5.3 IMM8 CONTROL BYTE OPERATION FOR PCMPESTRI / PCMPESTRM / PCMPISTRI / PCMPISTRM

5.3.1 General Description

5.3.1.1 Source Data Format

5.3.1.2 Aggregation Operation

5.3.1.3 Polarity

5.3.1.4 Output Selection

5.3.1.5 Valid/Invalid Override of Comparisons

5.3.1.6 Summary of IMM8 Control byte

5.3.1.7 Diagram Comparison and Aggregation Process

5.4 INSTRUCTION REFERENCE

BLENDPD — Blend Packed Double Precision Floating-Point Values

BLENDPS — Blend Packed Single Precision Floating-Point Values

BLENDVPD — Variable Blend Packed Double Precision Floating-Point Values

BLENDVPS — Variable Blend Packed Single Precision Floating-Point Values

CRC32 — Accumulate CRC32 Value

DPPD — Dot Product of Packed Double Precision Floating-Point Values

DPPS — Dot Product of Packed Single Precision Floating-Point Values

EXTRACTPS — Extract Packed Single Precision Floating-Point Value

INSERTPS — Insert Packed Single Precision Floating-Point Value

MOVNTDQA — Load Double Quadword Non-Temporal Aligned Hint

MPSADBW — Compute Multiple Packed Sums of Absolute Difference

PACKUSDW — Pack with Unsigned Saturation

PBLENDVB — Variable Blend Packed Bytes

PBLENDW — Blend Packed Words

PCMPEQQ — Compare Packed Qword Data for Equal

PCMPESTRI — Packed Compare Explicit Length Strings, Return Index

PCMPESTRM — Packed Compare Explicit Length Strings, Return Mask

PCMPISTRI — Packed Compare Implicit Length Strings, Return Index

PCMPISTRM — Packed Compare Implicit Length Strings, Return Mask

PCMPGTQ — Compare Packed Data for Greater Than

PEXTRB — Extract Byte

PEXTRD/PEXTRQ — Extract Dword/Qword

PEXTW — Extract Word

PHMINPOSUW — Packed Horizontal Word Minimum

PINSB — Insert Byte

PINSRD/PINSRQ — Insert Dword/Qword

PMAXSB — Maximum of Packed Signed Byte Integers

PMAXSD — Maximum of Packed Signed Dword Integers

PMAXUD — Maximum of Packed Unsigned Dword Integers

PMAXUW — Maximum of Packed Word Integers

PMINSB — Minimum of Packed Signed Byte Integers

PMINSQ — Minimum of Packed Signed Dword Integers

PMINUD — Minimum of Packed Dword Integers

PMINUU — Minimum of Packed Word Integers

PMOVsx — Packed Move with Sign Extend

PMOVzx — Packed Move with Zero Extend

PMULQD — Multiply Packed Signed Dword Integers

1.1 INTRODUCTION

Intel® Streaming SIMD Extensions 4 (SSE4) introduces 54 new instructions in Intel 64 processors made from 45 nm process technology.

- 47 of the SSE4 instructions are available in 45 nm Intel processors based on the successor of Intel Core™ microarchitecture (code named Penryn). This subset of 47 SSE4 instruction is referred to as SSE4.1 in this document.
- SSE4.1 and seven other new SSE4 instructions are supported in 45 nm Intel processors based on a new microarchitecture (code named Nehalem). The subset of the 7 new SSE4 instructions available to Intel processors based on the Nehalem microarchitecture is referred to as SSE4.2 in this document.

1.2 SSE4 OVERVIEW

SSE4.1 is targeted to improve the performance of media, imaging, and 3D workloads. SSE4.1 adds instructions that improve compiler vectorization and significantly increase support for packed dword computation. The technology also provides a hint that can improve memory throughput when reading from uncacheable WC memory type.

The 47 SSE4.1 instructions (see Appendix A, “Instruction Summary and Encodings”) include:

- Two instructions perform packed dword multiplies.
- Two instructions perform floating-point dot products with input/output selects.
- One instruction performs a load with a streaming hint.
- Six instructions simplify packed blending.
- Eight instructions expand support for packed integer MIN/MAX.
- Four instructions support floating-point round with selectable rounding mode and precision exception override.
- Seven instructions improve data insertion and extractions from XMM registers
- Twelve instructions improve packed integer format conversions (sign and zero extensions).
- One instruction improves SAD (sum absolute difference) generation for small block sizes.
- One instruction aids horizontal searching operations.
- One instruction improves masked comparisons.
STREAMING SIMD EXTENSIONS 4

• One instruction adds qword packed equality comparisons.
• One instruction adds dword packing with unsigned saturation.

The seven SSE4.2 instructions improve performance in the following areas:
• String and text processing that can take advantage of single-instruction multiple-data programming techniques.
• Application-targeted accelerator (ATA) instructions.
• A SIMD integer instruction that enhances the capability of the 128-bit integer SIMD capability in SSE4.1.

SSE4 requires no new OS support to save and restore the register state beyond what is required by Streaming SIMD Extensions (SSE). There are six SSE4.1 instructions which generate numeric (SIMD floating-point) exceptions, thus requiring the OS to provide IEEE-754 compliant event handlers for post-compute exception (similar to SSE/SSE2/SSE3 instructions). SSE4.2 instructions do not generate SIMD floating-point exceptions. See Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1, Appendix E.

SSE4 is fully compatible with software written for previous generations of Intel 64 and IA-32 architecture microprocessors. All existing software continues to run correctly without modification on microprocessors that incorporate SSE4, as well as in the presence of existing and new applications that incorporate SSE4.
2.1 NEW DATA TYPES
SSE4 does not introduce any new data types.

2.2 SSE4.1 INSTRUCTION SET
SSE4.1 instructions can use an XMM register as a source or destination. Programming SSE4.1 is similar to programming 128-bit Integer SIMD and floating-point SIMD instructions in SSE/SSE2/SSE3/SSSE3. SSE4.1 does not provide any 64-bit integer SIMD instructions.

2.2.1 Dword Multiply Instructions
SSE4.1 adds two dword multiply instructions that aid vectorization. They allow four simultaneous 32 bit by 32 bit multiplies. PMULLD returns a low 32-bits of the result and PMULDQ returns a 64-bit signed result. These represent the most common integer multiply operation. See Table 2-1.

<table>
<thead>

<td>PMULUDQ*</td>
</tr>
</tbody>
</table>

NOTE:  
* Available prior to SSE4.1.

2.2.2 Floating-Point Dot Product Instructions
SSE4.1 adds double-precision (for 2 elements; DPPD) and single-precision dot products (for up to 4 elements; DPPS).  
These dot-product instructions include source select and destination broadcast which generally improves the usability. For example, a single DPPS instruction can be used for a 2, 3, or 4 element dot product.
SSE4 FEATURES

2.2.3 Streaming Load Hint Instruction

Historically, CPU read accesses of WC memory type regions have significantly lower throughput than accesses to cacheable memory.

The streaming load instruction in SSE4.1, MOVNTDQA, provides a non-temporal hint that can cause adjacent 16-byte items within an aligned 64-byte region (a streaming line) to be fetched and held in a small set of temporary buffers (“streaming load buffers”). Subsequent streaming loads to other aligned 16-byte items in the same streaming line may be supplied from the streaming load buffer and can improve throughput.

Programmers are advised to use the following practices to improve the efficiency of MOVNTDQA streaming loads from WC memory:

• Streaming loads must be 16-byte aligned.
• Temporally group streaming loads of the same streaming cache line for effective use of the streaming load buffers. Loads issued much later may cause the streaming line to be refetched from memory.
• Temporally group streaming loads from at most a few streaming lines together. The number of streaming load buffers is small; grouping a modest number of streams will avoid running out of streaming load buffers and the resultant refetching of streaming lines from memory.
• Avoid writing to a streaming line until all reads to 16-byte items have occurred. Reading a 16-byte item from a streaming line that has been written, may cause the streaming line to be refetched.
• Avoid reading a given 16-byte item within a streaming line more than once; repeated loads of a particular 16-byte item are likely to cause the streaming line to be refetched.
• The streaming load buffers, reflecting the WC memory type characteristics, are not required to be snooped by operations from other agents. Software should not rely upon such coherency actions to provide any data coherency with respect to other logical processors or bus agents. Rather, software must employ memory fences (i.e. the MFENCE instruction) to insure the consistency of WC memory accesses between producers and consumers.
• Streaming loads must not be used to reference memory addresses that are mapped to I/O devices having side effects or when reads to these devices are destructive. This is because MOVNTDQA is speculative in nature.

2.2.4 Packed Blending Instructions

SSE4.1 adds 6 instructions used for blending (BLENDPS, BLENDPD, BLENDVPS, BLENDVPD, PBLENDVB, PBLENDW).

Blending conditionally copies a field in a source operand to the same field in the destination. SSE4.1 instructions improve blending operations for most field sizes. A single new SSE4.1 instruction can generally replace a sequence of 2 to 4 operations using previous architectures.
The variable blend instructions (BLENDVPS, PBLENDVPD, PBLENDW) introduce the use of control bits stored in an implicit XMM register (XMM0). The most significant bit in each field (the sign bit, for 2’s compliment integer or floating-point) is used as a selector. See Table 2-2.

### Table 2-2. Blend Field Size and Control Modes Supported by SSE4.1

</tr>
</tbody>
</table>

**NOTE:**
1. Use of floating-point SIMD instructions on integer data types may incur performance penalties.
2. Byte variable blend can be used for larger sized fields by reformatting (or shuffling) the blend control.

#### 2.2.5 Packed Integer MIN/MAX Instructions

SSE4.1 adds 8 packed integer MIN and MAX instructions (PMINUW, PMINUD, PMINSB, PMINSD; PMAXUW, PMAXUD, PMAXSB, PMAXSD).

Four 32-bit integer packed MIN and MAX instructions operate on unsigned and signed dwords. Two instructions operate on signed bytes. Two instructions operate on unsiged words. See Table 2-3.

</table>

**NOTE:**
* Available prior to SSE4.1.

#### 2.2.6 Floating-Point Round Instructions with Selectable Rounding Mode

High level languages and libraries often expose rounding operations having a variety
SSE4 FEATURES

of numeric rounding and exception behaviors. Using SSE/SSE2/SSE3 instructions to mitigate the rounding-mode-related problem is sometimes not straight forward. SSE4.1 introduces four rounding instructions (ROUNDPS, ROUNDPD, ROUNDSS, ROUNDSD) that cover scalar and packed single- and double-precision floating-point operands. The rounding mode can be selected using an immediate from one of the IEEE-754 modes (Nearest, -Inf, +Inf, and Truncate) without changing the current rounding mode; or the instruction can be forced to use the current rounding mode. Another bit in the immediate is used to suppress inexact precision exceptions. Rounding instructions in SSE4.1 generally permit single-instruction solutions to C99 functions ceil(), floor(), trunc(), rint(), nearbyint(). These instructions simplify the implementations of half-way-away-from-zero rounding modes as used by C99 round() and F90’s nint().

2.2.7 Insertion and Extractions from XMM Registers

SSE4.1 adds 7 instructions (corresponding to 9 assembly instruction mnemonics) that simplify data insertion and extraction between general-purpose register (GPR) and XMM registers (EXTRACTPS, INSERTPS, PINSRB, PINSRD, PINSRQ, PEXTRB, PEXTRW, PEXTRD, and PEXTRQ). When accessing memory, no alignment is required for any of these instructions (unless alignment checking is enabled). EXTRACTPS extracts a single-precision floating-point value from any offset in an XMM register and stores the result to memory or a general-purpose register. INSERTPS inserts a single floating-point value from either a 32-bit memory location or from an XMM register. In addition, INSERTPS allows the insertion of +0.0f into destination fields.

PINSRB, PINSRD, and PINSRQ insert byte, dword, or qword values from 32/64 registers or memory into an XMM register. Word values were already supported by SSE2 (PINSRW).

PEXTRB, PEXTRW, PEXTRD, and PEXTRQ extract byte, word, dword, and qword from an XMM register and insert the values into a general-purpose register or memory.

2.2.8 Packed Integer Format Conversions

A common type of operation on packed integers is the conversion by zero- or sign-extension of packed integers into wider data types. SSE4.1 adds 12 instructions that convert from a smaller packed integer type to a larger integer type (PMOVSBW, PMOVZXBW, PMOVSBWD, PMOVZXWBD, PMOVXSBW, PMOVXWBD, PMOVSBWD, PMOVXBD, PMOVXBQ, PMOVXQB, PMOVXSBQ, PMOVXWQB, PMOVXBDQ). The source operand is from either an XMM register or memory; the destination is an XMM register. See Table 2-4.

When accessing memory, no alignment is required for any of the instructions unless alignment checking is enabled. In which case, all conversions must be aligned to the width of the memory reference. The number of elements converted (and width of memory reference) is illustrated in Table 2-5. The alignment requirement is shown
in parenthesis.

</tbody>
</table>

2.2.9 Improved Sums of Absolute Differences (SAD) for 4-Byte Blocks

SSE4.1 adds an instruction (MPSADBW) that performs eight 4-byte wide SAD operations per instruction. Compared to PSADBW, MPSADBW operates on smaller chunks (4-byte instead of 8-byte chunks); this makes the instruction better suited to video coding standards such as VC.1 and H.264. MPSADBW performs four times the number of absolute difference operations than that of PSADBW (per instruction). This can improve performance for dense motion searches.

MPSADBW uses a 4-byte wide field from a source operand; the offset of the 4-byte field within the 128-bit source operand is specified by two immediate control bits. MPSADBW produces eight 16-bit SAD results. Each 16-bit SAD result is formed from overlapping pairs of 4 bytes in the destination with the 4-byte field from the source operand. MPSADBW uses eleven consecutive bytes in the destination operand, its offset is specified by a control bit in the immediate byte (i.e. the offset can be from byte 0 or from byte 4). Figure 2-1 illustrates the operation of MPSADBW. MPSADBW can simplify coding of dense motion estimation by providing source and destination offset control, higher throughput of SAD operations, and the smaller chunk size.
2.2.10 Horizontal Search

SSE4.1 adds a search instruction (PHMINPOSUW) that finds the value and location of the minimum unsigned word from one of 8 horizontally packed unsigned words. The resulting value and location (offset within the source) are packed into the low dword of the destination XMM register.

Rapid search is often a significant component of motion estimation. MPSADBW and PHMINPOSUW can be used together to improve video encode.

2.2.11 Packed Test

The packed test instruction PTEST is similar to a 128-bit equivalent to the legacy instruction TEST. With PTEST, the source argument is typically used like a bit mask. PTEST performs a logical AND between the destination with this mask and sets the ZF flag if the result is zero. The CF flag (zero for TEST) is set if the inverted mask AND’d with the destination is all zero. Because the destination is not modified, PTEST simplifies branching operations (such as branching on signs of packed floating-point numbers, or branching on zero fields).

2.2.12 Packed Qword Equality Comparisons

SSE4.1 adds a 128-bit packed qword equality test. The new instruction (PCMPEQQ) is identical to PCMPEQD, but has qword granularity.
2.2.13  **Dword Packing With Unsigned Saturation**

SSE4.1 adds a new instruction PACKUSDW to complete the set of small integer pack instructions in the family of SIMD instruction extensions. PACKUSDW packs dword to word with unsigned saturation. See Table 2-6 for the complete set of packing instructions for small integers.

<table>
<thead>
<tr>
<th>Pack Type</th>

<td>PACKSSDW</td>
<td>PACKSSWB</td>
</tr>
</tbody>
</table>

**Table 2-6. Enhanced SIMD Pack support by SSE4.1**

2.2.14  **IEEE 754 Compliance**

The six SSE4.1 instructions that perform floating-point arithmetic are:

- **DPPS**
- **DPPD**
- **ROUNDPS**
- **ROUNDPD**
- **ROUNDSS**
- **ROUNDSD**

Dot Product operations are not specified in IEEE-754. When neither FTZ nor DAZ are enabled, the dot product instructions resemble sequences of IEEE-754 multiplies and adds (with rounding at each stage), except that the treatment of input NaNs is implementation specific (there will be at least one NaN in the output). The input select fields (bits imm8[4:7]) force input elements to +0.0f prior to the first multiply and will suppress input exceptions that would otherwise have been generated.

As a convenience to the exception handler, any exceptions signaled from DPPS or DPPD leave the destination unmodified.

Round operations signal invalid and precision only.
SSE4 FEATURES

Table 2-7. SIMD numeric exceptions signaled by SSE4.1

<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

NOTE:
1. Invalid is signaled only if Src = SNaN.
2. Precision is ignored (regardless of the MXCSR precision mask) if imm8[3] = ‘1’.

The other SSE4.1 instructions with floating-point arguments (BLENDPS, BLENDPD, BLENDVPS, BLENDVPD, INSERTPS, EXTRACTPS) do not signal any SIMD numeric exceptions.

2.3 SSE4.2 INSTRUCTION SET

Five of the seven SSE4.2 instructions can use an XMM register as a source or destination. These include four text/string processing instructions and one packed quadword compare SIMD instruction. Programming these five SSE4.2 instructions is similar to programming 128-bit Integer SIMD in SSE2/SSSE3. SSE4.2 does not provide any 64-bit integer SIMD instructions.

The remaining two SSE4.2 instructions uses general-purpose registers to perform accelerated processing functions in specific application areas.

2.3.1 String and Text Processing Instructions

String and text processing instructions in SSE4.2 allocates 4 opcodes to provide a rich set of string and text processing capabilities that traditionally required many more opcodes. These 4 instructions use XMM registers to process string or text elements of up to 128-bits (16 bytes or 8 words). Each instruction uses an immediate byte to support a rich set of programmable controls. A string-processing SSE4.2 instruction returns the result of processing each pair of string elements using either an index or a mask.

The capabilities of the string/text processing instructions include:
- Handling string/text fragments consisting of bytes or words, either signed or unsigned
SSE4 FEATURES

- Support for partial string or fragments less than 16 bytes in length, using either explicit length or implicit null-termination
- Four types of string compare operations on word/byte elements
- Up to 256 compare operations performed in a single instruction on all string/text element pairs
- Built-in aggregation of intermediate results from comparisons
- Programmable control of processing on intermediate results
- Programmable control of output formats in terms of an index or mask
- Bi-directional support for the index format
- Support for two mask formats: bit or natural element width
- Not requiring 16-byte alignment for memory operand

The four SSE4.2 instructions that process text/string fragments are:

- PCMPESTRI — Packed compare explicit-length strings, return index in ECX/RCX
- PCMPESTRM — Packed compare explicit-length strings, return mask in XMM0
- PCMPISTRI — Packed compare implicit-length strings, return index in ECX/RCX
- PCMPISTRM — Packed compare implicit-length strings, return mask in XMM0

All four require the use of an immediate byte to control operation. The two source operands can be XMM registers or a combination of XMM register and memory address. The immediate byte provides programmable control with the following attributes:

- Input data format
- Compare operation mode
- Intermediate result processing
- Output selection

Depending on the output format associated with the instruction, the text/string processing instructions implicitly uses either a general-purpose register (ECX/RCX) or an XMM register (XMM0) to return the final result.

Two of the four text-string processing instructions specify string length explicitly. They use two general-purpose registers (EDX, EAX) to specify the number of valid data elements (either word or byte) in the source operands. The other two instructions specify valid string elements using null termination. A data element is considered valid only if it has a lower index than the least significant null data element.

2.3.1.1 Memory Operand Alignment

The text and string processing instructions in SSE4.2 do not perform alignment checking on memory operands. This is different from most other 128-bit SIMD instructions accessing the XMM registers. The absence of an alignment check for
SSE4 FEATURES

these four instructions does not imply any modification to the existing definitions of other instructions.

2.3.2 Packed Comparison SIMD integer Instruction

SSE4.2 also provides a 128-bit integer SIMD instruction PCMPGTQ that performs logical compare of greater-than on packed integer quadwords.

2.3.3 Application-Targeted Accelerator Instructions

There are two application-targeted accelerator instructions in SSE4.2:

- CRC32 — Provides hardware acceleration to calculate cyclic redundancy checks for fast and efficient implementation of data integrity protocols.
- POPCNT — Accelerates software performance in the searching of bit patterns.
The application programming environment for SSE4 is similar to that of Streaming SIMD Extensions (SSE), SSE2, SSE3, and SSSE3.

3.1 CPUID

The CPUID instruction is extended to provide additional information, including three feature flags that indicate support for SSE4 instructions. CPUID’s output is dependent on the contents of the EAX register upon execution. For example, the following pseudocode loads EAX with 00H and causes CPUID to return a Maximum Return Value and the Vendor Identification String in the appropriate registers:

```assembly
MOV EAX, 00H
CPUID
```

Table 3-1 shows information returned, depending on the initial value loaded into the EAX register. Table 3-2 shows the maximum CPUID input value recognized for each family of Intel 64 and IA-32 processors on which CPUID is implemented.

Two types of information are returned: basic and extended function information. If a value is entered for CPUID.EAX is invalid for a particular processor, the data for the highest basic information leaf is returned. For example, using the Intel® Core™2 Duo processor, the following is true:

- CPUID.EAX = 05H (* Returns MONITOR/MWAIT leaf. *)
- CPUID.EAX = 0AH (* Returns Architectural Performance Monitoring leaf. *)
- CPUID.EAX = 0BH (* INVALID: Returns the same information as CPUID.EAX = 0AH. *)
- CPUID.EAX = 80000008H (* Returns virtual/physical address size data. *)
- CPUID.EAX = 8000000AH (* INVALID: Returns same information as CPUID.EAX = 0AH. *)

CPUID can be executed at any privilege level to serialize instruction execution. Serializing instruction execution guarantees that any modifications to flags, registers, and memory for previous instructions are completed before the next instruction is fetched and executed.

**NOTES:**
* If CPUID.80000008H:EAX[7:0] is supported, the maximum physical address number supported should come from this field.

**INPUT EAX = 0: Returns CPUID’s Highest Value for Basic Processor Information and the Vendor Identification String**

When CPUID executes with EAX set to 0, the processor returns the highest value the CPUID recognizes for returning basic processor information. The value is returned in the EAX register (see Table 3-2) and is processor specific.
A vendor identification string is also returned in EBX, EDX, and ECX. For Intel processors, the string is "GenuineIntel" and is expressed:

EBX ← 756e6547h (* "Genu", with G in the low nibble of BL *)
EDX ← 49656e69h (* "ineI", with i in the low nibble of DL *)
ECX ← 6c65746eh (* "ntel", with n in the low nibble of CL *)

INPUT EAX = 80000000H: Returns CPUID’s Highest Value for Extended Processor Information

When CPUID executes with EAX set to 0, the processor returns the highest value the processor recognizes for returning extended processor information. The value is returned in the EAX register (see Table 3-2) and is processor specific.

IA32_BIOS_SIGN_ID Returns Microcode Update Signature

For processors that support the microcode update facility, the IA32_BIOS_SIGN_ID MSR is loaded with the update signature whenever CPUID executes. The signature is returned in the upper dword. For details, see Chapter 9 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

INPUT EAX = 1: Returns Model, Family, Stepping Information

When CPUID executes with EAX set to 1, version information is returned in EAX (see Figure 3-1). For example: extended family, extended model, model, family, and processor type for the processor code-named Penryn is as follows:

- Extended Model — 0001B
- Extended Family — 0000_0000B
- Model — 0111B
- Family — 0110B
- Processor Type — 00B

See Table 3-3 for available processor type values. Stepping IDs are provided as needed.

![Figure 3-1. Version Information Returned by CPUID in EAX](OM16525)
APPLICATION PROGRAMMING MODEL

Table 3-3. Processor Type Field

<table>
<thead>
<tr>
<th>Type</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original OEM Processor</td>
<td>00B</td>

</tr>
<tr>
<td>Dual processor (not applicable to Intel486 processors)</td>
<td>10B</td>
</tr>
<tr>
<td>Intel reserved</td>
<td>11B</td>
</tr>
</tbody>
</table>

Extended family, extended model, model, family, and processor type for the processor code-named Nehalem is as follows:

- Extended Model — 0001B
- Extended Family — 0000_0000B
- Model — 1010B
- Family — 0110B
- Processor Type — 00B

NOTE

See AP-485, Intel Processor Identification and the CPUID Instruction (Order Number 241618) and Chapter 14 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for information on identifying earlier IA-32 processors.

The Extended Family ID needs to be examined only when the Family ID is 0FH. Integrate the fields into a display using the following rule:

IF Family_ID ≠ 0FH
    THEN Displayed_Family = Family_ID;
    ELSE Displayed_Family = Extended_Family_ID + Family_ID;
(* Right justify and zero-extend 4-bit field. *)
FI;
(* Show Display_Family as HEX field. *)

The Extended Model ID needs to be examined only when the Family ID is 06H or 0FH. Integrate the field into a display using the following rule:

IF (Family_ID = 06H or Family_ID = 0FH)
    THEN Displayed_Model = (Extended_Model_ID << 4) + Model_ID;
(* Right justify and zero-extend Extended_Model_ID and Model_ID. *)
    ELSE Displayed_Model = Model_ID;
FI;
(* Show Display_Model as HEX field. *)
INPUT EAX = 1: Returns Additional Information in EBX

When CPUID executes with EAX set to 1, additional information is returned to the EBX register:

- Brand index (low byte of EBX) — this number provides an entry into a brand string table that contains brand strings for IA-32 processors. More information about this field is provided later in this section.

- CLFLUSH instruction cache line size (second byte of EBX) — this number indicates the size of the cache line flushed with CLFLUSH instruction in 8-byte increments. This field was introduced in the Pentium 4 processor.

- Local APIC ID (high byte of EBX) — this number is the 8-bit ID that is assigned to the local APIC on the processor during power up. This field was introduced in the Pentium 4 processor.

INPUT EAX = 1: Returns Feature Information in ECX and EDX

When CPUID executes with EAX set to 1, feature information is returned in ECX and EDX.

- Figure 3-2 and Table 3-4 show encodings for ECX.
- Figure 3-3 and Table 3-5 show encodings for EDX.

For all feature flags, a 1 indicates that the feature is supported. Use Intel to properly interpret feature flags.

NOTE

Software must confirm that a processor feature is present using feature flags returned by CPUID prior to using the feature. Software should not depend on future offerings retaining all features.

INPUT EAX = 2: Cache and TLB Information Returned in EAX, EBX, ECX, EDX

When CPUID executes with EAX set to 2, the processor returns information about the processor’s internal caches and TLBs in the EAX, EBX, ECX, and EDX registers.

The encoding is as follows:

- The least-significant byte in register EAX (register AL) indicates the number of times the CPUID instruction must be executed with an input value of 2 to get a complete description of the processor’s caches and TLBs. The first member of the family of Pentium 4 processors will return a 1.
- The most significant bit (bit 31) of each register indicates whether the register contains valid information (set to 0) or is reserved (set to 1).
- If a register contains valid information, the information is contained in 1 byte descriptors. Table 3-6 shows the encoding of these descriptors. Note that the order of descriptors in the EAX, EBX, ECX, and EDX registers is not defined; that is, specific bytes are not designated to contain descriptors for specific cache or TLB types. The descriptors may appear in any order.

Example 3-1. Example of Cache and TLB Interpretation

The first member of the family of Pentium 4 processors returns the following information about caches and TLBs when the CPUID executes with an input value of 2:

EAX 66 5B 50 01H
EBX 0H
ECX 0H
EDX 00 7A 70 00H

Which means:

- The least-significant byte (byte 0) of register EAX is set to 01H. This indicates that CPUID needs to be executed once with an input value of 2 to retrieve complete information about caches and TLBs.
- The most-significant bit of all four registers (EAX, EBX, ECX, and EDX) is set to 0, indicating that each register contains valid 1-byte descriptors.
- Bytes 1, 2, and 3 of register EAX indicate that the processor has:
  - 50H - a 64-entry instruction TLB, for mapping 4-KByte and 2-MByte or 4-MByte pages.
  - 5BH - a 64-entry data TLB, for mapping 4-KByte and 4-MByte pages.
  - 66H - an 8-KByte 1st level data cache, 4-way set associative, with a 64-Byte cache line size.
- The descriptors in registers EBX and ECX are valid, but contain NULL descriptors.
- Bytes 0, 1, 2, and 3 of register EDX indicate that the processor has:
  - 00H - NULL descriptor.
  - 70H - Trace cache: 12 K-μop, 8-way set associative.
— 7AH - a 256-KByte 2nd level cache, 8-way set associative, with a sectored, 64-byte cache line size.
— 00H - NULL descriptor.

**INPUT EAX = 4: Returns Deterministic Cache Parameters for Each Level**
When CPUID executes with EAX set to 4 and ECX contains an index value, the processor returns encoded data that describe a set of deterministic cache parameters (for the cache level associated with the input in ECX). Valid index values start from 0.

Software can enumerate the deterministic cache parameters for each level of the cache hierarchy starting with an index value of 0, until the parameters report the value associated with the cache type field is 0. The architecturally defined fields reported by deterministic cache parameters are documented in Table 3-1.

The CPUID leaf 4 also reports information about maximum number of cores in a physical package. This information is constant for all valid index values. Software can query maximum number of cores per physical package by executing CPUID with EAX=4 and ECX=0.

**INPUT EAX = 5: Returns MONITOR and MWAIT Features**
When CPUID executes with EAX set to 5, the processor returns information about features available to MONITOR/MWAIT instructions. The MONITOR instruction is used for address-range monitoring in conjunction with MWAIT instruction. The MWAIT instruction optionally provides additional extensions for advanced power management. See Table 3-1.

**INPUT EAX = 6: Returns Thermal and Power Management Features**
When CPUID executes with EAX set to 6, the processor returns information about thermal and power management features. See Table 3-1.

**INPUT EAX = 10: Returns Architectural Performance Monitoring Features**
When CPUID executes with EAX set to 10, the processor returns information about support for architectural performance monitoring capabilities. Architectural performance monitoring is supported if the version ID (see Table 3-1) is greater than Pn 0. See Table 3-1.

For each version of architectural performance monitoring capability, software must enumerate this leaf to discover the programming facilities and the architectural performance events available in the processor. The details are described in Chapter 18, "Debugging and Performance Monitoring," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3B*. 
APPLICATION PROGRAMMING MODEL

METHODS FOR RETURNING BRANDING INFORMATION

Use the following techniques to access branding information:

1. Processor brand string method; this method also returns the processor’s maximum operating frequency
2. Processor brand index; this method uses a software supplied brand string table.

These two methods are discussed in the following sections. For methods that are available in early processors, see Section: “Identification of Earlier IA-32 Processors” in Chapter 14 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1.

The Processor Brand String Method

Figure 3-4 describes the algorithm used for detection of the brand string. Processor brand identification software should execute this algorithm on all Intel 64 and IA-32 processors.

This method (introduced with Pentium 4 processors) returns an ASCII brand identification string and the maximum operating frequency of the processor to the EAX, EBX, ECX, and EDX registers.
How Brand Strings Work

To use the brand string method, execute CPUID with EAX input of 8000002H through 80000004H. For each input value, CPUID returns 16 ASCII characters using EAX, EBX, ECX, and EDX. The returned string will be NULL-terminated.

Table 3-7 shows the brand string that is returned by the first processor in the Pentium 4 processor family.
Figure 3-5 provides an algorithm which software can use to extract the maximum processor operating frequency from the processor brand string.

**NOTE**

When a frequency is given in a brand string, it is the maximum qualified frequency of the processor, not the frequency at which the processor is currently running.

The Processor Brand Index Method

The brand index method (introduced with Pentium® III Xeon® processors) provides an entry point into a brand identification table that is maintained in memory by system software and is accessible from system- and user-level code. In this table, each brand index is associated with an ASCII brand identification string that identifies the official Intel family and model number of a processor.

When CPUID executes with EAX set to 1, the processor returns a brand index to the low byte in EBX. Software can then use this index to locate the brand identification string for the processor in the brand identification table. The first entry (brand index 0) in this table is reserved, allowing for backward compatibility with processors that do not support the brand identification feature. Starting with processor signature...
family ID = 0FH, model = 03H, brand index method is no longer supported. Use brand string method instead. Table 3-8 shows brand indices that have identification strings associated with them.

NOTES:
1. Indicates versions of these processors that were introduced after the Pentium III
3.2 DETECTING SSE4 INSTRUCTIONS

3.2.1 Detecting SSE4.1 Instructions Using CPUID

In order for an application to use SSE4.1, the following conditions must exist. Otherwise, an invalid opcode exception (Int 6) is generated:

- CR0.EM = 0 (emulation disabled)
- CR4.OSFXSR = 1 (OS supports saving Streaming SIMD Extensions state during context switches)
- CPUID.01H:ECX.SSE4_1 [bit 19]= 1 (processor supports SSE4.1)

An application can determine whether SSE4.1 is supported by checking the CPUID feature flag at CPUID.01H:ECX[Bit 19]. The essential steps are illustrated in the pseudo code below.

Checking for SSE4.1 Support

unsigned RegECX;

boolean SSE4_1_instructions_work = TRUE;
asm{
    ; pseudo operation illustrating
    eax <- 1     ; which CPUID feature flag to check
    cpuid
    RegECX <- ecx
}
if (RegECX[bit 19] ) SSE4_1_instructions_work = TRUE;
// Add appropriate code as needed to ensure
// OS providing adequate support for context switching, etc...
return SSE4_1_instructions_work;

3.2.2 Detecting SSE4.2 Instructions Using CPUID

In order for an application to use PCMPGTQ and the text/string search instructions in SSE4.2, the following conditions must exist. Otherwise, an invalid opcode exception (Int 6) is generated:

- CR0.EM = 0 (emulation disabled)
- CR4.OSFXSR = 1 (OS supports saving SSE state during context switches)
- CPUID.01H:ECX.SSE4_2 [bit 20]= 1 (processor supports SSE4.2)

An application can determine whether the desired SSE4.2 instructions are supported by checking the CPUID feature flag at CPUID.01H:ECX[Bit 20]. The essential steps are illustrated in the pseudo code below.
APPLICATION PROGRAMMING MODEL

Example 3-2. Detecting SSE4.2 using CPUID

```c
unsigned RegECX;

boolean SSE4_2_instructions_work = TRUE;
asm{
  // pseudo operation illustrating
  eax <- 1  // which CPUID feature flag to check
  cpuid
  RegECX <- ecx
}
if (RegECX[bit 20] ) SSE4_2_instructions_work = TRUE;
// Add appropriate code as needed to ensure
// OS providing adequate support for context switching, etc...
return SSE4_2_instructions_work;
```

In order for an application to use CRC32 instruction, the following condition must exist. Otherwise, an invalid opcode exception (INT 6) is generated:

CPUID.01H:ECX.SSE4_2 [bit 20]= 1 (processor supports SSE4.2)

In order for an application to use POPCNT instruction, the following condition must exist. Otherwise, an invalid opcode exception (INT 6) is generated:

CPUID.01H:ECX.SSE4_2 [bit 23]= 1 (processor supports POPCNT)

3.3 EXCEPTIONS AND SSE4
The SSE4.1 and SSE4.2 instruction sets do not introduce new types of exceptions.
This chapter describes the interface of the SSE4 to the operating system.

### 4.1 Enabling SSE4

SSE4.1 and SSE4.2 are extensions of SSE, SSE2, SSE3, and SSSE3.

To check if the processor supports SSE4.1, execute CPUID with EAX = 1 as input. If bit 19 of ECX is set, then the processor supports SSE4.1. If the bit is cleared, the processor does not support SSE4.1.

To check if the processor supports SSE4.2 instructions for string/text processing, PCMPGTQ, and CRC32, execute CPUID with EAX = 1 as input. If bit 20 of ECX is set, then the processor supports these SSE4.2 instructions. If the bit is cleared, the processor does not support them.

Enabling OS support for SSE4.1, PCMPGTQ, string/text processing instructions of SSE4.2 has the same requirements as for SSE. See Chapter 12, "System Programming for Streaming SIMD Instruction Sets" of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

To check if the processor supports the POPCNT instruction, execute CPUID with EAX = 1 as input. If bit 23 of ECX is set, then the processor supports the POPCNT instruction. If the bit is cleared, the processor does not support it.

Operating system does not require special support to enable CRC32 or POPCNT beyond normal requirements of Intel 64 architecture.

### 4.2 Device Not Available (DNA) Exceptions

If CR0.TS is set, attempts to execute an SSE4.1 instruction will cause a DNA exception (#NM). Likewise, an attempt to execute PCMPGTQ or a string/text processing instruction of SSE4.2 will cause a DNA exception (#NM).

If CPUID.01H:ECX.SSE4.1 [bit 19] is clear, execution of any SSE4.1 instruction causes an invalid opcode fault regardless of the state of CR0.TS.

If CPUID.01H:ECX.SSE4.2 [bit 20] is clear, execution of PCMPGTQ or a string/text processing instruction of SSE4.2 causes an invalid opcode fault regardless of the state of CR0.TS.
4.3 **SSE4 EMULATION**

The CR0.EM bit enables emulation of x87 floating-point instructions. It cannot be used to emulate SSE4.1. Likewise, the bit cannot be used to emulate PCMPGTQ or any of the string text processing instructions of SSE4.2.

If an SSE4.1 instruction is executed when CR0.EM is set, an Invalid Opcode exception (Int 6) is generated instead of a Device Not Available exception (INT 7).

If PCMPGTQ or an SSE4.2 string text processing instruction is executed while CR0.EM = 1, an Invalid Opcode exception (INT 6) is generated instead of a Device Not Available exception (INT 7).

CRC32 and POPCNT are not impacted by CR0.TS or CR0.EM.
5.1 INSTRUCTION FORMATS
SSE4 uses existing instruction formats. Instructions use the ModR/M format and, in general, operations are not duplicated to provide two directions (i.e. separate load and store variants).

5.2 NOTATIONS
Besides opcodes, the following notation describes information in the ModR/M byte:

- **/digit:** (digit between 0 and 7) indicates that the instruction uses only the r/m (register and memory) operand. The reg field contains the digit that provides an extension to the instruction's opcode.

- **/digitR:** (digit between 0 and 7) indicates that the instruction uses only the register operand (ie, mod=11). The reg field contains the digit that provides an extension to the instruction's opcode.

- **/r:** indicates that the ModR/M byte of an instruction contains both a register operand and an r/m operand.

In addition, these abbreviations are used:

- **r32:** Intel Architecture 32-bit integer register
- **xmm/m128:** indicates a 128-bit Streaming SIMD Extensions/Streaming SIMD Extensions 2 register or a 128-bit memory location.
- **xmm/m64:** indicates a 128-bit Streaming SIMD Extensions/Streaming SIMD Extensions 2 register or a 64-bit memory location.
- **xmm/m32:** indicates a 128-bit Streaming SIMD Extensions/Streaming SIMD Extensions 2 register or a 32-bit memory location.
- **mm/m64:** indicates a 64-bit integer MMX™ multimedia register or a 64-bit memory location.
- **imm8:** indicates an immediate 8-bit operand.
- **ib:** indicates that an immediate byte operand follows the opcode, ModR/M byte or scaled-indexing byte.
- **<XMM0>:** indicates implied use of the XMM0 register.

When there is ambiguity, xmm1 indicates the first source operand using an XMM register and xmm2 the second source operand using an XMM register.
SSE4 INSTRUCTION SET

Some instructions use the XMM0 register as the third source operand, indicated by <XMM0>. The use of the third XMM register operand is implicit in the instruction encoding and does not affect the ModR/M encoding.

5.3 IMM8 CONTROL BYTE OPERATION FOR PCMPESTRI / PCMPESTRM / PCMPISTRI / PCMPISTRM

The operation of the immediate control byte (see Section 2.3.1) is common to the four string text processing instructions of SSE4.2. This section describes these common operations. Some of the notations introduced in this section are referenced in the reference pages of each instruction.

5.3.1 General Description

The operation of PCMPESTRI, PCMPESTRM, PCMPISTRI, PCMPISTRM is defined by the combination of the respective opcode and the interpretation of an immediate control byte that is part of the instruction encoding.

The opcode controls the relationship of input bytes/words to each other (determines whether the inputs terminated strings or whether lengths are expressed explicitly) as well as the desired output (index or mask).

The Imm8 Control Byte for PCMPESTRM/PCMPESTRI/PCMPISTRM/PCMPISTRI encodes a significant amount of programmable control over the functionality of those instructions. Some functionality is unique to each instruction while some is common across some or all of the four instructions. This section describes functionality which is common across the four instructions.

The arithmetic flags (ZF, CF, SF, OF, AF, PF) are set as a result of these instructions. However, the meanings of the flags have been overloaded from their typical meanings in order to provide additional information regarding the relationships of the two inputs.

PCMPxSTRx instructions perform arithmetic comparisons between all possible pairs of bytes or words, one from each packed input source operand. The boolean results of those comparisons are then aggregated in order to produce meaningful results. The Imm8 Control Byte is used to affect the interpretation of individual input elements as well as control the arithmetic comparisons used and the specific aggregation scheme.

Specifically, the Imm8 Control Byte consists of bit fields that control the following attributes:

• **Source data format** — Byte/word data element granularity, signed or unsigned elements
• **Aggregation operation** — Encodes the mode of per-element comparison operation and the aggregation of per-element comparisons into an intermediate result

• **Polarity** — Specifies intermediate processing to be performed on the intermediate result

• **Output selection** — Specifies final operation to produce the output (depending on index or mask) from the intermediate result

### 5.3.1.1 Source Data Format

<table>
<thead>
<tr>
<th>Imm8[1:0]</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00b</td>
<td>Unsigned bytes</td>
<td>Both 128-bit sources are treated as packed, unsigned bytes.</td>
</tr>
<tr>
<td>01b</td>
<td>Unsigned words</td>
<td>Both 128-bit sources are treated as packed, unsigned words.</td>
</tr>
<tr>
<td>10b</td>
<td>Signed bytes</td>
<td>Both 128-bit sources are treated as packed, signed bytes.</td>
</tr>
<tr>
<td>11b</td>
<td>Signed words</td>
<td>Both 128-bit sources are treated as packed, signed words.</td>
</tr>
</tbody>
</table>

Table 5-1. Source Data Format

If the Imm8 Control Byte has bit[0] cleared, each source contains 16 packed bytes. If the bit is set each source contains 8 packed words. If the Imm8 Control Byte has bit[1] cleared, each input contains unsigned data. If the bit is set each source contains signed data.
5.3.1.2 Aggregation Operation

All 256 (64) possible comparisons are always performed. The individual Boolean results of those comparisons are referred by “BoolRes[Reg/Mem element index, Reg element index].” Comparisons evaluating to “True” are represented with a 1, False with a 0 (positive logic). The initial results are then aggregated into a 16-bit (8-bit) intermediate result (IntRes1) using one of the modes described in the table below, as determined by Imm8 Control Byte bit[3:2].

See Section 5.3.1.5 for a description of the overrideIfDataInvalid() function used in Table 5-3.

Table 5-2. Aggregation Operation

<table>
<thead>

</tr>
<tr>
<td></td>
<td>IntRes1[i] OR= overrideIfDataInvalid(BoolRes[j,i])</td>
</tr>
</tbody>
</table>
### Table 5-3. Aggregation Operation (Contd.)

| Ranges (find characters from ranges) | UpperBound = imm8[0] ? 7 : 15;  
|                                      | IntRes1 = 0;  
|                                      | For j = 0 to UpperBound, j++  
|                                      | For i = 0 to UpperBound, i+=2  
|                                      | IntRes1[j] OR= (overrideIfDataInvalid(BoolRes[j,i]) AND overrideIfDataInvalid(BoolRes[j,i+1]));  
| Equal each (string compare) | UpperBound = imm8[0] ? 7 : 15;  
|                                      | IntRes1 = 0;  
|                                      | For i = 0 to UpperBound, i++  
|                                      | IntRes1[i] = overrideIfDataInvalid(BoolRes[i,i]);  
| Equal ordered (substring search) | UpperBound = imm8[0] ? 7 : 15;  
|                                      | IntRes1 = imm8[0] ? 0xFF : 0xFFFF  
|                                      | For j = 0 to UpperBound, j++  
|                                      | For i = 0 to UpperBound-j, k=j to UpperBound, k++, i++  
|                                      | IntRes1[j] AND= overrideIfDataInvalid(BoolRes[k,i]);  

5.3.1.3 Polarity

IntRes1 may then be further modified by performing a 1’s compliment, according to the value of the Imm8 Control Byte bit[4]. Optionally, a mask may be used such that only those IntRes1 bits which correspond to “valid” reg/mem input elements are complimented (note that the definition of a valid input element is dependant on the specific opcode and is defined in each opcode’s description). The result of the possible negation is referred to as IntRes2.

### Table 5-4. Polarity

<table>
<thead>
<tr>
<th>Imm8[5:4]</th>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00b</td>
<td>Positive Polarity (+)</td>
<td>IntRes2 = IntRes1</td>
</tr>
<tr>
<td>01b</td>
<td>Negative Polarity (-)</td>
<td>IntRes2 = -1 XOR IntRes1</td>
</tr>
<tr>
<td>10b</td>
<td>Masked (+)</td>
<td>IntRes2 = IntRes1</td>
</tr>
</tbody>
</table>

For PCMPESTRI/PCMPISTRI, the Imm8 Control Byte bit[6] is used to determine if the index is of the least significant or most significant bit of IntRes2.

### Table 5-5. Output Selection

<table>
<thead>
<tr>
<th>Imm8[6]</th>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>Least significant index</td>
<td>The index returned to ECX is of the least significant set bit in IntRes2.</td>
</tr>
<tr>
<td>1b</td>
<td>Most significant index</td>
<td>The index returned to ECX is of the most significant set bit in IntRes2.</td>
</tr>
</tbody>
</table>

### Table 5-6. Output Selection

<table>
<thead>
<tr>
<th>Imm8[6]</th>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>Bit mask</td>
<td>IntRes2 is returned as the mask to the least significant bits of XMM0 with zero extension to 128 bits.</td>
</tr>
<tr>
<td>1b</td>
<td>Byte/word mask</td>
<td>IntRes2 is expanded into a byte/word mask (based on imm8[1]) and placed in XMM0. The expansion is performed by replicating each bit into all of the bits of the byte/word of the same index.</td>
</tr>
</tbody>
</table>
Specifically for PCMPESTRM/PCMPISTRM, the Imm8 Control Byte bit[6] is used to determine if the mask is a 16 (8) bit mask or a 128 bit byte/word mask.

5.3.1.5 Valid/Invalid Override of Comparisons

PCMPxSTRx instructions allow for the possibility that an end-of-string (EOS) situation may occur within the 128-bit packed data value (see the instruction descriptions below for details). Any data elements on either source that are determined to be past the EOS are considered to be invalid, and the treatment of invalid data within a comparison pair varies depending on the aggregation function being performed.

In general, the individual comparison result for each element pair BoolRes[i,j] can be forced true or false if one or more elements in the pair are invalid. See Table 5-7.

BLENDPD — Blend Packed Double Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-bit Mode</th>
<th>Compat/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 3A 0D</td>
<td>BLENDPD xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Select packed DP-FP values from xmm1 and xmm2/m128 from mask specified in imm8 and store the values into xmm1.</td>
</tr>
</tbody>
</table>

Description

Double Precision Floating-Point values from the source operand (second operand) are conditionally written to the destination operand depending on bits in the immediate operand. The immediate bits 0-1 (third operand) determine whether the corresponding DP-FP value in the destination is copied from the source (second argument).

If a bit in the mask, corresponding to a DP-FP value, is "1", then the DP-FP value is copied, else the value is left unchanged.

Operation

BLENDPD

IF (imm8[0] == 1) THEN DEST[63:0] ← SRC[63:0];
ELSE DEST[63:0] ← DEST[63:0];
IF (imm8[1] == 1) THEN DEST[127:64] ← SRC[127:64];
ELSE DEST[127:64] ← DEST[127:64];

Intel C/C++ Compiler Intrinsic Equivalent

BLENDPD __m128d _mm_blend_pd(__m128d v1, __m128d v2, const int mask);

SIMD Floating-Point Exceptions

None

Protected Mode and Compatibility Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS, or GS segments.
If a memory operand is not aligned on a 16-byte boundary, regardless of segment.

### SSE4 INSTRUCTION SET

#### BLENDVPD — Variable Blend Packed Double Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 38 15 /r</td>
<td>BLENDVPD xmm1, xmm2/m128, &lt;XMM0&gt;</td>
</tr>
</tbody>
</table>

**Description**

Double-precision floating-point values from the source operand (second argument) are conditionally written to the destination operand (first argument) depending on bits in the implicit third register argument. The most significant bit in the corresponding qword of XMM0 determines whether the destination DP FP value is copied from the source. The presence of a "1" in the mask bit indicates that the DP FP value is copied; otherwise it is left unchanged. The register assignment of the third operand is defined to be the architectural register XMM0.

**Operation**

**BLENDVPD with implicit XMM0 register operand**

1. \( \text{MASK} \leftarrow XMM0 \)
2. \( \text{IF (MASK}[63] == 1) \text{ THEN DEST}[63:0] \leftarrow SRC[63:0]; \)
3. \( \text{ELSE DEST}[63:0] \leftarrow \text{DEST}[63:0]; \)
4. \( \text{IF (MASK}[127] == 1) \text{ THEN DEST}[127:64] \leftarrow SRC[127:64]; \)
5. \( \text{ELSE DEST}[127:64] \leftarrow \text{DEST}[127:64]; \)

**Intel C/C++ Compiler Intrinsic Equivalent**

BLENDVPD __m128d _mm_blendv_pd(__m128d v1, __m128d v2, __m128d v3);

**SIMD Floating-Point Exceptions**

None

**Protected Mode and Compatibility Mode Exceptions**

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS, or GS segments.

BLENDVPS — Variable Blend Packed Single Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-bit Mode</th>
<th>Compabit/</th>
<th>Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 38 14 /r</td>
<td>BLENDVPS xmm1, xmm2/m128, &lt;XMM0&gt;</td>
<td>Valid</td>
<td>Valid</td>
<td></td>
<td>Select packed single precision floating-point values from xmm1 and xmm2/m128 from mask specified in XMM0 and store the values into xmm1.</td>
</tr>
</tbody>
</table>

Description

Single-precision floating-point values from the source operand (second argument) are conditionally written to the destination operand (first argument) depending on bits in the third register argument. The most significant bit in the corresponding dword in the third register determines whether the destination single precision floating-point value is copied from the source dword. The presence of a "1" in the mask bit indicates that the single precision floating-point value is copied; otherwise it is not copied. The register assignment of the third operand is defined to be the architectural register XMM0.

Operation

**BLENDVPS with implicit XMM0 register operand**

\[
\text{MASK} \leftarrow \text{XMM0};
\]

\[
\begin{align*}
\text{IF } (\text{MASK}[31] == 1) & \text{ THEN } \text{DEST}[31:0] \leftarrow \text{SRC}[31:0]; \\
& \text{ELSE } \text{DEST}[31:0] \leftarrow \text{DEST}[31:0]; \\

</tr>
</tbody>
</table>

NOTES:
* In 64-bit mode, r/m8 can not be encoded to access the following byte registers if a REX prefix is used: AH, BH, CH, DH.

Description
Starting with an initial value in the first operand (destination operand), accumulates a CRC32 (polynomial 0x11EDC6F41) value for the second operand (source operand) and stores the result in the destination operand. The source operand can be a register or a memory location. The destination operand must be an r32 or r64 register. If the destination is an r64 register, then the 32-bit result is stored in the least significant double word and 00000000H is stored in the most significant double word of the r64 register.

The initial value supplied in the destination operand is a double word integer stored in the r32 register or the least significant double word of the r64 register. To incrementally accumulate a CRC32 value, software retains the result of the previous CRC32 operation in the destination operand, then executes the CRC32 instruction again with new input data in the source operand. Data contained in the source operand is processed in reflected bit order. This means that the most significant bit of the source operand is treated as the least significant bit of the quotient, and so on, for all the bits of the source operand. Likewise, the result of the CRC operation is stored in the destination operand in reflected bit order. This means that the most significant bit of the resulting CRC (bit 31) is stored in the least significant bit of the destination operand (bit 0), and so on, for all the bits of the CRC.

Operation
In the pseudocode below, BIT_REFLECT on an N-bit wide operand is the bit-by-bit reflect operation from the most-significant bit to least-significant bit, as described in the paragraph above.
SSE4 INSTRUCTION SET

CRC32 instruction for 64-bit source operand and 64-bit destination operand:

\[
\begin{align*}
\text{TEMP1}[63-0] & \leftarrow \text{BIT\_REFLECT64 (SRC[63-0])} \\

\text{TEMP6}[31-0] & \leftarrow \text{TEMP5}[63-0] \mod 0x11EDC6F41H \\
\text{DEST}[31-0] & \leftarrow \text{BIT\_REFLECT (TEMP6[31-0])}
\end{align*}
\]

CRC32 instruction for 16-bit source operand and 32-bit destination operand:

\[
\begin{align*}
\text{TEMP1}[15-0] & \leftarrow \text{BIT\_REFLECT16 (SRC[15-0])} \\
\text{TEMP2}[31-0] & \leftarrow \text{BIT\_REFLECT32 (DEST[31-0])} \\
\text{TEMP3}[47-0] & \leftarrow \text{TEMP1}[15-0] \ll 32 \\
\text{TEMP4}[47-0] & \leftarrow \text{TEMP2}[31-0] \ll 16 \\
\text{TEMP5}[47-0] & \leftarrow \text{TEMP3}[47-0] \oplus \text{TEMP4}[47-0] \\
\text{TEMP6}[31-0] & \leftarrow \text{TEMP5}[47-0] \mod 0x11EDC6F41H \\
\text{DEST}[31-0] & \leftarrow \text{BIT\_REFLECT (TEMP6[31-0])}
\end{align*}
\]

CRC32 instruction for 8-bit source operand and 64-bit destination operand:

\[
\begin{align*}
\text{TEMP1}[7-0] & \leftarrow \text{BIT\_REFLECT8(SRC[7-0])} \\
\text{TEMP2}[31-0] & \leftarrow \text{BIT\_REFLECT32 (DEST[31-0])} \\
\text{TEMP3}[39-0] & \leftarrow \text{TEMP1}[7-0] \ll 32 \\
\text{TEMP4}[39-0] & \leftarrow \text{TEMP2}[31-0] \ll 8 \\
\text{TEMP5}[39-0] & \leftarrow \text{TEMP3}[39-0] \oplus \text{TEMP4}[39-0] \\
\text{TEMP6}[31-0] & \leftarrow \text{TEMP5}[39-0] \mod 0x11EDC6F41H \\
\text{DEST}[31-0] & \leftarrow \text{BIT\_REFLECT (TEMP6[31-0])} \\
\text{DEST}[63-32] & \leftarrow 00000000H
\end{align*}
\]

CRC32 instruction for 8-bit source operand and 32-bit destination operand:

\[
\begin{align*}
\text{TEMP1}[7-0] & \leftarrow \text{BIT\_REFLECT8(SRC[7-0])} \\
\text{TEMP2}[31-0] & \leftarrow \text{BIT\_REFLECT32 (DEST[31-0])} \\
\text{TEMP3}[39-0] & \leftarrow \text{TEMP1}[7-0] \ll 32 \\
\text{TEMP4}[39-0] & \leftarrow \text{TEMP2}[31-0] \ll 8
\end{align*}
\]
TEMP5[39-0] ← TEMP3[39-0] XOR TEMP4[39-0]
TEMP6[31-0] ← TEMP5[39-0] MOD2 11EDC6F41H
DEST[31-0] ← BIT_REFLECT (TEMP6[31-0])

Notes:

BIT_REFLECT64: DST[63-0] = SRC[0-63]
BIT_REFLECT32: DST[31-0] = SRC[0-31]
BIT_REFLECT16: DST[15-0] = SRC[0-15]
BIT_REFLECT8: DST[7-0] = SRC[0-7]

DPPD — Dot Product of Packed Double Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-bit Mode</th>
<th>Comp/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 3A 41 /r ib</td>
<td>DPPD xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Selectively multiply packed DP floating-point values from xmm1 with packed DP floating-point values from xmm2, add and selectively store the packed DP floating-point values to xmm1.</td>
</tr>
</tbody>
</table>

Description

Conditionally multiplies the packed double precision floating-point values in the destination operand (first operand) with the packed double-precision floating-point values in the source (second operand) depending on a mask extracted from bits 4-5 of the immediate operand. Each of the two resulting double-precision values is summed and this sum is conditionally broadcast to each of 2 positions in the destination operand if the corresponding bit of the mask selected from bits 0-1 of the immediate operand is "1". If the corresponding low bit 0-1 of the mask is zero, the destination is set to zero.

DPPS follows the NaN forwarding rules stated in the Software Developer’s Manual, vol. 1, table 4.7. These rules do not cover horizontal prioritization of NaNs. Horizontal propagation of NaNs to the destination and the positioning of those NaNs in the destination is implementation dependent. NaNs on the input sources or computationally generated NaNs will have at least one NaN propagated to the destination.

Operation

```

</table>

**Description**

Extract the single-precision floating-point value from the source xmm register (second argument) at a 32 bit offset determined from imm8[1-0]. The extracted single precision floating-point value is stored into the low 32-bits of the destination register or to the 32-bit memory location. When a REX.W prefix is used in 64-bit mode to a general purpose register (GPR), the packed single quantity is zero extended to 64 bits.

**Operation**

**EXTRACTPS**

IF (64-Bit Mode and REX.W used and the destination is a GPR)

THEN

```
SRC_OFFSET ← imm8[1:0];
r/m64[31:0] ← (SRC >> (32 * SRC_OFFSET)) AND 0xFFFFFFFFh;
r/m64[63:32] ← ZERO_FILL;
```

ELSE

```
SRC_OFFSET ← imm8[1:0];
r/m32[31:0] ← (SRC >> (32 * SRC_OFFSET)) AND 0xFFFFFFFFh;
```

**Intel C/C++ Compiler Intrinsic Equivalent**

```
EXTRACTPS    int _mm_extract_ps(__m128 src, const int ndx);

MOVNTDQA — Load Double Quadword Non-Temporal Aligned Hint

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-bit Mode</th>
<th>Compat/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 38 2A /r</td>
<td>MOVNTDQA xmm1, m128</td>
<td>Valid</td>
<td>Valid</td>
<td>Move double quadword from m128 to xmm using non-temporal hint if WC memory type.</td>
</tr>
</tbody>
</table>

Description

MOVNTDQA loads a double quadword from the source operand (second operand) to the destination operand (first operand) using a non-temporal hint if the memory source is WC (write combining) memory type. For WC memory type, the non-temporal hint may be implemented by loading a temporary internal buffer with the equivalent of an aligned cache line without filling this data to the cache. Any memory-type aliased lines in the cache will be snooped and flushed. Subsequent MOVNTDQA reads to unread portions of the WC cache line will receive data from the temporary internal buffer if data is available. The temporary internal buffer may be flushed by the processor at any time for any reason, for example:

- A load operation other than a MOVNTDQA which references memory already resident in a temporary internal buffer.
- A non-WC reference to memory already resident in a temporary internal buffer.
- Interleaving of reads and writes to a single temporary internal buffer.
- Repeated MOVNTDQA loads of a particular 16-byte item in a streaming line.
- Certain micro-architectural conditions including resource shortages, detection of a mis-speculation condition, and various fault conditions

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when reading the data from memory. Using this protocol, the processor does not read the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being read can override the non-temporal hint, if the memory address specified for the non-temporal read is not a WC memory region. Information on non-temporal reads and writes can be found in Chapter 10, “Memory Cache Control” of Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with a MFENCE instruction should be used in conjunction with MOVNTDQA instructions if multiple processors might use different memory types for the referenced memory locations or in order to synchronize reads of a processor with writes by other agents in the system. Because of the speculative nature of fetching due to MOVNTDQA, software must not use MOVNTDQA to reference memory regions that are mapped to I/O devices having side effects or when reads to these devices are destructive.
SSE4 INSTRUCTION SET

A processor’s implementation of the streaming load hint does not override the effective memory type, but the implementation of the hint is processor dependent. For example, a processor implementation may choose to ignore the hint and process the instruction as a normal MOVDQA for any memory type. Alternatively, another implementation may optimize cache reads generated by MOVNTDQA on WB memory type to reduce cache evictions.

<td>Valid</td>
<td>Valid</td>
<td>Sums absolute 8-bit integer difference of adjacent groups of 4 byte integers in xmm1 and xmm2/m128 and writes the results in xmm1. Starting offsets within xmm1 and xmm2/m128 are determined by imm8.</td>
</tr>
</tbody>
</table>

Description

MPSADBW sums the absolute difference of 4 unsigned bytes, selected by bits [0:1] of the immediate byte (third operand), from the source (second operand) with sequential groups of 4 unsigned bytes in the destination operand. The first group of eight sequential groups of bytes from the destination operand (first operand) start at an offset determined by bit 2 of the immediate. The operation is repeated 8 times, each time using the same source input but selecting the next group of 4 bytes starting at the next higher byte in the destination. Each 16-bit sum is written to dest.

Operation

MPSADBW

PACKUSDW — Pack with Unsigned Saturation

Description
Converts packed signed doubleword integers into packed unsigned word integers using unsigned saturation to handle overflow conditions. If the signed doubleword value is beyond the range of an unsigned word (that is, greater than FFFFH or less than 0000H), the saturated unsigned word integer value of FFFFH or 0000H, respectively, is stored in the destination.

Operation
PACKUSDW
TMP[15:0] ← (DEST[31:0] < 0) ? 0 : DEST[15:0];
DEST[15:0] ← (DEST[31:0] > FFFFH) ? FFFFH : TMP[15:0];

PBLENDVB — Variable Blend Packed Bytes

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-bit Mode</th>
<th>Compat/Leg Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| 66 0F 38 10 /r | PBLENDVB xmm1, xmm2/m128, <XMM0> | Valid | Valid | Select byte values from xmm1 and xmm2/m128 from mask specified in the high bit of each byte in XMM0 and store the values into xmm1.

**Description**

Bytes from the source operand (second operand) are conditionally written to the destination operand (first operand) depending on mask bits defined in the implicit third register argument, XMM0. The most significant bit in the corresponding byte of XMM0 determines whether the destination byte is copied from the source byte. The presence of a "1" in the mask bit indicates that the byte is copied, else it is not copied and destination byte remains unchanged. The register assignment of the implicit third operand is defined to be the architectural register XMM0.

**Operation**

**PBLENDVB with implicit XMM0 register operand**

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 3A 0E</td>
<td>PBLENDW xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Select words from xmm1 and xmm2/m128 from mask specified in imm8 and store the values into xmm1.</td>
</tr>
</tbody>
</table>

Description

Words from the source operand (second operand) are conditionally written to the destination operand (first operand) depending on bits in the immediate operand (third operand). The immediate bits (bits 7-0) form a mask that determines whether the corresponding word in the destination is copied from the source. If a bit in the mask, corresponding to a word, is "1", then the word is copied, else the word is unchanged.

Operation

**PCMPESTRI — Packed Compare Explicit Length Strings, Return Index**

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-Bit Mode</th>
<th>Compat/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 3A 61</td>
<td>PCMPESTRI xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Perform a packed comparison of string data with explicit lengths, generating an index, and storing the result in ECX.</td>
</tr>
</tbody>
</table>

**Description**

The instruction compares and processes data from two string fragments based on the encoded value in the Imm8 Control Byte (see Section 5.3), and generates an index stored to ECX.

Each string fragment is represented by two values. The first value is an xmm (or possibly m128 for the second operand) which contains the data elements of the string (byte or word data). The second value is stored in EAX (for xmm1) or EDX (for xmm2/m128) and represents the number of bytes/words which are valid for the respective xmm/m128 data.

The length of each input is interpreted as being the absolute-value of the value in EAX (EDX). The absolute-value computation saturates to 16 (for bytes) and 8 (for words), based on the value of imm8[bit3] when the value in EAX (EDX) is greater than 16 (8) or less than -16 (-8).

The comparison and aggregation operations are performed according to the encoded value of Imm8 bit fields (see Section 5.3, "Imm8 Control Byte Operation for PCMPESTRI / PCMPESTRM / PCMPISTRI / PCMPISTRM"). The index of the first (or last, according to imm8[6]) set bit of IntRes2 (see Section 5.3.1.4) is returned in ECX. If no bits are set in IntRes2, ECX is set to 16 (8).

Note that the Arithmetic Flags are written in a non-standard manner in order to supply the most relevant information:

- CFlag – Reset if IntRes2 is equal to zero, set otherwise
- ZFlag – Set if absolute-value of EDX is < 16 (8), reset otherwise
- SFlag – Set if absolute-value of EAX is < 16 (8), reset otherwise

<td>Perform a packed comparison of string data with explicit lengths, generating a mask, and storing the result in XMM0</td>
</tr>
<tr>
<td>imm8</td>
<td>xmm2/m128, imm8</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The instruction compares data from two string fragments based on the encoded value in the imm8 control byte (see Section 5.3), and generates a mask stored to XMM0.

Each string fragment is represented by two values. The first value is an xmm (or possibly m128 for the second operand) which contains the data elements of the string (byte or word data). The second value is stored in EAX (for xmm1) or EDX (for xmm2/m128) and represents the number of bytes/words which are valid for the respective xmm/m128 data.

The length of each input is interpreted as being the absolute-value of the value in EAX (EDX). The absolute-value computation saturates to 16 (for bytes) and 8 (for words), based on the value of imm8[bit3] when the value in EAX (EDX) is greater than 16 (8) or less than -16 (-8).

The comparison and aggregation operations are performed according to the encoded value of Imm8 bit fields (see Section 5.3, “Imm8 Control Byte Operation for PCMPESTRI / PCMPESTRM / PCMPISTRI / PCMPISTRM”). As defined by imm8[6], IntRes2 is then either stored to the least significant bits of XMM0 (zero extended to 128 bits) or expanded into a byte/word-mask and then stored to XMM0.

Note that the Arithmetic Flags are written in a non-standard manner in order to supply the most relevant information:

- CFlag – Reset if IntRes2 is equal to zero, set otherwise
- ZFlag – Set if absolute-value of EDX is < 16 (8), reset otherwise
- SFlag – Set if absolute-value of EAX is < 16 (8), reset otherwise
- OFlag – IntRes2[0]

<td>Valid</td>
<td>Valid</td>
<td>Perform a packed comparison of string data with implicit lengths, generating an index, and storing the result in ECX.</td>
</tr>
</tbody>
</table>

### Description

The instruction compares data from two strings based on the encoded value in the Imm8 Control Byte (see Section 5.3), and generates an index stored to ECX.

Each string is represented by a single value. The value is an xmm (or possibly m128 for the second operand) which contains the data elements of the string (byte or word data). Each input byte/word is augmented with a valid/invalid tag. A byte/word is considered valid only if it has a lower index than the least significant null byte/word. (The least significant null byte/word is also considered invalid.)

The comparison and aggregation operations are performed according to the encoded value of Imm8 bit fields (see Section 5.3, "Imm8 Control Byte Operation for PCMPESTRI / PCMPESTRM / PCMPISTRI / PCMPISTRM"). The index of the first (or last, according to imm8[6]) set bit of IntRes2 is returned in ECX. If no bits are set in IntRes2, ECX is set to 16 (8).

Note that the Arithmetic Flags are written in a non-standard manner in order to supply the most relevant information:

- CFlag – Reset if IntRes2 is equal to zero, set otherwise
- ZFlag – Set if any byte/word of xmm2/mem128 is null, reset otherwise
- SFlag – Set if any byte/word of xmm1 is null, reset otherwise
- OFlag – IntRes2[0]

<td>PCMPGTQ xmm1,xmm2/m128</td>
<td>Valid</td>
<td>Valid</td>
<td>Compare packed qwords in xmm2/m128 and xmm1 for greater than.</td>
</tr>
</tbody>
</table>

Description
Performs an SIMD compare for the packed quadwords in the destination operand (first operand) and the source operand (second operand). If the data element in the first (destination) operand is greater than the corresponding element in the second (source) operand, the corresponding data element in the destination is set to all 1s; otherwise, it is set to 0s.

Operation
IF (DEST[63-0] > SRC[63-0])
    THEN DEST[63-0] ← FFFFFFFFFFFFFFFFH;
    ELSE DEST[63-0] ← 0;
FI
IF (DEST[127-64] > SRC[127-64])

PEXTRB — Extract Byte

**Description**

Extract a byte integer value from the source xmm register (second argument) at a byte offset determined from imm8[3:0]. The extracted integer value is stored into the low 8 bits of the destination. If the destination is a register, the upper bits of the register are zero extended.

**Operation**

**PEXTRB (dest=m8)**

 SRC_Offset ← Imm8[3:0];
 Mem8 ← (Src >> Src_Offset*8);

**PEXTRB (dest=r32)**

 IF (64-Bit Mode and REX.W used and 64-bit destination GPR)
 THEN
 SRC_Offset ← Imm8[3:0];
 r64 ← Zero_Extend64((Src >> Src_Offset*8) AND 0FFh);
 ELSE
 SRC_Offset ← Imm8[3:0];
 r32 ← Zero_Extend32((Src >> Src_Offset*8) AND 0FFh);

<td>ROUNDPD xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Round packed double precision floating-point values in xmm2/m128 and place the result in xmm1. The rounding mode is determined by imm8.</td>
</tr>
</tbody>
</table>

Description

Round the 2 double precision floating-point values in the source operand (second operand) by the rounding mode specified in the immediate operand (third operand) and place the result in the destination operand (first operand). The rounding process rounds each input value to an integer value. The immediate operand specifies control fields for the rounding operation, three bit fields are defined and shown in Figure 5-2. Bit 3 of the immediate byte controls processor behavior for a precision exception, bit 2 selects the source of rounding mode control. Bits 1:0 specify a non-sticky rounding-mode value (Table 5-9 lists the encoded values for rounding-mode field). The Precision Floating-Point Exception is signaled according to the immediate operand. If any source operand is an SNaN then it will be converted to a QNaN. If DAZ is set to ‘1 then denormals will be converted to zero before rounding.

  DEST[127:64] ← ConvertDPFPToInteger_I(SRC[127:64]);
FI // If SRC == SNaN then RoundToIntegralValue will set DEST ← QNaN

SIMD Floating-Point Exceptions

Invalid (signaled only if SRC = SNaN)
Precision (signaled only if imm[3] == '0; if imm[3] == '1, then the Precision Mask in the MXCSR is ignored and precision exception is not signaled.)
Note that Denormal is not signaled by ROUNDPD.

Protected Mode and Compatibility Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS, or GS segments.
SSE4 INSTRUCTION SET

If a memory operand is not aligned on a 16-byte boundary, regardless of segment.

#SS(0) For an illegal address in the SS segment.
#PF(fault-code) For a page fault.
#NM If CR0.TS[bit 3] = 1.
#UD If CR4.OSFXSR[bit 9] = 0.
If CPUID.01H:ECX.SSE4_1[bit 19] = 0.
If LOCK prefix is used.

Real Mode Exceptions

#GP(0) if any part of the operand lies outside of the effective address space from 0 to 0FFFFH.
If a memory operand is not aligned on a 16-byte boundary, regardless of segment.

#NM If CR0.TS[bit 3] = 1.
#UD If CR0.EM[bit 2] = 1.
If CR4.OSFXSR[bit 9] = 0.
If CPUID.01H:ECX.SSE4_1[bit 19] = 0.
If LOCK prefix is used.

Virtual 8086 Mode Exceptions

Same exceptions as in Real Address Mode.

#PF(fault-code) For a page fault.

Compatibility Mode Exceptions

Same exceptions as in Protected Mode.

64-Bit Mode Exceptions

#GP(0) If the memory address is in a non-canonical form.
If a memory operand is not aligned on a 16-byte boundary, regardless of segment.

#SS(0) If a memory address referencing the SS segment is in a non-canonical form.
#PF(fault-code) For a page fault.
#NM If TS in CR0 is set.
#UD If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag ECX.SSE4_1 is 0.
SSE4 INSTRUCTION SET

If LOCK prefix is used.
ROUNDPS — Round Packed Single Precision Floating-Point Values

<table>
<thead>
<tr>

<th>Compat/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 3A 08</td>
<td>ROUNDPS xmm1, xmm2/m128, imm8</td>
<td>Valid</td>
<td>Valid</td>
<td>Round packed single precision floating-point values in xmm2/m128 and place the result in xmm1. The rounding mode is determined by imm8.</td>
</tr>
</tbody>
</table>

Description

Round the 4 single precision floating-point values in the source operand (second operand) by the rounding mode specified in the immediate operand (third operand) and place the result in the destination operand (first operand). The rounding process rounds the input to an integral value and returns the result as a single precision floating-point value. The immediate operand specifies control fields for the rounding operation, three bit fields are defined and shown in Figure 5-2. Bit 3 of the immediate byte controls processor behavior for a precision exception, bit 2 selects the source of rounding mode control. Bits 1:0 specify a non-sticky rounding-mode value (Table 5-9 lists the encoded values for rounding-mode field). The Precision Floating-Point Exception is signaled according to the immediate operand. If any source operand is an SNaN then it will be converted to a QNaN. If DAZ is set to ‘1 then denormals will be converted to zero before rounding.

Operation

ROUNDPS

Table A-2 provides SSE4.1 formats and encodings. Some SSE4.1 instructions require a mandatory prefix (66H, F2H, F3H) as part of the three-byte opcode. These prefixes are included in the tables.

In 64-bit mode, some instructions requires REX.W, the byte sequence of REX.W prefix in the opcode sequence is shown.

</tr>
</tbody>
</table>
Table A-4 provides SSE4.2 formats and encodings. Some SSE4.2 instructions require a mandatory prefix (66H, F2H, F3H) as part of the three-byte opcode. These prefixes are included in the tables. In 64-bit mode, some instructions requires REX.W, the byte sequence of REX.W prefix in the opcode sequence is shown.
