMES.

PXFTIMES

POSIX Subroutine: Returns process times.

Module
USE IFPOSIX

Syntax
CALL PXFTIMES (jtms, itime, ierror)

jtms    (Output) INTEGER(4). A handle of structure tms.
itime  (Output) INTEGER(4). The returned time since system startup.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTIMES subroutine fills the fields of structure tms associated with handle jtms with components of
time that was spent by the current process. The structure fields are:

- tms_utime - User CPU time
- tms_stime - System CPU time
- tms_cutime - User time of child process
- tms_cstime - System time of child process

All members are measured in system clocks. The values can be converted to seconds by dividing by value
ival returned from the following call:

```fortran
PXFSYSCONF(IPXFCONST('_SC_CLK_TCK'), ival, ierror)
```

User time is the time charged for the execution of user instructions of the calling process. System time is the
time charged for execution by the system on behalf of the calling process.

**NOTE**
To get a handle for an instance of the tms structure, use PXFSTRUCTCREATE with the string 'tms' for
the structure name.

**Example**

```fortran
program test_uname
  use ifposix
  implicit none
  integer(jhandle_size) jtms1, jtms2
  integer(4) ierror,i
  integer(4),parameter :: n=10000000
  integer(SIZEOF_CLOCK_T) itime,time1,time2, user_time1,user_time2
  integer(SIZEOF_CLOCK_T) system_time1,system_time2
  integer(4) clocks_per_sec, iname
  real(8) s, PI
  real(8) seconds_user, seconds_system

  print *,"Create a first instance for structure 'tms'"

PXFSTRUCTCREATE

PXFTTYNAME (L*X, M*X)

**POSIX Subroutine:** Gets the terminal pathname.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFTTYNAME (ifildes, s, ilen, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **s** (Output) Character. The returned terminal pathname.
- **ilen** (Output) INTEGER(4). The length of the string stored in s.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

**PXFUCOMPARE**

**POSIX Subroutine:** Compares two unsigned integers.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFUCOMPARE (i1, i2, icmpr, idiff)

- **i1, i2** (Input) INTEGER(4). The two unsigned integers to compare.
- **icmpr** (Output) INTEGER(4). The result of the comparison; one of the following values:
  - -1  
    If i1 < i2
  - 0  
    If i1 = i2
  - 1  
    If i1 > i2

- **idiff** (Output) INTEGER(4). The absolute value of the difference.

The PXFUCOMPARE subroutine compares two unsigned integers and returns the absolute value of their difference into **idiff**.

**PXFUMASK**

**POSIX Subroutine:** Sets a new file creation mask and gets the previous one.
Module
USE IFPOSIX

Syntax
CALL PXFUMASK (icmask,iprevcmask,ierror)

  icmask            (Input) INTEGER(4). The new file creation mask.
  iprevcmask       (Output) INTEGER(4). The previous file creation mask.
  ierror           (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFUNAME

POSIX Subroutine: Gets the operation system name.

Module
USE IFPOSIX

Syntax
CALL PXFUNAME (jutsname,ierror)

  jutsname          (Input) INTEGER(4). A handle of structure utsname.
  ierror           (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFUNAME subroutine provides information about the operation system. The information is stored in the structure associated with handle jutsname.

Example
See the example in PXFSTRUCTCREATE

PXFUNLINK

POSIX Subroutine: Removes a directory entry.

Module
USE IFPOSIX

Syntax
CALL PXFUNLINK (path,ilen,ierror)

  path             (Input) Character. The name of the directory entry to remove.
  ilen             (Input) INTEGER(4). The length of path string.
  ierror           (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
**PXFUTIME**

**POSIX Subroutine:** Sets file access and modification times.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUTIME (path, ilen, jutimbuf, ierror)

- **path** (Input) Character. The path to the file.
- **ilen** (Input) INTEGER(4). The length of path string.
- **jutimbuf** (Input) INTEGER(4). A handle of structure utimbuf.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFUTIME subroutine sets access and modification times for the file pointed to by path. The time values are retrieved from structure utimbuf.

**PXFWAIT (L*X, M*X)**

**POSIX Subroutine:** Waits for a child process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFWAIT (istat, iretpid, ierror)

- **istat** (Output) INTEGER(4). The returned status of the child process.
- **iretpid** (Output) INTEGER(4). The process ID of the stopped child process.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFWAIT subroutine suspends execution of the current process until a child has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The subroutine returns in iretpid the value of the process ID of the child that exited, or zero if no child was available. The returned value in istat can be used in subroutines IPXFWEXITSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWFEXITED, PXFWFSIGNALLED, and PXFWIFSTOPPED.

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
    print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
```

1946
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
   call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid ", IPID
   print *," Now I am waiting for the end of the child process"
   call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program

PXFWAITPID (L*X, M*X)

POSIX Subroutine: Waits for a specific PID.

Module
USE IFPOSIX

Syntax
CALL PXFWAITPID (ipid,istat,ioptions,iretpid,ierror)

ipid

(Input) INTEGER(4). The PID to wait for. One of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; -1</td>
<td>Specifies to wait for any child process whose process group ID is equal to the absolute value of ipid.</td>
</tr>
<tr>
<td>-1</td>
<td>Specifies to wait for any child process; this is the same behavior as PXFWAIT.</td>
</tr>
</tbody>
</table>
**Value** | **Action**
---|---
0 | Specifies to wait for any child process whose process group ID is equal to that of the calling process.
> 0 | Specifies to wait for the child whose process ID is equal to the value of *ipid*.

**istat**
(Output) INTEGER(4). The returned status of the child process.

**ioptions**
(Input) INTEGER(4). One or more of the following constant values (which can be passed to PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WNOHANG</td>
<td>Specifies to return immediately if no child process has exited.</td>
</tr>
<tr>
<td>WUNTRACED</td>
<td>Specifies to return for child processes that have stopped, and whose status has not been reported.</td>
</tr>
</tbody>
</table>

**iretpid**
(Output) INTEGER(4). The PID of the stopped child process.

**ierror**
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFWAITPID subroutine suspends execution of the current process until the child specified by *ipid* has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child specified by *ipid* has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The returned value in *istat* can be used in subroutines IPXFWEXITSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWIFEXITED, PXFWIFSIGNALLED, and PXFWIFSTOPPED.

**PXFWIFEXITED (L*X, M*X)**

**POSIX Function:** Determines if a child process has exited.

**Module**

USE IFPOSIX
Syntax

```plaintext
result = PXFWIFEXITED (istat)
```

*istat* (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

Results

The result type is logical. The result value is .TRUE. if the child process has exited normally; otherwise, .FALSE..

Example

```plaintext
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(ipid, ierror)
call PXFGETPID(ipid_ret,ierror)
if(ipid.eq.0) then
  print *," I am a child process"
  print *," My child's pid is", IPID_RET
  call PXFGETPPID(ipid_ret,ierror)
  print *," The pid of my parent is", IPID_RET
  print *," Now I have exited with code 0xABCD"
  call PXFEXIT(Z'ABCD')
else
  print *," I am a parent process"
  print *," My parent pid is ", IPID_RET
  print *," I am creating the process with pid", IPID
  print *," Now I am waiting for the end of the child process"
  call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *," The child with pid ", IPID_RET," has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, " The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10," The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program
```

See Also

PXFWIFSIGNALED
PXFWIFSTOPPED

**PXFWIFSIGNALED (L*X, M*X)**

*POSIX Function:* Determines if a child process has exited because of a signal.

Module

USE IFPOSIX

Syntax

```plaintext
result = PXFWIFSIGNALED (istat)
```
istat

(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

Results
The result type is logical. The result value is .TRUE. if the child process has exited because of a signal that was not caught; otherwise, .FALSE..

See Also
PXFWIFEXITED
PXFWIFSTOPPED

PXFWIFSTOPPED (L*X, M*X)

POSIX Function: Determines if a child process has stopped.

Module
USE IFPOSIX

Syntax
result = PXFWIFSTOPPED (istat)

istat

(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

Results
The result type is logical. The result value is .TRUE. if the child process has stopped; otherwise, .FALSE..

See Also
PXFWIFEXITED
PXFWIFSIGNALED

PXWRITE

POSIX Subroutine: Writes to a file.

Module
USE IFPOSIX

Syntax
CALL PXWRITE (ifildes,buf,nbyte,nwritten,ierror)

ifildes

(Input) INTEGER(4). The file descriptor for the file to be written to.

buf

(Input) Character. The buffer that contains the data to write into the file.

nbyte

(Input) INTEGER(4). The number of bytes to write.

nwritten

(Output) INTEGER(4). The returned number of bytes written.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXWRITE subroutine writes \textit{nbyte} bytes from the storage \textit{buf} into a file specified by file descriptor \textit{ifildes}. The subroutine returns the total number of bytes read into \textit{nwritten}. If no error occurs, the value of \textit{nwritten} will equal the value of \textit{nbyte}.

PXFREAD

\textbf{Q to R}

\textbf{Q to R}

\textbf{QCMPLX}

\textit{Elemental Intrinsic Function (Specific): Converts an argument to COMPLEX(16) type. This function cannot be passed as an actual argument.}

\textbf{Syntax}

\begin{verbatim}
result = QCMPLX (x[,y])
\end{verbatim}

\textit{x} \hspace{1cm} (Input) Must be of type integer, real, or complex.

\textit{y} \hspace{1cm} (Input; optional) Must be of type integer or real. It must not be present if \textit{x} is of type complex.

\textbf{Results}

The result type is COMPLEX(16) (or COMPLEX*32).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If \textit{y} is not specified and \textit{x} is complex, the result value is CMPLX(REAL(\textit{x}), AIMAG(\textit{x})).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

QCMPLX(\textit{x}, \textit{y}) has the complex value whose real part is REAL(\textit{x}, \textit{kind}=16) and whose imaginary part is REAL(\textit{y}, \textit{kind}=16).

\textbf{Example}

QCMPLX (-3) has the value (-3.0Q0, 0.0Q0).

QCMPLX (4.1, 2.3) has the value (4.1Q0, 2.3Q0).

\textbf{See Also}

DCMPLX

FLOAT

INT

IFIX

REAL

SNGL
QEXT

**Elemental Intrinsic Function (Generic):** Converts a number to quad precision (REAL(16)) type.

**Syntax**

```
result = QEXT (a)
```

*a* (Input) Must be of type integer, real, or complex.

**Results**

The result type is REAL(16) (REAL*16). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If *a* is of type REAL(16), the result is the value of the *a* with no conversion (QEXT(a) = a).

If *a* is of type integer or real, the result has as much precision of the significant part of *a* as a REAL(16) value can contain.

If *a* is of type complex, the result has as much precision of the significant part of the real part of *a* as a REAL(16) value can contain.

<table>

<td>REAL(16)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

**Example**

QEXT (4) has the value 4.0 (rounded; there are 32 places to the right of the decimal point).

QEXT ((3.4, 2.0)) has the value 3.4 (rounded; there are 32 places to the right of the decimal point).

QFLOAT

**Elemental Intrinsic Function (Generic):** Converts an integer to quad precision (REAL(16)) type.

**Syntax**

```
result = QFLOAT (a)
```

1952
a  (Input) Must be of type integer.

Results

The result type is REAL(16) (REAL*16).

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

Example

QFLOAT (-4) has the value -4.0 (rounded; there are 32 places to the right of the decimal point).

QNUM

**Elemental Intrinsic Function (Specific):** Converts a character string to a REAL(16) value. This function cannot be passed as an actual argument.

Syntax

```
result = QNUM (i)
```

i  (Input) Must be of type character.

Results

The result type is REAL(16). The result value is the real value represented by the character string i.

Example

QNUM ("-174.23") has the value -174.23 of type REAL(16).

QRANSET

**Portability Subroutine:** Sets the seed for a sequence of pseudo-random numbers.

Module

USE IFPORT

Syntax

```
CALL QRANSET (rseed)
```

rseed  (Input) INTEGER(4). The reset value for the seed.

QREAL

**Elemental Intrinsic Function (Specific):** Converts the real part of a COMPLEX(16) argument to REAL(16) type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax

```
result = QREAL (a)
```
(Input) Must be of type COMPLEX(16) (or COMPLEX*32).

Results
The result type is quad-precision real (REAL(16) or REAL*16).

Example
QREAL ((2.0q0, 3.0q0)) has the value 2.0q0.

REAL
DREAL

QSORT
Portability Subroutine: Performs a quick sort on an array of rank one.

Module
USE IFPORT

Syntax
CALL QSORT (array, len, isize, compar)

array (Input) Any type except assumed-length character. A one-dimensional array to be sorted.

If the data type does not conform to one of the predefined interfaces for QSORT, you may have to create a new interface (see Note and Example below).

len (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in array.

isize (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Size, in bytes, of a single element of array:

• 4 if array is of type REAL(4)
• 8 if array is of type REAL(8) or complex
• 16 if array is of type COMPLEX(8)

compar (Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of compar takes the form:

INTEGER(2) FUNCTION compar(arg1, arg2)

where arg1 and arg2 have the same type as array (above) and are not assumed-length character. Assume-length characters should be wrapped in a derived type. After you have created an ordering scheme, implement your sorting function so that it returns the following:

• Negative if arg1 should precede arg2
• Zero if arg1 is equivalent to arg2
• Positive if arg1 should follow arg2

Dummy argument compar must be declared as external.
In place of an INTEGER kind, you can specify the constant SIZEOF_SIZE_T, defined in IFPORT.F90, for argument len or isize. Use of this constant ensures correct compilation.

**NOTE**

If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module's source file, IFPORT.F90.

**Example**

```fortran
! program showing how to call 'QSORT' on
! a user-defined type.
!
! Define the type to be shared.
!
module share_type
  type element_type
    integer :: data
    character(10) :: key
  end type
end module
!
!
! Main program calls QSORT.
!
program main
  use, intrinsic :: iso_c_binding, only: c_size_t
  use IFPORT      ! To get QSORT
  use share_type  ! To get shared type

  ! Define an overload of the default QSORT signature
  ! with a signature using the shared type.
  !
  interface
    subroutine QSORT_element_types(array, len, isize, comp)
      use, intrinsic :: iso_c_binding, only: c_size_t
      use share_type
      type(element_type) array(len)
      integer(C_SIZE_T) len, isize
      integer(2), external :: comp
    end subroutine QSORT_element_types
  end interface
!
!
! Hook the overload to the real thing but be careful
! to connect to the correct qsort: the Fortran one, not
! the C one!
!
! We need to call the _Fortran_qsort, not the _C_one, or
! there will be errors from the 1-origin vs. 0-origin indexing
! and the row-major vs. column-major ordering.
!
! The symptom is that "OrderCharCI" is called with pointer values
! which are outside the bounds of the array to be sorted.
!

RADIX

Inquiry Intrinsic Function (Generic): Returns the base of the model representing numbers of the same type and kind as the argument.

Syntax
result = RADIX (x)

x (Input) Must be of type integer or real; it can be scalar or array valued.

Results
The result is a scalar of type default integer. For an integer argument, the result has the value r (as defined in Model for Integer Data). For a real argument, the result has the value b (as defined in Model for Real Data).

Example
If X is a REAL(4) value, RADIX (X) has the value 2.

Data Representation Models
RAISEQQ

Portability Function: Sends a signal to the executing program.

Module

USE IFPORT

Syntax

result = RAISEQQ (sig)

(sig) (Input) INTEGER(4). Signal to raise. One of the following constants (defined in IFPORT.F90):

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+C signal
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

If a signal-handling routine for sig has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).

SIGNALQQ
SIGNAL
KILL

RAN

Nonelemental Intrinsic Function (Specific):

Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax

result = RAN (i)

(i) (Input; output) Must be an INTEGER(4) variable or array element.

It should initially be set to a large, odd integer value. The RAN function stores a value in the argument that is later used to calculate the next random number.
There are no restrictions on the seed, although it should be initialized with different values on separate runs to obtain different random numbers.

Results
The result type is REAL(4). The result is a floating-point number that is uniformly distributed in the range between 0.0 inclusive and 1.0 exclusive. It is set equal to the value associated with the argument \( i \).

RAN is not a pure function.

Example
In RAN (I), if variable I has the value 3, RAN has the value 4.8220158E-05.

See Also
RANDOM
RANDOM_NUMBER

RAND, RANDOM

*Portability Functions:* Return real random numbers in the range 0.0 to 1.0, not including the end points.

Module
USE IFPORT

Syntax

\[
\text{result} = \text{RAND} ([ \text{iflag} ])
\]

\[
\text{result} = \text{RANDOM} (\text{iflag})
\]

\( \text{iflag} \) (Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

Results
The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 to 1.0, not including the end points.

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

When RAND is called without an argument, the following applies:
- The value of iflag is assumed to be 0.
- You must specify USE IFPORT.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them.
The intrinsic functions RANDOM_NUMBER and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

You can use SRAND to restart the pseudorandom number generator used by RAND.

**NOTE**

RANDOM is available as a function or subroutine.

**Example**

The following example shows how to use both the RANDOM function and the RANDOM subroutine:

```fortran
use ifport
real(4) ranval

call seed(1995) ! initialize
call random(ranval) ! get next random number
print *,ranval

ranval = random(1) ! initialize
ranval = random(0) ! get next random number
print *,ranval
end
```

**See Also**

RANDOM_NUMBER
RANDOM_SEED
SRAND

**RANDOM Subroutine**

*Portability Subroutine:* Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.

**Module**

USE IFPORT

**Syntax**

```fortran
CALL RANDOM (ranval)
```

*ranval*  
(Output) REAL(4). Pseudorandom number, 0 < ranval < 1, from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFCORE.F90) to SEED before the first call to RANDOM.

The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.
Example

USE IFPORT
REAL(4) ran

CALL SEED(1995)
CALL RANDOM(ran)

The following example shows how to use both the RANDOM subroutine and the `RANDOM` function:

```
use ifport
real(4) ranval
! from libifcore.lib
call seed(1995)     ! initialize
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number

print *,ranval
! from libifport.lib
ranval = random(1)  ! initialize
! same
ranval = random(0)  ! get next random number

print *,ranval
end
```

See Also

RANDOM_NUMBER
SEED
DRAND and DRANDM
IRAND and IRANDM
RAN
RAND

**RANDOM_NUMBER**

*Intrinsic Subroutine:* Returns one pseudorandom number or an array of such numbers.

**Syntax**

```
CALL RANDOM_NUMBER (harvest)
```

- **harvest** (Output) Must be of type real. It can be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution within the range $0 \leq x < 1$.

The seed for the pseudorandom number generator used by RANDOM_NUMBER can be set or queried with `RANDOM_SEED`. If `RANDOM_SEED` is not used, the processor sets the seed for RANDOM_NUMBER to a processor-dependent value.

The RANDOM_NUMBER generator uses two separate congruential generators together to produce a period of approximately $10^{18}$, and produces real pseudorandom results with a uniform distribution in $(0, 1)$. It accepts two integer seeds, the first of which is reduced to the range $[1, 2147483562]$. The second seed is reduced to the range $[1, 2147483398]$. This means that the generator effectively uses two 31-bit seeds.

The RANDOM_NUMBER generator does not produce subnormal numbers.

For more information on the algorithm, see the following:
Example

Consider the following:

```fortran
REAL Y, Z (5, 5)
! Initialize Y with a pseudorandom number
CALL RANDOM_NUMBER (HARVEST = Y)
CALL RANDOM_NUMBER (Z)
```

Y and Z contain uniformly distributed random numbers.

The following shows another example:

```fortran
REAL x, array1 (5, 5)
CALL RANDOM_SEED()
CALL RANDOM_NUMBER(x)
CALL RANDOM_NUMBER(array1)
```

The following shows another example:

```fortran
program testrand
  intrinsic random_seed, random_number
  integer size
  integer, allocatable :: seed(:), gseed(:), hiseed(:), zseed(:)
  real harvest(10)
  call random_seed(SIZE=size)
  print *, "size ", size
  allocate(seed(size), gseed(size), hiseed(size), zseed(size))
  hiseed = -1
  zseed = 0
  seed = 123456789
  seed(size) = 987654321
  call random_seed(PUT=hiseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "hiseed gseed", hiseed, gseed
  call random_seed(PUT=zseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "zseed gseed ", zseed, gseed
  call random_seed(PUT=seed(1:size))
  call random_seed(GET=seed(1:size))
  call random_number(HARVEST=harvest)
  print *, "seed gseed ", seed, gseed
  print *, "harvest"
  call random_seed(GET=gseed(1:size))
  print *, "gseed after harvest ", gseed
end program testrand
```

RANDOM_SEED

RANDOM
SEED
DRAND and DRANDM
IRAND and IRANDM
RAN
RAND and RANDOM

RANDOM_SEED

Intrinsic Subroutine (Generic): Changes or queries the seed (starting point) for the pseudorandom number generator used by intrinsic subroutine RANDOM_NUMBER. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL RANDOM_SEED ([size] [,put] [,get])

size  (Output; optional) Must be scalar and of type integer. Set to the number of integers (N) that the processor uses to hold the value of the seed.

put  (Input; optional) Must be an integer array of rank one and size greater than or equal to N. It is used to reset the value of the seed.

get  (Output; optional) Must be an integer array of rank one and size greater than or equal to N. It is set to the current value of the seed.

No more than one argument can be specified. If no argument is specified, a random number based on the date and time is assigned to the seed.

You can determine the size of the array the processor uses to store the seed by calling RANDOM_SEED with the size argument (see the second example below).

If RANDOM_SEED is called with no arguments, the seed is set to a different, unpredictable value on each call.

Example

Consider the following:

```fortran
CALL RANDOM_SEED                        ! Processor initializes the
!   seed randomly from the date
CALL RANDOM_SEED (SIZE = M)             ! Sets M to N
CALL RANDOM_SEED (PUT = SEED (1 : M))   ! Sets user seed
CALL RANDOM_SEED (GET = OLD (1 : M))    ! Reads the current seed
```

The following shows another example:

```fortran
INTEGER I
INTEGER, ALLOCATABLE :: new (:), old(:)
CALL RANDOM_SEED ( )                    ! Processor reinitializes the
!   seed randomly from the date
!   and time
CALL RANDOM_SEED (SIZE = I)            ! I is set to the size of
!   the seed array
CALL RANDOM_SEED (GET=old(1:I))        ! Gets the current seed
ALLOCATE (new(I))
ALLOCATE (old(I))
WRITE(*,*) old
new = 5
```

1964
CALL RANDOM_SEED (PUT=new(1:I)) ! Sets seed from array
    ! new
END

RANDOM_NUMBER
SEED
SRAND

RANDU

**Intrinsic Subroutine (Generic):** Computes a pseudorandom number as a single-precision value. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```call randu (i1, i2, x)
```

*i1, i2* (Input; output) Must be scalars of type INTEGER(2) or INTEGER(4). They contain the seed for computing the random number. These values are updated during the computation so that they contain the updated seed.

*x* (Output) Must be a scalar of type REAL(4). This is where the computed random number is returned.

The result is returned in *x*, which must be of type REAL(4). The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for *i1* and *i2*.

The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for *i1* and *i2*.

If *i1* = 0 and *i2* = 0, the generator base is set as follows:

```
x(n + 1) = 2**16 + 3
```

Otherwise, it is set as follows:

```
x(n + 1) = (2**16 + 3) * x(n) mod 2**32
```

The generator base *x(n + 1)* is stored in *i1, i2*. The result is *x(n + 1)* scaled to a real value *y(n + 1)*, for 0.0 <= *y(n + 1)* < 1.

**Example**

Consider the following:

```call randu (i, j, x)
```

If *i* and *j* are values 4 and 6, *x* has the value 5.4932479E-04.
**RANF Intrinsic Procedure**

*Elemental Intrinsic Function (Generic):* Generates a random number between 0.0 and RAND_MAX. This function must not be passed as an actual argument. RANF can be used as an intrinsic procedure or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

**Syntax**

\[
\text{result} = \text{RANF}()
\]

**Results**

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and \((2**31) - 1\).

The initial seed is set by the following:

```fortran
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

The intrinsic function RANF generates a different sequence of random numbers than the RANF portability function generates for the same seed. The intrinsic function RANF used inside a loop can be vectorized into one call that returns four results, but the portability function RANF cannot be so optimized.

**See Also**

RANDOM_NUMBER

RANF portability routine

SRAND

---

**RANF Portability Routine**

*Portability Function:* Generates a random number between 0.0 and RAND_MAX. RANF can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{RANF}()
\]

**Results**

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and \((2**31) - 1\).

The initial seed is set by the following:

```fortran
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

RANDOM_NUMBER

RANF intrinsic procedure

SRAND

RANGE

Inquiry Intrinsic Function (Generic): Returns the decimal exponent range in the model representing numbers with the same kind parameter as the argument.

Syntax

result = RANGE (x)

x (Input) Must be of type integer, real, or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

For an integer argument, the result has the value INT(LOG10( HUGE(x) )). For information on the integer model, see Model for Integer Data.

For a real or complex argument, the result has the value INT(MIN (LOG10( HUGE( x ) ), - LOG10( TINY( x ) ))). For information on the real model, see Model for Real Data.

Example

If X is a REAL(4) value, RANGE (X) has the value 37. (HUGE(X) = (1 - 2 \textsuperscript{-24}) \times 2 \textsuperscript{128} and TINY(X) = 2 \textsuperscript{-126})

See Also
HUGE
TINY

RANGET

Portability Subroutine: Returns the current seed.

Module
USE IFPORT

Syntax

CALL RANGET (seed)

seed (Output) INTEGER(4). The current seed value.

RANK

Inquiry Intrinsic Function (Generic): Returns the rank of a data object.
Syntax
result = RANK (a)

a (Input) Is a data object. It can be of any type.

Results
The result type is default integer scalar. The result value is the rank of a.

Example
If object C is an assumed-rank dummy argument and its associated argument is an array of rank 5, RANK(C) returns the value 5.
If D is an array declared DIMENSION (2, 3, 4), RANK(D) returned the value 3.

See Also
Assumed-Rank Specifications

RANSET
Portability Subroutine: Sets the seed for the random number generator.

Module
USE IFPORT

Syntax
CALL RANSET (seed)

seed (Input) REAL(4). The reset value for the seed.

READ Statement
Statement: Transfers input data from external sequential, direct-access, or internal records.

Syntax
Sequential
Formatted:
READ form[, io-list]

Formatted - List-Directed:
READ *[, io-list]

Formatted - Namelist:
READ nml
Unformatted:

Direct-Access Formatted:

Unformatted:
Internal
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]
Internal Namelist
READ (iunit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]

eunit
  Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if eunit is not the first specifier in the list.

format
  Is a format specifier. It is optionally prefaced by FMT= if format is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

For internal READs, an asterisk (*) indicates list-directed formatting. For direct-access READs, an asterisk is not permitted.

advance
  Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous
  Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

blank
  Is a blank control specifier (BLANK = blnk). If the value of blnk is 'NULL', all blanks are ignored. If the value is 'ZERO', all blanks are treated as zeros. The default value is 'NULL'.

decimal
  Is a decimal mode specifier (DECIMAL=dmode) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.

id
  Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

pad
  Is a blank padding specifier (PAD = pd). If the value of pad is 'YES', the record will be padded with blanks when necessary. If the value is 'NO', the record will not be padded with blanks. The default value is 'YES'.

Language Reference
pos

Is a **pos specifier** (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

round

Is a **rounding specifier** (ROUND=rmode) that determines the I/O rounding mode for this READ statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.

size

Is a **character count specifier** (SIZE=i-var).

iostat

Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

err, end, eor

Are **branch specifiers** if an error (ERR=label), end-of-file (END=label), or end-of-record (EOR=label) condition occurs.

EOR can only be specified for nonadvancing READ statements.

iomsg

Is an **I/O message specifier** (IOMSG=msg-var).

io-list

Is an **I/O list**: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

If an item in **io-list** is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as **eunit**.

If I/O is to or from a formatted device, **io-list** cannot contain derived-type variables, but it can contain components of derived types. If I/O is to a binary or unformatted device, **io-list** can contain either derived type components or a derived type variable.

form

Is the nonkeyword form of a format specifier (no FMT=).

* 

Is the format specifier indicating list-directed formatting. (It can also be specified as FMT=*.)

nml-group

Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if **nml-group** is not the second I/O specifier. For more information, see Namelist Specifier.

nml

Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist I/O.

rec

Is the cell number of a record to be accessed directly. It must be prefaced by REC=.

iunit

Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if **iunit** is not the first specifier in the list. It must be a character variable. It must not be an array section with a vector subscript.

If you specify EOR= or SIZE=, you must also specify ASYNCHRONOUS='NO'.

If you specify BLANK=, DECIMAL=, PAD=, or ROUND=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

1970
Caution
The READ statement can disrupt the results of certain graphics text functions (such as SETTEXTWINDOW) that alter the location of the cursor. You can avoid the problem by getting keyboard input with the GETCHARQQ function and echoing the keystrokes to the screen using OUTTEXT. Alternatively, you can use SETTEXTEXPOSITORY to control cursor location.

Example

```plaintext
DIMENSION ia(10,20)
! Read in the bounds for the array.
! Then read in the array in nested implied-DO lists
! with input format of 8 columns of width 5 each.
READ (6, 990) il, jl, ((ia(i,j), j = 1, jl), i =1, il)
990 FORMAT (2I5, /, (8I5))

! Internal read gives a variable string-represented numbers
CHARACTER*12 str
str = '123456'
READ (str,'(i6)') i

! List-directed read uses no specified format
REAL x, y
INTEGER i, j
READ (*,*), x, y, i, j
```

WRITE
I/O Formatting

REAL Directive

General Compiler Directive: Specifies the default real kind.

Syntax

```
!DIR$ REAL:{ 4 | 8 | 16 }
```

The REAL directive selects a size of 4 (KIND=4), 8 (KIND=8), or 16 (KIND=16) bytes for default real numbers. When the directive is in effect, all default real and complex variables are of the kind specified in the directive. Only numbers specified or implied as REAL without KIND are affected.

The REAL directive can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. REAL cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.
Example

```fortran
REAL r ! a 4-byte REAL
WRITE(*,*) KIND(r)
CALL REAL8(
WRITE(*,*) KIND(r) ! still a 4-byte REAL ! not affected by setting in subroutine
END
SUBROUTINE REAL8(
!DIR$ REAL:8
REAL s ! an 8-byte REAL
WRITE(*,*) KIND(s)
END SUBROUTINE
```

See Also

REAL
COMPLEX
General Compiler Directives
Syntax Rules for Compiler Directives

REAL Function

Elemental Intrinsic Function (Generic): Converts a value to real type.

Syntax

```
result = REAL (a[,kind])
```

- `a` (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
- `kind` (Input; optional) Must be a scalar integer constant expression.

Results

The result type is real. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of `a` as follows:

- If `a` is integer or real, the result is equal to an approximation of `a`. If `a` is complex, the result is equal to an approximation of the real part of `a`.
- If `a` is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of `a` as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by `a` is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by `a` is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.
  - If a binary, octal, or hexadecimal literal constant is truncated as an argument to intrinsic function REAL, the discarded bits must all be zero.

1 These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying real size can affect FLOAT, REAL, and SNGL.

3 Or FLOATJ. For compatibility with older versions of Fortran, FLOAT is generic, allowing any kind of INTEGER argument, and returning a default real result.

4 For compatibility with older versions of Fortran, SNGL is generic, allowing any kind of REAL argument, and returning a default real result.

If the argument is a binary, octal, or hexadecimal constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

Example
REAL (-4) has the value -4.0.
REAL (Y) has the same kind parameter and value as the real part of complex variable Y.

If C is complex, C%RE is the same as REAL (C).

assume compiler option

REAL Statement
Statement: Specifies the REAL data type.

Syntax
REAL
REAL ([KIND=] n)
REAL* \( n \)

DOUBLE PRECISION \( n \)

Is a constant expression that evaluates to kind 4, 8 or 16.

**Description**

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

REAL(4) and REAL*4 (single precision) are the same data type. REAL(8), REAL*8, and DOUBLE PRECISION are the same data type.

**Example**

```
! type declarations with attribute specifiers
REAL (8), PARAMETER :: testval=50.d0
REAL, SAVE :: a(10), b(20,30)
REAL, PARAMETER :: x = 100.

! attribute statements to declare the same entities
REAL x, a, b, testval*8
DIMENSION a(10), b(20,30)
SAVE a, b
PARAMETER (x = 100., testval=50.d0)
```

**RECORD**

**Statement:** Declares a record structure as an entity with a name.

**Syntax**

```
RECORD /structure-name/record-namelist [, /structure-name/record-namelist]...
```

- `structure-name`: Is the name of a previously declared structure.
- `record-namelist`: Is a list of one or more variable names, array names, or array specifications, separated by commas. All of the records named in this list have the same structure and are allocated separately in memory.

You can use record names in COMMON and DIMENSION statements, but not in DATA or NAMELIST statements.
Records initially have undefined values unless you have defined their values in structure declarations.

STRUCTURE and RECORD constructs have been replaced by derived types, which should be used in writing new code. See Derived Data Types.

Example

```plaintext
STRUCTURE /address/
   LOGICAL*2  house_or_apt
   INTEGER*2  apt
   INTEGER*2  housenumber
   CHARACTER*30 street
   CHARACTER*20 city
   CHARACTER*2  state
   INTEGER*4   zip
END STRUCTURE

RECORD /address/ mailing_addr(20), shipping_addr(20)
```

The following shows another example:

```plaintext
RECORD /T1/ a, b, /T2/ c, /T3/ d, e, f
```

**RECTANGLE, RECTANGLE_W (W*S)**

**Graphics Functions:** Draw a rectangle using the current graphics color, logical write mode, and line style.

**Module**

USE IFQWIN

**Syntax**

```
result = RECTANGLE (control, x1, y1, x2, y2)
result = RECTANGLE_W (control, wx1, wy1, wx2, wy2)
```

- **control** (Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90:
  - $GFILLINTERIOR - Draws a solid figure using the current color and fill mask.
  - $GBORDER - Draws the border of a rectangle using the current color and line style.

- **x1, y1** (Input) INTEGER(2). Viewport coordinates for upper-left corner of rectangle.

- **x2, y2** (Input) INTEGER(2). Viewport coordinates for lower-right corner of rectangle.
wx1, wy1  (Input) REAL(8). Window coordinates for upper-left corner of rectangle.

wx2, wy2  (Input) REAL(8). Window coordinates for lower-right corner of rectangle.

Results
The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0.

The RECTANGLE function uses the viewport-coordinate system. The viewport coordinates (x1, y1) and (x2, y2) are the diagonally opposed corners of the rectangle.

The RECTANGLE_W function uses the window-coordinate system. The window coordinates (wx1, wy1) and (wx2, wy2) are the diagonally opposed corners of the rectangle.

SETCOLORRGB sets the current graphics color. SETFILLMASK sets the current fill mask. By default, filled graphic shapes are filled solid with the current color.

If you fill the rectangle using FLOODFILLRGB, the rectangle must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE
The RECTANGLE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Rectangle routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Rectangle.

Example
This program draws the rectangle shown below.

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
dummy = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
END
```

RECURSIVE and NON_RECURSIVE

Keywords: RECURSIVE specifies that a subroutine or function can call itself directly or indirectly. NON_RECURSIVE specifies that a subroutine or function does not call itself directly or indirectly.

Description

RECURSIVE or NON_RECURSIVE can be specified once in a FUNCTION or SUBROUTINE statement. They cannot both appear in the same statement.

Procedures not specified as RECURSIVE or NON_RECURSIVE are currently compiled as NON_RECURSIVE.

The default behavior can be changed by using the -assume [no]recursion option, or in an OPTIONS statement.

NOTE
