Introduction to Intel(R) C++ Compiler Reference

This reference for the Intel® C++ Compiler for Linux* includes the following sections:

- Compiler Limits
- Key Files
- Predefined Macros
- Intel® Math Library
- Intel® C++ Class Libraries

Compiler Limits

The following table shows the size or number of each item that the compiler can process. All capacities shown in the table are tested values; the actual number can be greater than the number shown.

<table>

Intel(R) C++ Compiler Pragmas

Overview: Using Intel(R) C++ Compiler Pragmas

Pragmas are directives that provide instructions to the compiler for use in specific cases. For example, you can use the `novector` pragma to specify that a loop should never be vectorized. The keyword `#pragma` is standard in the C++ language, but individual pragmas are machine-specific or operating system-specific, and vary by compiler.

Some pragmas provide the same functionality as do compiler options. Pragmas override behavior specified by compiler options.

Using Pragmas

You enter pragmas into your C++ source code using the following syntax:

```cpp
#pragma <pragma name>
```

Example

The `vector always` directive instructs the compiler to override any efficiency heuristic during the decision to vectorize or not, and will vectorize non-unit strides or very unaligned memory accesses.

Example of the `vector always` directive

```cpp
#pragma vector always

for(i=0; i<=N; i++)
{
    a[32*i]=b[99*i];
}
```
## Intel®-Specific Pragmas

The following pragmas are specific to the Intel® C++ Compiler:

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>force_align</td>
<td>specifies the alignment of a class type</td>
</tr>
<tr>
<td>ivdep</td>
<td>instructs the compiler to ignore assumed vector dependencies</td>
</tr>
<tr>
<td>nounroll</td>
<td>instructs the compiler not to unroll a loop</td>
</tr>
<tr>
<td>nvector</td>
<td>specifies that the loop should never be vectorized</td>
</tr>
<tr>
<td>optimization_level</td>
<td>enables control of optimization for a specific function</td>
</tr>
<tr>
<td>intel_omp_task</td>
<td>specifies a unit of work, potentially executed by a different thread</td>
</tr>
<tr>
<td>intel_omp_taskq</td>
<td>specifies an environment for the while loop in which to enqueue the units of work specified by the enclosed task pragma</td>
</tr>
<tr>
<td>unroll</td>
<td>tells the compiler how many times to unroll a loop</td>
</tr>
<tr>
<td>vector</td>
<td>specifies how to vectorize the loop and indicates that efficiency heuristics should be ignored</td>
</tr>
</tbody>
</table>

## Other Pragmas

Please also see Intel®-Specific Pragmas.

The Intel® C++ Compiler supports the following pragmas:

<table>
<thead>
<tr>
<th>Pragma</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alloc_text</td>
<td>names the code section where the specified function definitions are to reside</td>
</tr>
<tr>
<td>auto_inline</td>
<td>excludes any function defined within the range where off is specified from being considered as candidates for automatic inline expansion</td>
</tr>
<tr>
<td>check_stack</td>
<td>on argument indicates that stack checking should be enabled for functions that follow and off argument indicates that stack checking should be disabled for functions that follow.</td>
</tr>
<tr>
<td>code_seg</td>
<td>specifies a code section where functions are to be allocated</td>
</tr>
<tr>
<td>comment</td>
<td>places a comment record into an object file or executable file</td>
</tr>
<tr>
<td>conform</td>
<td>specifies the run-time behavior of the /Zc:forScope compiler option</td>
</tr>
<tr>
<td>stdc</td>
<td>informs the implementation that the usual formulas are acceptable</td>
</tr>
<tr>
<td>cx_limited_range</td>
<td></td>
</tr>
<tr>
<td><strong>Compiler Reference</strong></td>
<td></td>
</tr>
<tr>
<td>------------------------</td>
<td></td>
</tr>
<tr>
<td><strong>data_seg</strong></td>
<td>specifies the default section for initialized data</td>
</tr>
<tr>
<td><strong>stdc_fenv_access</strong></td>
<td>informs an implementation that a program may test status flags or run under a non-default control mode</td>
</tr>
<tr>
<td><strong>float_control</strong></td>
<td>specifies floating-point behavior for a function</td>
</tr>
<tr>
<td><strong>stdc_fp_contract</strong></td>
<td>allows or disallows the implementation to contract expressions</td>
</tr>
<tr>
<td><strong>ident</strong></td>
<td>places the string in the comment section of the executable</td>
</tr>
<tr>
<td><strong>init_seg</strong></td>
<td>specifies the section to contain C++ initialization code for the translation unit</td>
</tr>
<tr>
<td><strong>message</strong></td>
<td>displays the specified string literal to the standard output device</td>
</tr>
<tr>
<td><strong>optimize</strong></td>
<td>specifies optimizations to be performed on a function-by-function basis</td>
</tr>
<tr>
<td><strong>pointers_to_members</strong></td>
<td>specifies whether a pointer to a class member can be declared before its associated class definition and is used to control the pointer size and the code required to interpret the pointer</td>
</tr>
<tr>
<td><strong>pop_macro</strong></td>
<td>sets the value of the macro_name macro to the value on the top of the stack for this macro</td>
</tr>
<tr>
<td><strong>push_macro</strong></td>
<td>saves the value of the macro_name macro on the top of the stack for this macro</td>
</tr>
<tr>
<td><strong>section</strong></td>
<td>creates a section in an .obj file. Once a section is defined, it remains valid for the remainder of the compilation</td>
</tr>
<tr>
<td><strong>vtordisp</strong></td>
<td>on argument enables the generation of hidden vtordisp members and off disables them</td>
</tr>
<tr>
<td><strong>warning</strong></td>
<td>allows selective modification of the behavior of compiler warning messages</td>
</tr>
<tr>
<td><strong>weak</strong></td>
<td>declares symbol you enter to be weak</td>
</tr>
</tbody>
</table>

### Predefined Macros

#### ANSI Standard Predefined Macros

The ANSI/ISO standard for the C language requires that certain predefined macros be supplied with conforming compilers. The following table lists the macros that the Intel C++ Compiler supplies in accordance with this standard:

The compiler includes predefined macros in addition to those required by the standard.

<table>
<thead>
<tr>
<th><strong>Macro</strong></th>
<th><strong>Value</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DATE</strong></td>
<td>The date of compilation as a string literal in the form <em>Mmm dd yyyy</em>.</td>
</tr>
</tbody>
</table>
Printed Documentation

\_FILE\_  
A string literal representing the name of the file being compiled.

\_LINE\_  
The current line number as a decimal constant.

\_STDC\_  
The name \_STDC\_ is defined when compiling a C translation unit.

\_STDC_HOSTED\_ 1

\_TIME\_  
The time of compilation as a string literal in the form hh:mm:ss.

### Trigonometric Functions

The Intel Math library supports the following trigonometric functions:

- `acos`
**Description:** The `acos` function returns the principal value of the inverse cosine of $x$ in the range $[0, \pi]$ radians for $x$ in the interval $[-1,1]$.

**errno:** EDOM, for $|x| > 1$

**Calling interface:**

double acos(double x);
long double acosl(long double x);
float acosf(float x);

**acosd**

**Description:** The `acosd` function returns the principal value of the inverse cosine of $x$ in the range $[0,180]$ degrees for $x$ in the interval $[-1,1]$.

**errno:** EDOM, for $|x| > 1$

**Calling interface:**

double acosd(double x);
long double acosdl(long double x);
float acosdf(float x);

**asin**

**Description:** The `asin` function returns the principal value of the inverse sine of $x$ in the range $[-\pi/2, +\pi/2]$ radians for $x$ in the interval $[-1,1]$.

**errno:** EDOM, for $|x| > 1$

**Calling interface:**

double asin(double x);
long double asinl(long double x);
float asinf(float x);

**asind**

**Description:** The `asind` function returns the principal value of the inverse sine of $x$ in the range $[-90,90]$ degrees for $x$ in the interval $[-1,1]$.

**errno:** EDOM, for $|x| > 1$

**Calling interface:**

double asind(double x);
long double asindl(long double x);
float asindf(float x);

**atan**

**Description:** The `atan` function returns the principal value of the inverse tangent of $x$ in the range $[-\pi/2, +\pi/2]$ radians.
Calling interface:

double atan(double x);
long double atanl(long double x);
float atanf(float x);

atan2

Description: The `atan2` function returns the principal value of the inverse tangent of \( y/x \) in the range \([-\pi, +\pi]\) radians.

\textbf{errno}: EDOM, for \( x = 0 \) and \( y = 0 \)

Calling interface:

double atan2(double y, double x);
long double atan2l(long double y, long double x);
float atan2f(float y, float x);

atand

Description: The `atand` function returns the principal value of the inverse tangent of \( x \) in the range \([-90,90]\) degrees.

Calling interface:

double atand(double x);
long double atandl(long double x);
float atandf(float x);

atan2d

Description: The `atan2d` function returns the principal value of the inverse tangent of \( y/x \) in the range \([-180, +180]\) degrees.

\textbf{errno}: EDOM, for \( x = 0 \) and \( y = 0 \).

Calling interface:

double atan2d(double x, double y);
long double atan2dl(long double x, long double y);
float atan2df(float x, float y);

cos

Description: The `cos` function returns the cosine of \( x \) measured in radians. This function may be inlined by the Itanium® compiler.

Calling interface:

double cos(double x);
long double cosl(long double x);
float cosf(float x);

cosd
Description: The `cosd` function returns the cosine of `x` measured in degrees.

Calling interface:
```c
double cosd(double x);
long double cosdl(long double x);
float cosdf(float x);
```

cot

Description: The `cot` function returns the cotangent of `x` measured in radians.

**errno:** ERANGE, for overflow conditions at `x = 0`.

Calling interface:
```c
double cot(double x);
long double cotl(long double x);
float cotf(float x);
```

cotd

Description: The `cotd` function returns the cotangent of `x` measured in degrees.

**errno:** ERANGE, for overflow conditions at `x = 0`.

Calling interface:
```c
double cotd(double x);
long double cotdl(long double x);
float cotdf(float x);
```

sin

Description: The `sin` function returns the sine of `x` measured in radians. This function may be inlined by the Itanium® compiler.

Calling interface:
```c
double sin(double x);
long double sinl(long double x);
float sinf(float x);
```

sincos

Description: The `sincos` function returns both the sine and cosine of `x` measured in radians. This function may be inlined by the Itanium® compiler.

Calling interface:
```c
void sincos(double x, double *sinval, double *cosval);
void sincosl(long double x, long double *sinval, long double *cosval);
void sincosf(float x, float *sinval, float *cosval);
```

sincosd
Description: The sin cosd function returns both the sine and cosine of \( x \) measured in degrees.

Calling interface:
void sin cosd(double x, double *sinval, double *cosval);
void sin cosdl(long double x, long double *sinval, long double *cosval);
void sin cosdf(float x, float *sinval, float *cosval);

sind

Description: The sind function computes the sine of \( x \) measured in degrees.

Calling interface:
double sind(double x);
long double sindl(long double x);
float sindf(float x);

tan

Description: The tan function returns the tangent of \( x \) measured in radians.

Calling interface:
double tan(double x);
long double tanl(long double x);
float tanf(float x);

tand

Description: The tand function returns the tangent of \( x \) measured in degrees.

errno: ERANGE, for overflow conditions

Calling interface:
double tand(double x);
long double tandl(long double x);
float tandf(float x);
Hyperbolic Functions

The Intel Math library supports the following hyperbolic functions:

**acosh**

*Description:* The *acosh* function returns the inverse hyperbolic cosine of *x*.

*errno:* EDOM, for *x* < 1

*Calling interface:*

```c
double acosh(double x);
long double acoshl(long double x);
float acoshf(float x);
```

**asinh**

*Description:* The *asinh* function returns the inverse hyperbolic sine of *x*. 

Calling interface:
double asinh(double x);
long double asinhl(long double x);
float asinhf(float x);

atanh

Description: The `atanh` function returns the inverse hyperbolic tangent of \( x \).

**errno**: EDOM, for \( x > 1 \)
**errno**: ERANGE, for \( x = 1 \)

Calling interface:
double atanh(double x);
long double atanhl(long double x);
float atanhf(float x);

cosh

Description: The `cosh` function returns the hyperbolic cosine of \( x \), \( \frac{e^x + e^{-x}}{2} \).

**errno**: ERANGE, for overflow conditions

Calling interface:
double cosh(double x);
long double coshl(long double x);
float coshf(float x);

sinh

Description: The `sinh` function returns the hyperbolic sine of \( x \), \( \frac{e^x - e^{-x}}{2} \).

**errno**: ERANGE, for overflow conditions

Calling interface:
double sinh(double x);
long double sinh1(long double x);
float sinhf(float x);

sinhcosh

Description: The `sinhcosh` function returns both the hyperbolic sine and hyperbolic cosine of \( x \).

**errno**: ERANGE, for overflow conditions

Calling interface:
void sinhcosh(double x, float *sinval, float *cosval);
void sinhcoshl(long double x, long double *sinval, long double *cosval);
void sinhcoshf(float x, float *sinval, float *cosval);
tanh

**Description:** The `tanh` function returns the hyperbolic tangent of `x`, \((e^x - e^{-x}) / (e^x + e^{-x})\).

**Calling interface:**
```c
double tanh(double x);
long double tanhl(long double x);
float tanhf(float x);
```
Exponential Functions

The Intel Math library supports the following exponential functions:

cbrt

**Description:** The cbrt function returns the cube root of $x$.

**Calling interface:**

double cbrt(double x);
long double cbrtl(long double x);
float cbrtf(float x);

exp

**Description:** The exp function returns $e$ raised to the $x$ power, $e^x$. This function may be inlined by the Itanium® compiler.

**errno:** ERANGE, for underflow and overflow conditions

**Calling interface:**

double exp(double x);
long double expl(long double x);
float expf(float x);

exp10

**Description:** The exp10 function returns 10 raised to the $x$ power, $10^x$.

**errno:** ERANGE, for underflow and overflow conditions

**Calling interface:**

double exp10(double x);
long double exp10l(long double x);
float exp10f(float x);

exp2

**Description:** The exp2 function returns 2 raised to the $x$ power, $2^x$.

**errno:** ERANGE, for underflow and overflow conditions

**Calling interface:**

double exp2(double x);
long double exp2l(long double x);
float exp2f(float x);

expm1

**Description:** The expm1 function returns $e$ raised to the $x$ power minus 1, $e^x - 1$. 
errno: ERANGE, for overflow conditions

**Calling interface:**
```c
double expm1(double x);
long double expm1l(long double x);
float expm1f(float x);
```

**frexp**

**Description:** The `frexp` function converts a floating-point number `x` into signed normalized fraction in \([\frac{1}{2}, 1)\) multiplied by an integral power of two. The signed normalized fraction is returned, and the integer exponent stored at location `exp`.

**Calling interface:**
```c
double frexp(double x, int *exp);
long double frexpd(long double x, int *exp);
float frexpf(float x, int *exp);
```

**hypot**

**Description:** The `hypot` function returns the square root of \((x^2 + y^2)\).

**errno:** ERANGE, for overflow conditions

**Calling interface:**
```c
double hypot(double x, double y);
long double hypotl(long double x, long double y);
float hypotf(float x, float y);
```

**ilogb**

**Description:** The `ilogb` function returns the exponent of `x` base two as a signed int value.

**errno:** ERANGE, for `x = 0`

**Calling interface:**
```c
int ilogb(double x);
int ilogbl(long double x);
int ilogbf(float x);
```

**invsqrt**

**Description:** The `invsqrt` function returns the inverse square root. This function may be inlined by the Itanium® compiler.

**Calling interface:**
```c
double invsqrt(double x);
long double invsqrtl(long double x);
float invsqrtf(float x);
```
ldexp

**Description:** The ldexp function returns x*2^"exp", where exp is an integer value.

**errno:** ERANGE, for underflow and overflow conditions

**Calling interface:**
- double ldexp(double x, int exp);
- long double ldexpl(long double x, int exp);
- float ldexpf(float x, int exp);

log

**Description:** The log function returns the natural log of x, \( \ln(x) \). This function may be inlined by the Itanium® compiler.

**errno:** EDOM, for x < 0
**errno:** ERANGE, for x = 0

**Calling interface:**
- double log(double x);
- long double logl(long double x);
- float logf(float x);

log10

**Description:** The log10 function returns the base-10 log of x, \( \log_{10}(x) \). This function may be inlined by the Itanium® compiler.

**errno:** EDOM, for x < 0
**errno:** ERANGE, for x = 0

**Calling interface:**
- double log10(double x);
- long double log10l(long double x);
- float log10f(float x);

log1p

**Description:** The log1p function returns the natural log of \( (x+1) \), \( \ln(x + 1) \).

**errno:** EDOM, for x < -1
**errno:** ERANGE, for x = -1

**Calling interface:**
- double log1p(double x);
- long double log1pl(long double x);
- float log1pf(float x);

log2
**Description:** The \(\log_2\) function returns the base-2 log of \(x\), \(\log_2(x)\).

**errno:** EDOM, for \(x < 0\)

**errno:** ERANGE, for \(x = 0\)

**Calling interface:**

```c
double log2(double x);
long double log2l(long double x);
float log2f(float x);
```

### logb

**Description:** The \(\logb\) function returns the signed exponent of \(x\).

**errno:** EDOM, for \(x = 0\)

**Calling interface:**

```c
double logb(double x);
long double logbl(long double x);
float logbf(float x);
```

### pow

**Description:** The \(\text{pow}\) function returns \(x\) raised to the power of \(y\), \(x^y\). This function may be inlined by the Itanium® compiler.

**errno:** EDOM, for \(x = 0\) and \(y < 0\)

**errno:** EDOM, for \(x < 0\) and \(y\) is a non-integer

**errno:** ERANGE, for overflow and underflow conditions

```c
double pow(double x, double y);
long double powl(double x, double y);
float powf(float x, float y);
```

### scalb

**Description:** The \(\text{scalb}\) function returns \(x*2^y\), where \(y\) is a floating-point value.

**errno:** ERANGE, for underflow and overflow conditions

**Calling interface:**

```c
double scalb(double x, double y);
long double scalbl(long double x, long double y);
float scalbf(float x, float y);
```

### scalbn

**Description:** The \(\text{scalbn}\) function returns \(x*2^n\), where \(n\) is an integer value.
**errno**: ERANGE, for underflow and overflow conditions

**Calling interface:**
- `double scalbn(double x, int n);`
- `long double scalbnl (long double x, int n);`
- `float scalbnf(float x, int n);`

**scalbn**

**Description**: The `scalbn` function returns \(x \times 2^n\), where \(n\) is a long integer value.

**errno**: ERANGE, for underflow and overflow conditions

**Calling interface:**
- `double scalbln(double x, long int n);`
- `long double scalblnl (long double x, long int n);`
- `float scalblnf(float x, long int n);`

**sqrt**

**Description**: The `sqrt` function returns the correctly rounded square root.

**errno**: EDOM, for \(x < 0\)

**Calling interface:**
- `double sqrt(double x);`
- `long double sqrtl(long double x);`
- `float sqrtf(float x);`
Special Functions

The Intel Math library supports the following special functions:

**annuity**

Description: The *annuity* function computes the present value factor for an annuity, \( \frac{1 - (1+x)^{-y}}{x} \), where \( x \) is a rate and \( y \) is a period.

*errno*: ERANGE, for underflow and overflow conditions

Calling interface:
- `double annuity(double x, double y);`
- `long double annuityl(long double x, long double y);`
- `float annuityf(float x, float y);`

**compound**

Description: The *compound* function computes the compound interest factor, \((1+x)^y\), where \( x \) is a rate and \( y \) is a period.

*errno*: ERANGE, for underflow and overflow conditions

Calling interface:
- `double compound(double x, double y);`
- `long double compoundl(long double x, long double y);`
- `float compoundf(float x, float y);`

**erf**

Description: The *erf* function returns the error function value.
Calling interface:

double erf(double x);
long double erfl(long double x);
float erff(float x);

erfc

Description: The erfc function returns the complementary error function value.

errno: ERANGE, for underflow conditions

Calling interface:

double erfc(double x);
long double erfcl(long double x);
float erfcf(float x);

gamma

Description: The gamma function returns the value of the logarithm of the absolute value of gamma.

errno: ERANGE, for overflow conditions when x is a negative integer.

Calling interface:

double gamma(double x);
long double gammal(long double x);
float gammaf(float x);

gamma_r

Description: The gamma_r function returns the value of the logarithm of the absolute value of gamma. The sign of the gamma function is returned in the integer signgam.

Calling interface:

double gamma_r(double x, int *signgam);
long double gammal_r(long double x, int *signgam);
float gammaf_r(float x, int *signgam);

j0

Description: Computes the Bessel function (of the first kind) of x with order 0.

Calling interface:

double j0(double x);
long double j0l(long double x);
float j0f(float x);

j1

Description: Computes the Bessel function (of the first kind) of x with order 1.
**Calling interface:**
```c
double j1(double x);
long double j1l(long double x);
float j1f(float x);
```

**j1**

**Description:** Computes the Bessel function (of the first kind) of \( x \) with order \( n \).

**Calling interface:**
```c
double jn(int n, double x);
long double jnl(int n, long double x);
float jnf(int n, float x);
```

**jn**

**Description:** Computes the Bessel function (of the first kind) of \( x \) with order \( n \).

**Calling interface:**
```c
double lgamma(double x);
long double lgammal(long double x);
float lgammaf(float x);
```

**lgamma**

**Description:** The \( \text{lgamma} \) function returns the value of the logarithm of the absolute value of gamma.

**errno:** ERANGE, for overflow conditions, \( x=0 \) or negative integers.

**Calling interface:**
```c
double lgamma_r(double x, int *signgam);
long double lgammal_r(long double x, int *signgam);
float lgammaf_r(float x, int *signgam);
```

**lgamma_r**

**Description:** The \( \text{lgamma} \_r \) function returns the value of the logarithm of the absolute value of gamma. The sign of the \( \text{gamma} \) function is returned in the integer \( \text{signgam} \).

**errno:** ERANGE, for overflow conditions, \( x=0 \) or negative integers.

**Calling interface:**
```c
double lgamma_r(double x, int *signgam);
long double lgammal_r(long double x, int *signgam);
float lgammaf_r(float x, int *signgam);
```

**tgamma**

**Description:** The \( \text{tgamma} \) function computes the gamma function of \( x \).

**errno:** EDOM, for \( x=0 \) or negative integers.

**Calling interface:**
```c
double tgamma(double x);
long double tgammal(long double x);
float tgammaf(float x);
```

**y0**
**Description**: Computes the Bessel function (of the second kind) of \( x \) with order 0.

*errno*: EDOM, for \( x \leq 0 \)

**Calling interface**:
- double y0(double x);
- long double y0l(long double x);
- float y0f(float x);

**y1**

**Description**: Computes the Bessel function (of the second kind) of \( x \) with order 1.

*errno*: EDOM, for \( x \leq 0 \)

**Calling interface**:
- double y1(double x);
- long double y1l(long double x);
- float y1f(float x);

**yn**

**Description**: Computes the Bessel function (of the second kind) of \( x \) with order \( n \).

*errno*: EDOM, for \( x \leq 0 \)

**Calling interface**:
- double yn(int n, double x);
- long double ynl(int n, long double x);
- float ynf(int n, float x);
Nearest Integer Functions

The Intel Math library supports the following nearest integer functions:

**ceil**

**Description:** The `ceil` function returns the smallest integral value not less than \( x \) as a floating-point number. This function may be inlined by the Itanium® compiler.

**Calling interface:**
```
double ceil(double x);
long double ceill(long double x);
float ceilf(float x);
```

**floor**

**Description:** The `floor` function returns the largest integral value not greater than \( x \) as a floating-point value. This function may be inlined by the Itanium® compiler.

**Calling interface:**
```
double floor(double x);
long double floorl(long double x);
float floorf(float x);
```

**llrint**

**Description:** The `llrint` function returns the rounded integer value (according to the current rounding direction) as a `long long int`. 

**errno**: ERANGE, for values too large

**Calling interface:**
```c
long long int llrint(double x);
long long int llrintl(long double x);
long long int llrintf(float x);
```

**llround**

**Description**: The `llround` function returns the rounded integer value as a long long int.

**errno**: ERANGE, for values too large

**Calling interface:**
```c
long long int llround(double x);
long long int llroundl(long double x);
long long int llroundf(float x);
```

**lrint**

**Description**: The `lrint` function returns the rounded integer value (according to the current rounding direction) as a long int.

**errno**: ERANGE, for values too large

**Calling interface:**
```c
long int lrint(double x);
long int lrintl(long double x);
long int lrintf(float x);
```

**lround**

**Description**: The `lround` function returns the rounded integer value as a long int. Halfway cases are rounded away from zero.

**errno**: ERANGE, for values too large

**Calling interface:**
```c
long int lround(double x);
long int lroundl(long double x);
long int lroundf(float x);
```

**modf**

**Description**: The `modf` function returns the value of the signed fractional part of `x` and stores the integral part at `*iptr` as a floating-point number.

**Calling interface:**
```c
double modf(double x, double *iptr);
```
long double modfl(long double x, long double *iptr);
float modff(float x, float *iptr);

nearbyint

Description: The nearbyint function returns the rounded integral value as a floating-point number, using the current rounding direction.

Calling interface:
double nearbyint(double x);
long double nearbyintl(long double x);
float nearbyintf(float x);

rint

Description: The rint function returns the rounded integral value as a floating-point number, using the current rounding direction.

Calling interface:
double rint(double x);
long double rintl(long double x);
float rintf(float x);

round

Description: The round function returns the nearest integral value as a floating-point number. Halfway cases are rounded away from zero.

Calling interface:
double round(double x);
long double roundl(long double x);
float roundf(float x);

trunc

Description: The trunc function returns the truncated integral value as a floating-point number.

Calling interface:
double trunc(double x);
long double trunc1(long double x);
float truncf(float x);
Remainder Functions

The Intel Math library supports the following remainder functions:

**fmod**

**Description:** The `fmod` function returns the value `x - n*y` for integer `n` such that if `y` is nonzero, the result has the same sign as `x` and magnitude less than the magnitude of `y`.

**errno:** EDOM, for `y = 0`

**Calling interface:**
- `double fmod(double x, double y);`
- `long double fmodl(long double x, long double y);`
- `float fmodf(float x, float y);`
remainder

**Description:** The `remainder` function returns the value of `x REM y` as required by the IEEE standard.

**Calling interface:**
```c
double remainder(double x, double y);
long double remainderl(long double x, long double y);
float remainderf(float x, float y);
```

remquo

**Description:** The `remquo` function returns the value of `x REM y`. In the object pointed to by `quo` the function stores a value whose sign is the sign of `x/y` and whose magnitude is congruent modulo $2^n$ (for IA-32 and Intel® EM64T) or congruent modulo $2^n$ (for Itanium®-based systems) of the integral quotient of `x/y`, where `n` is an implementation-defined integer greater than or equal to 3.

**Calling interface:**
```c
double remquo(double x, double y, int *quo);
long double remquol(long double x, long double y, int *quo);
float remquof(float x, float y, int *quo);
```
Miscellaneous Functions

The Intel Math library supports the following miscellaneous functions:

**copysign**

**Description:** The `copysign` function returns the value with the magnitude of \( x \) and the sign of \( y \).

**Calling interface:**
- `double copysign(double x, double y);`
- `long double copysignl(long double x, long double y);`
- `float copysignf(float x, float y);`

**fabs**

**Description:** The `fabs` function returns the absolute value of \( x \).

**Calling interface:**
- `double fabs(double x);`
- `long double fabsl(long double x);`
- `float fabsf(float x);`

**fdim**

**Description:** The `fdim` function returns the positive difference value, \( x-y \) (for \( x > y \)) or \(+0\) (for \( x \leq y \)).

**errno:** \texttt{ERANGE}, for values too large

**Calling interface:**
- `double fdim(double x, double y);`
- `long double fdiml(long double x, long double y);`
- `float fdimf(float x, float y);`
finite

**Description:** The `finite` function returns 1 if \( x \) is not a NaN or +/- infinity. Otherwise 0 is returned.

**Calling interface:**
```c
int finite(double x);
int finitel(long double x);
int finitef(float x);
```

fma

**Description:** The `fma` functions return \((x*y)+z\).

**Calling interface:**
```c
double fma(double x, double y, double z);
long double fmal(long double x, long double y, long double z);
float fmaf(float x, float y, float z);
```

fmax

**Description:** The `fmax` function returns the maximum numeric value of its arguments.

**Calling interface:**
```c
double fmax(double x, double y);
long double fmaxl(long double x, long double y);
float fmaxf(float x, float y);
```

fmin

**Description:** The `fmin` function returns the minimum numeric value of its arguments.

**Calling interface:**
```c
double fmin(double x, double y);
long double fminl(long double x, long double y);
float fminf(float x, float y);
```

fpclassify

**Description:** The `fpclassify` function returns the value of the number classification macro appropriate to the value of its argument.

<table>
<thead>
<tr>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (NaN)</td>
</tr>
<tr>
<td>1 (Infinity)</td>
</tr>
<tr>
<td>2 (Zero)</td>
</tr>
<tr>
<td>3 (Subnormal)</td>
</tr>
</tbody>
</table>
Calling interface:
double fpclassify(double x);
long double fpclassifyl(long double x);
float fpclassifyf(float x);

isfinite

Description: The isfinite function returns 1 if x is not a NaN or +/- infinity. Otherwise 0 is returned.

Calling interface:
int isfinite(double x);
int isfinitel(long double x);
int isfinitef(float x);

isgreater

Description: The isgreater function returns 1 if x is greater than y. This function does not raise the invalid floating-point exception.

Calling interface:
int isgreater(double x, double y);
int isgreatequl(long double x, long double y);
int isgreaterf(float x, float y);

isgreaterequal

Description: The isgreaterequal function returns 1 if x is greater than or equal to y. This function does not raise the invalid floating-point exception.

Calling interface:
int isgreaterequal(double x, double y);
int isgreaterequall(long double x, long double y);
int isgreaterequalf(float x, float y);

isinf

Description: The isinf function returns a non-zero value if and only if its argument has an infinite value.

Calling interface:
int isinf(double x);
int isinfl(long double x);
int isinff(float x);

isless
Description: The `isless` function returns 1 if \( x \) is less than \( y \). This function does not raise the invalid floating-point exception.

Calling interface:
```
int isless(double x, double y);
int islessl(long double x, long double y);
int islessf(float x, float y);
```

islessequal

Description: The `islessequal` function returns 1 if \( x \) is less than or equal to \( y \). This function does not raise the invalid floating-point exception.

Calling interface:
```
int islessequal(double x, double y);
int islessequall(long double x, long double y);
int islessequalf(float x, float y);
```

islessgreater

Description: The `islessgreater` function returns 1 if \( x \) is less than or greater than \( y \). This function does not raise the invalid floating-point exception.

Calling interface:
```
int islessgreater(double x, double y);
int islessgreaterl(long double x, long double y);
int islessgreaterf(float x, float y);
```

isnan

Description: The `isnan` function returns a non-zero value if and only if \( x \) has a NaN value.

Calling interface:
```
int isnan(double x);
int isnanl(long double x);
int isnanf(float x);
```

isnormal

Description: The `isnormal` function returns a non-zero value if and only if \( x \) is normal.

Calling interface:
```
int isnormal(double x);
int isnormall(long double x);
int isnormalf(float x);
```

isunordered

Description: The `isunordered` function returns 1 if either \( x \) or \( y \) is a NaN. This function does not raise the invalid floating-point exception.
Calling interface:
int isunordered(double x, double y);
int isunorderedl(long double x, long double y);
int isunorderedf(float x, float y);

definition

nextafter

Description: The nextafter function returns the next representable value in the specified format after x in the direction of y.

errno: ERANGE, for overflow and underflow conditions

Calling interface:
double nextafter(double x, double y);
long double nextafterl(long double x, long double y);
float nextafterf(float x, float y);

nexttoward

Description: The nexttoward function returns the next representable value in the specified format after x in the direction of y. If x equals y, then the function returns y converted to the type of the function.

errno: ERANGE, for overflow and underflow conditions

Calling interface:
double nexttoward(double x, long double y);
long double nexttowardl(long double x, long double y);
float nexttowardf(float x, long double y);

signbit

Description: The signbit function returns a non-zero value if and only if the sign of x is negative.

Calling interface:
int signbit(double x);
int signbitl(long double x);
int signbitf(float x);

significand

Description: The significand function returns the significand of x in the interval [1,2). For x equal to zero, NaN, or +/- infinity, the original x is returned.

Calling interface:
double significand(double x);
long double significandl(long double x);
float significandf(float x);
Complex Functions

The Intel Math library supports the following complex functions:

**cabs**

**Description:** The `cabs` function returns the complex absolute value of `z`.

**Calling interface:**

```c
double cabs(double _Complex z);
```
long double cabs1(long double _Complex z);
float cabsf(float _Complex z);

**cacos**

**Description:** The `cacos` function returns the complex inverse cosine of z.

**Calling interface:**

double _Complex cacos(double _Complex z);
long double _Complex cacosl(long double _Complex z);
float _Complex cacosf(float _Complex z);

cacosh

**Description:** The `cacosh` function returns the complex inverse hyperbolic cosine of z.

**Calling interface:**

double _Complex cacosh(double _Complex z);
long double _Complex cacoshl(long double _Complex z);
float _Complex cacoshf(float _Complex z);

carg

**Description:** The `carg` function returns the value of the argument in the interval [-pi, +pi].

**Calling interface:**

double carg(double _Complex z);
long double cargl(long double _Complex z);
float cargf(float _Complex z);

casin

**Description:** The `casin` function returns the complex inverse sine of z.

**Calling interface:**

double _Complex casin(double _Complex z);
long double _Complex casinl(long double _Complex z);
float _Complex casinf(float _Complex z);

casinh

**Description:** The `casinh` function returns the complex inverse hyperbolic sine of z.

**Calling interface:**

double _Complex casinh(double _Complex z);
long double _Complex casinhl(long double _Complex z);
float _Complex casinhf(float _Complex z);

catan
Description: The `catan` function returns the complex inverse tangent of \( z \).

**Calling interface:**
```c
double _Complex catan(double _Complex z);
long double _Complex catanl(long double _Complex z);
float _Complex catanf(float _Complex z);
```

**catanh**

Description: The `catanh` function returns the complex inverse hyperbolic tangent of \( z \).

**Calling interface:**
```c
double _Complex catanh(double _Complex z);
long double _Complex catanhl(long double _Complex z);
float _Complex catanhf(float _Complex z);
```

**ccos**

Description: The `ccos` function returns the complex cosine of \( z \).

**Calling interface:**
```c
double _Complex ccos(double _Complex z);
long double _Complex ccosl(long double _Complex z);
float _Complex ccosf(float _Complex z);
```

**ccosh**

Description: The `ccosh` function returns the complex hyperbolic cosine of \( z \).

**Calling interface:**
```c
double _Complex ccosh(double _Complex z);
long double _Complex ccoshl(long double _Complex z);
float _Complex ccoshf(float _Complex z);
```

**cexp**

Description: The `cexp` function returns \( e^z \) (\( e \) raised to the power \( z \)).

**Calling interface:**
```c
double _Complex cexp(double _Complex z);
long double _Complex cexpl(long double _Complex z);
float _Complex cexpf(float _Complex z);
```

**cexp2**

Description: The `cexp` function returns \( 2^z \) (2 raised to the power \( z \)).

**Calling interface:**
```c
double _Complex cexp2(double _Complex z);
long double _Complex cexp2l(long double _Complex z);
float _Complex cexp2f(float _Complex z);
```
cexp10

**Description:** The `cexp10` function returns $10^z$ (10 raised to the power $10^z$).

**Calling interface:**
```c
double _Complex cexp10(double _Complex z);
long double _Complex cexp10l(long double _Complex z);
float _Complex cexp10f(float _Complex z);
```

cimag

**Description:** The `cimag` function returns the imaginary part value of $z$.

**Calling interface:**
```c
double cimag(double _Complex z);
long double cimagl(long double _Complex z);
float cimagf(float _Complex z);
```

cis

**Description:** The `cis` function returns the cosine and sine (as a complex value) of $z$ measured in radians.

**Calling interface:**
```c
double _Complex cis(double z);
long double _Complex cisl(long double z);
float _Complex cisf(float z);
```

cisd

**Description:** The `cisd` function returns the cosine and sine (as a complex value) of $z$ measured in degrees.

**Calling interface:**
```c
double _Complex cis(double z);
long double _Complex cisl(long double z);
float _Complex cisf(float z);
```

clog

**Description:** The `clog` function returns the complex natural logarithm of $z$.

**Calling interface:**
```c
double _Complex clog(double _Complex z);
long double _Complex clogl(long double _Complex z);
float _Complex clogf(float _Complex z);
```

clog2

**Description:** The `clog2` function returns the complex logarithm base 2 of $z$. 
Calling interface:
double _Complex clog2(double _Complex z);
long double _Complex clog2l(long double _Complex z);
float _Complex clog2f(float _Complex z);

clog10

Description: The clog10 function returns the complex logarithm base 10 of z.

Calling interface:
double _Complex clog10(double _Complex z);
long double _Complex clog10l(long double _Complex z);
float _Complex clog10f(float _Complex z);

conj

Description: The conj function returns the complex conjugate of z by reversing the sign of its imaginary part.

Calling interface:
double _Complex conj(double _Complex z);
long double _Complex conjl(long double _Complex z);
float _Complex conjf(float _Complex z);

cpow

Description: The cpow function returns the complex power function, \(x^y\).

Calling interface:
double _Complex cpow(double _Complex x, double _Complex y);
long double _Complex cpowl(long double _Complex x, long double _Complex y);
float _Complex cpowf(float _Complex x, float _Complex y);

cproj

Description: The cproj function returns a projection of z onto the Riemann sphere.

Calling interface:
double _Complex cproj(double _Complex z);
long double _Complex cprojl(long double _Complex z);
float _Complex cprojf(float _Complex z);

creal

Description: The creal function returns the real part of z.

Calling interface:
double creal(double _Complex z);
long double creall(long double _Complex z);
float crealf(float _Complex z);
csin

**Description:** The `csin` function returns the complex sine of `z`.

**Calling interface:**
```c
double _Complex csin(double _Complex z);
long double _Complex csinl(long double _Complex z);
float _Complex csinf(float _Complex z);
```

csinh

**Description:** The `csinh` function returns the complex hyperbolic sine of `z`.

**Calling interface:**
```c
double _Complex csinh(double _Complex z);
long double _Complex csinhl(long double _Complex z);
float _Complex csinhf(float _Complex z);
```

csqrt

**Description:** The `csqrt` function returns the complex square root of `z`.

**Calling interface:**
```c
double _Complex csqrt(double _Complex z);
long double _Complex csqrtl(long double _Complex z);
float _Complex csqrtf(float _Complex z);
```

ctan

**Description:** The `ctan` function returns the complex tangent of `z`.

**Calling interface:**
```c
double _Complex ctan(double _Complex z);
long double _Complex ctanl(long double _Complex z);
float _Complex ctanf(float _Complex z);
```

ctanh

**Description:** The `ctanh` function returns the complex hyperbolic tangent of `z`.

**Calling interface:**
```c
double _Complex ctanh(double _Complex z);
long double _Complex ctanhl(long double _Complex z);
float _Complex ctanhf(float _Complex z);
```
C99 Macros

The Intel Math library and `mathimf.h` header file support the following C99 macros:

```c
int fpclassify(x);
int isfinite(x);
int isgreater(x, y);
int isgreaterequal(x, y);
int isinf(x);
int isless(x, y);
```
int islessequal(x, y);
int islessgreater(x, y);
int isnan(x);
int isnormal(x);
int isunordered(x, y);
int signbit(x);

Intel(R) C++ Class Libraries

Introduction to the Class Libraries

Overview: Intel® C++ Class Libraries

The Intel® C++ Class Libraries enable Single-Instruction, Multiple-Data (SIMD) operations. The principle of SIMD operations is to exploit microprocessor architecture through parallel processing. The effect of parallel processing is increased data throughput using fewer clock cycles. The objective is to improve application performance of complex and computation-intensive audio, video, and graphical data bit streams.

Hardware and Software Requirements

The Intel® C++ Class Libraries are functions abstracted from the instruction extensions available on Intel processors as specified in the table that follows:

**Processor Requirements for Use of Class Libraries**

<table>
<thead>
<tr>
<th>Header File</th>
<th>Extension Set</th>
<th>Available on These Processors</th>
</tr>
</thead>
<tbody>
<tr>
<td>ivec.h</td>
<td>MMX™ technology</td>
<td>Pentium® processor with MMX technology, Pentium® II processor, Pentium® III processor, Pentium® 4 processor, Intel® Xeon® processor, and Itanium® processor</td>
</tr>
<tr>
<td>fvec.h</td>
<td>Streaming SIMD Extensions</td>
<td>Pentium III processor, Pentium 4 processor, Intel Xeon processor, and Itanium processor</td>
</tr>
<tr>
<td>dvec.h</td>
<td>Streaming SIMD Extensions 2</td>
<td>Pentium 4 processor and Intel Xeon processors</td>
</tr>
</tbody>
</table>
About the Classes

The Intel® C++ Class Libraries for SIMD Operations include:

- Integer vector (Ivec) classes
- Floating-point vector (Fvec) classes

You can find the definitions for these operations in three header files: ivec.h, fvec.h, and dvec.h. The classes themselves are not partitioned like this. The classes are named according to the underlying type of operation. The header files are partitioned according to architecture:

- ivec.h is specific to architectures with MMX(TM) technology
- fvec.h is specific to architectures with Streaming SIMD Extensions
- dvec.h is specific to architectures with Streaming SIMD Extensions 2

Streaming SIMD Extensions 2 intrinsics cannot be used on Itanium®-based systems. The mmclass.h header file includes the classes that are usable on the Itanium architecture.

This documentation is intended for programmers writing code for the Intel architecture, particularly code that would benefit from the use of SIMD instructions. You should be familiar with C++ and the use of C++ classes.

Details About the Libraries

The Intel® C++ Class Libraries for SIMD Operations provide a convenient interface to access the underlying instructions for processors as specified in Processor Requirements for Use of Class Libraries. These processor-instruction extensions enable parallel processing using the single instruction-multiple data (SIMD) technique as illustrated in the following figure.

**SIMD Data Flow**

<table>
<thead>
<tr>
<th>A3</th>
<th>A2</th>
<th>A1</th>
<th>A0</th>
</tr>
</thead>
<tbody>
<tr>
<td>B3</td>
<td>B2</td>
<td>B1</td>
<td>B0</td>
</tr>
</tbody>
</table>

Performing four operations with a single instruction improves efficiency by a factor of four for that particular instruction.
These new processor instructions can be implemented using assembly inlining, intrinsics, or the C++ SIMD classes. Compare the coding required to add four 32-bit floating-point values, using each of the available interfaces:

### Comparison Between Inlining, Intrinsics and Class Libraries

<table>
<thead>
<tr>
<th>Assembly Inlining</th>
<th>Intrinsics</th>
<th>SIMD Class Libraries</th>
</tr>
</thead>
<tbody>
<tr>
<td>... __m128 a,b,c; __asm{ movaps xmm0,b movaps xmm1,c addps xmm0,xmm1 movaps a, xmm0 } ...</td>
<td>#include &lt;mmintrin.h&gt; ... __m128 a,b,c; a = _mm_add_ps(b,c); ...</td>
<td>#include &lt;fvec.h&gt; ... F32vec4 a,b,c; a = b +c; ...</td>
</tr>
</tbody>
</table>

This table shows an addition of two single-precision floating-point values using assembly inlining, intrinsics, and the libraries. You can see how much easier it is to code with the Intel C++ SIMD Class Libraries. Besides using fewer keystrokes and fewer lines of code, the notation is like the standard notation in C++, making it much easier to implement over other methods.

### C++ Classes and SIMD Operations

The use of C++ classes for SIMD operations is based on the concept of operating on arrays, or vectors of data, in parallel. Consider the addition of two vectors, A and B, where each vector contains four elements. Using the integer vector (Ivec) class, the elements A[i] and B[i] from each array are summed as shown in the following example.

#### Typical Method of Adding Elements Using a Loop

```c
short a[4], b[4], c[4];
for (i=0; i<4; i++) /* needs four iterations */
c[i] = a[i] + b[i]; /* returns c[0], c[1], c[2], c[3] */
```

The following example shows the same results using one operation with Ivec Classes.

#### SIMD Method of Adding Elements Using Ivec Classes

```c
sIs16vec4 ivecA, ivecB, ivec C; /*needs one iteration */
ivecC = ivecA + ivecB; /*returns ivecC0, ivecC1, ivecC2, ivecC3 */
```

### Available Classes

The Intel C++ SIMD classes provide parallelism, which is not easily implemented using typical mechanisms of C++. The following table shows how the Intel C++ SIMD classes use the classes and libraries.

### SIMD Vector Classes

</tbody>
</table>

Most classes contain similar functionality for all data types and are represented by all available intrinsics. However, some capabilities do not translate from one data type to another without suffering from poor performance, and are therefore excluded from individual classes.
Intrinsics that take immediate values and cannot be expressed easily in classes are not implemented. (For example, `_mm_shuffle_ps`, `_mm_shuffle_pi16`, `_mm_extract_pi16`, `_mm_insert_pi16`).

**Access to Classes Using Header Files**

The required class header files are installed in the include directory with the Intel® C++ Compiler. To enable the classes, use the `#include` directive in your program file as shown in the table that follows.

**Include Directives for Enabling Classes**

<table>
<thead>
<tr>
<th>Instruction Set Extension</th>
<th>Include Directive</th>
</tr>
</thead>
<tbody>
<tr>
<td>MMX Technology</td>
<td><code>#include &lt;ivec.h&gt;</code></td>
</tr>
<tr>
<td>Streaming SIMD Extensions</td>
<td><code>#include &lt;fvec.h&gt;</code></td>
</tr>
<tr>
<td>Streaming SIMD Extensions 2</td>
<td><code>#include &lt;dvec.h&gt;</code></td>
</tr>
</tbody>
</table>

Each succeeding file from the top down includes the preceding class. You only need to include `fvec.h` if you want to use both the `Ivec` and `Fvec` classes. Similarly, to use all the classes including those for the Streaming SIMD Extensions 2, you need only to include the `dvec.h` file.

**Usage Precautions**

When using the C++ classes, you should follow some general guidelines. More detailed usage rules for each class are listed in Integer Vector Classes, and Floating-point Vector Classes.

**Clear MMX Registers**

If you use both the `Ivec` and `Fvec` classes at the same time, your program could mix MMX instructions, called by `Ivec` classes, with Intel x87 architecture floating-point instructions, called by `Fvec` classes. Floating-point instructions exist in the following `Fvec` functions:

- `fvec constructors`
- `debug functions` (`cout` and element access)
- `rsqrt_nr`

**Note**
MMX registers are aliased on the floating-point registers, so you should clear the MMX state with the EMMS instruction intrinsic before issuing an x87 floating-point instruction, as in the following example.

```
ivecA = ivecA & ivecB;  // Ivec logical operation that uses MMX instructions
empty ();            // clear state
cout << f32vec4a;    // F32vec4 operation that uses x87 floating-point instructions
```

⚠️ Caution

Failure to clear the MMX registers can result in incorrect execution or poor performance due to an incorrect register state.

**Follow EMMS Instruction Guidelines**

Intel strongly recommends that you follow the guidelines for using the EMMS instruction. Refer to this topic before coding with the Ivec classes.

**Capabilities**

The fundamental capabilities of each C++ SIMD class include:

- computation
- horizontal data motion
- branch compression/elimination
- caching hints

Understanding each of these capabilities and how they interact is crucial to achieving desired results.

**Computation**

The SIMD C++ classes contain vertical operator support for most arithmetic operations, including shifting and saturation.

Computation operations include: _+, -, *, /_, reciprocal (rcp and rcp_nr), square root (sqrt), reciprocal square root (rsqrt and rsqrt_nr)._  

Operations rcp and rsqrt are new approximating instructions with very short latencies that produce results with at least 12 bits of accuracy. Operations rcp_nr and rsqrt_nr use software refining techniques to enhance the accuracy of the approximations, with a minimal impact on performance. (The "nr" stands for Newton-Raphson, a mathematical technique for improving performance using an approximate result.)
Horizontal Data Support

The C++ SIMD classes provide horizontal support for some arithmetic operations. The term "horizontal" indicates computation across the elements of one vector, as opposed to the vertical, element-by-element operations on two different vectors.

The `add_horizontal`, `unpack_low` and `pack_sat` functions are examples of horizontal data support. This support enables certain algorithms that cannot exploit the full potential of SIMD instructions.

Shuffle intrinsics are another example of horizontal data flow. Shuffle intrinsics are not expressed in the C++ classes due to their immediate arguments. However, the C++ class implementation enables you to mix shuffle intrinsics with the other C++ functions. For example:

```c++
F32vec4 fveca, fvecb, fvecd;
fveca += fvecb;
fvecd = _mm_shuffle_ps(fveca,fvecb,0);
```

Typically every instruction with horizontal data flow contains some inefficiency in the implementation. If possible, implement your algorithms without using the horizontal capabilities.

Branch Compression/Elimination

Branching in SIMD architectures can be complicated and expensive, possibly resulting in poor predictability and code expansion. The SIMD C++ classes provide functions to eliminate branches, using logical operations, max and min functions, conditional selects, and compares. Consider the following example:

```c++
short a[4], b[4], c[4];
for (i=0; i<4; i++)
c[i] = a[i] > b[i] ? a[i] : b[i];
```

This operation is independent of the value of i. For each i, the result could be either A or B depending on the actual values. A simple way of removing the branch altogether is to use the `select_gt` function, as follows:

```c++
Is16vec4 a, b, c
c = select_gt(a, b, a, b)
```

Caching Hints

Streaming SIMD Extensions provide prefetching and streaming hints. Prefetching data can minimize the effects of memory latency. Streaming hints allow you to indicate that certain data should not be cached. This results in higher performance for data that should be cached.
Integer Vector Classes

Overview: Integer Vector Classes

The Ivec classes provide an interface to SIMD processing using integer vectors of various sizes. The class hierarchy is represented in the following figure.

Ivec Class Hierarchy

The M64 and M128 classes define the __m64 and __m128i data types from which the rest of the Ivec classes are derived. The first generation of child classes are derived based solely on bit sizes of 128, 64, 32, 16, and 8 respectively for the I128vec1, I64vec1, I64vec2, I32vec2, I32vec4, I16vec4, I16vec8, I8vec16, and I8vec8 classes. The latter seven of the these classes require specification of signedness and saturation.

⚠️ Caution

Do not intermix the M64 and M128 data types. You will get unexpected behavior if you do.

The signedness is indicated by the s and u in the class names:

Is64vec2
Iu64vec2
Is32vec4
Iu32vec4
Is16vec8
Iu16vec8
Is8vec16
Iu8vec16
Is32vec2
Iu32vec2
Is16vec4
Iu16vec4
Is8vec8
Iu8vec8
Terms, Conventions, and Syntax

The following are special terms and syntax used in this chapter to describe functionality of the classes with respect to their associated operations.

Ivec Class Syntax Conventions

The name of each class denotes the data type, signedness, bit size, number of elements using the following generic format:

\(<\text{type}>\langle\text{signedness}\rangle\langle\text{bits}\rangle\text{vec}\langle\text{elements}\rangle\>

\{ F \mid I \}\{ s \mid u \}\{ 64 \mid 32 \mid 16 \mid 8 \}\text{vec}\{ 8 \mid 4 \mid 2 \mid 1 \}

where

<table>
<thead>
<tr>
<th>type</th>
<th>indicates floating point (F) or integer (I)</th>
</tr>
</thead>
<tbody>
<tr>
<td>signedness</td>
<td>indicates signed (s) or unsigned (u). For the Ivec class, leaving this field blank indicates an intermediate class. There are no unsigned Fvec classes, therefore for the Fvec classes, this field is blank.</td>
</tr>
<tr>
<td>bits</td>
<td>specifies the number of bits per element</td>
</tr>
<tr>
<td>elements</td>
<td>specifies the number of elements</td>
</tr>
</tbody>
</table>

Special Terms and Conventions

The following terms are used to define the functionality and characteristics of the classes and operations defined in this manual.

- **Nearest Common Ancestor** -- This is the intermediate or parent class of two classes of the same size. For example, the nearest common ancestor of \(\text{Iu8vec8}\) and \(\text{Is8vec8}\) is \(\text{I8vec8}\). Also, the nearest common ancestor between \(\text{Iu8vec8}\) and \(\text{I16vec4}\) is \(\text{M64}\).

- **Casting** -- Changes the data type from one class to another. When an operation uses different data types as operands, the return value of the operation must be assigned to a single data type. Therefore, one or more of the data types must be converted to a required data type. This conversion is known as a typecast. Sometimes, typecasting is automatic, other times you must use special syntax to explicitly typecast it yourself.

- **Operator Overloading** -- This is the ability to use various operators on the same user-defined data type of a given class. Once you declare a variable, you can add, subtract, multiply, and perform a range of operations. Each family of classes accepts a specified range of operators, and must comply by rules and restrictions regarding typecasting and operator overloading as defined in the header files. The following table shows the notation used in this documentation to address typecasting, operator overloading, and other rules.

Class Syntax Notation Conventions
### Rules for Operators

To use operators with the `Ivec` classes you must use one of the following three syntax conventions:

```
```

**Example 1:**

```
I64vec1 R = I64vec1 A & I64vec1 B;
```

```
```

**Example 2:**

```
I64vec1 R = andnot(I64vec1 A, I64vec1 B);
```

```
[ Ivec_Class ] R [ operator ]= [ Ivec_Class ] A
```

**Example 3:**

```
I64vec1 R &= I64vec1 A;
```

**operator** - an operator (for example, &, |, or ^ )

**[ Ivec_Class ]** - an Ivec class

R, A, B variables declared using the pertinent Ivec classes

The table that follows shows automatic and explicit sign and size typecasting. "Explicit" means that it is illegal to mix different types without an explicit typecasting. "Automatic" means that you can mix types freely and the compiler will do the typecasting for you.

### Summary of Rules Major Operators

<td>I8vec16 A(char A15, ..., char A0);</td>
<td>Is8vec16 A(signed char A15, ..., signed char A0);</td>
</tr>
</tbody>
</table>

Assignment Operator

Any Ivec object can be assigned to any other Ivec object; conversion on assignment from one Ivec object to another is automatic.

Assignment Operator Examples

Is16vec4 A;
Is8vec8 B;
I64vec1 C;
A = B; /* assign Is8vec8 to Is16vec4 */
B = C; /* assign I64vec1 to Is8vec8 */
B = A & C; /* assign M64 result of '&' to Is8vec8 */

Logical Operators

The logical operators use the symbols and intrinsics listed in the following table.

<table>
<thead>
<tr>
<th>Bitwise Operation</th>
<th>Operator Symbols</th>
<th>Syntax Usage</th>
<th>Corresponding Intrinsic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Standard w/assign</td>
<td>Standard w/assign</td>
<td></td>
</tr>
</tbody>
</table>
| AND              | &               | &=           | R = A & B               | _mm_and_si64
|                  |                 |              | R &= A                  | _mm_and_si128
| OR               | |               | R = A | B | R |= A | _mm_and_si64
|                  |                 |              |                         | _mm_and_si128
Logical Operators and Miscellaneous Exceptions.

A and B converted to M64. Result assigned to `Iu8vec8`.

```
I64vec1 A;
Is8vec8 B;
Iu8vec8 C;
C = A & B;
```

Same size and signedness operators return the nearest common ancestor.

```
I32vec2 R = Is32vec2 A ^ Iu32vec2 B;
```

A&B returns M64, which is cast to `Iu8vec8`.

```
C = Iu8vec8(A&B) + C;
```

When A and B are of the same class, they return the same type. When A and B are of different classes, the return value is the return type of the nearest common ancestor.

The logical operator returns values for combinations of classes, listed in the following tables, apply when A and B are of different classes.

### Ivec Logical Operator Overloading

<table>
<thead>

<td>I{s</td>
</tr>
</tbody>
</table>

### Addition and Subtraction Operators

The addition and subtraction operators return the class of the nearest common ancestor when the right-side operands are of different signs. The following code provides examples of usage and miscellaneous exceptions.

#### Syntax Usage for Addition and Subtraction Operators

Return nearest common ancestor type, I16vec4.

```plaintext
Iu16vec4 A;
Iu16vec4 B;
I16vec4 C;
C = A + B;
```

Returns type left-hand operand type.

```plaintext
Is16vec4 A;
Iu16vec4 B;
A += B;
B -= A;
```

Explicitly convert B to Is16vec4.
Is16vec4 A, C;
Iu32vec24 B;
C = A + C;
C = A + (Is16vec4)B;

Addition and Subtraction Operators with Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbols</th>
<th>Syntax</th>
<th>Corresponding Intrinsics</th>
</tr>
</thead>
<tbody>
<tr>

<th>Sub</th>
<th>Right Side (A)</th>
</tr>
</thead>
</table>
I[x]32vec4 R I[x]32vec2 R += I[s|u]32vec4 A;
I[x]32vec2 R I[x]32vec2 R += I[s|u]32vec2 A;
I[x]16vec8 I[x]16vec8 += I[s|u]16vec8 A;
I[x]16vec4 I[x]16vec4 += I[s|u]16vec4 A;
I[x]8vec16 I[x]8vec16 += I[s|u]8vec16 A;
I[x]8vec8 I[x]8vec8 += I[s|u]8vec8 A;

**Multiplication Operators**

The multiplication operators can only accept and return data types from the I[s|u]16vec4 or I[s|u]16vec8 classes, as shown in the following example.

**Syntax Usage for Multiplication Operators**

Explicitly convert B to Is16vec4.

Is16vec4 A,C;
Iu32vec2 B;
C = A * C;
C = A * (Is16vec4)B;

Return nearest common ancestor type, I16vec4

Is16vec4 A;
Iu16vec4 B;
I16vec4 C;
C = A + B;

The mul_high and mul_add functions take Is16vec4 data only.

Is16vec4 A,B,C,D;
C = mul_high(A,B);
D = mul_add(A,B);

**Multiplication Operators with Corresponding Intrinsics**

<table>
<thead>
<tr>
<th>Symbols</th>
<th>Syntax Usage</th>
<th>Intrinsic</th>
</tr>
</thead>
</table>

---

63
The multiplication return operators always return the nearest common ancestor as listed in the table that follows. The two operands must be 16 bits in size, otherwise you must explicitly indicate typecasting.

### Multiplication Operator Overloading

<table>
<thead>
<tr>
<th>R</th>
<th>Mul</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>I16vec4</td>
<td>I[s</td>
<td>u]16vec4</td>

<td>Is32vec8 A</td>
<td>Is16vec8 B</td>
</tr>
</tbody>
</table>

The following table shows the return values and data type assignments for operands of the multiplication operators with assignment. All operands must be 16 bytes in size. If the operands are not the right size, you must use an explicit typecast.

### Multiplication with Assignment

<table>
<thead>
<tr>
<th>Return Value (R)</th>

<td>*</td>
<td>I[s</td>
</tr>
</tbody>
</table>

### Shift Operators

The right shift argument can be any integer or Ivec value, and is implicitly converted to a M64 data type. The first or left operand of a << can be of any type except I[s|u]8vec[8|16].

### Example Syntax Usage for Shift Operators

Automatic size and sign conversion.

Is16vec4 A, C;

Iu32vec2 B;
C = A;

A&B returns I16vec4, which must be cast to Iu16vec4 to ensure logical shift, not arithmetic shift.

Is16vec4 A, C;
Iu16vec4 B, R;
R = (Iu16vec4)(A & B) C;

A&B returns I16vec4, which must be cast to Is16vec4 to ensure arithmetic shift, not logical shift.

R = (Is16vec4)(A & B) C;

### Shift Operators with Corresponding Intrinsics

</tbody>
</table>
Comparison Operators

The equality and inequality comparison operands can have mixed signedness, but they must be of the same size. The comparison operators for less-than and greater-than must be of the same sign and size.

Example of Syntax Usage for Comparison Operator

The nearest common ancestor is returned for compare for equal/not-equal operations.

```c
Iu8vec8 A;
Is8vec8 B;
I8vec8 C;
C = cmpneq(A, B);
```

Type cast needed for different-sized elements for equal/not-equal comparisons.

```c
Iu8vec8 A, C;
Is16vec4 B;
C = cmpeq((Iu8vec8)A, (Iu8vec8)B);
```

Type cast needed for sign or size differences for less-than and greater-than comparisons.

```c
Iu16vec4 A;
Is16vec4 B, C;
C = cmpge((Is16vec4)A, B);
C = cmpgt(B, C);
```

Inequality Comparison Symbols and Corresponding Intrinsics

<table>

</tr>
<tr>
<td>I8vec8</td>
<td></td>
<td>Is8vec8</td>
<td>B8vec8</td>
</tr>
</tbody>
</table>

### Conditional Select Operators

For conditional select operands, the third and fourth operands determine the type returned. Third and fourth operands with same size, but different signedness, return the nearest common ancestor data type.

### Conditional Select Syntax Usage

Return the nearest common ancestor data type if third and fourth operands are of the same size, but different signs.

```plaintext
I16vec4 R = select_neq(Is16vec4, Is16vec4, Is16vec4, Iu16vec4);
```

### Conditional Select for Equality

```plaintext
R0 := (A0 == B0) ? C0 : D0;
R1 := (A1 == B1) ? C1 : D1;
```
R2 := (A2 == B2) ? C2 : D2;
R3 := (A3 == B3) ? C3 : D3;

Conditional Select for Inequality
R0 := (A0 != B0) ? C0 : D0;
R1 := (A1 != B1) ? C1 : D1;
R2 := (A2 != B2) ? C2 : D2;
R3 := (A3 != B3) ? C3 : D3;

### Conditional Select Symbols and Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Conditional Select For:</th>
<th>Operators</th>
<th>Syntax</th>
<th>Corresponding Intrinsic</th>
<th>Additional Intrinsic (Applies to All)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td>select_eq</td>
<td>R = select_eq(A, B, C, D)</td>
<td>mm_cmpeq_pi32, mm_cmpeq_pi16, mm_cmpeq_pi8</td>
<td>mm_and_si64, mm_or_si64, mm_andnot_si64</td>
</tr>
<tr>
<td>Inequality</td>
<td>select_neq</td>
<td>R = select_neq(A, B, C, D)</td>
<td>mm_cmpeq_pi32, mm_cmpeq_pi16, mm_cmpeq_pi8</td>
<td></td>
</tr>
<tr>
<td>Greater Than</td>
<td>select_gt</td>

<td></td>
<td></td>
</tr>
<tr>
<td>R7:= A0 == != &gt; &gt;= &lt; &lt;= B0 ? C7 : D7;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Debug

The debug operations do not map to any compiler intrinsics for MMX(TM) instructions. They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

### Output

The four 32-bit values of A are placed in the output buffer and printed in the following format (default in decimal):

```cpp
cout << Is32vec4 A;
cout << Iu32vec4 A;
cout << hex << Iu32vec4 A; /* print in hex format */
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none
The two 32-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):

```cpp
cout << Is32vec2 A;
cout << Iu32vec2 A;
cout << hex << Iu32vec2 A; /* print in hex format */
"[1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The eight 16-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):

```cpp
cout << Is16vec8 A;
cout << Iu16vec8 A;
cout << hex << Iu16vec8 A; /* print in hex format */
"[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The four 16-bit values of $A$ are placed in the output buffer and printed in the following format (default in decimal):

```cpp
cout << Is16vec4 A;
cout << Iu16vec4 A;
cout << hex << Iu16vec4 A; /* print in hex format */
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The sixteen 8-bit values of $A$ are placed in the output buffer and printed in the following format (default is decimal):

```cpp
cout << Is8vec16 A; cout << Iu8vec16 A; cout << hex << Iu8vec8 A;
/* print in hex format instead of decimal*/
```

Corresponding Intrinsics: none
The eight 8-bit values of $A$ are placed in the output buffer and printed in the following format (default is decimal):

```cpp
    cout << Is8vec8 A; cout << Iu8vec8 A; cout << hex << Iu8vec8 A;
    /* print in hex format instead of decimal*/
    
    "[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

**Element Access Operators**

```cpp
int R = Is64vec2 A[i];
unsigned int R = Iu64vec2 A[i];
int R = Is32vec4 A[i];
unsigned int R = Iu32vec4 A[i];
int R = Is32vec2 A[i];
unsigned int R = Iu32vec2 A[i];
short R = Is16vec8 A[i];
unsigned short R = Iu16vec8 A[i];
short R = Is16vec4 A[i];
unsigned short R = Iu16vec4 A[i];
signed char R = Is8vec16 A[i];
unsigned char R = Iu8vec16 A[i];
signed char R = Is8vec8 A[i];
unsigned char R = Iu8vec8 A[i];
```

Access and read element $i$ of $A$. If DEBUG is enabled and the user tries to access an element outside of $A$, a diagnostic message is printed and the program aborts.

Corresponding Intrinsics: none

**Element Assignment Operators**

```cpp
Is64vec2 A[i] = int R;
Is32vec4 A[i] = int R;
```
Printed Documentation

Iu32vec4 A[i] = unsigned int R;
Is32vec2 A[i] = int R;
Iu32vec2 A[i] = unsigned int R;
Is16vec8 A[i] = short R;
Iu16vec8 A[i] = unsigned short R;
Is16vec4 A[i] = short R;
Iu16vec4 A[i] = unsigned short R;
Is8vec16 A[i] = signed char R;
Iu8vec16 A[i] = unsigned char R;
Is8vec8 A[i] = signed char R;
Iu8vec8 A[i] = unsigned char R;

Assign \( R \) to element \( i \) of \( A \). If \texttt{DEBUG} is enabled and the user tries to assign a value to an element outside of \( A \), a diagnostic message is printed and the program aborts.

Corresponding Intrinsics: none

Unpack Operators

Interleave the 64-bit value from the high half of \( A \) with the 64-bit value from the high half of \( B \).

I364vec2 unpack_high(I64vec2 A, I64vec2 B);
Is64vec2 unpack_high(Is64vec2 A, Is64vec2 B);
Iu64vec2 unpack_high(Iu64vec2 A, Iu64vec2 B);

\( R_0 = A_1 \);
\( R_1 = B_1 \);

Corresponding intrinsic: \texttt{_mm_unpackhi_epi64}

Interleave the two 32-bit values from the high half of \( A \) with the two 32-bit values from the high half of \( B \).

I32vec4 unpack_high(I32vec4 A, I32vec4 B);
Is32vec4 unpack_high(Is32vec4 A, Is32vec4 B);

R5 = B2;
R6 = A3;
R7 = B3;

**Corresponding intrinsic: _mm_unpacklo_epi16**

Interleave the two 16-bit values from the low half of A with the two 16-bit values from the low half of B.

Ii16vec4 unpack_low(Ii16vec4 A, Ii16vec4 B);
Is16vec4 unpack_low(Is16vec4 A, Is16vec4 B);
Iu16vec4 unpack_low(Iu16vec4 A, Iu16vec4 B);

R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;

**Corresponding intrinsic: _mm_unpacklo_pi16**

Interleave the four 8-bit values from the high low of A with the four 8-bit values from the low half of B.

Ii8vec16 unpack_low(Ii8vec16 A, Ii8vec16 B);
Is8vec16 unpack_low(Is8vec16 A, Is8vec16 B);
Iu8vec16 unpack_low(Iu8vec16 A, Iu8vec16 B);

R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;
R4 = A2;
R5 = B2;
R6 = A3;
R7 = B3;
R8 = A4;
R9 = B4;
R10 = A5;
R11 = B5;
R12 = A6;
R13 = B6;
R14 = A7;
R15 = B7;

**Corresponding intrinsic: _mm_unpacklo_epi8**

Interleave the four 8-bit values from the high low of A with the four 8-bit values from the low half of B.
I8vec8 unpack_low(I8vec8 A, I8vec8 B);
Is8vec8 unpack_low(Is8vec8 A, Is8vec8 B);
Iu8vec8 unpack_low(Iu8vec8 A, Iu8vec8 B);

R0 = A0;
R1 = B0;
R2 = A1;
R3 = B1;
R4 = A2;
R5 = B2;
R6 = A3;
R7 = B3;

**Corresponding intrinsic:** _mm_unpacklo_pi8

**Pack Operators**

Pack the eight 32-bit values found in A and B into eight 16-bit values with signed saturation.

Is16vec8 pack_sat(Is32vec2 A, Is32vec2 B);
**Corresponding intrinsic:** _mm_packs_epi32

Pack the four 32-bit values found in A and B into eight 16-bit values with signed saturation.

Is16vec4 pack_sat(Is32vec2 A, Is32vec2 B);
**Corresponding intrinsic:** _mm_packs_pi32

Pack the sixteen 16-bit values found in A and B into sixteen 8-bit values with signed saturation.

Is8vec16 pack_sat(Is16vec4 A, Is16vec4 B);
**Corresponding intrinsic:** _mm_packs_epi16

Pack the eight 16-bit values found in A and B into eight 8-bit values with signed saturation.

Is8vec8 pack_sat(Is16vec4 A, Is16vec4 B);
**Corresponding intrinsic:** _mm_packs_pi16

Pack the sixteen 16-bit values found in A and B into sixteen 8-bit values with unsigned saturation.

Iu8vec16 packu_sat(Is16vec4 A, Is16vec4 B);
**Corresponding intrinsic:** _mm_packus_epi16

Pack the eight 16-bit values found in A and B into eight 8-bit values with unsigned saturation.
Iu8vec8 packu_sat(Is16vec4 A, Is16vec4 B);
  Corresponding intrinsic: _mm_packs_pu16

Clear MMX(TM) Instructions State Operator

Empty the MMX(TM) registers and clear the MMX state. Read the guidelines for using the EMMS instruction intrinsic.

void empty(void);
  Corresponding intrinsic: _mm_empty

Integer Functions for Streaming SIMD Extensions

Note

You must include fvec.h header file for the following functionality.

Compute the element-wise maximum of the respective signed integer words in A and B.

Is16vec4 simd_max(Is16vec4 A, Is16vec4 B);
  Corresponding intrinsic: _mm_max_pi16

Compute the element-wise minimum of the respective signed integer words in A and B.

Is16vec4 simd_min(Is16vec4 A, Is16vec4 B);
  Corresponding intrinsic: _mm_min_pi16

Compute the element-wise maximum of the respective unsigned bytes in A and B.

Iu8vec8 simd_max(Iu8vec8 A, Iu8vec8 B);
  Corresponding intrinsic: _mm_max_pu8

Compute the element-wise minimum of the respective unsigned bytes in A and B.

Iu8vec8 simd_min(Iu8vec8 A, Iu8vec8 B);
  Corresponding intrinsic: _mm_min_pu8

Create an 8-bit mask from the most significant bits of the bytes in A.

int move_mask(I8vec8 A);
  Corresponding intrinsic: _mm_movemask_pi8

Conditionally store byte elements of A to address p. The high bit of each byte in the selector B determines whether the corresponding byte in A will be stored.

void mask_move(I8vec8 A, I8vec8 B, signed char *p);
  Corresponding intrinsic: _mm_maskmove_si64
Store the data in \( A \) to the address \( p \) without polluting the caches. \( A \) can be any Ivec type.

```c
void store_nta(__m64 *p, M64 A);
```

Corresponding intrinsic: \_mm\_stream\_pi

Compute the element-wise average of the respective unsigned 8-bit integers in \( A \) and \( B \).

```c
Iu8vec8 simd_avg(Iu8vec8 A, Iu8vec8 B);
```

Corresponding intrinsic: \_mm\_avg\_pu8

Compute the element-wise average of the respective unsigned 16-bit integers in \( A \) and \( B \).

```c
Iu16vec4 simd_avg(Iu16vec4 A, Iu16vec4 B);
```

Corresponding intrinsic: \_mm\_avg\_pu16

## Conversions Between Fvec and Ivec

Convert the lower double-precision floating-point value of \( A \) to a 32-bit integer with truncation.

```c
int F64vec2ToInt(F64vec4 A);
r := (int)A0;
```

Convert the four floating-point values of \( A \) to two the two least significant double-precision floating-point values.

```c
F64vec2 F32vec4ToF64vec2(F32vec4 A);
r0 := (double)A0;
r1 := (double)A1;
```

Convert the two double-precision floating-point values of \( A \) to two single-precision floating-point values.

```c
F32vec4 F64vec2ToF32vec4(F64vec2 A);
r0 := (float)A0;
r1 := (float)A1;
```

Convert the signed int in \( B \) to a double-precision floating-point value and pass the upper double-precision value from \( A \) through to the result.

```c
F64vec2 InttoF64vec2(F64vec4 A, int B);
r0 := (double)B;
r1 := A1;
```

Convert the lower floating-point value of \( A \) to a 32-bit integer with truncation.

```c
int F32vec4ToInt(F32vec4 A);
r := (int)A0;
```
Printed Documentation

Convert the two lower floating-point values of \( A \) to two 32-bit integer with truncation, returning the integers in packed form.

\[
\text{Is32vec2 F32vec4ToIs32vec2 (F32vec4 A);} \\
r0 := (\text{int})A0; \\
r1 := (\text{int})A1;
\]

Convert the 32-bit integer value \( B \) to a floating-point value; the upper three floating-point values are passed through from \( A \).

\[
\text{F32vec4 IntToF32vec4(F32vec4 A, int B);} \\
r0 := (\text{float})B; \\
r1 := A1; \\
r2 := A2; \\
r3 := A3;
\]

Convert the two 32-bit integer values in packed form in \( B \) to two floating-point values; the upper two floating-point values are passed through from \( A \).

\[
\text{F32vec4 Is32vec2ToF32vec4(F32vec4 A, Is32vec2 B);} \\
r0 := (\text{float})B0; \\
r1 := (\text{float})B1; \\
r2 := A2; \\
r3 := A3;
\]

### Floating-point Vector Classes

The floating-point vector classes, \( \text{F64vec2} \), \( \text{F32vec4} \), and \( \text{F32vec1} \), provide an interface to SIMD operations. The class specifications are as follows:

\[
\text{F64vec2 A(double x, double y);} \\
\text{F32vec4 A(float z, float y, float x, float w);} \\
\text{F32vec1 B(float w);} \\
\]

The packed floating-point input values are represented with the right-most value lowest as shown in the following table.

### Single-Precision Floating-point Elements
This reference uses the following conventions for syntax and return values.

**Fvec Classes Syntax Notation**

Fvec classes use the syntax conventions shown in the following examples:

```
```

**Example 1:**

```
F64vec2 R = F64vec2 A & F64vec2 B;
```

**Example 2:**

```
[Fvec_Class] R = [operator] ([Fvec_Class] A, [Fvec_Class] B);
```

**Example 3:**

```
F64vec2 R &= F64vec2 A;
```

where

- **[operator]** is an operator (for example, &, |, or ^)
- **[Fvec_Class]** is any Fvec class (F64vec2, F32vec4, or F32vec1)
- R, A, B are declared Fvec variables of the type indicated

**Return Value Notation**
Because the \texttt{Fvec} classes have packed elements, the return values typically follow the conventions presented in the Return Value Convention Notation Mappings table. \texttt{F32vec4} returns four single-precision, floating-point values (R0, R1, R2, and R3); \texttt{F64vec2} returns two double-precision, floating-point values, and \texttt{F32vec1} returns the lowest single-precision floating-point value (R0).

\begin{center}
\textbf{Return Value Convention Notation Mappings}
\begin{tabular}{|c|c|c|c|}
\hline
Example 1: & Example 2: & Example 3: & \texttt{F32vec4} & \texttt{F64vec2} & \texttt{F32vec1} \\
\hline
R0 := A0 & B0; & R0 := A0 andnot B0; & R0 &= A0; & x & x & x \\
R1 := A1 & B1; & R1 := A1 andnot B1; & R1 &= A1; & x & x & N/A \\
R2 := A2 & B2; & R2 := A2 andnot B2; & R2 &= A2; & x & N/A & N/A \\
R3 := A3 & B3 & R3 := A3 andnot B3; & R3 &= A3; & x & N/A & N/A \\
\hline
\end{tabular}
\end{center}

\section*{Data Alignment}

Memory operations using the Streaming SIMD Extensions should be performed on 16-byte-aligned data whenever possible.

\texttt{F32vec4} and \texttt{F64vec2} object variables are properly aligned by default. Note that floating point arrays are not automatically aligned. To get 16-byte alignment, you can use the alignment \texttt{declspec}:

\begin{verbatim}
__declspec( align(16) ) float A[4];
\end{verbatim}

\section*{Conversions}

All \texttt{Fvec} object variables can be implicitly converted to \texttt{__m128} data types. For example, the results of computations performed on \texttt{F32vec4} or \texttt{F32vec1} object variables can be assigned to \texttt{__m128} data types.

\begin{verbatim}
__m128d mm = A & B; /* where A,B are F64vec2 object variables */
__m128 mm = A & B; /* where A,B are F32vec4 object variables */
__m128 mm = A & B; /* where A,B are F32vec1 object variables */
\end{verbatim}

\section*{Constructors and Initialization}

The following table shows how to create and initialize \texttt{F32vec} objects with the \texttt{Fvec} classes.

\begin{center}
\textbf{Constructors and Initialization for Fvec Classes}
\begin{tabular}{|c|c|c|}
\hline
Example & Intrinsic & Returns \\
\hline
\textbf{Constructor Declaration} & & \\
\hline
\end{tabular}
\end{center}
### __m128 Object Initialization

| F64vec2 A; | N/A | N/A |
| F32vec4 B; | N/A | N/A |
| F32vec1 C; | N/A | N/A |

#### Double Initialization

/__ Initialize two doubles. */
F64vec2 A(double d0, double d1);
F64vec2 A = F64vec2(double d0, double d1);

| _mm_set_pd | A0 := d0; |
| A1 := d1; |

F64vec2 A(double d0);
/* Initialize both return values with the same double precision value */.

| _mm_set1_pd | A0 := d0; |
| A1 := d0; |

#### Float Initialization

F32vec4 A(float f3, float f2, float f1, float f0);
F32vec4 A = F32vec4(float f3, float f2, float f1, float f0);

| _mm_set_ps | A0 := f0; |
| A1 := f1; |
| A2 := f2; |
| A3 := f3; |

F32vec4 A(float f0);
/* Initializes all return values with the same floating point value. */

| _mm_set1_ps | A0 := f0; |
| A1 := f0; |
| A2 := f0; |
| A3 := f0; |

F32vec4 A(double d0);
/* Initialize all return values with the same double-precision value. */

| _mm_set1_ps(d) | A0 := d0; |
| A1 := d0; |
| A2 := d0; |
| A3 := d0; |

F32vec1 A(double d0);
/* Initializes the lowest value of A with d0 and the other values with 0. */

| _mm_set_ss(d) | A0 := d0; |
| A1 := 0; |
| A2 := 0; |
| A3 := 0; |

F32vec1 B(float f0);
/* Initializes the lowest value of B with f0 and the other values with 0. */

| _mm_set_ss | B0 := f0; |
| B1 := 0; |
| B2 := 0; |
| B3 := 0; |

F32vec1 B(int I);
/* Initializes the lowest value of B with f0, other values are undefined. */

| _mm_cvtsi32_ss | B0 := f0; |
| B1 := {}; |
| B2 := {}; |
| B3 := {}; |

### Arithmetic Operators
The following table lists the arithmetic operators of the $Fvec$ classes and generic syntax. The operators have been divided into standard and advanced operations, which are described in more detail later in this section.

### Fvec Arithmetic Operators

<table>
<thead>
<tr>
<th>Category</th>
<th>Operation</th>
<th>Operators</th>
<th>Generic Syntax</th>
</tr>
</thead>
<tbody>
<tr>

</table>
Minimum and Maximum Operators

Compute the minimums of the two double precision floating-point values of A and B.

\[
\begin{align*}
F64vec2 \ R &= \ simd\_min(F64vec2 \ A, \ F64vec2 \ B) \\
R0 &= \ \text{min}(A0, B0); \\
R1 &= \ \text{min}(A1, B1); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{min}\_pd
\end{align*}
\]

Compute the minimums of the four single precision floating-point values of A and B.

\[
\begin{align*}
F32vec4 \ R &= \ simd\_min(F32vec4 \ A, \ F32vec4 \ B) \\
R0 &= \ \text{min}(A0, B0); \\
R1 &= \ \text{min}(A1, B1); \\
R2 &= \ \text{min}(A2, B2); \\
R3 &= \ \text{min}(A3, B3); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{min}\_ps
\end{align*}
\]

Compute the minimum of the lowest single precision floating-point values of A and B.

\[
\begin{align*}
F32vec1 \ R &= \ simd\_min(F32vec1 \ A, \ F32vec1 \ B) \\
R0 &= \ \text{min}(A0, B0); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{min}\_ss
\end{align*}
\]

Compute the maximums of the two double precision floating-point values of A and B.

\[
\begin{align*}
F64vec2 \ simd\_\text{max}(F64vec2 \ A, \ F64vec2 \ B) \\
R0 &= \ \text{max}(A0, B0); \\
R1 &= \ \text{max}(A1, B1); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{max}\_pd
\end{align*}
\]

Compute the maximums of the four single precision floating-point values of A and B.

\[
\begin{align*}
F32vec4 \ simd\_\text{max}(F32vec4 \ A, \ F32vec4 \ B) \\
R0 &= \ \text{max}(A0, B0); \\
R1 &= \ \text{max}(A1, B1); \\
R2 &= \ \text{max}(A2, B2); \\
R3 &= \ \text{max}(A3, B3); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{max}\_ps
\end{align*}
\]

Compute the maximum of the lowest single precision floating-point values of A and B.

\[
\begin{align*}
F32vec1 \ simd\_\text{max}(F32vec1 \ A, \ F32vec1 \ B) \\
R0 &= \ \text{max}(A0, B0); \\
\text{Corresponding intrinsic:} \quad & \_\text{mm}\_\text{max}\_ss
\end{align*}
\]
Logical Operators

The following table lists the logical operators of the Fvec classes and generic syntax. The logical operators for F32vec1 classes use only the lower 32 bits.

### Fvec Logical Operators Return Value Mapping

<table>
<thead>
<tr>
<th>Bitwise Operation</th>
<th>Operators</th>
<th>Generic Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AND</strong></td>
<td>&amp; &amp;=</td>
<td>R = A &amp; B; R &amp;= A;</td>
</tr>
<tr>
<td><strong>OR</strong></td>
<td></td>
<td>R = A</td>
</tr>
<tr>
<td><strong>XOR</strong></td>
<td>^ ^=</td>
<td>R = A ^ B; R ^= A;</td>
</tr>
<tr>
<td><strong>andnot</strong></td>
<td>andnot</td>
<td>R = andnot(A);</td>
</tr>
</tbody>
</table>

The following table lists standard logical operators syntax and corresponding intrinsics. Note that there is no corresponding scalar intrinsic for the F32vec1 classes, which accesses the lower 32 bits of the packed vector intrinsics.

### Logical Operations for Fvec Classes

<table>
<thead>
<tr>
<th>Operation</th>

</table>

### Compare Operators
The operators described in this section compare the single precision floating-point values of \( A \) and \( B \). Comparison between objects of any \( \mathbf{Fvec} \) class return the same class being compared.

The following table lists the compare operators for the \( \mathbf{Fvec} \) classes.

### Compare Operators and Corresponding Intrinsics

<table>
<thead>
<tr>
<th>Compare For:</th>
<th>Operators</th>
<th>Syntax</th>
</tr>

Conditional Select Operators for Fvec Classes

Each conditional function compares single-precision floating-point values of A and B. The C and D parameters are used for return value. Comparison between objects of any Fvec class returns the same class.

### Conditional Select Operators for Fvec Classes

<table>
<thead>
<tr>
<th>Conditional Select for:</th>
<th>Operators</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td>select_eq</td>
<td>R = select_eq(A, B)</td>
</tr>
<tr>
<td>Inequality</td>
<td>select_neq</td>
<td>R = select_neq(A, B)</td>
</tr>
<tr>
<td>Greater Than</td>
<td>select_gt</td>
<td>R = select_gt(A, B)</td>
</tr>
<tr>
<td>Greater Than or Equal To</td>
<td>select_ge</td>
<td>R = select_ge(A, B)</td>
</tr>
<tr>
<td>Not Greater Than</td>
<td>select_ge</td>
<td>R = select_ge(A, B)</td>
</tr>
<tr>
<td>Not Greater Than or Equal To</td>
<td>select_ge</td>
<td>R = select_ge(A, B)</td>
</tr>
<tr>
<td>Less Than</td>
<td>select_lt</td>
<td>R = select_lt(A, B)</td>
</tr>
<tr>
<td>Less Than or Equal To</td>
<td>select_le</td>
<td>R = select_le(A, B)</td>
</tr>
<tr>
<td>Not Less Than</td>
<td>select_nlt</td>
<td>R = select_nlt(A, B)</td>
</tr>
<tr>
<td>Not Less Than or Equal To</td>
<td>select_nle</td>
<td>R = select_nle(A, B)</td>
</tr>
</tbody>
</table>

### Conditional Select Operator Usage
For conditional select operators, the return value is stored in C if the comparison is true or in D if false. The following table shows the return values for each class of the conditional select operators, using the Return Value Notation described earlier.

### Compare Operator Return Value Mapping

<table>
<thead>
<tr>
<th>R</th>
<th>A0</th>
<th>Operators</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F32vec4</th>
<th>F64vec2</th>
<th>F32vec1</th>
</tr>
</thead>
<tbody>
<tr>
<td>R0:=</td>
<td>![A1]</td>
<td>select_eq</td>
<td>![B0]</td>
<td>![C0]</td>
<td>![D0]</td>
<td>X</td>
<td>X</td>

<td>_mm_cmpnge_ss</td>
</tr>
</tbody>
</table>

### Cacheability Support Operations

Stores (non-temporal) the two double-precision, floating-point values of $A$. Requires a 16-byte aligned address.

```c
void store_nta(double *p, F64vec2 A);
```

Corresponding intrinsic: \_mm\_stream\_pd

Stores (non-temporal) the four single-precision, floating-point values of $A$. Requires a 16-byte aligned address.

```c
void store_nta(float *p, F32vec4 A);
```
void store_nta(float *p, F32vec4 A);
Corresponding intrinsic: _mm_stream_ps

**Debugging**

The debug operations do not map to any compiler intrinsics for MMX(TM) technology or Streaming SIMD Extensions. They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

**Output Operations**

The two single, double-precision floating-point values of A are placed in the output buffer and printed in decimal format as follows:

```cpp
cout << F64vec2 A;
"[1]:A1 [0]:A0"
Corresponding intrinsics: none
```

The four, single-precision floating-point values of A are placed in the output buffer and printed in decimal format as follows:

```cpp
cout << F32vec4 A;
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
Corresponding intrinsics: none
```

The lowest, single-precision floating-point value of A is placed in the output buffer and printed.

```cpp
cout << F32vec1 A;
Corresponding intrinsics: none
```

**Element Access Operations**

double d = F64vec2 A[int i]

Read one of the two, double-precision floating-point values of A without modifying the corresponding floating-point value. Permitted values of i are 0 and 1. For example:

If DEBUG is enabled and i is not one of the permitted values (0 or 1), a diagnostic message is printed and the program aborts.

```cpp
double d = F64vec2 A[1];
Corresponding intrinsics: none
```

Read one of the four, single-precision floating-point values of A without modifying the corresponding floating point value. Permitted values of i are 0, 1, 2, and 3. For example:

```cpp
float f = F32vec4 A[int i]
```
If DEBUG is enabled and \( i \) is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

\[
\text{float } f = \text{F32vec4 } A[2];
\]

Corresponding intrinsics: none

**Element Assignment Operations**

\[
\text{F64vec4 } A[\text{int } i] = \text{double } d;
\]

Modify one of the two, double-precision floating-point values of \( A \). Permitted values of \( \text{int } i \) are 0 and 1. For example:

\[
\text{F32vec4 } A[1] = \text{double } d;
\text{F32vec4 } A[\text{int } i] = \text{float } f;
\]

Modify one of the four, single-precision floating-point values of \( A \). Permitted values of \( \text{int } i \) are 0, 1, 2, and 3. For example:

If DEBUG is enabled and \( \text{int } i \) is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

\[
\text{F32vec4 } A[3] = \text{float } f;
\]

Corresponding intrinsics: none.

**Load and Store Operators**

Loads two, double-precision floating-point values, copying them into the two, floating-point values of \( A \). No assumption is made for alignment.

\[
\text{void loadu(F64vec2 } A, \text{double } *p)\]

Corresponding intrinsic: \_mm_loadu_pd

Stores the two, double-precision floating-point values of \( A \). No assumption is made for alignment.

\[
\text{void storeu(float } *p, \text{F64vec2 } A);\]

Corresponding intrinsic: \_mm_storeu_pd

Loads four, single-precision floating-point values, copying them into the four floating-point values of \( A \). No assumption is made for alignment.

\[
\text{void loadu(F32vec4 } A, \text{double } *p)\]

Corresponding intrinsic: \_mm_loadu_ps

Stores the four, single-precision floating-point values of \( A \). No assumption is made for alignment.

\[
\text{void storeu(float } *p, \text{F32vec4 } A);\]

Corresponding intrinsic: \_mm_storeu_ps
Unpack Operators for Fvec Operators

Selects and interleaves the lower, double-precision floating-point values from $A$ and $B$.

```c
F64vec2 R = unpack_low(F64vec2 A, F64vec2 B);
```

**Corresponding intrinsic:** `_mm_unpacklo_pd(a, b)`

Selects and interleaves the higher, double-precision floating-point values from $A$ and $B$.

```c
F64vec2 R = unpack_high(F64vec2 A, F64vec2 B);
```

**Corresponding intrinsic:** `_mm_unpackhi_pd(a, b)`

Selects and interleaves the lower two, single-precision floating-point values from $A$ and $B$.

```c
F32vec4 R = unpack_low(F32vec4 A, F32vec4 B);
```

**Corresponding intrinsic:** `_mm_unpacklo_ps(a, b)`

Selects and interleaves the higher two, single-precision floating-point values from $A$ and $B$.

```c
F32vec4 R = unpack_high(F32vec4 A, F32vec4 B);
```

**Corresponding intrinsic:** `_mm_unpackhi_ps(a, b)`

Move Mask Operator

Creates a 2-bit mask from the most significant bits of the two, double-precision floating-point values of $A$, as follows:

```c
int i = move_mask(F64vec2 A)
i := sign(a1)<<1 | sign(a0)<<0
```

**Corresponding intrinsic:** `_mm_movemask_pd`

Creates a 4-bit mask from the most significant bits of the four, single-precision floating-point values of $A$, as follows:

```c
int i = move_mask(F32vec4 A)
i := sign(a3)<<3 | sign(a2)<<2 | sign(a1)<<1 | sign(a0)<<0
```

**Corresponding intrinsic:** `_mm_movemask_ps`

Classes Quick Reference

This appendix contains tables listing the class, functionality, and corresponding intrinsics for each class in the Intel® C++ Class Libraries for SIMD Operations. The following table lists all Intel C++ Compiler intrinsics that are not implemented in the C++ SIMD classes.

### Logical Operators: Corresponding Intrinsics and Classes

Programming Example

This sample program uses the F32vec4 class to average the elements of a 20 element floating point array.

```c
#include <fvec.h>

#define SHUFFLE(a,b,i) (F32vec4)_mm_shuffle_ps(a,b,i)
#include <stdio.h>

#define SIZE 20

// Global variables
float result;
_MMAligned float array[SIZE];

void Add20ArrayElements (F32vec4 *array, float *result) {
    F32vec4 vec0, vec1;
    vec0 = mm load ps ((float *) array); // Load array's first 4 floats

    vec0 += array[1]; // Add elements 5-8
    vec0 += array[2]; // Add elements 9-12
    vec0 += array[3]; // Add elements 13-16
    vec0 += array[4]; // Add elements 17-20

    vec1 = SHUFFLE(vec1, vec0, 0x40);
    vec0 += vec1;
    vec1 = SHUFFLE(vec1, vec0, 0x30);
    vec0 += vec1;
    vec0 = SHUFFLE(vec0, vec0, 2);
    _mm_store_ss (result, vec0); // Store the final sum
}

void main(int argc, char *argv[]) {
    int i;
    // Initialize the array
    for (i=0; i < SIZE; i++)
    { array[i] = (float) i;
```
}  

// Call function to add all array elements
Add20ArrayElements (array, &result);

// Print average array element value
printf("Average of all array values = %f\n", result/20.);
printf("The correct answer is %f\n\n\n", 9.5);
