</tbody>
</table>
## I/O Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ=rd</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file can be read.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>READONLY</td>
<td></td>
<td>Specifies that only READ statements can refer to this connection.</td>
<td>OPEN</td>
</tr>
<tr>
<td>READWRITE=rdwr</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file can be both read and written to.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>REC=rec</td>
<td>Positive integer variable or expression</td>
<td>Specifies the first (or only) record of a file to be read from, or written to.</td>
<td>READ, WRITE</td>
</tr>
<tr>
<td>RECL=length(RECORDSIZE=length)</td>
<td>Positive integer variable or expression</td>
<td>Specifies the record length in direct access files, or the maximum record length in sequential files.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>RECORDTYPE=typ</td>
<td>'FIXED', 'VARIABLE', 'SEGMENTED', 'STREAM', 'STREAM_LF', or 'STREAM_CR'</td>
<td>Specifies the type of records in a file.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>SEQUENTIAL=seq</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file is connected for sequential access.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>SHARE=share</td>
<td>'COMPAT', 'DENYNONE', 'DENYWR', 'DENYRD', or 'DENYRW' (default is 'DENYNONE')</td>
<td>Controls how other processes can simultaneously access a file on networked systems.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>SHARED</td>
<td></td>
<td>Specifies that a file is connected for shared access by more than one program executing simultaneously.</td>
<td>OPEN</td>
</tr>
<tr>
<td>SIZE=size</td>
<td>Integer variable</td>
<td>Returns the number of characters read in a nonadvancing READ before an end-of-record condition occurred.</td>
<td>READ</td>
</tr>
<tr>
<td>STATUS=status(TYPE=status)</td>
<td>'OLD', 'NEW', 'UNKNOWN' or 'SCRATCH' (default is 'UNKNOWN')</td>
<td>Specifies the status of a file on opening and/or closing.</td>
<td>CLOSE, OPEN</td>
</tr>
<tr>
<td>TITLE=name</td>
<td>Character expression</td>
<td>Specifies the name of a child window in a QuickWin application.</td>
<td>OPEN</td>
</tr>

### INQUIRE Statement Specifiers

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see INQUIRE.

The following table lists the INQUIRE statement specifiers and contains links to their descriptions:

<table>
<thead>
<tr>
<th>ACCESS</th>
<th>DELIM</th>
<th>NEXTREC</th>
<th>RECL</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>DIRECT</td>
<td>NUMBER</td>
<td>RECORDTYPE</td>

- I/O Status Specifier (IOSTAT=)
- OPEN: RECL Specifier
- OPEN: FILE Specifier
- OPEN: DEFAULTFILE Specifier
INQUIRE: ACCESS Specifier
The ACCESS specifier asks how a file is connected. It takes the following form:

\[ \text{ACCESS} = acc \]

\[ acc \]

Is a scalar default character variable that is assigned one of the following values:

| 'SEQUENTIAL'   | If the file is connected for sequential access |
| 'STREAM'      | If the file is connected for stream access   |
| 'DIRECT'      | If the file is connected for direct access   |
| 'UNDEFINED'   | If the file is not connected                 |

INQUIRE: ACTION Specifier
The ACTION specifier asks which I/O operations are allowed for a file. It takes the following form:

\[ \text{ACTION} = act \]

\[ act \]

Is a scalar default character variable that is assigned one of the following values:

| 'READ'       | If the file is connected for input only       |
| 'WRITE'      | If the file is connected for output only      |
| 'READWRITE'  | If the file is connected for both input and output |
| 'UNDEFINED'  | If the file is not connected                  |

INQUIRE: ASYNCHRONOUS Specifier
The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:

\[ \text{ASYNCHRONOUS} = asyn \]

\[ asyn \]

Is a scalar default character variable that is assigned one of the following values:

| 'NO'          | If the file or unit is connected and asynchronous input/output is not in effect. |
| 'YES'         | If the file or unit is connected and asynchronous input/output is in effect.     |
| 'UNKNOWN'     | If the file or unit is not connected.                                            |
**INQUIRE: BINARY Specifier (W*S)**

The BINARY specifier asks whether a file is connected to a binary file. It takes the following form:

\[ \text{BINARY} = \text{bin} \]

<table>
<thead>
<tr>
<th>bin</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected to a binary file</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is connected to a nonbinary file</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: BLANK Specifier**

The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:

\[ \text{BLANK} = \text{blnk} \]

<table>
<thead>
<tr>
<th>blnk</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>If null blank control is in effect for the file</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>If zero blank control is in effect for the file</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected, or it is not connected for formatted data transfer</td>
</tr>
</tbody>
</table>

**INQUIRE: BLOCKSIZE Specifier**

The BLOCKSIZE specifier asks about the physical I/O transfer size. It takes the following form:

\[ \text{BLOCKSIZE} = \text{bks} \]

<table>
<thead>
<tr>
<th>bks</th>
<th>Is a scalar integer variable.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The ( \text{bks} ) is assigned the current size of the physical I/O transfer. If the unit or file is not connected, the value assigned is zero.</td>
</tr>
</tbody>
</table>

**INQUIRE: BUFFERED Specifier**

The BUFFERED specifier asks whether run-time buffering is in effect. It takes the following form:

\[ \text{BUFFERED} = \text{bf} \]

<table>
<thead>
<tr>
<th>bf</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit is connected and buffering is not in effect.</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is connected and buffering is in effect.</td>
</tr>
</tbody>
</table>
### INQUIRE: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

\[ \text{CARRIAGECONTROL} = \text{cc} \]

- \( cc \) is a scalar default character variable that is assigned one of the following values:
  - `'FORTRAN'` if the file is connected with Fortran carriage control in effect
  - `'LIST'` if the file is connected with implied carriage control in effect
  - `'NONE'` if the file is connected with no carriage control in effect
  - `'UNKNOWN'` if the file is not connected

### INQUIRE: CONVERT Specifier

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

\[ \text{CONVERT} = \text{fm} \]

- \( fm \) is a scalar default character variable that is assigned one of the following values:
  - `'LITTLE_ENDIAN'` if the file is connected with little endian integer and IEEE* floating-point data conversion in effect
  - `'BIG_ENDIAN'` if the file is connected with big endian integer and IEEE floating-point data conversion in effect
  - `'CRAY'` if the file is connected with big endian integer and CRAY* floating-point data conversion in effect
  - `'FDX'` if the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE X_floating data conversion in effect
  - `'FGX'` if the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE X_floating data conversion in effect
'IBM'  If the file is connected with big endian integer and IBM* System\370 floating-point data conversion in effect

'VAXD'  If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect

'VAXG'  If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect

'NATIVE'  If the file is connected with no data conversion in effect

'UNKNOWN'  If the file or unit is not connected for unformatted data transfer

**INQUIRE: DECIMAL Specifier**

The DECIMAL specifier asks which decimal editing mode is in effect for a file connection. It takes the following form:

\[
\text{DECIMAL} = \text{dmode}
\]

\(dmode\)  Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'COMMA'</td>
<td>If a decimal comma is used during decimal editing mode.</td>
</tr>
<tr>
<td>'POINT'</td>
<td>If a decimal point is used during decimal editing mode.</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If there is no connection or if the connection is not for formatted I/O.</td>
</tr>
</tbody>
</table>

**INQUIRE: DELIM Specifier**

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:

\[
\text{DELIM} = \text{del}
\]

\(del\)  Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'APOSTROPHE'</td>
<td>If apostrophes are used to delimit character constants in list-directed and namelist output</td>
</tr>
<tr>
<td>'QUOTE'</td>
<td>If quotation marks are used to delimit character constants in list-directed and namelist output</td>
</tr>
</tbody>
</table>
'NONE'  If no delimiters are used
'UNDEFINED'  If the file is not connected, or is not connected for formatted data transfer

INQUIRE: DIRECT Specifier
The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

DIRECT = dir

dir
Is a scalar default character variable that is assigned one of the following values:

'YES'  If the file is connected for direct access
'NO'  If the file is not connected for direct access
'UNKNOWN'  If the file is not connected

INQUIRE: ENCODING Specifier
The ENCODING specifier asks what type of encoding is in effect for a file. It takes the following form:

ENCODING = enc

enc
Is a scalar default character expression that is assigned one of the following values:

'UTF-8'  If the file is connected with UTF-8 encoding in effect.
'UNDEFINED'  If the file is connected for unformatted I/O.
'UNKNOWN'  If the processor is unable to determine the encoding form of the file.

INQUIRE: EXIST Specifier
The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

EXIST = ex

ex
Is a scalar default logical variable that is assigned one of the following values:

.TRUE.  If the specified file exists and can be opened, or if the specified unit exists
.FALSE.  If the specified file or unit does not exist or if the file exists but cannot be opened

The unit exists if it is a number in the range allowed by the processor.
INQUIRE: FORM Specifier

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

FORM = fm

fm

Is a scalar default character variable that is assigned one of the following values:

| 'FORMATTED' | If the file is connected for formatted data transfer |
| 'UNFORMATTED' | If the file is connected for unformatted data transfer |
| 'BINARY' | If the file is connected for binary data transfer |
| 'UNDEFINED' | If the file is not connected |

INQUIRE: FORMATTED Specifier

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

FORMATTED = fmt

fmt

Is a scalar default character variable that is assigned one of the following values:

| 'YES' | If the file is connected for formatted data transfer |
| 'NO' | If the file is not connected for formatted data transfer |
| 'UNKNOWN' | If the processor cannot determine whether the file is connected for formatted data transfer |

INQUIRE: IOFOCUS Specifier (W*S)

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. It takes the following form:

IOFOCUS = iof

iof

Is a scalar default logical variable that is assigned one of the following values:

| .TRUE. | If the specified unit is the active window in a QuickWin application |
| .FALSE. | If the specified unit is not the active window in a QuickWin application |

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..
A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

**INQUIRE: MODE Specifier**

MODE is a nonstandard synonym for ACTION.

**INQUIRE: NAME Specifier**

The NAME specifier returns the name of a file. It takes the following form:

\[
NAME = nme
\]

\(nme\) is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, \(nme\) is undefined.

The value assigned to \(nme\) is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of \(nme\) is too small to contain the entire value.)

**NOTE**

The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

**See Also**

*The appropriate manual in your operating system documentation set* for details on the maximum size of file pathnames

**INQUIRE: NAMED Specifier**

The NAMED specifier asks whether a file is named. It takes the following form:

\[
NAMED = nmd
\]

\(nmd\) is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>.TRUE.</th>
<th>If the file has a name</th>
</tr>
</thead>
<tbody>
<tr>
<td>.FALSE.</td>
<td>If the file does not have a name</td>
</tr>
</tbody>
</table>

**INQUIRE: NEXTREC Specifier**

The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:

\[
NEXTREC = nr
\]

\(nr\) is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record \((r)\) was previously read or written, the value assigned is \(r + 1\).
- If no record has been read or written, the value assigned is 1.
• If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.
• If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

**INQUIRE: NUMBER Specifier**
The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:
NUMBER = num

num Is a scalar integer variable.
The num is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

**INQUIRE: OPENED Specifier**
The OPENED specifier asks whether a file is connected. It takes the following form:
OPENED = od

od Is a scalar default logical variable that is assigned one of the following values:

| .TRUE. | If the specified file or unit is connected |
| .FALSE. | If the specified file or unit is not connected |

**INQUIRE: ORGANIZATION Specifier**
The ORGANIZATION specifier asks how the file is organized. It takes the following form:
ORGANIZATION = org

org Is a scalar default character variable that is assigned one of the following values:

| 'SEQUENTIAL' | If the file is a sequential file |
| 'RELATIVE' | If the file is a relative file |
| 'UNKNOWN' | If the processor cannot determine the file's organization |

**INQUIRE: PAD Specifier**
The PAD specifier asks whether blank padding was specified for the file. It takes the following form:
PAD = pd

pd Is a scalar default character variable that is assigned one of the following values:

| 'NO' | If the file or unit was connected with PAD='NO' |
'YES' If the file or unit is not connected, or it was connected with PAD='YES'

### INQUIRE: PENDING Specifier

The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:

```plaintext
PENDING = pnd
```

*pnd* is a scalar default logical variable that is assigned the value .TRUE. or .FALSE..

The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable *pnd* is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable *pnd* is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.
- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable *pnd* is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable *pnd* is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.

### See Also

ID Specifier (ID=)

INQUIRE

### INQUIRE: POS Specifier

The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:

```plaintext
POS = p
```

*p* is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, *p* is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, *p* is assigned the value one.

### INQUIRE: POSITION Specifier

The POSITION specifier asks the position of the file. It takes the following form:

```plaintext
POSITION = pos
```

*pos* is a scalar default character variable that is assigned one of the following values:
INQUIRE: READ Specifier

The READ specifier asks whether a file can be read. It takes the following form:

\[ \text{READ} = rd \]

\( rd \)

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file can be read</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file cannot be read</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file can be read</td>
</tr>
</tbody>
</table>

INQUIRE: READWRITE Specifier

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

\[ \text{READWRITE} = rdwr \]

\( rdwr \)

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file can be both read and written to</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file cannot be both read and written to</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file can be both read and written to</td>
</tr>
</tbody>
</table>

INQUIRE: RECL Specifier

The RECL specifier asks the maximum record length for a file. It takes the following form:

\[ \text{RECL} = rcl \]

\( rcl \)

Is a scalar integer variable that is assigned a value as follows:
If the file or unit is connected, the value assigned is the maximum record length allowed.

If the file does not exist, or is not connected, the value assigned is zero.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer; otherwise, the value is expressed in bytes.

**INQUIRE: RECORDTYPE Specifier**

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:

```
RECORDTYPE = rtype
```

<table>
<thead>
<tr>
<th>rtype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>If the file is connected for fixed-length records</td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td>If the file is connected for variable-length records</td>
</tr>
<tr>
<td>'SEGMENTED'</td>
<td>If the file is connected for unformatted sequential data transfer using segmented records</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>If the file's records are not terminated</td>
</tr>
<tr>
<td>'STREAM_CR'</td>
<td>If the file's records are terminated with a carriage return</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>If the file's records are terminated with a line feed</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>If the file's records are terminated with a carriage return/line feed pair</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: ROUND Specifier**

The ROUND specifier asks which rounding mode is in effect for a file connection. It takes the following form:

```
ROUND = rmode
```

<table>
<thead>
<tr>
<th>rmode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UP'</td>
<td>If the I/O rounding is set to the smallest representable value that is greater than or equal to the original value.</td>
</tr>
<tr>
<td>'DOWN'</td>
<td>If the I/O rounding is set to the largest representable value that is less than or equal to the original value.</td>
</tr>
</tbody>
</table>
### INQUIRE: SEQUENTIAL Specifier
The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

**SEQUENTIAL = seq**

*seq*  
Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for sequential access</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for sequential access</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file is connected for sequential access</td>
</tr>
</tbody>
</table>

### INQUIRE: SHARE Specifier
The SHARE specifier asks the current share status of a file or unit. It takes the following form:

**SHARE = shr**

*shr*  
Is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for deny-read/write mode</td>
</tr>
<tr>
<td>'DENYWR'</td>
<td>If the file is connected for deny-write mode</td>
</tr>
</tbody>
</table>
'DENYRD' If the file is connected for deny-read mode

'DENYNONE' If the file is connected for deny-none mode

'UNKNOWN' If the file or unit is not connected

On Linux* and OS X* systems, this variable is assigned one of the following values:

'DENYRW' If the file is connected for exclusive access

'DENYNONE' If the file is connected for shared access

'NODENY' If the file is connected with default locking

'UNKNOWN' If the file or unit is not connected

INQUIRE: SIGN Specifier
The SIGN specifier asks what treatment for plus signs is in effect during a connection. It takes the following form:

SIGN = sn

sn Is a scalar default character expression that is assigned one of the following values:

'PLUS' If the file is connected with addition of plus signs in effect.

'SUPPRESS' If the file is connected with suppression of plus signs in effect.

'PROCESSOR_DEFINED' If the file is connected with plus signs added at the discretion of the processor.

'UNDEFINED' If there is no connection, or if the connection is not for formatted input/output.

INQUIRE: SIZE Specifier
The SIZE specifier asks the size of a file in file storage units. It takes the following form:

SIZE = sz

sz Is a scalar integer variable.

The sz variable is assigned the size of the file in file storage units. If the file size cannot be determined, the variable is assigned the value -1.

For a file that is connected for stream access, the file size is the number of the highest-numbered file storage unit in the file.
For a file that is connected for sequential or direct access, the file size may be different from the number of storage units implied by the data in the records; the exact relationship is processor-dependent.

**INQUIRE: UNFORMATTED Specifier**

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

\[ \text{UNFORMATTED} = \text{unf} \]

Is a scalar default character variable that is assigned one of the following values:

- 'YES' If the file is connected for unformatted data transfer
- 'NO' If the file is not connected for unformatted data transfer
- 'UNKNOWN' If the processor cannot determine whether the file is connected for unformatted data transfer

**INQUIRE: WRITE Specifier**

The WRITE specifier asks whether a file can be written to. It takes the following form:

\[ \text{WRITE} = \text{wr} \]

Is a scalar default character variable that is assigned one of the following values:

- 'YES' If the file can be written to
- 'NO' If the file cannot be written to
- 'UNKNOWN' If the processor cannot determine whether the file can be written to

**OPEN Statement Specifiers**

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.

The following table summarizes the OPEN statement specifiers and contains links to their descriptions:

**OPEN Statement Specifiers and Values**

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Function</th>

</tr>
</tbody>
</table>

1 The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

2 If you use the compiler option specifying OpenVMS defaults, and the unit is connected to a terminal, the default is 'FORTRAN'.

3 n is the unit number.

4 If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE.. 

5 On Linux* and OS X* systems, the default depends only on the FORM setting.

6 W*S

7 The default differs under certain conditions (see SHARE Specifier).

8 The default differs under certain conditions (see STATUS Specifier).

**Key to Values**

- c_expr: A scalar default character expression
- func: An external function
- label: A statement label
- n_expr: A scalar numeric expression
- var: A scalar integer variable
See Also
INQUIRE Statement Specifiers for details on using the INQUIRE statement to get file attributes of existing files

OPEN: ACCESS Specifier
The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:
ACCESS = acc

<table>
<thead>
<tr>
<th>acc</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DIRECT'</td>
<td>Indicates direct access.</td>
</tr>
<tr>
<td>'SEQUENTIAL'</td>
<td>Indicates sequential access.</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>Indicates stream access, where the file storage units of the file are accessible sequentially or by position.</td>
</tr>
<tr>
<td>'APPEND'</td>
<td>Indicates sequential access, but the file is positioned at the end-of-file record.</td>
</tr>
</tbody>
</table>

The default is 'SEQUENTIAL'.
There are limitations on record access by file organization and record type.

OPEN: ACTION Specifier
The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:
ACTION = act

<table>
<thead>
<tr>
<th>act</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'READ'</td>
<td>Indicates that only READ statements can refer to this connection.</td>
</tr>
<tr>
<td>'WRITE'</td>
<td>Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.</td>
</tr>
<tr>
<td>'READWRITE'</td>
<td>Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.</td>
</tr>
</tbody>
</table>

The default is 'READWRITE'.
However, if compiler option fpscomp general is specified on the command line and action is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting action is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

See Also
fpscomp
**OPEN: ASSOCIATEVARIABLE Specifier**

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

```
ASSOCIATEVARIABLE = asv
```

*asv* Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of *asv*.

This specifier is valid only for direct access; it is ignored for other access modes.

**OPEN: ASYNCHRONOUS Specifier**

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

```
ASYNCHRONOUS = asyn
```

*asyn* Is a scalar expression of type default character that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>Indicates that asynchronous I/O is allowed for a unit.</td>
</tr>
<tr>
<td>'NO'</td>
<td>Indicates that asynchronous I/O is not allowed for a unit.</td>
</tr>
</tbody>
</table>

The default is 'NO'.

**OPEN: BLANK Specifier**

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

```
BLANK = blnk
```

*blnk* Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>Indicates all blanks (other than leading blanks) are treated as zeros.</td>
</tr>
</tbody>
</table>

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

**See Also**

Blank Editing for details on the BN and BZ edit descriptors

f66

**OPEN: BLOCKSIZE Specifier**

The BLOCKSIZE specifier indicates the physical I/O transfer size in bytes for the file. It takes the following form:
BLOCKSIZE = bks

*bks* is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for *bks*, it is rounded up to a multiple of 512 byte blocks. The maximum valid value of BLOCKSIZE is 2147467264.

If you do not specify BLOCKSIZE or you specify zero for *bks*, the default value of 128 KB (131,072 bytes) is assumed. However, if you compile with the `assume buffered_stdout` option, the default blocksize for `stdout` is 8 KB.

The default BLOCKSIZE value can be changed by using the FORT_BLOCKSIZE environment variable or by specifying the BLOCKSIZE parameter on the unit's OPEN. The BLOCKSIZE value can be changed for `stdout` by re-opening the unit corresponding to `stdout` with an explicit BLOCKSIZE parameter; for example:

```
OPEN(6,ACCESS='SEQUENTIAL',FORM='FORMATTED',BUFFERED='YES',BLOCKSIZE=1048576)
```

**OPEN: BUFFERCOUNT Specifier**

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

```
BUFFERCOUNT = bc
```

*bc* is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for *bc*, the default is 1.

**See Also**

OPEN: BLOCKSIZE Specifier

OPEN: BUFFERED Specifier

**OPEN: BUFFERED Specifier**

The BUFFERED specifier indicates run-time library behavior for READ and WRITE operations. Buffering of input records only applies to variable length, unformatted records. This specifier takes the following form:

```
BUFFERED = bf
```

*bf* is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>For WRITE operations: Requests that the run-time library send output data to the file system after each operation. For READ operations on variable length, unformatted files: Requests that the run-time library transfer input data directly from disk to user variables for each operation.</td>
</tr>
<tr>
<td>'YES'</td>
<td>Requests that the run-time library accumulate data in its internal buffer, possibly across several READ or WRITE operations, before the data is transferred to, or from, the file system.</td>
</tr>
</tbody>
</table>
Buffering may improve run-time performance for output-intensive applications.

The default is 'NO' for buffering output. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If both BLOCKSIZE and BUFFERCOUNT for OPEN have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. Otherwise, the default size of the internal buffer is 8 KB (8192 bytes).

NOTE
On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

See Also
Rules for Unformatted Sequential READ Statements

OPEN: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

CARRIAGECONTROL = cc

<table>
<thead>
<tr>
<th>cc</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORTRAN'</td>
<td>Indicates normal Fortran interpretation of the first character.</td>
</tr>
<tr>
<td>'LIST'</td>
<td>Indicates one line feed between records.</td>
</tr>
<tr>
<td>'NONE'</td>
<td>Indicates no carriage control processing.</td>
</tr>
</tbody>
</table>

The default for binary (W*S) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option vms or fpscomp general, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the fortp3 format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.

See Also
Printing of Formatted Records for details on valid control characters for printing
vms compiler option
fpscomp compiler option
OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

\[
\text{CONVERT} = \text{fm}
\]

\( \text{fm} \)

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>specifier</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'</td>
<td>Little endian integer data (^2) and IEEE(^*) floating-point data. (^3)</td>
</tr>
<tr>
<td>'BIG_ENDIAN'</td>
<td>Big endian integer data (^2) and IEEE floating-point data. (^3)</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>Big endian integer data (^2) and CRAY(^*) floating-point data of size REAL(8) or COMPLEX(8).</td>
</tr>
<tr>
<td>'FDX'</td>
<td>Little endian integer data (^2) and VAX(^*) processor floating-point data of format F(<em>{\text{floating}}) for REAL(4) or COMPLEX(4), D(</em>{\text{floating}}) for size REAL(8) or COMPLEX(8), and IEEE X(_{\text{floating}}) for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'FGX'</td>
<td>Little endian integer data (^2) and VAX processor floating-point data of format F(<em>{\text{floating}}) for REAL(4) or COMPLEX(4), G(</em>{\text{floating}}) for size REAL(8) or COMPLEX(8), and IEEE X(_{\text{floating}}) for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'IBM'</td>
<td>Big endian integer data (^2) and IBM(^*) System(^370) floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).</td>
</tr>
<tr>
<td>'VAXD'</td>
<td>Little endian integer data (^2) and VAX processor floating-point data of format F(<em>{\text{floating}}) for size REAL(4) or COMPLEX(4), D(</em>{\text{floating}}) for size REAL(8) or COMPLEX(8), and H(_{\text{floating}}) for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'VAXG'</td>
<td>Little endian integer data (^2) and VAX processor floating-point data of format F(<em>{\text{floating}}) for size REAL(4) or COMPLEX(4), G(</em>{\text{floating}}) for size REAL(8) or COMPLEX(8), and H(_{\text{floating}}) for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'NATIVE'</td>
<td>No data conversion. This is the default.</td>
</tr>
</tbody>
</table>
1 INTEGER(1) data is the same for little endian and big endian.

2 Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or INTEGER(8)

3 Of the appropriate size and type: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), or COMPLEX(16)

You can use CONVERT to specify multiple formats in a single program, usually one format for each specified unit number.

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a run-time message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

<table>
<thead>
<tr>
<th>Method Used</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>An environment variable</td>
<td>Highest</td>
</tr>
<tr>
<td>OPEN (CONVERT=)</td>
<td>.</td>
</tr>
<tr>
<td>OPTIONS/CONVERT</td>
<td>.</td>
</tr>
<tr>
<td>The convert compiler option</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20:

```fortran
OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
... OPEN (FILE='graph3_native.dat', FORM='UNFORMATTED', UNIT=20)
```

See Also

Data Types, Constants, and Variables Overview for details on supported ranges for data types

convert

OPEN: DECIMAL Specifier

The DECIMAL specifier controls the representation of the decimal symbol for a connection. It takes the following form:

```
DECIMAL = dmode
```

*dmode* Is a scalar default character expression that evaluates to one of the following values:

| 'COMMA' | Indicates that a decimal comma should be used for decimal editing mode. |
| 'POINT' | Indicates that a decimal point should be used for decimal editing mode. |

The default decimal editing mode is 'POINT'.

You can only use this specifier for a formatted I/O connection.

When the mode is DECIMAL='COMMA', all floating-point output will produce a decimal comma instead of a decimal point, and all floating-point input will expect a decimal comma.

If you specify DECIMAL='COMMA', you must use a semicolon delimiter in list-directed input.
The decimal editing mode can be temporarily changed within a READ or WRITE statement by the corresponding DC and DP edit descriptors.

**OPEN: DEFAULTFILE Specifier**

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

\[
\text{DEFAULTFILE} = \text{def}
\]

\text{def} 

Is a character expression indicating a default file pathname string.

The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE. If \text{def} does not end in a slash (/), a slash is added.

If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

**OPEN: DELIM Specifier**

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

\[
\text{DELIM} = \text{del}
\]

\text{del} 

Is a scalar default character expression that evaluates to one of the following values:

\begin{align*}
\text{'APOSTROPHE'} & \quad \text{Indicates apostrophes delimit character constants. All internal apostrophes are doubled.} \\
\text{'QUOTE'} & \quad \text{Indicates quotation marks delimit character constants. All internal quotation marks are doubled.} \\
\text{'NONE'} & \quad \text{Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.}
\end{align*}

The default is 'NONE'.

The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input.

**OPEN: DISPOSE Specifier**

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:

\[
\text{DISPOSE} = \text{dis}
\]

\text{DISP} = \text{dis}

\text{dis} 

Is a scalar default character expression that evaluates to one of the following values:

\begin{align*}
\text{'KEEP'} \text{ or 'SAVE'} & \quad \text{Retains the file after the unit closes.}
\end{align*}
'DELETE'
Deletes the file after the unit closes.

'PRINT' ¹
Submits the file to the line printer spooler and retains it.

'PRINT/DELETE' ¹
Submits the file to the line printer spooler and then deletes it.

'SUBMIT'
Forks a process to execute the file.

'SUBMIT/DELETE'
Forks a process to execute the file, and then deletes the file after the fork is completed.

¹ Use only on sequential files.

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

**OPEN: ENCODING Specifier**

The ENCODING specifier indicates the encoding form for a file. It takes the following form:

ENCODING = enc

enc
Is a scalar default character expression that evaluates to one of the following values:

'UTF-8'
Indicates that the encoding form of the file is UTF-8 (a unicode file). All characters therein are of ISO 10646 character type, as specified by ISO/IEC 10646-1:2000.

This value must not be specified if the processor does not support the ISO 10646 character type.

'DEFAULT'
Indicates that the encoding form of the file is determined by the processor.

The default is 'DEFAULT'.

You can only use this specifier for a formatted I/O connection.

**OPEN: FILE Specifier**

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:

FILE = name

name
Is a character or numeric expression.

The name can be any pathname allowed by the operating system.

Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
The unit is not connected to a file

\textbf{STATUS='SCRATCH' is not specified}

The corresponding \texttt{FORTn} environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort\texttt{.n}, where \texttt{n} is the logical unit number. On Windows systems, if compiler option \texttt{fpscomp general} is specified, omitting \texttt{FILE} implies \texttt{STATUS='SCRATCH'}.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console.

In a Windows® QuickWin application, you can specify \texttt{FILE='USER'} to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the \texttt{name} can be blank (\texttt{FILE=' '}) if the compatibility compiler option \texttt{fpscomp filesfromcmd} is specified. If the \texttt{name} is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (""), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.

2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

Assume the following command line started the program \texttt{MYPROG} (note that quotation marks (""") are used):

\texttt{myprog first.fil " " third.txt}

\texttt{MYPROG} contains four OPEN statements with blank filenames, in the following order:

\begin{verbatim}
OPEN (2, FILE = ' ')
OPEN (4, FILE = ' ')
OPEN (5, FILE = ' ')
OPEN (10, FILE = ' ')
\end{verbatim}

Unit 2 is associated with the file \texttt{FIRST.FIL}. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

\texttt{Filename missing or blank - Please enter name UNIT 4?}

Unit 5 is associated with the file \texttt{THIRD.TXT}. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

\texttt{Filename missing or blank - Please enter name UNIT 10?}

\textbf{See Also}

\texttt{fpscomp}

\textbf{OPEN: FORM Specifier}

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

\texttt{FORM = \textit{fm}}

\texttt{fm}

Is a scalar default character expression that evaluates to one of the following values:

\begin{tabular}{ll}
\textbf{`FORMATTED'} & Indicates formatted data transfer \\
\textbf{`UNFORMATTED'} & Indicates unformatted data transfer \\
\textbf{`BINARY'} & Indicates binary data transfer \\
\end{tabular}

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.
The data is stored and retrieved in a file according to the file's access (set by the `ACCESS` specifier) and the form of the data the file contains.

A *formatted file* is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.

An *unformatted file* is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

*Binary sequential files* are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.

*Binary direct files* have very little structure. A record length is assigned by the RECL specifier in an OPEN statement. This establishes record boundaries, which are used only for repositioning and padding before and after read and write operations and during BACKSPACE operations. Record boundaries do not restrict the number of bytes that can be transferred during a read or write operation. If an I/O operation attempts to read or write more values than are contained in a record, the read or write operation is continued on the next record.

**OPEN: IOFOCUS Specifier (W*S)**

The IOFOCUS specifier indicates whether a particular unit is the active window in a QuickWin application. It takes the following form:

```
IOFOCUS = iof
```

`iof` is a scalar default logical expression that evaluates to one of the following values:

| `.TRUE.` | Indicates the QuickWin child window is the active window |
| `.FALSE.` | Indicates the QuickWin child window is not the active window |

If unit `*` is specified, the default is `.FALSE.`; otherwise, the default is `.TRUE.`.

A value of `.TRUE.` causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window. OUTTEXT, OUTGTEXT, or any other graphics routine call does not cause the focus to shift.

**OPEN: MAXREC Specifier**

The MAXREC specifier indicates the maximum number of records that can be transferred from or to a direct access file while the file is connected. It takes the following form:

```
MAXREC = mr
```

`mr` is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

The default is an unlimited number of records.

**OPEN: MODE Specifier**

MODE is a nonstandard synonym for ACTION.

**OPEN: NAME Specifier**

NAME is a nonstandard synonym for FILE.
OPEN: NEWUNIT Specifier

The NEWUNIT specifier opens a file on an unused unit number that is automatically chosen. It also returns the unit number that was chosen. It takes the following form:

`NEWUNIT = u-var`

`u-var` is a scalar integer variable that is assigned the automatically chosen unit number. It is always a negative integer.

If the OPEN is successful, `u-var` can be used in subsequent I/O statements to access the connected file. If an error occurs during execution of the OPEN statement containing the `NEWUNIT=` specifier, the processor does not change the value of the variable.

OPEN: NOSHARED Specifier

The NOSHARED specifier indicates that the file is connected for exclusive access by the program. It takes the following form:

`NOSHARED`

OPEN: ORGANIZATION Specifier

The ORGANIZATION specifier indicates the internal organization of the file. It takes the following form:

`ORGANIZATION = org`

`org` is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SEQUENTIAL'</td>
<td>Indicates a sequential file.</td>
</tr>
<tr>
<td>'RELATIVE'</td>
<td>Indicates a relative file.</td>
</tr>
</tbody>
</table>

The default is 'SEQUENTIAL'.

OPEN: PAD Specifier

The PAD specifier indicates whether a formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

The PAD specifier takes the following form:

`PAD = pd`

`pd` is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>Indicates the record will be padded with blanks when necessary.</td>
</tr>
<tr>
<td>'NO'</td>
<td>Indicates the record will not be padded with blanks. The input record must contain the data required by the input list and format specification.</td>
</tr>
</tbody>
</table>

The default is 'YES'.

This behavior is different from FORTRAN 77, which never pads short records with blanks. For example, consider the following:

```fortran
READ (5,'(I5)') J
```
If you enter 123 followed by a carriage return, FORTRAN 77 turns the I5 into an I3 and J is assigned 123. However, Intel® Fortran pads the 123 with 2 blanks unless you explicitly open the unit with PAD='NO'. You can override blank padding by explicitly specifying the BN edit descriptor. The PAD specifier is ignored during output.

**OPEN: POSITION Specifier**

The POSITION specifier indicates the position of a file connected for sequential access. It takes the following form:

```plaintext
POSITION = pos
```

`pos` is a scalar default character expression that evaluates to one of the following values:

- `'ASIS'` Indicates the file position is unchanged if the file exists and is already connected. The position is unspecified if the file exists but is not connected.
- `'REWIND'` Indicates the file is positioned at its initial point.
- `'APPEND'` Indicates the file is positioned at its terminal point (or before its end-of-file record, if any).

The default is 'ASIS'. (On Fortran I/O systems, this is the same as 'REWIND'.)

A new file (whether specified as new explicitly or by default) is always positioned at its initial point.

In addition to the POSITION specifier, you can use position statements. The BACKSPACE statement positions a file back one record. The REWIND statement positions a file at its initial point. The ENDFILE statement writes an end-of-file record at the current position and positions the file after it. Note that ENDFILE does not go the end of an existing file, but creates an end-of-file where it is.

**OPEN: READONLY Specifier**

The READONLY specifier indicates only READ statements can refer to this connection. It takes the following form:

```plaintext
READONLY
```

READONLY is similar to specifying ACTION='READ', but READONLY prevents deletion of the file if it is closed with STATUS='DELETE' in effect.

The Fortran I/O system's default privileges for file access are READWRITE. If access is denied, the I/O system automatically retries accessing the file for READ access.

However, if you use compiler option vms, the I/O system does not retry accessing for READ access. So, runtime I/O errors can occur if the file protection does not permit WRITE access. To prevent such errors, if you wish to read a file for which you do not have write access, specify READONLY.

**OPEN: RECL Specifier**

The RECL specifier indicates the length of each record in a file connected for direct access, or the maximum length of a record in a file connected for sequential access.

The RECL specifier takes the following form:

```plaintext
RECL = rl
```
\( rl \) is a positive numeric expression indicating the length of records in the file. If necessary, the value is converted to integer data type before use.

If the file is connected for formatted data transfer, the value must be expressed in bytes (characters). Otherwise, the value is expressed in 4-byte units (longwords). If the file is connected for unformatted data transfer, the value can be expressed in bytes if compiler option assume byterecl is specified.

Except for segmented records, the \( rl \) is the length for record data only, it does not include space for control information. If \( rl \) is too large, you can exhaust your program's virtual memory resources trying to create room for the record.

The length specified is interpreted depending on the type of records in the connected file, as follows:

- For segmented records, \( RECL \) indicates the maximum length for any segment (including the four bytes of control information).
- For fixed-length records, \( RECL \) indicates the size of each record; it must be specified. If the records are unformatted, the size must be expressed as an even multiple of four.
- You can use the \( RECL \) specifier in an INQUIRE statement to get the record length before opening the file.
- For variable-length records, \( RECL \) indicates the maximum length for any record.

If you read a fixed-length file with a record length different from the one used to create the file, indeterminate results can occur.

The maximum length for \( rl \) depends on the record type and the setting of the \( CARRIAGECONTROL \) specifier, as shown in the following table:

### Maximum Record Lengths (RECL)

<table>
<thead>
<tr>
<th>Record Type</th>
<th>CARRIAGECONTROL</th>
<th>Formatted (size in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-length</td>
<td>'NONE'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td>Variable-length</td>
<td>'NONE'</td>
<td>2147483640 (2**31-8)</td>
</tr>
<tr>
<td>Segmented</td>
<td>'NONE'</td>
<td>32764 (2**15-4)</td>
</tr>
<tr>
<td>Stream</td>
<td>'NONE'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td>Stream_CR</td>
<td>'LIST'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td>Stream_LF</td>
<td>'LIST'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td></td>
<td>'FORTRAN'</td>
<td>2147483646 (2**31-2)</td>
</tr>
</tbody>
</table>

1 Subtract 1 if compiler option vms is used.

The default value depends on the setting of the \( RECORDTYPE \) specifier, as shown in the following table:

### Default Record Lengths (RECL)

<table>
<thead>
<tr>
<th>RECORDTYPE</th>
<th>RECL value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>None; value must be explicitly specified.</td>
</tr>
<tr>
<td>All other settings</td>
<td>132 bytes for formatted records; 510 longwords for unformatted records.</td>
</tr>
</tbody>
</table>

1 To change the default record length values, you can use environment variable FORT_FMT_RECL or FORT_UFMT_RECL.

For formatted records with other than \( RECORDTYPE='FIXED' \), the default RECL is 132.

There is a property of list-directed sequential WRITE statements called the right margin. If you do not specify RECL as an OPEN statement specifier or in environmental variable FORT_FMT_RECL, the right margin value defaults to 80. When RECL is specified, the right margin is set to the value of RECL. If the length of a
list-directed sequential WRITE exceeds the value of the right margin value, the remaining characters will wrap to the next line. Therefore, writing 100 characters will produce two lines of output, and writing 180 characters will produce three lines of output. You can turn off the right margin using the wrap-margin compiler option or the FORT_FMT_NO_WRAP_MARGIN environment variable.

assume
vms
Record Transfer

**OPEN: RECORDSIZE Specifier**

RECORDSIZE is a nonstandard synonym for RECL.

**OPEN: RECORDTYPE Specifier**

The RECORDTYPE specifier indicates the type of records in a file. It takes the following form:

```
RECORDTYPE = typ
```

<table>
<thead>
<tr>
<th>typ</th>
<th>Is a scalar default character expression that evaluates to one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>Indicates fixed-length records.</td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td>Indicates variable-length records.</td>
</tr>
<tr>
<td>'SEGMENTED'</td>
<td>Indicates segmented records.</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>Indicates stream-type variable length data with no record terminators.</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>Indicates stream-type variable length records, terminated with a line feed.</td>
</tr>
<tr>
<td>'STREAM_CR'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return.</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return/line feed pair.</td>
</tr>
</tbody>
</table>

When you open a file, default record types are as follows:

<table>
<thead>
<tr>
<th>typ</th>
<th>For relative files</th>
<th>For direct access sequential files</th>
<th>For formatted sequential access files on Linux* and OS X* systems</th>
<th>For formatted sequential access files on Windows systems</th>
<th>For unformatted sequential access files</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'FIXED'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A segmented record is a logical record consisting of segments that are physical records. Since the length of a segmented record can be greater than 65,535 bytes, only use segmented records for unformatted sequential access to disk or raw magnetic tape files.
Files containing segmented records can be accessed only by unformatted sequential data transfer statements.

If an output statement does not specify a full record for a file containing fixed-length records, the following occurs:

- In formatted files, the record is filled with blanks
- In unformatted files, the record is filled with zeros

**OPEN: ROUND Specifier**

The ROUND specifier indicates the I/O rounding mode for the duration of a connection. It takes the following form:

```
ROUND = rmode
```

`rmode` is a scalar default character expression that evaluates to one of the following values:

- `'UP'`: The smallest representable value that is greater than or equal to the original value.
- `'DOWN'`: The largest representable value that is less than or equal to the original value.
- `'ZERO'`: The value closest to the original value, but no greater in magnitude than the original value.
- `'NEAREST'`: The closer of the two nearest representable values, if one is closer than the other.
  
  If the two nearest representable values are equidistant from the original value, the processor determines which one of them is chosen.
  
  On processors that support IEEE rounding on conversions, NEAREST corresponds to round to nearest, as specified in the IEEE International Standard.
- `'COMPATIBLE'`: The closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero.
- `'PROCESSOR_DEFINED'`: The value is determined by the default settings in the processor, which may correspond to one of the other modes.

The default I/O rounding mode is 'PROCESSOR_DEFINED'.

You can only use this specifier for a formatted I/O connection.

The rounding mode can be temporarily changed within a READ or WRITE statement by the corresponding RU, RD, RZ, RN, RC, and RP edit descriptors.

**OPEN: SHARE Specifier**

The SHARE specifier indicates whether file locking is implemented while the unit is open. It takes the following form:

\[
\text{SHARE} = shr
\]

*shr*  
Is a scalar default character expression.

On Windows* systems, this expression evaluates to one of the following values:

- **'DENYRW'** Indicates deny-read/write mode. No other process can open the file.
- **'DENYWR'** Indicates deny-write mode. No process can open the file with write access.
- **'DENYRD'** Indicates deny-read mode. No process can open the file with read access.
- **'DENYNONE'** Indicates deny-none mode. Any process can open the file in any mode.

On Linux* and OS X* systems, this expression evaluates to one of the following values:

- **'DENYRW'** Indicates exclusive access for cooperating processes.
- **'DENYNONE'** Indicates shared access for cooperating processes.

On Windows systems, the default is 'DENYWR'. However, if you specify compiler option fpscomp general or the SHARED specifier, the default is 'DENYNONE'.

On Linux and OS X systems, no restrictions are applied to file opening if you do not use a locking mechanism.

'COMPAT' is accepted for compatibility with previous versions. It is equivalent to 'DENYNONE'.

Use the ACCESS specifier in an INQUIRE statement to determine the access permission for a file.

Be careful not to permit other users to perform operations that might cause problems. For example, if you open a file intending only to read from it, and want no other user to write to it while you have it open, you could open it with ACTION='READ' and SHARE='DENYRW'. Other users would not be able to open it with ACTION='WRITE' and change the file.

Suppose you want several users to read a file, and you want to make sure no user updates the file while anyone is reading it. First, determine what type of access to the file you want to allow the original user. Because you want the initial user to read the file only, that user should open the file with ACTION='READ'. Next, determine what type of access the initial user should allow other users; in this case, other users should be able only to read the file. The first user should open the file with SHARE='DENYWR'. Other users can also open the same file with ACTION='READ' and SHARE='DENYWR'.

**See Also**

fpscomp

**OPEN: SHARED Specifier**

The SHARED specifier indicates that the file is connected for shared access by more than one program executing simultaneously. It takes the following form:
SHARED
On Linux* and OS X* systems, shared access is the default for the Fortran I/O system. On Windows* systems, it is the default if SHARED or compiler option fpscomp general is specified.

See Also
fpscomp

OPEN: SIGN Specifier
The SIGN specifier controls the optional plus characters in formatted numeric output created during the connection. It takes the following form:
SIGN = sn

Is a scalar default character expression that evaluates to one of the following values:

- **'PLUS'**: Indicates that the processor should produce a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SP edit descriptor.
- **'SUPPRESS'**: Indicates that the processor should suppress a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SS edit descriptor.
- **'PROCESSOR_DEFINED'**: Indicates that the processor determines whether a plus sign is added in any subsequent position where it would be otherwise optional. This has the same effect as the S edit descriptor.

The default is 'PROCESSOR_DEFINED'.
The setting can be overwritten by a SIGN= specifier in a WRITE statement.

OPEN: STATUS Specifier
The STATUS specifier indicates the status of a file when it is opened. It takes the following form:
STATUS = sta

Is a scalar default character expression that evaluates to one of the following values:

- **'OLD'**: Indicates an existing file.
- **'NEW'**: Indicates a new file; if the file already exists, an error occurs. Once the file is created, its status changes to 'OLD'.
<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SCRATCH'</td>
<td>Indicates a new file that is unnamed (called a scratch file). When the file is closed or the program terminates, the scratch file is deleted.</td>
</tr>
<tr>
<td>'REPLACE'</td>
<td>Indicates the file replaces another. If the file to be replaced exists, it is deleted and a new file is created with the same name. If the file to be replaced does not exist, a new file is created and its status changes to 'OLD'.</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>Indicates the file may or may not exist. If the file does not exist, a new file is created and its status changes to 'OLD'.</td>
</tr>
</tbody>
</table>

Scratch files go into a temporary directory and are visible while they are open. Scratch files are deleted when the unit is closed or when the program terminates normally, whichever occurs first.

To specify the path for scratch files, you can use one of the following environment variables:

- On Windows* OS: FORT_TMPDIR, TMP, or TEMP, searched in that order
- On Linux* OS and OS X*: FORT_TMPDIR or TMPDIR, searched in that order

If no environment variable is defined, the default is the current directory.

The default is 'UNKNOWN'. This is also the default if you implicitly open a file by using WRITE. However, if you implicitly open a file using READ, the default is 'OLD'. If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'NEW'.

**NOTE**
The STATUS specifier can also appear in CLOSE statements to indicate the file's status after it is closed. However, in CLOSE statements the STATUS values are the same as those listed for the DISPOSE specifier.

**See Also**
f66

**OPEN: TITLE Specifier (W*S)**
The TITLE specifier indicates the name of a child window in a QuickWin application. It takes the following form:

```
TITLE = name
```

*name* is a character expression.

If TITLE is specified in a non-Quickwin application, a run-time error occurs.

**OPEN: TYPE Specifier**
TYPE is a nonstandard synonym for STATUS.
OPEN: USEROPEN Specifier

The USEROPEN specifier lets you pass control to a routine that directly opens a file. The file can use system calls or library routines to establish a special context that changes the effect of subsequent Fortran I/O statements.

The USEROPEN specifier takes the following form:

USEROPEN = function-name

function-name

Is the name of an external function of type INTEGER(INT_PTR_KIND()) on Windows and INTEGER(4) on Linux and OS X. The external function can be written in Fortran, C, or other languages.

If the function is written in Fortran, do not execute a Fortran OPEN statement to open the file named in USEROPEN.

The Intel® Fortran Run-time Library (RTL) I/O support routines call the function named in USEROPEN in place of the system calls normally used when the file is first opened for I/O.

On Windows* systems, the Fortran RTL normally calls CreateFile( ) to open a file. When USEROPEN is specified, the called function opens the file (or pipe, etc.) by using CreateFile( ) and returns the handle of the file (return value from CreateFile( )) when it returns control to the calling Fortran program.

On Linux* and OS X* systems, the Fortran RTL normally calls the open function to open a file. When USEROPEN is specified, the called function opens the file by calling open and returns the file descriptor of the file when it returns control to the calling Fortran program.

When opening the file, the called function usually specifies options different from those provided by a normal Fortran OPEN statement.

NOTE
You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures/USEROPEN Specifier.

Examples

The following shows an example on Linux and OS X systems and an example on Windows systems.

Example on Linux and OS X systems:

```fortran
PROGRAM UserOpenMain
IMPLICIT NONE

EXTERNAL      UOPEN
INTEGER(4)    UOPEN

CHARACTER(10) :: FileName="UOPEN.DAT"
INTEGER       :: IOS
CHARACTER(255):: InqFullName
CHARACTER(100):: InqFileName
INTEGER       :: InqLun
CHARACTER(30) :: WriteOutBuffer="Write_One_Record_to_the_File."
CHARACTER(30) :: ReadInBuffer = "??????????????????????????????"

110 FORMAT( X,"FortranMain: ",A," Created (iostat=",I0,""
115 FORMAT( X,"FortranMain: ",A," : Creation Failed (iostat=",I0,""
120 FORMAT( X,"FortranMain: ",A," : ERROR: INQUIRE Returned Wrong FileName"
130 FORMAT( X,"FortranMain: ",A," : ERROR: ReadIn and WriteOut Buffers Do Not Match"
```
WRITE(*,'(X,"FortranMain: Test the USEROPEN Facility of Open")')

OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
IOSTAT=ios, ACTION='READWRITE')

! When the OPEN statement is executed, the uopen_ function receives control.
! The uopen_ function opens the file by calling open(), and subsequently
! returns control with the handle returned by open().

IF (IOS .EQ. 0) THEN
  WRITE(*,110) TRIM(FileName), IOS
  INQUIRE(10, NAME=InqFullName)
  CALL ParseForFileName(InqFullName,InqFileName)
  IF (InqFileName .NE. FileName) THEN
    WRITE(*,120) TRIM(FileName)
  END IF
ELSE
  WRITE(*,115) TRIM(FileName), IOS
  GOTO 9999
END IF

WRITE(10,*) WriteOutBuffer
REWIND(10)
READ(10,*) ReadInBuffer
IF (ReadinBuffer .NE. WriteOutbuffer) THEN
  WRITE(*,130) TRIM(FileName)
END IF
CLOSE(10)
WRITE(*,'(X,"FortranMain: Test of USEROPEN Completed")')

9999 CONTINUE
END

!---------------------------------------------------------------
! SUBROUTINE: ParseForFileName
! Takes a full pathname and returns the filename
! with its extension.
!---------------------------------------------------------------
SUBROUTINE ParseForFileName(FullName,FileName)
CHARACTER(255):: FullName
CHARACTER(255):: FileName
INTEGER       :: P

P = INDEX(FullName,'/','',.TRUE.)
FileName = FullName(P+1:)
END

#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>

// File: UserOpen_Sub.c
//
// This routine opens a file using data passed from the Intel(c) Fortran OPEN statement.
//
#include <sys/types.h>
#include <sys/stat.h>
#include <sys/file.h>
#include <errno.h>

int uopen_ ( char *file_name,   /* access read: name of the file to open (null terminated) * /
    int *open_flags,  /* access read: READ/WR ITE, see file.h or open(2) */
    int *create_mode, /* access read: set if the file is to be created */
    int *unit_num,    /* access read: logical unit number to be opened */
    int filenam_len ) /* access read: number of characters in file_name */
{
    /*
    ** The returned value is the following:
    **    value >= 0 is a valid file descriptor
    **    value < 0 is an error
    */
    int return_value;

    printf(" %s: Opening FILENAME = %s\n", __FILE__, file_name);
    printf(" %s: open_flags = 0x%8.8x\n", __FILE__, *open_flags);
    if ( *open_flags & O_CREAT ) {
        printf(" %s: the file is being created, create_mode = 0x%8.8x\n", __FILE__, *create_mode);
    }

    printf(" %s: open() ", __FILE__);
    return_value = open(file_name, *open_flags, *create_mode);
    if (return_value < 0) {
        printf("FAILED.\n");
    } else {
        printf("SUCCEEDED.\n");
    }
}

return (return_value);
} /* end of uopen_() */

Example on Windows systems:

In the calling Fortran program, the function named in USEROPEN must first be declared in an EXTERNAL statement. For example, the following Fortran code might be used to call the USEROPEN procedure UOPEN:

```
IMPLICIT INTEGER (A-Z)
EXTERNAL UOPEN
INTEGER(INT_PTR_KIND()) UOPEN
...
OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='NEW',USEROPEN=UOPEN)
```

When the OPEN statement is executed, the UOPEN function receives control. The function opens the file by calling CreateFile( ), performs whatever operations were specified, and subsequently returns control (with the handle returned by CreateFile( )) to the calling Fortran program.

Here is what the UOPEN function might look like:

```
INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME, &
    DESIRED_ACCESS, &
    SHARE_MODE, &
    A_NULL, &
    CREATE_DISP, &
    FLAGS_ATTR, &
    B_NULL, &
    UNIT, &
    FLEN )

!DIR$ ATTRIBUTES C, ALIAS:'UOPEN' :: UOPEN
!DIR$ ATTRIBUTES REFERENCE :: FILENAME
!DIR$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
```
USE IFWIN
IMPLICIT INTEGER (A-Z)
CHARACTER*(FLEN) FILENAME
TYPE(T_SECURITY_ATTRIBUTES), POINTER :: NULL_SEC_ATTR

! Set the FILE_FLAG_WRITE_THROUGH bit in the flag attributes to CreateFile( )
! (for whatever reason)
FLAGS_ATTR = FLAGS_ATTR + FILE_FLAG_WRITE_THROUGH

! Do the CreateFile( ) call and return the status to the Fortran rtl
STS = CreateFile( FILENAME,             
                 DESIRED_ACCESS,       
                 SHARE_MODE,           
                 NULL_SEC_ATTR,        
                 CREATE_DISP,          
                 FLAGS_ATTR,           
                 0 )

UOPEN = STS
RETURN
END

The UOPEN function is declared to use the cdecl calling convention, so it matches the Fortran rtl declaration of a useropen routine.

The following function definition and arguments are passed from the Intel Fortran Run-time Library to the function named in USEROPEN:

```
INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME,       
     DESIRED_ACCESS, 
     SHARE_MODE,     
     A_NULL,         
     CREATE_DISP,    
     FLAGS_ATTR,     
     B_NULL,         
     UNIT,           
     FLEN )

!DIR$ ATTRIBUTES C, ALIAS:_UOPEN' :: UOPEN
!DIR$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
!DIR$ ATTRIBUTES REFERENCE :: SHARE_MODE
!DIR$ ATTRIBUTES REFERENCE :: CREATE_DISP
!DIR$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
!DIR$ ATTRIBUTES REFERENCE :: UNIT
```

The first 7 arguments correspond to the CreateFile( ) api arguments. The value of these arguments is set according the caller's OPEN( ) arguments:

FILENAME
Is the address of a null terminated character string that is the name of the file.

DESIRED_ACCESS
Is the desired access (read-write) mode passed by reference.

SHARE_MODE
Is the file sharing mode passed by reference.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A_NULL</td>
<td>Is always null. The Fortran runtime library always passes a NULL for the pointer to a SECURITY_ATTRIBUTES structure in its CreateFile() call.</td>
</tr>
<tr>
<td>CREATE_DISP</td>
<td>Is the creation disposition specifying what action to take on files that exist, and what action to take on files that do not exist. It is passed by reference.</td>
</tr>
<tr>
<td>FLAGS_ATTR</td>
<td>Specifies the file attributes and flags for the file. It is passed by reference.</td>
</tr>
<tr>
<td>B_NULL</td>
<td>Is always null. The Fortran runtime library always passes a NULL for the handle to a template file in its CreateFile() call.</td>
</tr>
</tbody>
</table>

The last 2 arguments are the Fortran unit number and length of the file name:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIT</td>
<td>Is the Fortran unit number on which this OPEN is being done. It is passed by reference.</td>
</tr>
<tr>
<td>FLEN</td>
<td>Is the length of the file name, not counting the terminating null, and passed by value.</td>
</tr>
</tbody>
</table>
In addition to specifying options on the compiler command line, you can specify the following lines and statements in a program unit to influence compilation:

- **The INCLUDE Line**
  Incorporates external source code into programs.
- **The OPTIONS Statement**
  Sets options usually specified in the compiler command line. OPTIONS statement settings override command line options.
Directive Enhanced Compilation Overview

Directive enhanced compilation is performed by using compiler directives. Compiler directives are special commands that let you perform various tasks during compilation. They are similar to compiler options, but can provide more control within your program.

Compiler directives are preceded by a special prefix that identifies them to the compiler.

Syntax Rules for Compiler Directives

The following syntax rules apply to all general and OpenMP* Fortran compiler directives. You must follow these rules precisely to compile your program properly and obtain meaningful results.

A directive prefix (tag) takes one of the following forms:

General compiler directives: !DIR$

OpenMP Fortran compiler directives: !$OMP

The following prefix forms can be used in place of !DIR$: cDIR$, cDEC$, or !MS$, where c is one of the following: C (or c), !, or *.

The following prefix forms can be used in place of !$OMP: c$OMP, where c is one of the following: C (or c), !, or *.

The following are source form rules for directive prefixes:

- In fixed and tab source forms, prefixes begin with !, C (or c), or *.
  - The prefix must appear in columns 1 through 5; column 6 must be a blank or a tab (except for prefix !MS $). From column 7 on, blanks are insignificant, so the directive can be positioned anywhere on the line after column 6.
- In free source form, prefixes begin with !.
  - The prefix can appear in any column, but it cannot be preceded by any nonblank, nontab characters on the same line.
- In all source forms, directives spelled with two keywords can be separated by an optional space; for example, "LOOP COUNT" and "LOOPCOUNT" are both valid spellings for the same directive. However, when a directive name is preceded by the prefix "NO", this is not considered to be two keywords. For example, "NO DECLARE" is not a valid spelling; the only valid spelling for this directive is "NODECLAIM".

A compiler directive ends in column 72 (or column 132, if compiler option extend-source is specified).

General compiler directives and OpenMP Fortran directives can be continued in the same way as Fortran statements can be continued:

- In fixed form, the first line of the directive {initial line} has the directive prefix is in columns 1 through 5 and has a blank, a tab, or a zero in column 6; each continued line of the directive has the directive prefix in columns 1 through 5 and has a character other than a blank, a tab, or a zero in column 6.
• In free form, the initial line of the directive ends with an ampersand followed by an optional comment beginning with an exclamation point. Each continued line of the directive has the directive prefix optionally preceded by blanks or tabs, followed by an ampersand optionally preceded by blanks or tabs.

A comment beginning with an ! can follow a compiler directive on the same line.

Additional Fortran statements (or directives) cannot appear on the same line as the compiler directive.

Compiler directives cannot appear within a continued Fortran statement.

Blank common used in a compiler directive is specified by two slashes (/ /).

If the source line starts with a valid directive prefix but the directive is not recognized, the compiler displays an informational message and ignores the line.

General Compiler Directives

Intel® Fortran provides several general-purpose compiler directives to perform tasks during compilation. You do not need to specify a compiler option to enable general directives.

The following general compiler directives are available:

• **ALIAS**
  Specifies an alternate external name to be used when referring to external subprograms.

• **ASSUME**
  Provides heuristic information to the compiler optimizer.

• **ASSUME_ALIGNED**
  Specifies that an entity in memory is aligned.

• **ATTRIBUTES**
  Specifies properties for data objects and procedures.

• **BLOCK_LOOP and NOBLOCK_LOOP**
  Enables or disables loop blocking for the immediately following nested DO loops.

• **DECLARE and NODECLARE**
  Generates or disables warnings for variables that have been used but not declared.

• **DEFINE and UNDEFINE**
  Defines (or undefines) a symbolic variable whose existence (or value) can be tested during conditional compilation.

• **DISTRIBUTE POINT**
  Suggests a location at which a DO loop may be split.

• **FIXEDFORMLINESIZE**
  Sets the line length for fixed-form source code.

• **FMA and NOFMA**
  Enables (or disables) the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.

• **FREEFORM and NOFREEFORM**
  Specifies free-format or fixed-format source code.

• **IDENT**
  Specifies an identifier for an object module.

• **IF and IF DEFINED**
  Specifies a conditional compilation construct.

• **INLINE, FORCEINLINE, NOINLINE**
  Tell the compiler to perform the specified inlining on routines within statements or DO loops.

• **INTEGER**
  Specifies the default integer kind.
• **IVDEP**  
  Assists the compiler's dependence analysis of iterative DO loops.

• **LOOP COUNT**  
  Specifies the typical trip count for a DO loop; this assists the optimizer.

• **MESSAGE**  
  Specifies a character string to be sent to the standard output device during the first compiler pass.

• **NOFUSION**  
  Prevents a loop from fusing with adjacent loops.

• **OBJCOMMENT**  
  Specifies a library search path in an object file.

• **OPTIMIZE and NOOPTIMIZE**  
  Enables or disables optimizations for the program unit.

• **OPTIONS**  
  Affects data alignment and warnings about data alignment.

• **PACK**  
  Specifies the memory alignment of derived-type items.

• **PARALLEL and NOPARALLEL**  
  Facilitates or prevents auto-parallelization by assisting the compiler's dependence analysis of the immediately following DO loop.

• **PREFETCH and NOPREFETCH**  
  Enables or disables hint to the compiler to prefetch data from memory.

• **PSECT**  
  Modifies certain characteristics of a common block.

• **REAL**  
  Specifies the default real kind.

• **SIMD**  
  Requires and controls SIMD vectorization of loops.

• **STRICT and NOSTRICT**  
  Disables or enables language features not found in the language standard specified on the command line.

• **UNROLL and NOUNROLL**  
  Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop.

• **UNROLL_AND_JAM and NOUNROLL_AND_JAM**  
  Enables or disables loop unrolling and jamming.

• **VECTOR and NOVECTOR**  
  Overrides default heuristics for vectorization of DO loops.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**Syntax Rules for Compiler Directives**  
**Rules for General Directives that Affect DO Loops**
Rules for Placement of Directives

Directives can have different effects depending on placement:

- Some directives affect the next statement only.
- Some directives can appear only at the beginning of a scope and affect the rest of that scope.
- Some directives affect the statements starting at that point in the source and continue until changed by another directive or until the end of the scope containing the directive.

The scope can be a contained procedure or a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. A directive does not affect modules invoked with the USE statement in the program unit that contains it, but it does affect INCLUDE statements that follow the directive.

Certain directives may appear before program units or between program units in a source file. These directives affect only the next program unit that lexically follows the directive. The effect of the directive ceases at the end of the affected program unit. For example:

```fortran
!dir$ integer:2
program m
integer k
print *, kind(k), kind(42) ! this prints 2, 2 which means the directive took effect
end

subroutine sub()
integer kk
print *, kind(kk), kind(-42) ! this prints 4, 4 because the INTEGER:2 directive has no effect here
end
```

The following directives have this behavior:

- ALIAS
- ATTRIBUTES
- DECLARE and NODECLARE
- DEFINE and UNDEFINE
- FIXEDFORMLINESIZE
- FREEFORM and NOFREEFORM
- IDENT
- INTEGER
- OPTIMIZE and NOOPTIMIZE
- PACK
- PREFETCH
- PSECT
- REAL
- STRICT and NOSTRICT

Other rules may apply to these directives. For more information, see the description of each directive.

Rules for General Directives that Affect DO Loops

This table lists the general directives that affect DO loops:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK_LOOP</td>
<td>NOPARALLEL</td>
</tr>
<tr>
<td>DISTRIBUTE POINT</td>
<td>NOUNROLL</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>NOUNROLL_AND_JAM</td>
</tr>
<tr>
<td>INLINE</td>
<td>NOVECTOR</td>
</tr>
</tbody>
</table>
The PREFETCH and NOPREFETCH directives also affect DO loops, but they are only available on Intel® MIC Architecture.

The following rules apply to all of the general directives:

- The directive must precede the DO statement for each DO loop it affects. The DO statement can be any of the following:
  - A counted DO loop
  - A DO WHILE loop
  - A DO CONCURRENT loop
- No source code lines, other than the following, can be placed between the directive statement and the DO statement:
  - One of the other general directives that affect DO loops
  - An OpenMP* Fortran PARALLEL DO directive
  - Comment lines
  - Blank lines

Other rules may apply to these directives. For more information, see the description of each directive.

**See Also**
PREFETCH and NOPREFETCH

Rules for Loop Directives that Affect Array Assignment Statements

**Rules for Loop Directives that Affect Array Assignment Statements**

When certain loop directives precede an array assignment statement, they affect the implicit loops that are generated by the compiler.

The following loop directives can affect array assignment statements:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK_LOOP</td>
<td>NOPARALLEL</td>
</tr>
<tr>
<td>DISTRIBUTE POINT</td>
<td>NOUNROLL</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>NOUNROLL_AND_JAM</td>
</tr>
<tr>
<td>INLINE</td>
<td>NOVECTOR</td>
</tr>
<tr>
<td>IVDEP</td>
<td>PARALLEL</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>SIMD</td>
</tr>
<tr>
<td>NOBLOCK_LOOP</td>
<td>UNROLL</td>
</tr>
<tr>
<td>NOFUSION</td>
<td>UNROLL_AND_JAM</td>
</tr>
<tr>
<td>NOINLINE</td>
<td>VECTOR</td>
</tr>
</tbody>
</table>

The PREFETCH and NOPREFETCH directives also affect array assignment statements, but they are only available on Intel® MIC Architecture.

Usually only one of the general directives can precede the array assignment statement (one-dimensional-array = expression) to affect it. The BLOCK_LOOP and NOBLOCK_LOOP directives may precede array assignment statements with any rank variable on the left-hand-side of the assignment.

Other rules may apply to the general directives. For more information, see the description of each directive.
**Examples**

Consider the following:

```fortran
REAL A(10), B(10)
...
!DIR$ IVDEP
A = B + 3
```

This has the same effect as writing the following explicit loop:

```fortran
!DIR$ IVDEP
DO I = 1, 10
   A (I) = B (I) + 3
END DO
```

Rules for General Directives that Affect DO Loops

**OpenMP* Fortran Compiler Directives**

Intel® Fortran provides OpenMP* Fortran compiler directives that comply with most of OpenMP Fortran Application Program Interface (API) specification Version 4.0 and some of Version 4.1. The user-defined reduction feature of OpenMP 4.0 is not yet implemented.

To use these directives, you must specify compiler option `[q or Q]openmp`.

Options that use OpenMP* are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

This section discusses clauses used in multiple OpenMP* Fortran directives, conditional compilation rules, nesting and binding rules, and the following directives:

- **ATOMIC directive**
  Specifies that a specific memory location is to be updated atomically.

- **BARRIER directive**
  Synchronizes all the threads in a team.

- **CANCEL directive**
  Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

- **CANCELLATION POINT directive**
  Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.

- **CRITICAL directive**
  Restricts access for a block of code to only one thread at a time.

- **DECLARE SIMD directive**
  Generates a SIMD procedure.

- **DECLARE TARGET directive**
  Causes the creation of a device-specific version of a named routine that can be called from a target region. This directive only applies to Intel® MIC Architecture.

- **DISTRIBUTE directive**
  Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.

- **DISTRIBUTE PARALLEL DO directive**
  Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
• **DISTRIBUTE PARALLEL DO SIMD directive**
  Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.

• **DISTRIBUTE SIMD**
  Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.

• **DO directive**
  Specifies that the iterations of the immediately following DO loop must be executed in parallel.

• **DO SIMD directive**
  Specifies a loop that can be executed concurrently using SIMD instructions.

• **FLUSH directive**
  Specifies synchronization points where the threads in a team must have a consistent view of memory.

• **MASTER directive**
  Specifies a block of code to be executed by the master thread of the team.

• **ORDERED directive**
  Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.

• **PARALLEL directive**
  Defines a parallel region.

• **PARALLEL DO directive**
  Defines a parallel region that contains a single DO directive.

• **PARALLEL DO SIMD directive**
  Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.

• **PARALLEL SECTIONS directive**
  Defines a parallel region that contains a single SECTIONS directive.

• **PARALLEL WORKSHARE directive**
  Defines a parallel region that contains a single WORKSHARE directive.

• **SECTIONS directive**
  Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team.

• **SIMD directive**
  Requires and controls SIMD vectorization of loops.

• **SINGLE directive**
  Specifies a block of code to be executed by only one thread in a team at a time.

• **TARGET directive**
  Creates a device data environment and executes the construct on the same device. This directive only applies to Intel® MIC Architecture.

• **TARGET DATA directive**
  Creates a device data environment for the extent of the region. This directive only applies to Intel® MIC Architecture.

• **TARGET ENTER DATA**
  Specifies that variables are mapped to a device data environment. This directive only applies to Intel® MIC Architecture.

• **TARGET EXIT DATA**
  Specifies that variables are unmapped from a device data environment. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS**
  Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies to Intel® MIC Architecture.
• **TARGET TEAMS DISTRIBUTE**
  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE PARALLEL DO**
  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD**
  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

• **TARGET TEAMS DISTRIBUTE SIMD**
  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

• **TARGET UPDATE directive**
  Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies to Intel® MIC Architecture.

• **TASK directive**
  Defines a task region.

• **TASKGROUP directive**
  Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

• **TASKWAIT directive**
  Specifies a wait on the completion of child tasks generated since the beginning of the current task.

• **TASKYIELD directive**
  Specifies that the current task can be suspended at this point in favor of execution of a different task.

• **TEAMS**
  Creates a group of thread teams to be used in a parallel region.

• **TEAMS DISTRIBUTE**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.

• **TEAMS DISTRIBUTE PARALLEL DO**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

• **TEAMS DISTRIBUTE PARALLEL DO SIMD**
  Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.

• **TEAMS DISTRIBUTE SIMD**
  Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.

• **THREADPRIVATE directive**
  Makes named common blocks private to each thread, but global within the thread.

• **WORKSHARE directive**
  Divides the work of executing a block of statements or constructs into separate units.
The OpenMP parallel directives can be grouped into the categories. For more information about the categories for these directives, see OpenMP* Directives Summary.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Clauses Used in Multiple OpenMP* Fortran Directives

This topic summarizes clauses that are used in more than one OpenMP* Fortran directive.

Other clauses (or keywords) are available for some OpenMP* Fortran directives. For more information, see each directive description.

Some of the OpenMP* Fortran directives have clauses (or options) you can specify to control the scope attributes of variables for the duration of the directive.

Data Scope Attribute Clauses

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Lets you specify a scope for all variables in the lexical extent of a parallel region.</td>
</tr>
<tr>
<td>FIRSTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.</td>
</tr>
<tr>
<td>LASTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.</td>
</tr>
<tr>
<td>LINEAR</td>
<td>Specifies that all variables in a list are private to a SIMD task and that they have a linear relationship within the iteration space of a loop.</td>
</tr>
<tr>
<td>PRIVATE</td>
<td>Declares one or more variables to be private to each thread in a team.</td>
</tr>
<tr>
<td>REDUCTION</td>
<td>Performs a reduction operation on the specified variables.</td>
</tr>
<tr>
<td>SHARED</td>
<td>Specifies variables that will be shared by all the threads in a team.</td>
</tr>
</tbody>
</table>

The data copying clauses let you copy data values from private or threadprivate variables in one implicit task or thread to the corresponding variables in other implicit tasks or threads in the team.
Data Copying Clauses

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COPYIN</td>
<td>Specifies that the data in the master thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.</td>
</tr>
<tr>
<td>COPYPRIVATE</td>
<td>Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.</td>
</tr>
</tbody>
</table>

The data motion clause MAP is used in OpenMP* Fortran TARGET directives. This data motion clause does not modify the values of any of the internal control variables (ICVs).

List items that appear in this data motion clause may have corresponding new list items created in the device data environment that is associated with the construct. If a new list item is created, a new list item of the same type, kind, and rank is allocated. The initial value of the new list item is undefined.

The original list items and new list items may share storage. This means that data races can occur. Data races are caused by unintended sharing of data; for example, when WRITEs to either item by one task or device are followed by a READ of the other item by another task or device without intervening synchronization.

Data Motion Clause

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAP</td>
<td>Maps a variable from the data environment of the current task to the data environment of the device associated with the construct.</td>
</tr>
</tbody>
</table>

The following are other clauses that can be used in more than one OpenMP* Fortran directive.

Miscellaneous Clauses

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIGNED</td>
<td>Specifies that all variables in a list are aligned.</td>
</tr>
<tr>
<td>COLLAPSE</td>
<td>Specifies how many loops are associated with the loop construct.</td>
</tr>
<tr>
<td>DEPEND</td>
<td>Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.</td>
</tr>
<tr>
<td>DEVICE</td>
<td>Specifies the target device for certain TARGET directives.</td>
</tr>
<tr>
<td>IF</td>
<td>Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.</td>
</tr>
<tr>
<td>NOWAIT</td>
<td>Specifies that threads may resume execution before the execution of the region completes.</td>
</tr>
</tbody>
</table>

Conditional Compilation Rules

The OpenMP* Fortran API lets you conditionally compile Intel® Fortran statements if you use the appropriate directive prefix.

The prefix depends on which source form you are using, although !$ is valid in all forms.

The prefix must be followed by a valid Intel Fortran statement on the same line.
Free Source Form

The free source form conditional compilation prefix is !$. This prefix can appear in any column as long as it is preceded only by white space. It must appear as a single word with no intervening white space. Free-form source rules apply to the directive line.

Initial lines must have a space after the prefix. Continued lines must have an ampersand as the last nonblank character on the line. Continuation lines can have an ampersand after the prefix with optional white space before and after the ampersand.

Fixed Source Form

For fixed source form programs, the conditional compilation prefix is one of the following: !$, C$ (or c$), or *$.

The prefix must start in column one and appear as a single string with no intervening white space. Fixed-form source rules apply to the directive line.

After the prefix is replaced with two spaces, initial lines must have a space or zero in column six, and continuation lines must have a character other than a space or zero in column six. For example, the following forms for specifying conditional compilation are equivalent:

```
c23456789
!$ IAM = OMP_GET_THREAD_NUM( ) +
!$ INDEX
#IFDEF _OPENMP
IAM = OMP_GET_THREAD_NUM( ) +
INDEX
#ENDIF
```

Nesting and Binding Rules

This section describes the dynamic nesting and binding rules for OpenMP Fortran API directives.

Binding Rules

The following rules apply to dynamic binding:

- The DO, SECTIONS, SINGLE, MASTER, and BARRIER directives bind to the dynamically enclosing PARALLEL directive, if one exists.
- The ORDERED directive binds to the dynamically enclosing DO directive.
- The ATOMIC directive enforces exclusive access with respect to ATOMIC directives in all threads, not just the current team.
- The CRITICAL directive enforces exclusive access with respect to CRITICAL directives in all threads, not just the current team.
- A directive can never bind to any directive outside the closest enclosing PARALLEL directive.

Nesting Rules

The following rules apply to dynamic nesting:

- A PARALLEL directive dynamically inside another PARALLEL directive logically establishes a new team, which is composed of only the current thread unless nested parallelism is enabled.
- DO, SECTIONS, and SINGLE directives that bind to the same PARALLEL directive are not allowed to be nested one inside the other.
- DO, SECTIONS, and SINGLE directives are not permitted in the dynamic extent of CRITICAL and MASTER directives.
- BARRIER directives are not permitted in the dynamic extent of DO, SECTIONS, SINGLE, MASTER, and CRITICAL directives.
- MASTER directives are not permitted in the dynamic extent of DO, SECTIONS, and SINGLE directives.
• ORDERED sections are not allowed in the dynamic extent of CRITICAL sections.
• Any directive set that is legal when executed dynamically inside a PARALLEL region is also legal when executed outside a parallel region. When executed dynamically outside a user-specified parallel region, the directive is executed with respect to a team composed of only the master thread.

Examples

The following example shows nested PARALLEL regions:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
  DO I =1, N
  !$OMP PARALLEL SHARED(I,N)
  !$OMP DO
    DO J =1, N
      CALL WORK(I,J)
    END DO
  !$OMP END PARALLEL
  END DO
!$OMP END PARALLEL
```

Note that the inner and outer DO directives bind to different PARALLEL regions.

The following example shows a variation of the preceding example:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO

OFFLOAD Compiler Directives

Intel® Fortran provides several OFFLOAD compiler directives to perform offloading tasks during compilation. These directives are recognized by default; there is a command line option to tell the compiler to ignore them. These directives only apply to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The following OFFLOAD compiler directives are available:

- **OFFLOAD**
  Enables statements to execute on the target.

- **OFFLOAD BEGIN** and **END OFFLOAD**
  Enables a group of statements to execute on the target.

- **OFFLOAD_TRANSFER**
  Initiates asynchronous data transfer, or initiates and completes synchronous data transfer.

- **OFFLOAD_WAIT**
  Specifies a wait for a previously initiated asynchronous activity.
### Equivalent Compiler Options

Some compiler directives and compiler options have the same effect, as shown in the table below. However, compiler directives can be turned on and off throughout a program, while compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

The following table shows compiler directives and equivalent command-line compiler options:

<table>

Scope and Association

Scope and Association Overview

Program entities are identified by names, labels, input/output unit numbers, operator symbols, or assignment symbols. For example, a variable, a derived type, or a subroutine is identified by its name. Scope refers to the area in which a name is recognized. A scoping unit is the program or part of a program in which a name is defined or known. It can be any of the following:

- An entire executable program
- A single scoping unit
- A single statement (or part of a statement)

The region of the program in which a name is known and accessible is referred to as the scope of that name. These different scopes allow the same name to be used for different things in different regions of the program.

Association is the language concept that allows different names to refer to the same entity in a particular region of a program.

Association

Scope

Program entities have the following kinds of scope (as shown in the table below):

- **Global**
  
  Entities that are accessible throughout an executable program. The name of a global entity must be unique. It cannot be used to identify any other global entity in the same executable program.

- **Scoping unit (Local scope)**
  
  Entities that are declared within a scoping unit. These entities are local to that scoping unit. The names of local entities are divided into classes (see the table below).

A *scoping unit* is one of the following:

- A derived-type definition
- A procedure interface body (excluding any derived-type definitions and interface bodies contained within it)
- A program unit or subprogram (excluding any derived-type definitions, interface bodies, and subprograms contained within it)

A scoping unit that immediately surrounds another scoping unit is called the host scoping unit. Named entities within the host scoping unit are accessible to the nested scoping unit by host association. (For information about host association, see Use and Host Association.)

Once an entity is declared in a scoping unit, its name can be used throughout that scoping unit. An entity declared in another scoping unit is a different entity even if it has the same name and properties.

Within a scoping unit, a local entity name that is not generic must be unique within its class. However, the name of a local entity in one class can be used to identify a local entity of another class.
Within a scoping unit, a generic name can be the same as any one of the procedure names in the interface block.

A component name has the same scope as the derived type of which it is a component. It can appear only within a component designator of a structure of that type.

For information on interactions between local and global names, see the table below.

- **Statement**

Entities that are accessible only within a statement or part of a statement; such entities cannot be referenced in subsequent statements.

The name of a statement entity can also be the name of a global or local entity in the same scoping unit; in this case, the name is interpreted within the statement as that of the statement entity.

### Scope of Program Entities

<tr>
<td>Statement labels</td>
<td>Local</td>
</tr>
<tr>
<td>External I/O unit numbers</td>
<td>Global</td>
</tr>
<tr>
<td>Intrinsic assignment</td>
<td>Global(^4)</td>
</tr>
</tbody>
</table>
Names of common blocks can also be used to identify local entities.

If an intrinsic procedure is not used in a scoping unit, its name can be used as a local entity within that scoping unit. For example, if intrinsic function COS is not used in a program unit, COS can be used as a local variable there.

The DO variable in an implied-DO list of an I/O list has local scope.

The scope of the assignment symbol (=) is global, but it can identify additional operations (see Defining Generic Assignment).

Scoping units can contain other scoping units. For example, the following shows six scoping units:

```plaintext
MODULE MOD_1                    ! Scoping unit 1
...                          ! Scoping unit 1
CONTAINS                        ! Scoping unit 1
  FUNCTION FIRST                !   Scoping unit 2
  TYPE NAME                   !     Scoping unit 3
  ...                         !     Scoping unit 3
  END TYPE NAME               !     Scoping unit 3
  ...                         !   Scoping unit 2
  CONTAINS                      !   Scoping unit 2
  SUBROUTINE SUB_B            !       Scoping unit 4
  TYPE PROCESS              !         Scoping unit 5
  ...                       !         Scoping unit 5
  END TYPE PROCESS          !         Scoping unit 5
  INTERFACE                 !         Scoping unit 5
  SUBROUTINE SUB_A        !           Scoping unit 6
  ...                     !           Scoping unit 6
  END SUBROUTINE SUB_A    !           Scoping unit 6
  END INTERFACE             !         Scoping unit 5
  END SUBROUTINE SUB_B        !       Scoping unit 4
  END FUNCTION   FIRST          !   Scoping unit 2
END MODULE                      ! Scoping unit 1
```

Unambiguous Generic Procedure References

When a generic procedure reference is made, a specific procedure is invoked. If the following rules are used, the generic reference will be unambiguous:

- Two dummy arguments are said to be distinguishable if any of the following are true:
  - One is a procedure and the other is a data object
  - One has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN)
  - They are both data objects or both known to be functions, and they have different type and kind parameters, or different rank
• One is a function with nonzero rank and the other is not known to be a function
• Within a scoping unit, two procedures that have the same generic name must both be subroutines (or both be functions). One of the procedures must have a nonoptional dummy argument that is one of the following:
  • Not present by position or argument keyword in the other argument list
  • Is present, but is distinguishable from the dummy argument in the other argument list
• Within a scoping unit, two procedures that have the same generic operator must both have the same number of arguments or both define assignment. One of the procedures must have a dummy argument that corresponds by position in the argument list to a dummy argument of the other procedure that dummy argument of the other procedure that is distinguishable from the dummy argument in the other argument list.

When an interface block extends an intrinsic procedure, operator, or assignment, the rules apply as if the intrinsic consists of a collection of specific procedures, one for each allowed set of arguments.

When a generic procedure is accessed from a module, the rules apply to all the specific versions, even if some of them are inaccessible by their specific names.

Defining Generic Names for Procedures for details on generic procedure names

Resolving Procedure References
The procedure name in a procedure reference is either established to be generic or specific, or is not established. The rules for resolving a procedure reference differ depending on whether the procedure is established and how it is established.

This section discusses the following topics:
• References to Generic Names
• References to Specific Names
• References to Nonestablished Names

References to Generic Names
Within a scoping unit, a procedure name is established to be generic if any of the following is true:
• The scoping unit contains an interface block with that procedure name.
• The procedure name matches the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
• The procedure name is established to be generic in a module, and the scoping unit contains a USE statement making that procedure name accessible.
• The scoping unit contains no declarations for that procedure name, but the procedure name is established to be generic in a host scoping unit.

To resolve a reference to a procedure name established to be generic, the following rules are used in the order shown:

1. If an interface block with that procedure name appears in one of the following, the reference is to the specific procedure providing that interface:
   a. The scoping unit that contains the reference
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with one of the specific interfaces of the interface block.

2. If the procedure name is specified with the INTRINSIC attribute in one of the following, the reference is to that intrinsic procedure:
   a. The same scoping unit
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with the interface of that intrinsic procedure.
3. If the following is true, the reference is resolved by applying rules 1 and 2 to the host scoping unit:
   a. The procedure name is established to be generic in the host scoping unit
   b. There is agreement between the scoping unit and the host scoping unit as to whether the
      procedure is a function or subroutine name.

4. If none of the preceding rules apply, the reference must be to the generic intrinsic procedure with that
   name. The reference must be consistent with the interface of that intrinsic procedure.

Examples

The following example shows how a module can define three separate procedures, and a main program give
them a generic name DUP through an interface block. Although the main program calls all three by the
generic name, there is no ambiguity since the arguments are of different data types, and DUP is a function
rather than a subroutine. The module UN_MOD must give each procedure a different name.

```fortran
MODULE UN_MOD
  !
  CONTAINS
    subroutine dup1(x,y)
      real x,y
      print *, ' Real arguments', x, y
      end subroutine dup1

    subroutine dup2(m,n)
      integer m,n
      print *, ' Integer arguments', m, n
      end subroutine dup2

    character function dup3 (z)
    character(len=2) z
    dup3 = 'String argument '// z
    end function dup3

END MODULE

PROGRAM UNCLEAR
  ! shows how to use generic procedure references

  USE UN_MOD
  INTERFACE DUP
    MODULE PROCEDURE dup1, dup2, dup3
  END INTERFACE

  real a,b
  integer c,d
  character (len=2) state

  a = 1.5
  b = 2.32
  c = 5
  d = 47
  state = 'WA'

  call dup(a,b)
  call dup(c,d)
  print *, dup(state)       !actual output is 'S' only

END PROGRAM
```

Note that the function DUP3 only prints one character, since module UN_MOD specifies no length parameter
for the function result.
If the dummy arguments x and y for DUP were declared as integers instead of reals, then any calls to DUP would be ambiguous. If this is the case, a compile-time error results.

The subroutine definitions, DUP1, DUP2, and DUP3, must have different names. The generic name is specified in the first line of the interface block, and in the example is DUP.

References to Specific Names

In a scoping unit, a procedure name is established to be specific if it is not established to be generic and any of the following is true:

- The scoping unit contains an interface body with that procedure name.
- The scoping unit contains an internal procedure, module procedure, or statement function with that procedure name.
- The procedure name is the same as the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is specified with the EXTERNAL attribute in that scoping unit.
- The procedure name is established to be specific in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be specific in a host scoping unit.

To resolve a reference to a procedure name established to be specific, the following rules are used in the order shown:

1. If either of the following is true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram, and it contains an interface body with that procedure name.
   b. The procedure name has been declared EXTERNAL, and the procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If the scoping unit contains an interface body or the procedure name has been declared EXTERNAL, and Rule 1 does not apply, the reference is to an external procedure with that name.

3. If the scoping unit contains an internal procedure or statement function with that procedure name, the reference is to that entity.

4. If the procedure name has been declared INTRINSIC in the scoping unit, the reference is to the intrinsic procedure with that name.

5. If the scoping unit contains a USE statement that makes the name of a module procedure accessible, the reference is to that procedure. (The USE statement allows renaming, so the name referenced may differ from the name of the module procedure.)

6. If none of the preceding rules apply, the reference is resolved by applying these rules to the host scoping unit.

References to Nonestablished Names

In a scoping unit, a procedure name is not established if it is not determined to be generic or specific.

To resolve a reference to a procedure name that is not established, the following rules are used in the order shown:

1. If both of the following are true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram.
   b. The procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If both of the following are true, the procedure is an intrinsic procedure and the reference is to that intrinsic procedure:
   a. The procedure name matches the name of an intrinsic procedure.
b. There is agreement between the intrinsic procedure definition and the reference of the name as a function or subroutine.

3. If neither of the preceding rules apply, the reference is to an external procedure with that name.

Defining Generic Names for Procedures for details on generic procedure names

Association
Association allows different program units to access the same value through different names. Entities are associated when each is associated with the same storage location.

There are four kinds of association:

- Name association
- Pointer association
- Storage association
- Inheritance association

The following example shows name, pointer, and storage association between an external program unit and an external procedure.

Example of Name, Pointer, and Storage Association

```
! Scoping Unit 1: An external program unit

REAL A, B(4)
REAL, POINTER :: M(:)
REAL, TARGET :: N(12)
COMMON /COM/...
EQUIVALENCE (A, B(1))        ! Storage association between A and B(1)
M => N                       ! Pointer association
CALL P (actual-arg,...)
...

! Scoping Unit 2: An external procedure

SUBROUTINE P (dummy-arg,...)  ! Name and storage association between
                               ! these arguments and the calling
                               ! routine's arguments in scoping unit 1
COMMON /COM/...              ! Storage association with common block COM
                               ! in scoping unit 1
REAL Y
CALL Q (actual-arg,...)
CONTAINS
  SUBROUTINE Q (dummy-arg,...) ! Name and storage association between
                              ! these arguments and the calling
                              ! routine's arguments in host procedure
                              ! P (subprogram Q has host association
                              ! with procedure P)
  Y = 2.0*(Y-1.0)       ! Name association with Y in host procedure P
...
```

The following example shows inheritance association:

```
TYPE POINT                  ! A base type
REAL :: X, Y
```
END TYPE POINT

TYPE, EXTENDS(POINT) :: COLOR_POINT   ! An extension of TYPE(POINT)
   ! Components X and Y, and component name POINT,
   ! are inherited from the parent type POINT
INTEGER :: COLOR
END TYPE COLOR_POINT

Name Association
Name association allows an entity to be accessed from different scoping units by the same name or by different names. There are five types of name association: argument, use, host, linkage, and construct.

Argument Association
Arguments are the values passed to and from functions and subroutines through calling program argument lists.

Execution of a procedure reference establishes argument association between an actual argument and its corresponding dummy argument. The name of a dummy argument can be different from the name of its associated actual argument (if any).

When the procedure completes execution, the argument association is terminated. A dummy argument of that procedure can be associated with an entirely different actual argument in a subsequent invocation of the procedure.

Association Between Actual Arguments and Dummy Data Objects
A scalar dummy argument of a nonelemental procedure can be associated only with a scalar actual argument.

If the actual argument is scalar, the corresponding dummy argument must be scalar unless the actual argument is of type default character, of type character with the C character kind, or is an element or substring of an element of an array that is not an assumed-shape or pointer array. If the procedure is nonelemental and is referenced by a generic name or as a defined operator or defined assignment, the ranks of the actual arguments and corresponding dummy arguments must agree.

If a scalar dummy argument is of type default character, the length of the dummy argument must be less than or equal to the length of the actual argument. The dummy argument becomes associated with the leftmost len characters of the actual argument. If an array dummy argument is of type default character and is not assumed shape, it becomes associated with the leftmost characters of the actual argument element sequence and it must not extend beyond the end of that sequence.

If a dummy argument is not allocatable and is not a pointer, it must be type compatible with the associated actual argument. If a dummy argument is allocatable or a pointer, the associated actual argument must be polymorphic if and only if the dummy argument is polymorphic, and the declared type of the actual argument must be the same as the declared type of the dummy argument.

If the dummy argument is a pointer, the actual argument must be a pointer and the nondeferred type parameters and ranks must agree. If a dummy argument is allocatable, the actual argument must be allocatable and the nondeferred type parameters and ranks must agree. The actual argument can have an allocation status of unallocated.

At the invocation of the procedure, the pointer association status of an actual argument associated with a pointer dummy argument becomes undefined if the dummy argument has INTENT(OUT).

The dynamic type of a polymorphic, allocatable, or pointer dummy argument can change as a result of execution of an allocate statement or pointer assignment in the subprogram. Because of this, the corresponding actual argument needs to be polymorphic and have a declared type that is the same as the declared type of the dummy argument, or an extension of that type.

The values of assumed type parameters of a dummy argument are assumed from the corresponding type parameters of the associated actual argument.
Except in references to intrinsic inquiry functions, if the dummy argument is not a pointer and the corresponding actual argument is a pointer, the actual argument must be associated with a target and the dummy argument becomes associated with that target.

Except in references to intrinsic inquiry functions, if the dummy argument is not allocatable and the actual argument is allocatable, the actual argument must be allocated.

If the dummy argument has the VALUE attribute, it becomes associated with a definable anonymous data object whose initial value is that of the actual argument. Subsequent changes to the value or definition status of the dummy argument do not affect the actual argument.

If the dummy argument does not have the TARGET or POINTER attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument on invocation of the procedure.

If the dummy argument has the TARGET attribute, does not have the VALUE attribute, and is either a scalar or an assumed-shape array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript then the following is true:

- Any pointers associated with the actual argument become associated with the corresponding dummy argument on invocation of the procedure.
- When execution of the procedure completes, any pointers that do not become undefined and are associated with the dummy argument remain associated with the actual argument.

Any pointers associated with the dummy argument become undefined when execution of the procedure completes in these cases:

- If the dummy argument has the TARGET attribute and the corresponding actual argument does not have the TARGET attribute, or is an array section with a vector subscript.
- If the dummy argument has the TARGET attribute and the VALUE attribute.

If a nonpointer dummy argument has INTENT (OUT) or INTENT (INOUT), the actual argument must be definable. If a dummy argument has INTENT (OUT), the corresponding actual argument becomes undefined at the time the association is established, except for components of an object of derived type for which default initialization has been specified. If the dummy argument is not polymorphic and the type of the actual argument is an extension type of the type of the dummy argument, only the part of the actual argument that is of the same type as the dummy argument becomes undefined.

**Association Between Actual Arguments and Dummy Procedure Entities**

If a dummy argument is a procedure pointer, the associated actual argument must be a procedure pointer, a reference to a function that returns a procedure pointer, or a reference to the NULL intrinsic function.

If a dummy argument is a dummy procedure without the POINTER attribute, the associated actual argument must be the specific name of an external, module, dummy, or intrinsic procedure, an associated procedure pointer, or a reference to a function that returns an associated procedure pointer. If the specific name is also a generic name, only the specific procedure is associated with the dummy argument.

For generic declarations, a dummy argument is type, kind, and rank compatible with another dummy argument if following is true:

- The first is type compatible with the second
- The kind type parameters of the first have the same values as the corresponding kind type parameters of the second
- Both have the same rank or either is assumed-rank

If an external procedure name or a dummy procedure name is used as an actual argument, its interface must be explicit or it must be explicitly declared to have the EXTERNAL attribute.

If the interface of the dummy argument is explicit, the procedure characteristics must be the same for the associated actual argument and the corresponding dummy argument, except that a pure actual argument can be associated with a dummy argument that is not pure and an elemental intrinsic actual procedure can be associated with a dummy procedure that is prohibited from being elemental.
If the interface of the dummy argument is implicit and either the name of the dummy argument is explicitly typed or it is referenced as a function, the dummy argument must not be referenced as a subroutine and the actual argument must be a function, function procedure pointer, or dummy procedure.

If the interface of the dummy argument is implicit and a reference to it appears as a subroutine reference, the actual argument must be a subroutine, subroutine procedure pointer, or dummy procedure.

An assumed-rank dummy argument can correspond to an actual argument of any rank. If the actual argument has rank zero (is a scaler), the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including the lack of a final extent in the case of an assumed-size array. If the actual argument is an array and the dummy argument is allocatable or a pointer, the bounds of the dummy argument are assumed from the actual argument.

An assumed-type dummy argument must not correspond to an actual argument that is of a derived type that has type parameters, type-bound procedures, or final subroutines.

Association For C Interoperability

When a Fortran procedure that has an INTENT(OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated upon entry to the Fortran procedure.

When a C function is invoked from a Fortran procedure by means of an interface with an INTENT(OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

Procedure Characteristics

Use and Host Association Overview

Use association allows the entities in a module to be accessible to other scoping units. Host association allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program.

Use association and host association remain in effect throughout the execution of the executable program.

An interface body does not access named entities by host association, but it can access entities by use association.

Examples

The following example shows host and use association:

```fortran
MODULE SHARE_DATA
  REAL Y, Z
END MODULE

PROGRAM DEMO
  USE SHARE_DATA             ! All entities in SHARE_DATA are available
  REAL B, Q                  ! through use association.
  ...
  CALL CONS (Y)              ! Y is a local entity (dummy argument).
CONTAINS

    REAL C, Y
    ...
    Y = B + C + Q + Z        ! B and Q are available through host association.
    ...
  END SUBROUTINE CONS       ! C is a local entity, explicitly declared.
  ...
END PROGRAM DEMO
```
Use Association

Use association allows the entities in a module to be accessible to other scoping units. This association remains in effect throughout the execution of the program. The mechanism for use association is the USE statement. The USE statement provides access to all public entities in the module, unless ONLY is specified. In this case, only the entities named in the ONLY list can be accessed.

If an entity that is accessed by use association has the same nongeneric name as a host entity, the host entity is inaccessible. A name that appears in the scoping unit as an external name in an EXTERNAL statement is a global name, and any entity of the host that has this as its nongeneric name is inaccessible.

For more information on rules that apply to use association, see the USE statement.

Host Association

Host association allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program. This association remains in effect throughout the execution of the program.

The following also have access to entities from its host:

- A module procedure interface body
- A derived-type definition
- An interface body that is not a separate interface body has access by means of host association to the named entities from its host that are made accessible by IMPORT statements in the interface body.

The accessed entities are known by the same name and have the same attributes as in the host, except that a local entity can have the ASYNCHRONOUS attribute even if the host entity does not, and a noncoarray local entity can have the VOLATILE attribute even if the host entity does not. The accessed entities can be named data objects, derived types, abstract interfaces, procedures, generic identifiers, and namelist groups.

Entities that are local to a procedure are not accessible to its host.

The following are considered local identifiers within a scoping unit, so they are not accessible to their hosts:

- A function name in a statement function, an entity declaration in a type declaration statement, or the name of an entity declared by an interface body, unless any of these are global identifiers.
- An object name in an entity declaration in a type declaration statement or a POINTER, SAVE, ALLOCATABLE, or TARGET statement.
- A type name in a derived type statement.
- A procedure pointer that has the EXTERNAL attribute.
- The name of a variable that is wholly or partially initialized in a DATA statement.
- The name of an object that is wholly or partially initialized in an EQUIVALENCE statement.
- A namelist group name in a NAMELIST statement.
- A generic name in a generic specification in an INTERFACE statement.
- The name of a named construct.
- The name of a dummy argument in a FUNCTION, SUBROUTINE, or ENTRY statement, or a statement function.
- A named constant defined in a PARAMETER statement.
- An array name in a DIMENSION statement.
- A variable name in a common block object in a COMMON statement.
• A result name in a FUNCTION or ENTRY statement.
• An intrinsic procedure name in an INTRINSIC statement.

A name that appears in an ASYNCHRONOUS or VOLATILE statement is not necessarily the name of a local variable. In an internal or module procedure, if a variable that is accessible via host association is specified in an ASYNCHRONOUS or VOLATILE statement, that host variable is given the ASYNCHRONOUS or VOLATILE attribute in the local scope.

If an intrinsic procedure is accessed by means of host association, it must be established to be intrinsic in the host scoping unit by one of the following methods:

• It must be explicitly given the INTRINSIC attribute.
• It must be invoked as an intrinsic procedure.
• It must be accessed from a module or from its host where it is established to be intrinsic.

If a procedure gains access to a pointer by host association, the association of the pointer with a target that is current at the time the procedure is invoked remains current within the procedure. This pointer association can be changed within the procedure. After execution of the procedure, the pointer association remains current, unless the execution caused the target to become undefined. If this occurs, the host associated pointer becomes undefined.

NOTE
Implicit declarations can cause problems for host association. It is recommended that you use IMPLICIT NONE in both the host and the contained procedure, and that you explicitly declare all entities.

When all entities are explicitly declared, local declarations override host declarations, and host declarations that are not overridden are available in the contained procedure.

Examples
The following example shows how a host and an internal procedure can use host-associated entities:

```
program INTERNAL
  ! shows use of internal subroutine and CONTAINS statement
  real a,b,c
  call find
  print *, c
contains
  subroutine find
    read *, a,b
    c = sqrt(a**2 + b**2)
  end subroutine find
end
```

In this case, the variables a, b, and c are available to the internal subroutine find through host association. They do not have to be passed as arguments to the internal procedure. In fact, if they are, they become local variables to the subroutine and hide the variables declared in the host program.

Conversely, the host program knows the value of c, when it returns from the internal subroutine that has defined c.

See Also
Use Association Scope for details on entities with local scope

Linkage Association
Linkage association occurs between the following:

• A module variable that has the BIND attribute and the C variable with which it interoperates
A Fortran common block and the C variable with which it interoperates

This association remains in effect throughout the execution of the program.

**See Also**

USE
Host Association
Scope for details on entities with local scope

**Construct Association**

Construct association establishes an association between each selector and the corresponding associate name of an ASSOCIATE or SELECT TYPE construct.

If the selector is allocatable, it must be allocated. The associate name is associated with the data object and does not have the ALLOCATABLE attribute.

If the selector has the POINTER attribute, it must be associated, The associate name is associated with the target of the pointer and does not have the POINTER attribute.

If the selector is a variable other than an array section having a vector subscript, the association is with the data object specified by the selector; otherwise, the association is with the value of the selector expression, which is evaluated before the execution of the block.

Each associate name remains associated with the corresponding selector throughout the execution of the executed block. Within the block, each selector is known by and can be accessed by the corresponding associate name. When the construct is terminated, the association is terminated.

**See Also**

USE
Host Association
Scope for details on entities with local scope

**Pointer Association**

A pointer can be associated with a target. At different times during the execution of a program, a pointer can be undefined, associated with different targets, or be disassociated. The initial association status of a pointer is undefined. A pointer can become associated by the following:

- By pointer assignment (pointer => target)
  The target must be associated, or specified with the TARGET attribute. If the target is allocatable, it must be currently allocated.
- By allocation (successful execution of an ALLOCATE statement)
  The ALLOCATE statement must reference the pointer.

A pointer becomes disassociated if any of the following occur:

- The pointer is nullified by a NULLIFY statement.
- The pointer is deallocated by a DEALLOCATE statement.
- The pointer is assigned a disassociated pointer (or the NULL intrinsic function).
- The pointer is an ultimate component of an object of a type for which default initialization is specified for the component and one of the following is true:
  - A procedure is invoked with this object as an actual argument corresponding to a nonpointer, nonallocatable, dummy argument with INTENT (OUT).
  - A procedure is invoked with this object as an unsaved, nonpointer, nonallocatable local object that is not accessed by use or host association.
  - This object is allocated.

When a pointer is associated with a target, the definition status of the pointer is defined or undefined, depending on the definition status of the target. A target is undefined in the following cases:

- If it was never allocated
• If it is not deallocated through the pointer
• If a RETURN or END statement causes it to become undefined

If a pointer is associated with a definable target, the definition status of the pointer can be defined or undefined, according to the rules for a variable.

The association status of a pointer becomes undefined when a DO CONCURRENT construct is terminated and the pointer’s association status was changed in more than one iteration of the construct.

If the association status of a pointer is disassociated or undefined, the pointer must not be referenced or deallocated.

Whatever its association status, a pointer can always be nullified, allocated, or associated with a target. When a pointer is nullified, it is disassociated. When a pointer is allocated, it becomes associated, but is undefined. When a pointer is associated with a target, its association and definition status are determined by its target.

Storage Association

Storage association describes the relationships that exist among data objects. It is the association of two or more data objects that occurs when two or more storage sequences share (or are aligned with) one or more storage units. Storage sequences are used to describe relationships among variables, common blocks, and result variables.

See Also
Storage Units and Storage Sequence
Array Association

Storage Units and Storage Sequence

A storage unit is a fixed unit of physical memory allocated to certain data. A storage sequence is a sequence of storage units. The size of a storage sequence is the number of storage units in the storage sequence. A storage unit can be numeric, character, or unspecified.

A nonpointer scalar of type default real, integer, or logical occupies one numeric storage unit. A nonpointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel Fortran, one numeric storage unit corresponds to 4 bytes of memory.

A nonpointer scalar of type default character with character length 1 occupies one character storage unit. A nonpointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel Fortran, one character storage unit corresponds to 1 byte of memory.

A nonpointer scalar of type default character with character length len occupies len contiguous character storage units. In Intel Fortran, one character storage unit corresponds to 1 byte of memory.

A nonpointer scalar of nondefault data type occupies a single unspecified storage unit. The number of bytes corresponding to the unspecified storage unit differs depending on the data type.

The following table lists the storage requirements (in bytes) for the intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Requirements (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>2, 4, or 8¹</td>
</tr>
<tr>
<td>LOGICAL(1)</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td>4</td>
</tr>
</tbody>
</table>

¹ Depending on the data type.
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Requirements (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER</td>
<td>2, 4, or 8 ¹</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>8</td>
</tr>
<tr>
<td>REAL</td>
<td>4, 8, or 16 ²</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>8, 16, or 32 ²</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16)</td>
<td>32</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>1</td>
</tr>
<tr>
<td>CHARACTER*len</td>
<td>len ³</td>
</tr>
<tr>
<td>CHARACTER*(*</td>
<td>assumed-length ⁴</td>
</tr>
</tbody>
</table>

¹ Depending on default integer, LOGICAL and INTEGER can have 2, 4, or 8 bytes. The default allocation is four bytes.
² Depending on default real, REAL can have 4, 8, or 16 bytes and COMPLEX can have 8, 16, or 32 bytes. The default allocations are four bytes for REAL and eight bytes for COMPLEX.
³ The value of len is the number of characters specified. The largest valid value is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture. Negative values are treated as zero.
⁴ The assumed-length format *(*) applies to dummy arguments, PARAMETER statements, or character functions, and indicates that the length of the actual argument or function is used. (See Assumed-Length Character Arguments.)

A nonpointer scalar of sequence derived type occupies a sequence of storage sequences corresponding to the components of the structure, in the order they occur in the derived-type definition. (A sequence derived type has a SEQUENCE statement.)

A pointer occupies a single unspecified storage unit that is different from that of any nonpointer object and is different for each combination of type, type parameters, and rank.

The definition status and value of a data object affects the definition status and value of any storage-associated entity.

When two objects occupy the same storage sequence, they are totally storage-associated. When two objects occupy parts of the same storage sequence, they are partially associated. An EQUIVALENCE statement, a COMMON statement, or an ENTRY statement can cause total or partial storage association of storage sequences.

Assumed-Length Character Arguments
COMMON
Entry Points in Subprograms
EQUIVALENCE

Array Association
A nonpointer array occupies a sequence of contiguous storage sequences, one for each array element, in array element order.

Two or more arrays are associated when each one is associated with the same storage location. They are partially associated when part of the storage associated with one array is the same as part or all of the storage associated with another array.

If arrays with different data types are associated (or partially associated) with the same storage location, and the value of one array is defined (for example, by assignment), the value of the other array becomes undefined. This happens because an element of an array is considered defined only if the storage associated with it contains data of the same type as the array name.

An array element, array section, or whole array is defined by a DATA statement before program execution. (The array properties must be declared in a previous specification statement.) During program execution, array elements and sections are defined by an assignment or input statement, and entire arrays are defined by input statements.

Arrays
DATA
Array Elements for details on array element order

Inheritance Association

_Inheritance association_ occurs between components of a parent component and components inherited by type extension into an extended type.

This association is not affected by the accessibility of the inherited components.

Storage Association
Pointer Association
Deleted and Obsolescent Language Features

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 and Fortran 2003 deleted some Fortran 90 features, and identified some Fortran 90 language features to be obsolescent. Fortran 2008 has also identified some earlier standard language features to be obsolescent. Features considered obsolescent may be removed from future revisions of the Fortran Standard.

To have these features flagged, you can specify compiler option stand.

NOTE
Intel® Fortran fully supports features identified as deleted from or obsolescent in the Fortran Standard.

See Also
stand

Deleted Language Features in Fortran 2003 and Fortran 95

Some language features, considered redundant in FORTRAN 77, are not included in Fortran 95 or Fortran 2003. However, they are still fully supported by Intel® Fortran.

In the examples below, both forms are supported by Intel® Fortran, but the Fortran 2003 Standard only supports the second form:

- ASSIGN and assigned GO TO statements

The ASSIGN statement, when assigning a label for use with the assigned GO TO statement, can be replaced by assigning the integer value of the label to an integer variable; the assigned GO TO statement can then be replaced by an IF statement that tests the integer variable for various values and then goes to the label that represents that value. For example, replace:

```
ASSIGN 10 TO J
...
ASSIGN 20 TO J
...
GO TO J
```

with:

```
J = 10
...
J = 20
...
IF (J .EQ. 10) THEN
    GO TO 10
ELSE IF (J .EQ. 20) THEN
    GO TO 20
END IF
```

- Assigned FORMAT specifier
The assigned FORMAT specifier sets an integer variable to the label of a FORMAT statement and then the integer variable is used in an I/O statement instead of the FORMAT label. You can replace the integer variable with a character variable whose value is the contents of the FORMAT statement, and then use the character variable in the I/O statement as the format. For example, replace:

```fortran
ASSIGN 1000 TO IFMT
...
WRITE (6, IFMT) X, Y
...
1000     FORMAT (2E10.2)
```

with:

```fortran
CHARACTER(20) :: IFMT = "(2E10.2)"
...
WRITE (6, IFMT) X, Y
```

- **Branching to an END IF statement from outside its IF block**

The END IF statement can no longer be a target of a GO TO statement that is outside the IF block that ends with that END IF statement. Use a CONTINUE statement after the END IF as the target of the GO TO statement. For example, replace:

```fortran
IF ...
   GO TO 100
ELSE IF ...
100  END IF
```

with:

```fortran
IF ...
   GO TO 100
ELSE IF ...
END IF
100  CONTINUE
```

- **H edit descriptor**

Replace the H edit descriptor of the form \(n\)Hcharacters with "characters". Remember to double any quotes or apostrophes in the string characters.

- **PAUSE statement**

The PAUSE statement displays a character string on the standard output device and then suspends program execution until any character is typed on the standard input device. You can replace the PAUSE statement with a WRITE statement followed by a READ statement. For example, replace:

```fortran
PAUSE " don't forget to buy milk"
```

with:

```fortran
WRITE (6, ") " don't forget to buy milk"
READ (5, ") ! no io-list is necessary, the input is ignored
```

- **Real and double precision DO control variables and DO loop control expressions**

REAL variables of any KIND can no longer be used as DO loop control variables and expressions. You can replace such DO loops with the appropriate DO WHILE loop that explicitly initializes, increments, and tests the REAL variable. For example, replace:

```fortran
DO X = 0.1, 0.5, 0.01
...
END DO
```

with:

```fortran
X = 0.1
DO WHILE (X .LE. 0.5)
   ...
   X = X + 0.01
END DO
```

- **Vertical format control**
Formatted output to certain printing output units used to result in the first character of each record being interpreted as controlling vertical spacing on the unit. There is no standard way to detect whether output to such a unit should result in such vertical format control and no way to specify that it should be applied. The effect can be achieved by post-processing a formatted file after it is created to interpret the first character as some form of control character. This is left to the user.

Intel Fortran flags these features if you specify compiler option stand.

See Also
Obsolescent Language Features in the Fortran Standard
stand compiler option

Obsolescent Language Features in the Fortran Standard
Some language features, considered redundant in Fortran 90 are identified as obsolescent in Fortran 2008, Fortran 2003 and Fortran 95.
Intel® Fortran flags these features if you specify compiler option stand.
Other methods are suggested to achieve the functionality of the following obsolescent features:

- ENTRY statement
  To replace this functionality, it is recommended that you use multiple module procedures that can access shared data in the module.
- Alternate returns (labels in an argument list)
  To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program use a CASE construct to test the value and perform operations.
- Arithmetic IF
  To replace this functionality, it is recommended that you use an IF statement or construct.
- Assumed-length character functions
  To replace this functionality, it is recommended that you use one of the following:
  - An automatic character-length function, where the length of the function result is declared in a specification expression
  - A subroutine whose arguments correspond to the function result and the function arguments
  Dummy arguments of a function can still have assumed character length; this feature is not obsolescent.
- CHARACTER*(*) form of CHARACTER declaration
  To replace this functionality, it is recommended that you use the Fortran 90 forms of specifying a length selector in CHARACTER declarations (see Declaration Statements for Character Types).
- Computed GO TO statement
  To replace this functionality, it is recommended that you use a CASE construct.
- DATA statements among executable statements
  This functionality has been included since FORTRAN 66, but is considered to be a potential source of errors.
- Fixed source form
  Newer methods of entering data have made this source form obsolescent and error-prone.
  The recommended method for coding is to use free source form.
- Shared DO termination and termination on a statement other than END DO or CONTINUE
  To replace this functionality, it is recommended that you use an END DO statement or a CONTINUE statement.
- Statement functions
  To replace this functionality, it is recommended that you use an internal function.
Additional Language Features

Overview

To facilitate compatibility with older versions of Fortran, Intel® Fortran provides the following additional language features:

- The DEFINE FILE statement
- The ENCODE and DECODE statements
- The FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL Statement
- An alternative syntax for the PARAMETER statement
- The VIRTUAL statement
- An alternative syntax for octal and hexadecimal constants
- An alternative syntax for a record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

These language features are particularly useful in porting older Fortran programs to Standard Fortran. However, you should avoid using them in new programs on these systems, and in new programs for which portability to other Standard Fortran implementations is important.

FORTRAN-66 Interpretation of the EXTERNAL Statement

If you specify compiler option f66, the EXTERNAL statement is interpreted in the way that was specified by the FORTRAN IV (FORTRAN-66) standard. This interpretation became incompatible with FORTRAN 77 and later revisions of the Fortran standard.

The FORTRAN-66 interpretation of the EXTERNAL statement combines the functionality of the INTRINSIC statement with that of the EXTERNAL statement.

This lets you use subprograms as arguments to other subprograms. The subprograms to be used as arguments can be either user-supplied procedures or Fortran intrinsic procedures.

The FORTRAN-66 EXTERNAL statement takes the following form:

EXTERNAL [\*]v [\*, [\*]v] ...

* Specifies that a user-supplied external procedure is to be used instead of a Fortran intrinsic procedure having the same name. This modifier is not standard FORTRAN-66, but was an extension in some FORTRAN-66 compilers, and provides the FORTRAN 77 meaning of EXTERNAL where required.

v Is the name of a subprogram or the name of a dummy argument associated with the name of a subprogram.
Description
The FORTRAN-66 EXTERNAL statement declares that each name in its list is an external procedure name. Such a name can then be used as an actual argument to a subprogram, which then can use the corresponding dummy argument in a function reference or CALL statement.

However, when used as an argument, a complete function reference represents a value, not a subprogram name; for example, SQRT(B) in CALL SUBR(A, SQRT(B), C). Therefore, it does not need to be defined in an EXTERNAL statement. Note that the incomplete reference SQRT would need to be defined in an EXTERNAL statement.

Examples
The following example, when compiled with compiler option f66, shows the FORTRAN-66 EXTERNAL statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprograms</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL SIN, COS, &quot;TAN&quot;, SINDEG</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td></td>
<td>Y = F(X)</td>
</tr>
<tr>
<td></td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, SIN, SINE)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, COS, COSINE)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, TAN, TANGNT)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>CALL TRIG(ANGLED, SINDEG, SINE)</td>
<td></td>
</tr>
</tbody>
</table>

The CALL statements pass the name of a function to the subroutine TRIG. The function reference F(X) subsequently invokes the function in the second statement of TRIG. Depending on which CALL statement invoked TRIG, the second statement is equivalent to one of the following:

- Y = SIN(X)
- Y = COS(X)
- Y = TAN(X)
- Y = SINDEG(X)

The functions SIN and COS are examples of trigonometric functions supplied in the Fortran intrinsic procedure library. The function TAN is also supplied in the library, but the asterisk (*) in the EXTERNAL statement specifies that the user-supplied function be used, instead of the intrinsic function. The function SINDEG is also a user-supplied function. Because no library function has the same name, no asterisk is required.

See Also
f66

Alternative Syntax for the PARAMETER Statement
The PARAMETER statement discussed here is similar to the one discussed in PARAMETER; they both assign a name to a constant. However, this PARAMETER statement differs from the other one in the following ways:

- Its list is not bounded with parentheses.
- The form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

This PARAMETER statement takes the following form:
PARAMETER $c = expr [, c = expr] ...$

$c$ Is the name of the constant.

$expr$ Is an initialization expression. It can be of any data type.

**Description**

Each name $c$ becomes a constant and is defined as the value of expression $expr$. Once a name is defined as a constant, it can appear in any position in which a constant is allowed. The effect is the same as if the constant were written there instead of the name.

The name of a constant cannot appear as part of another constant, except as the real or imaginary part of a complex constant. For example:

| PARAMETER I=3           | ! Not allowed |
| PARAMETER M=I.25        | ! Not allowed |
| PARAMETER N=(1.703, I)  | ! Allowed    |

The name used in the PARAMETER statement identifies only the name's corresponding constant in that program unit. Such a name can be defined only once in PARAMETER statements within the same program unit.

The name of a constant assumes the data type of its corresponding constant expression. The data type of a parameter constant cannot be specified in a type declaration statement. Nor does the initial letter of the constant's name implicitly affect its data type.

**Examples**

The following are valid examples of this form of the PARAMETER statement:

| PARAMETER PI=3.1415927, DPI=3.141592653589793238D0 |
| PARAMETER PIOV2=PI/2, DPIOV2=DPI/2                   |
| PARAMETER FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS' |

**See Also**

PARAMETER for details on compile-time constant expressions

**Alternative Syntax for Binary, Octal, and Hexadecimal Constants**

In Intel® Fortran, you can use an alternative syntax for binary, octal, and hexadecimal constants. The following table shows the alternative syntax and equivalents:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Alternative Syntax</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>'0..1'B</td>
<td>B'0..1'</td>
</tr>
<tr>
<td>Octal</td>
<td>'0..7'O</td>
<td>O'0..7'</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>'0..F'X</td>
<td>Z'0..F'</td>
</tr>
<tr>
<td></td>
<td>X'0..F'</td>
<td></td>
</tr>
</tbody>
</table>

You can use a quotation mark (") in place of an apostrophe in all the above syntax forms.

For information on the # syntax for integers not in base 10, see Integer Constants.

**See Also**

Binary Constants
Octal Constants
Hexadecimal Constants
**Alternative Syntax for a Record Specifier**

In Intel® Fortran, you can specify the following form for a record specifier in an I/O control list:

'r

r

Is a numeric expression with a value that represents the position of the record to be accessed using direct access I/O.

The value must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file. If necessary, a record number is converted to integer data type before being used.

If this nonkeyword form is used in an I/O control list, it must immediately follow the nonkeyword form of the io-unit specifier.

**Alternative Syntax for the DELETE Statement**

In Intel® Fortran, you can specify the following form of the DELETE statement when deleting records from a relative file:

DELETE (io-unit 'r [, ERR=label] [, IOSTAT=i-var])

io-unit

Is the number of the logical unit containing the record to be deleted.

r

Is the positional number of the record to be deleted.

label

Is the label of an executable statement that receives control if an error condition occurs.

i-var

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

This form deletes the direct access record specified by r.

**See Also**

DELETE

**Alternative Form for Namelist External Records**

In Intel® Fortran, you can use the following form for an external record:

$group-nameobject = value [object = value] ...$[END]

group-name

Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit.

object

Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks, but it can be preceded or followed by blanks.

value

Is a null value, a constant (or list of constants), a repetition of constants in the form r*c, or a repetition of null values in the form r*.

If more than one object=value or more than one value is specified, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks.

Rules for Namelist Sequential READ Statement for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Record Structures

The record structure was defined in earlier versions of Intel® Fortran as a language extension. It is still supported, although its functionality has been replaced by Standard Fortran derived data types. Record structures in existing code can be easily converted to Standard Fortran derived type structures for portability, but can also be left in their old form. In most cases, an Intel Fortran record and a Standard Fortran derived type can be used interchangeably.

Intel Fortran record structures are similar to Standard Fortran derived types.

A record structure is an aggregate entity containing one or more elements. (Record elements are also called fields or components.) You can use records when you need to declare and operate on multi-field data structures in your programs.

Creating a record is a two-step process:
1. You must define the form of the record with a multistatement structure declaration.
2. You must use a RECORD statement to declare the record as an entity with a name. (More than one RECORD statement can refer to a given structure.)

Examples

Intel Fortran record structures, using only intrinsic types, easily convert to Standard Fortran derived types. The conversion can be as simple as replacing the keyword STRUCTURE with TYPE and removing slash (/) marks. The following shows an example conversion:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_name/</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*25 last_name</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*15 first_name</td>
<td></td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td></td>
</tr>
<tr>
<td>STRUCTURE /employee_addr/</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*20 street_name</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) street_number</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) apt_number</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*20 city</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*2 state</td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) zip</td>
<td></td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td></td>
</tr>
<tr>
<td>TYPE employee_name</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*25 last_name</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*15 first_name</td>
<td></td>
</tr>
<tr>
<td>END TYPE</td>
<td></td>
</tr>
<tr>
<td>TYPE employee_addr</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*20 street_name</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) street_number</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) apt_number</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*20 city</td>
<td></td>
</tr>
<tr>
<td>CHARACTER*2 state</td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) zip</td>
<td></td>
</tr>
<tr>
<td>END TYPE</td>
<td></td>
</tr>
</tbody>
</table>

The record structures can be used as subordinate record variables within another record, such as the employee_data record. The equivalent Standard Fortran derived type would use the derived-type objects as components in a similar manner, as shown below:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_data/</td>
<td></td>
</tr>
<tr>
<td>RECORD /employee_name/ name</td>
<td></td>
</tr>
<tr>
<td>RECORD /employee_addr/ addr</td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) telephone</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) date_of_birth</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) date_of_hire</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) social_security(3)</td>
<td></td>
</tr>
<tr>
<td>TYPE employee_data</td>
<td></td>
</tr>
<tr>
<td>TYPE (employee_name) name</td>
<td></td>
</tr>
<tr>
<td>TYPE (employee_addr) addr</td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) telephone</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) date_of_birth</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) date_of_hire</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2) social_security(3)</td>
<td></td>
</tr>
</tbody>
</table>

**Record Structure**

<table>
<thead>
<tr>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(2) married</td>
</tr>
<tr>
<td>INTEGER(2) dependents</td>
</tr>
<tr>
<td>END STRUCTURE</td>
</tr>
<tr>
<td>LOGICAL(2) married</td>
</tr>
<tr>
<td>INTEGER(2) dependents</td>
</tr>
<tr>
<td>END TYPE</td>
</tr>
</tbody>
</table>

**Structure Declarations**

A *structure declaration* defines the field names, types of data within fields, and order and alignment of fields within a record. Fields and structures can be initialized, but records cannot be initialized. For more information, see STRUCTURE.

Type Declarations within Record Structures

Substructure Declarations

UNION and END UNION

**Type Declarations within Record Structures**

The syntax of a type declaration within a record structure is identical to that of a normal Fortran type statement.

The following rules and behavior apply to type declarations in record structures:

- %FILL can be specified in place of a field name to leave space in a record for purposes such as alignment. This creates an unnamed field.
  
  %FILL can have an array specification; for example:
  
  ```fortran
  INTEGER %FILL (2,2)
  ```

  Unnamed fields cannot be initialized. For example, the following statement is invalid and generates an error message:
  
  ```fortran
  INTEGER %FILL /1980/
  ```

- Initial values can be supplied in field declaration statements. Unnamed fields cannot be initialized; they are always undefined.
- Field names must always be given explicit data types. The IMPLICIT statement does not affect field declarations.
- Any required array dimensions must be specified in the field declaration statements. DIMENSION statements cannot be used to define field names.
- Adjustable or assumed sized arrays and assumed-length CHARACTER declarations are not allowed in field declarations.

**Substructure Declarations**

A field within a structure can itself be a structured item composed of other fields, other structures, or both. You can declare a substructure in two ways:

- By nesting structure declarations within other structure or union declarations (with the limitation that you cannot refer to a structure inside itself at any level of nesting).
  
  One or more field names must be defined in the STRUCTURE statement for the substructure, because all fields in a structure must be named. In this case, the substructure is being used as a field within a structure or union.

  Field names within the same declaration nesting level must be unique, but an inner structure declaration can include field names used in an outer structure declaration without conflict.

- By using a RECORD statement that specifies another previously defined record structure, thereby including it in the structure being declared.
References to Record Fields

References to record fields must correspond to the kind of field being referenced. Aggregate field references refer to composite structures (and substructures). Scalar field references refer to singular data items, such as variables.

An operation on a record can involve one or more fields.

Record field references take one of the following forms:

**Aggregate Field Reference:**

```
record-name [.aggregate-field-name] ...
```

**Scalar Field Reference:**

```
record-name [.aggregate-field-name] ... .scalar-field-name
```

- `record-name` is the name used in a RECORD statement to identify a record.
- `aggregate-field-name` is the name of a field that is a substructure (a record or a nested structure declaration) within the record structure identified by the record name.
- `scalar-field-name` is the name of a data item (having a data type) defined within a structure declaration.

Description

Records and record fields cannot be used in DATA statements, but individual fields can be initialized in the STRUCTURE definition.

An automatic array cannot be a record field.

A scalar field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names followed by the name of a scalar field. A scalar field reference refers to a single data item (having a data type) and can be treated like a normal reference to a Fortran variable or array element.

You can use scalar field references in statement functions and in executable statements. However, they cannot be used in COMMON, SAVE, NAMELIST, or EQUIVALENCE statements, or as the control variable in an indexed DO-loop.

Type conversion rules for scalar field references are the same as those for variables and array elements.

An aggregate field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names.

You can only assign an aggregate field to another aggregate field (record = record) if the records have the same structure. Intel® Fortran supports no other operations (such as arithmetic or comparison) on aggregate fields.

Intel Fortran requires qualification on all levels. While some languages allow omission of aggregate field names when there is no ambiguity as to which field is intended, Intel Fortran requires all aggregate field names to be included in references.

You can use aggregate field references in unformatted I/O statements; one I/O record is written no matter how many aggregate and array name references appear in the I/O list. You cannot use aggregate field references in formatted, namelist, and list-directed I/O statements.
You can use aggregate field references as actual arguments and record dummy arguments. The declaration of the dummy record in the subprogram must match the form of the aggregate field reference passed by the calling program unit; each structure must have the same number and types of fields in the same order. The order of map fields within a union declaration is irrelevant.

Records are passed by reference. Aggregate field references are treated like normal variables. You can use adjustable arrays in RECORD statements that are used as dummy arguments.

Examples

The following examples show record and field references. Consider the following structure declarations:

Structure DATE:

```fortran
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
STRUCTURE
```

Structure APPOINTMENT:

```fortran
STRUCTURE /APPOINTMENT/
  RECORD /DATE/      APP_DATE
  STRUCTURE /TIME/   APP_TIME(2)
    INTEGER*1 HOUR, MINUTE
  END STRUCTURE
  CHARACTER*20     APP_MEMO(4)
  LOGICAL*1        APP_FLAG
END STRUCTURE
```

The following RECORD statement creates a variable named NEXT_APP and a 10-element array named APP_LIST. Both the variable and each element of the array take the form of the structure APPOINTMENT.

```fortran
RECORD /APPOINTMENT/    NEXT_APP, APP_LIST(10)
```

Each of the following examples of record and field references are derived from the previous structure declarations and RECORD statement:

**Aggregate Field References**

- The record NEXT_APP:
  ```fortran
  NEXT_APP
  ```

- The field APP_DATE, a 4-byte array field in the record array APP_LIST(3):
  ```fortran
  APP_LIST(3).APP_DATE
  ```

**Scalar Field References**

- The field APP_FLAG, a LOGICAL field of the record NEXT_APP:
  ```fortran
  NEXT_APP.APP_FLAG
  ```

- The first character of APP_MEMO(1), a CHARACTER*20 field of the record NEXT_APP:
  ```fortran
  NEXT_APP.APP_MEMO(1)(1:1)
  ```

**NOTE**

Because periods are used in record references to separate fields, you should avoid using relational operators (.EQ., .XOR.), logical constants (.TRUE., .FALSE.), and logical expressions (.AND., .NOT., .OR.) as field names in structure declarations. Dots can also be used instead of % to separate fields of a derived type.

Consider the following example:

```fortran
module mod
  type T1_t
    integer :: i
  end type
end module
```
end type T1_t
type T2_t
  type (T1_t) :: eq
  integer    :: i
end type T2_t

interface operator (.eq.)
  module procedure eq_func
end interface operator (.eq.)
contains
  function eq_func(t2, i) result (rslt)
    type(T2_t), intent (in) :: t2
    integer,    intent (in) :: i
    rslt = t2%eq%i + i
  end function eq_func
end module mod

use mod
type (T2_t) :: t2
integer    :: i
   t2%eq%i = 0
t2%i     = -10
   i       = -10
   print *, t2.eq.i, (t2).eq.i
end

In this case, the reference "t2.eq.i" prints 0. The reference "(t2).eq.i" will invoke eq_func and will print -10.

- [STRUCTURE and END STRUCTURE](#) for details on structure declarations
- [UNION and END UNION](#) for details on UNION and MAP statements

**Aggregate Assignment**

For aggregate assignment statements, the variable and expression must have the same structure as the aggregate they reference.

The aggregate assignment statement assigns the value of each field of the aggregate on the right of an equal sign to the corresponding field of the aggregate on the left. Both aggregates must be declared with the same structure.

**Examples**

The following example shows valid aggregate assignments:

```fortran
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

RECORD /DATE/ TODAY, THIS_WEEK(7)
STRUCTURE /APPOINTMENT/
  ...
  RECORD /DATE/ APP_DATE
END STRUCTURE

RECORD /APPOINTMENT/ MEETING

DO I = 1,7
  CALL GET_DATE (TODAY)
  THIS_WEEK(I) = TODAY
```

...
THIS_WEEK(I).DAY = TODAY.DAY + 1
END DO
MEETING.APP_DATE = TODAY
Additional Character Sets

Additional Character Sets Overview
This topic contains information about the following additional character sets:

- Character and Key Code Charts for Windows* OS
- The ASCII Character Set for Linux* OS and OS X*

See Also
Character Sets for details on the Standard Fortran character set

Character and Key Code Charts for Windows*
This topic contains the ASCII and ANSI character code charts, and the Key code charts that are available on Windows* OS.

ASCII Character Codes for Windows*
The ASCII character code charts contain the decimal and hexadecimal values of the extended ASCII (American Standards Committee for Information Interchange) character set. The extended character set includes the ASCII character set (Chart 1) and 128 other characters for graphics and line drawing (Chart 2), often called the "IBM* character set".

## ANSI Character Codes for Windows*

The ANSI character code chart lists the extended character set of most of the programs used by Windows* operating systems. The codes of the ANSI (American National Standards Institute) character set from 32 through 126 are displayable characters from the ASCII character set. The ANSI characters displayed as solid blocks are undefined characters and may appear differently on output devices.
Key Codes for Windows*

Some keys, such as function keys, cursor keys, and ALT+KEY combinations, have no ASCII code. When a
key is pressed, a microprocessor within the keyboard generates an "extended scan code" of two bytes.

The first (low-order) byte contains the ASCII code, if any. The second (high-order) byte has the scan code--a
unique code generated by the keyboard when a key is either pressed or released. Because the extended scan
code is more extensive than the standard ASCII code, programs can use it to identify keys which do not have
an ASCII code.

For more details on key codes, see:
- Key Codes Chart 1
- Key Codes Chart 2

### ASCII Character Set for Linux* and OS X*

This topic describes the ASCII character set that is available on Linux* and OS X* operating systems. The ASCII character set contains characters with decimal values 0 through 127. The first half of each of the numbered columns identifies the character as you would enter it on a terminal or as you would see it on a printer. Except for SP and HT, the characters with names are nonprintable. In the figure, the characters with names are defined as follows:

- **NUL**: Null
- **SOH**: Start of Heading
- **STX**: Start of Text
- **ETX**: End of Text
- **EOT**: End of Transmission
- **ENQ**: Enquiry

For more details, please refer to the ASCII character set chart provided.

<td>DEL</td>
<td>Delete</td>
</tr>
</tbody>
</table>

The remaining half of each column identifies the character by the binary value of the byte; the value is stated in three radices—octal, decimal, and hexadecimal. For example, the uppercase letter A has, under ASCII conventions, a storage value of hexadecimal 41 (a bit configuration of 01000001), equivalent to 101 in octal notation and 65 in decimal notation.

**ASCII Character Set (L*X, M*X)**
Data Representation Models

Several of the numeric intrinsic functions are defined by a model set for integers (for each intrinsic kind used) and reals (for each real kind used). The bit functions are defined by a model set for bits (binary digits).

The following intrinsic functions provide information on the data representation models:

<table>
<thead>
<tr>
<th>Intrinsic function</th>
<th>Model</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Bit</td>
<td>The number of bits (s) in the bit model</td>
</tr>

<td>The reciprocal of the relative spacing near the argument</td>
</tr>
<tr>
<td>SCALE</td>
<td>Real</td>
<td>The value of the exponent part (of the model for the argument) changed by a specified value</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>Real</td>
<td>The value of the exponent part (of the model for the argument) set to a specified value</td>
</tr>
<tr>
<td>Intrinsic function</td>
<td>Model</td>
<td>Value returned</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------</td>
<td>----------------------------------------------------</td>
</tr>
<tr>
<td>SPACING</td>
<td>Real</td>
<td>The value of the absolute spacing of model numbers near the argument</td>
</tr>
<tr>
<td>TINY</td>
<td>Real</td>
<td>The smallest positive number in the model for the argument</td>
</tr>
</tbody>
</table>

For more information on the range of values for each data type (and kind), see the Data and I/O in the Compiler Reference.

This appendix discusses the following topics:

- The model for Integer Data
- The model for Real Data
- The model for Bit Data

### Model for Integer Data

In general, the model set for integers is defined as follows:

\[
i = s \times \sum_{k=1}^{q} w_k \times r^{k-1}
\]

The following values apply to this model set:

- \( i \) is the integer value.
- \( s \) is the sign (either +1 or -1).
- \( q \) is the number of digits (a positive integer).
- \( r \) is the radix (an integer greater than 1).
- \( w_k \) is a nonnegative number less than \( r \).

The model for INTEGER(4) follows:

\[
i = s \times \sum_{k=1}^{31} w_k \times 2^{k-1}
\]

The following example shows the general integer model for \( i = -20 \) using a base \( r \) of 2:

\[
i = (-1) \times (0 \times 2^0 + 0 \times 2^1 + 1 \times 2^2 + 0 \times 2^3 + 1 \times 2^4)
\]

\[
i = (-1) \times (4 + 16)
\]

\[
i = -1 \times 20
\]

\[
i = -20
\]

### Model for Real Data

The model set for reals, in general, is defined as one of the following:

\[
x = 0
\]
The following values apply to this model set:

- \( x \) is the real value.
- \( s \) is the sign (either +1 or -1).
- \( b \) is the base (real radix; an integer greater than 1; \( b = 2 \) in Intel® Fortran).
- \( p \) is the number of mantissa digits (an integer greater than 1). The number of digits differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>Type</th>
<th>Digits</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE S_floating</td>
<td>24</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE T_floating</td>
<td>53</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE X_floating</td>
<td>113</td>
</tr>
</tbody>
</table>

- \( e \) is an integer in the range \( e_{\text{min}} \) to \( e_{\text{max}} \) inclusive. This range differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>Type</th>
<th>( e_{\text{min}} )</th>
<th>( e_{\text{max}} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE S_floating</td>
<td>-125</td>
<td>128</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE T_floating</td>
<td>-1021</td>
<td>1024</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE X_floating</td>
<td>-16381</td>
<td>16384</td>
</tr>
</tbody>
</table>

- \( f_k \) is a nonnegative number less than \( b \) (\( f_1 \) is also nonzero).

For \( x = 0 \), its exponent \( e \) and digits \( f_k \) are defined to be zero.

The model set for single-precision real (REAL(4)) is defined as one of the following:

\[
x = 0
\]

\[
x = s \times 2^e \times \left( 1/2 + \sum_{k=2}^{24} f_k \times 2^{-k} \right), -125 \leq e \leq 128
\]

The following example shows the general real model for \( x = 20.0 \) using a base (\( b \)) of 2:

\[
x = 1 \times 2^5 \times (1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3})
\]

\[
x = 1 \times 32 \times (0.5 + 0.125)
\]

\[
x = 32 \times (0.625)
\]

\[
x = 20.0
\]

**Model for Bit Data**

The model set for bits (binary digits) interprets a binary digit \( w \) located at position \( k \) of a nonnegative integer scalar object based on a model nonnegative integer defined by the following:

\[
j = \sum_{k=0}^{s-1} w_k \times 2^k
\]
The following values apply to this model set:

- $j$ is the integer value.
- $s$ is the number of bits (the length of a sequence of bits).
- $w_k$ is a bit value of 0 or 1. This defines a sequence of bits $w_{s-1}...w_0$, with $w_{s-1}$ the leftmost bit and $w_0$ the rightmost bit. The positions of bits in the sequence are numbered from right to left, with the position of the rightmost bit being zero.

The interpretation of a negative integer as a sequence of bits is processor dependent.

The inquiry function BIT_SIZE provides the value of the parameter $s$ of the model.

The following example shows the bit model for $j = 1001$ (integer 9) using a bit number ($s$) of 4:

```
1 0 0 1
↓ ↓ ↓ ↓
ws−1 ws−2 ws−1 w0
```

\[
\begin{align*}
j &= (w_0 \times 2^0) + (w_1 \times 2^1) + (w_2 \times 2^2) + (w_3 \times 2^3) \\
&= 1 + 0 + 0 + 8 \\
&= 9
\end{align*}
\]

**See Also**

BIT_SIZE

**Bit Sequence Comparisons**

When bit sequences of unequal length are compared, the shorter sequence is padded with zero bits on the left, so that it is the same length as the longer sequence.

Bit sequences are compared from left to right, one bit at a time, until unequal bits are found, or until all bits have been compared and found to be equal.

If unequal bits are found, the sequence with zero in the unequal position is considered to be less than the sequence with one in the unequal position. Otherwise the sequences are considered to be equal.
Module Routines Overview

Intel® Fortran provides library modules containing the following routines:

- Routines that help you write programs for graphics, QuickWin, and other applications (in modules IFQWIN, IFLOGM, and IFCORE):
  - QuickWin routines (W*S)
  - Graphics routines (W*S)
  - Dialog routines (W*S)
  - Miscellaneous run-time routines
- Routines systems that help you write programs using Component Object Model (COM) and Automation servers (in modules IFCOM and IFAUTO):
  - COM routines (W*S)
  - AUTO routines (W*S)
- Portability routines that help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows* systems (in module IFPORT).
- National Language Support routines that help you write foreign language programs for international markets (in module IFNLS). These routines are only available on Windows* systems.
- POSIX routines that help you write Fortran programs that comply with the POSIX* Standard (in module IFPOSIX).
- ESTABLISHQQ lets you specify a routine to handle Run-Time Library (RTL) errors (in module IFESTABLISH).
- FOR__SET_FTN_ALLOC lets you specify a user-defined routine to dynamically allocate commons. The caller of FOR__SET_FTN_ALLOC must include module IFCOMMONALLOC.

When you include the statement USE module-name in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement.

Note that routines that are only available on Windows, including routines that are labeled as (W*S), are not available on Intel® MIC Architecture.

USE

Overview of NLS and MCBS Routines (Windows* OS)

The NLS and MCBS routines are only available on Windows* systems. These library routines for handling extended and multibyte character sets are divided into three categories:

- Locale Setting and Inquiry routines to set locales (local code sets) and inquire about their current settings
  - At program startup, the current language and country setting is retrieved from the operating system. The user can change this setting through the Control Panel Regional Settings icon. The current codepage is also retrieved from the system.
  - There is a system default console codepage and a system default Windows codepage. Console programs retrieve the system console codepage, while Windows programs (including QuickWin applications) retrieve the system Windows codepage.
The NLS Library provides routines to determine the current locale (local code set), to return parameters of the current locale, to provide a list of all the system supported locales, and to set the locale to another language, country and/or codepage. These routines are summarized in the following table. Note that the locales and codepages set with these routines affect only the program or console that calls the routine. They do not change the system defaults or affect other programs or consoles.

- **NLS Formatting routines to format dates, currency, and numbers**

You can set time, date, currency and number formats from the Control Panel, by clicking on the Regional Settings icon. The NLS Library also provides formatting routines for the current locale. These routines are summarized in the following table. These routines return strings in the current codepage, set by default at program start or by NLSSetLocale.

All the formatting routines return the number of bytes in the formatted string (not the number of characters, which can vary if multibyte characters are included). If the output string is longer than the formatted string, the output string is blank padded. If the output string is shorter than the formatted string, an error occurs, NLS$ErrorInsufficientBuffer is returned, and nothing is written to the output string.

- **Multibyte Character Set (MBCS) routines for using multi-byte characters**

Examples of multibyte character sets are Japanese, Korean, and Chinese.

- The MBCS inquiry routines provide information on the maximum length of multibyte characters, the length, number and position of multibyte characters in strings, and whether a multibyte character is a leading or trailing byte. These routines are summarized in the following table. The NLS library provides a parameter, MBLenMax, defined in the NLS module to be the longest length (in bytes) of any character, in any codepage. This parameter can be useful in comparisons and tests. To determine the maximum character length of the current codepage, use the MBCurMax function.

- There are four MBCS conversion routines. Two convert Japan Industry Standard (JIS) characters to Microsoft Kanji characters or vice versa. Two convert between a codepage multibyte character string and a Unicode string.

- There are several MBCS Fortran equivalent routines. They are the exact equivalents of Fortran intrinsic routines except that the MBCS equivalents allow character strings to contain multibyte characters.

**Examples**

The following example uses Locale Setting and Inquiry routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str

strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str ! prints Monday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints Tuesday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str ! prints Wednesday

! Change locale to Spanish, Mexico
status = NLSSetLocale("Spanish", "Mexico")
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str ! prints lunes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints martes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str ! prints miércoles
END
```

The following example uses NLS Formatting routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str

strlen = NLSFormatTime(str)
print *, str ! prints 11:42:24 AM
strlen = NLSFormatDate(str, flags= NLS$LongDate)
print *, str ! prints Friday, July 14, 2000
```

Intel® Fortran Compiler 16.0 User and Reference Guide
37
status =
strlen =
print *,
print *,

NLSSetLocale ("Spanish", "Mexico")
NLSFormatTime(str)
str
! prints
11:42:24
str
! prints viernes 14 de julio de 2000

The following example uses Multibyte Character Set (MBCS) inquiry routines:

USE IFNLS
CHARACTER(4) str
INTEGER status
status = NLSSetLocale ("Japan")
str = " ·, " ¿"
PRINT '(1X,''String by char = '',\)'
DO i = 1, len(str)
PRINT '(A2,\)',str(i:i)
END DO
PRINT '(/,1X,''MBLead = '',\)'
DO i = 1, len(str)
PRINT '(L2,\)',mblead(str(i:i))
END DO
PRINT '(/,1X,''String as whole = '',A,\)',str
PRINT '(/,1X,''MBStrLead = '',\)'
DO i = 1, len(str)
PRINT '(L1,\)',MBStrLead(str,i)
END DO
END
This code produces the following output for str = · , " ¿

The following example uses Multibyte Character Set (MBCS) Fortran equivalent routines:

USE IFNLS
INTEGER(4) i, len(7), infotype(7)
CHARACTER(10) str(7)
LOGICAL(4) log4
data infotype / NLS$LI_SDAYNAME1, NLS$LI_SDAYNAME2, &
& NLS$LI_SDAYNAME3, NLS$LI_SDAYNAME4, &
& NLS$LI_SDAYNAME5, NLS$LI_SDAYNAME6, &
& NLS$LI_SDAYNAME7 /
WRITE(*,*) 'NLSGetLocaleInfo'
WRITE(*,*) '----------------'
WRITE(*,*) ' '
WRITE(*,*) 'Getting the names of the days of the week...'
DO i = 1, 7
len(i) = NLSGetLocaleInfo(infotype(i), str(i))
WRITE(*, 11) 'len/str/hex = ', len(i), str(i), str(i)
END DO
11 FORMAT (1X, A, I2, 2X, A10, 2X, '[', Z20, ']')
WRITE(*,*) ' '
WRITE(*,*) 'Lexically comparing the names of the days...'
DO i = 1, 6
log4 = MBLGE(str(i), str(i+1), NLS$IgnoreCase)
WRITE(*, 12) 'Is day ', i, ' GT day ', i+1, '? Answer = ', log4
END DO
12 FORMAT (1X, A, I1, A, I1, A, L1)

1061


This code produces the following output when the locale is Japan:

```
WRITE(*,*) ' '
WRITE(*,*) 'Done.'
END
```

```
NLSGetLocaleInfo
----------

Getting the names of the days of the week...
len/str/hex = 6 月曜日 [8C8E976A93FA20202020]
len/str/hex = 6 火曜日 [88CE976A93FA20202020]
len/str/hex = 6 水曜日 [9085976A93FA20202020]
len/str/hex = 6 木曜日 [96D976A93FA20202020]
len/str/hex = 6 金曜日 [88E0976A93FA20202020]
len/str/hex = 6 土曜日 [9379976A93FA20202020]
len/str/hex = 6 日曜日 [89FA976A93FA20202020]

Lexically comparing the names of the days...
Is day 1 GT day 2? Answer = T
Is day 2 GT day 3? Answer = F
Is day 3 GT day 4? Answer = F
Is day 4 GT day 5? Answer = T
Is day 5 GT day 6? Answer = F
Is day 6 GT day 7? Answer = F

Done.

**Standard Fortran Routines That Handle MBCS Characters (Windows* OS)**

This section describes Fortran routines that work as usual even if MBCS characters are included in strings. Because a space can never be a lead or tail byte, many routines that deal with spaces work as expected on strings containing MBCS characters. Such functions include:

- ADJUSTL (string)
- ADJUSTR (string)
- TRIM (string)

Some routines work with the computer collating sequence to return a character in a certain position in the sequence or the position in the sequence of a certain character. These functions are not dependent on a particular collating sequence. (You should note, however, that elsewhere in this manual the ASCII collating sequence is mentioned in reference to these functions.) Such functions use position and c values between 0 and 255 (inclusive) and include:

- ACHAR (position)
- CHAR (position[,kind ])
- IACHAR (c)
- ICHAR (c)
Because Fortran uses character lengths instead of NULLs to indicate the length of a string, some functions work solely from the length of the string, and not with the contents of the string. This function works as usual on strings containing MBCS characters, and include:

REPEAT (string, ncopies)

Overview of Portability Routines
This section summarizes portability routines.

Information Retrieval Routines
Information retrieval routines return information about system commands, command-line arguments, environment variables, and process or user information.

Group, user, and process ID are INTEGER(4) variables. Login name and host name are character variables. The functions GETGID and GETUID are provided for portability, but always return 1.

Process Control Routines
Process control routines control the operation of a process or subprocess. You can wait for a subprocess to complete with either SLEEP or ALARM, monitor its progress and send signals via KILL, and stop its execution with ABORT.

In spite of its name, KILL does not necessarily stop execution of a program. Rather, the routine signaled could include a handler routine that examines the signal and takes appropriate action depending on the code passed.

Note that when you use SYSTEM, commands are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The portability library does not include the FORK routine. On Linux* and OS X* systems, FORK creates a duplicate image of the parent process. Child and parent processes each have their own copies of resources, and become independent from one another.

On Windows* systems, you can create a child process (called a thread), but both parent and child processes share the same address space and share system resources. If you need to create another process, use the CreateProcessWindows API routine.

Numeric Values and Conversion Routines
Numeric values and conversion routines are available for calculating Bessel functions, data type conversion, and generating random numbers. Some of these functions have equivalents in Standard Fortran, in which case the standard Fortran routines should be used.

Data object conversion can be accomplished by using the INT intrinsic function instead of LONG or SHORT. The intrinsic subroutines RANDOM_NUMBER and RANDOM_SEED perform the same functions as the random number functions listed in the table showing numeric values and conversion routines.

Other bit manipulation functions such as AND, XOR, OR, LSHIFT, and RSHIFT are intrinsic functions. You do not need the IFPORT module to access them. Standard Fortran includes many bit operation routines, which are listed in the Bit Operation and Representation Routines table.

Input and Output Routines
The portability library contains routines that change file properties, read and write characters and buffers, and change the offset position in a file. These input and output routines can be used with standard Fortran input or output statements such as READ or WRITE on the same files, provided that you take into account the following:
• When used with direct files, after an fseek, getc, or putc operation, the record number is the number of the next whole record. Any subsequent normal Fortran I/O to that unit occurs at the next whole record. For example, if you seek to absolute location 1 of a file whose record length is 10, the nextrec returned by an inquire would be 2. If you seek to absolute location 10, nextrec would still return 2.
• On units with carriagecontrol='forTRAN' (the default), putc and fprintf characters are treated as carriage control characters if they appear in column 1.
• On sequentially formatted units, the C string "\n"c, which represents the carriage return/line feed escape sequence, is written as char(13) (carriage return) and char(10) (line feed), instead of just line feed, or char(10). On input, the sequence 13 followed by 10 is returned as just 10. (The length of character string "\n"c is 1 character, whose ASCII value, indicated by ichar("\n"c), is 10.)
• Reading and writing is in a raw form for direct files. Separators between records can be read and overwritten. Therefore, be careful if you continue using the file as a direct file.

I/O errors arising from the use of these routines result in an Intel® Fortran run-time error.

Some portability file I/O routines have equivalents in Standard Fortran. For example, you could use the access function to check a file specified by name for accessibility according to mode. It tests a file for read, write, or execute permission, as well as checking to see if the file exists. It works on the file attributes as they exist on disk, not as a program's open statement specifies them.

Instead of access, you can use the inquire statement with the action specifier to check for similar information. (The access function always returns 0 for read permission on FAT files, meaning that all files have read permission.)

Date and Time Routines
Various date and time routines are available to determine system time, or convert it to local time, Greenwich Mean Time, arrays of date and time elements, or an ASCII character string.

date and time are available as either a function or subroutine. Because of the name duplication, if your programs do not include the use ifport statement, each separately compiled program unit can use only one of these versions. For example, if a program calls the subroutine time once, it cannot also use time as a function.

Standard Fortran includes date and time intrinsic subroutines. For more information, see date_and_time.

Error Handling Routines
Error handling routines detect and report errors.

IERRNO error codes are analogous to errno on Linux* and OS X* systems. The IFPORT module provides parameter definitions for many of UNIX's errno names, found typically in errno.h on UNIX systems.

IERRNO is updated only when an error occurs. For example, if a call to the getc function results in an error, but two subsequent calls to putc succeed, a call to ierrno returns the error for the getc call. Examine IERRNO immediately after returning from one of the portability library routines. Other Standard Fortran routines might also change the value to an undefined value.

If your application uses multithreading, remember that IERRNO is set on a per-thread basis.

System, Drive, or Directory Control and Inquiry Routines
You can retrieve information about devices, directories, and files with the functions listed below. File names can be long file names or UNC file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications.

Standard Fortran provides the inquire statement, which returns detailed file information either by file name or unit number. Use inquire as an equivalent to fstat, lstat, or stat. Lstat and stat return the same information; stat is the preferred function.
Serial Port Routines (Windows* only)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on systems using IA-32 architecture.

Additional Routines
You can also use portability routines for program call and control, keyboards and speakers, file management, arrays, floating-point inquiry and control, IEEE* functionality, and other miscellaneous uses.

**NOTE**
On Windows* systems, all portability routines that take path names also accept long file names or UNC (Universal Naming Convention) file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications as well as MBCS (multiple-byte character set) characters.

Overview of Serial Port I/O Routines (Windows* OS)

Overview of Serial Port I/O Routines (Windows* OS)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on Windows* systems.

The programming model is much the same as a normal file except the user does a connect (SPORT_CONNECT, SPORT_CONNECT_EX) and release (SPORT_RELEASE) to the port instead of an open and close of a file.

Two types of read and write operations (as determined in a mode on the connect call) are provided:

- Read and write arbitrary data from/to the port using SPORT_READ_DATA and SPORT_WRITE_DATA.
- Read and writes line-terminated data using SPORT_READ_LINE and SPORT_WRITE_LINE.

Once any I/O operation has been requested on the port, an additional thread is started that keeps a read outstanding on the port so that data will not be missed.

The SPORT_SET_STATE, SPORT_SET_STATE_EX, and SPORT_SET_TIMEOUTS (W*32 W*64) routines allow you to set basic port parameters such as baud rate, stop bits, timeouts, and so on. Additionally, you can call SPORT_GET_HANDLE to return the Windows* handle to the port so that you can call Windows* Communication Functions to implement additional needs.

Calling the Serial Port I/O Routines
The SPORT_xxx routines are functions that return an error status:

- An error status of 0 (zero) indicates success
- Other values are Windows* error values that indicate an error

As described in the calling syntax, these routines require the following USE statement:

```
USE IFPORT
```

The USE IFPORT statement includes the routine definitions in the compilation. You may also need to add a USE IFWINITY statement to your program because some Windows* constants may be required that are typically defined in the IFWINITY module.

Many arguments are optional. If a constant is used where an argument is both input and output, a probe for writeability is done before the output. Thus, in many cases, a constant may be used without creating a temporary variable. It should be noted, however, that doing so may not be compatible with all Fortran implementations.
Run-Time Behavior of the Serial Port I/O Routines

To help ensure that data overruns do not occur, the SPORT_xxx run-time support creates a separate thread that maintains an outstanding read to the connected port. This thread is started when any read or write operation is performed to the port using the affiliated read/write routine. As such, port parameters must not be changed after you have started reading or writing to the port. Instead, you should set up the port parameters after connecting to the port and then leave them unchanged until after the port has been released.

If the parameters of the port must be changed more dynamically, use the SPORT_CANCEL_IO routine to ensure that no I/O is in progress. Additionally, that call will kill the helper thread so that it will automatically pick up the new, correct, parameters when it restarts during the next I/O operation.

Serial Port Usage

Depending upon the application, serial port programming can be very simple or very complex. The SPORT_xxx routines are intended to provide a level of support that will help the user implement simple applications as well as providing a foundation that can be used for more complex applications. Users needing to implement full serial port protocols (such as a PPP/SLIP implementation or some other complex protocol) should use the Windows* Communication Functions directly to achieve the detailed level of control needed in those cases. Simple tasks, such as communicating with a terminal or some other data collection device are well suited for implementations using the SPORT_xxx routines.

You should first familiarize yourself with the hardware connection to the serial device. Typical connections used today involve either a 9 pin/wire connector or a 25 pin/wire connector. Many cables do not implement all 9 or 25 connections in order to save on costs. For certain applications these subset cables may work just fine but others may require the full 9 or 25 connections. All cables will implement the Receive/SendData signals as well as the SignalGround. Without these signals, there can be no data transfer. There are two other categories of important signals:

- Signals used for flow control

  Flow control signals tell the device/computer on the other end of the cable that data may be sent or that they should wait. Typically, the RequestToSend/ClearToSend signals are used for this purpose. Other signals such as DataSetReady or DataTerminalReady may also be used. Make sure that the cable used implements all the signals required by your hardware/software solution. Special characters (normally as XON/XOFF) may also be used to control the flow of data instead of or in addition to the hardware signals. Check your specific application to see what cabling is needed.

- Signals that indicate status or state of a modem or phone connection.

  These signals may not be required if the connection between the computer and the device is direct and not through a modem. This signals typically convey information such as the state of the carrier (CarrierDetect) or if the phone line is ringing (Ring). Again, make sure the cable used implements all the signals required for your application.

After the correct physical connection has been set up the programmer must become familiar with the data protocol used to communicate with the remote device/system.

Many simple devices terminate parcels of data with a "record terminator" (often a carriage return or line feed character). Other devices may simply send data in fixed length packets or packets containing some sort of count information. The two types of I/O routines provided by the SPORT_xxx support (line oriented using SPORT_READ_LINE and SPORT_WRITE_LINE or transfer raw data using SPORT_READ_DATA and SPORT_WRITE_DATA) can handle these two types of data transfer. The programmer must become familiar with the particular application to determine which type of I/O is more appropriate to use.

The SPORT_xxx routines call Windows* routines. For example, the SPORT_SET_STATE routine calls the routine SetCommState, which uses the DCB Communications Structure.

**OpenMP® Fortran Routines Overview**

The following table summarizes the OpenMP® Fortran API run-time library routines you can use for directed parallel decomposition. These routines are all external procedures.

To use these routines, you must add a USE OMP_LIB statement to the program unit containing the routine.

Options that use OpenMP® are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

**Summary of OpenMP Fortran Parallel Routines**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_GET_DEFAULT_DEVICE</td>
<td>Gets the value of the internal control variable (ICV) named default-device-var, which determines the default device number.</td>
</tr>
<tr>
<td>OMP_GET_DEVICE_NUM</td>
<td>Gets the value of the internal control variable (ICV) named device-num-var, which determines the default device number.</td>
</tr>
<tr>
<td>OMP_GET_NUM_DEVICES</td>
<td>Gets the number of target devices.</td>
</tr>
<tr>
<td>OMP_GET_NUM_TEAMS</td>
<td>Gets the number of teams in the current parallel region.</td>
</tr>
<tr>
<td>OMP_GET_TEAM_NUM</td>
<td>Gets the team number of the calling thread.</td>
</tr>
<tr>
<td>OMP_SET_DEFAULT_DEVICE</td>
<td>Sets the value of the internal control variable (ICV) named default-device-var, which determines the default device number.</td>
</tr>
<tr>
<td>OMP_SET_DEVICE_NUM</td>
<td>Sets the value of the internal control variable (ICV) named device-num-var, which determines the default device number.</td>
</tr>
<tr>
<td>OMP_SET_NUM_THREADS</td>
<td>Sets the number of threads to use for the next parallel region.</td>
</tr>
<tr>
<td>OMP_GET_NUM_THREADS</td>
<td>Gets the number of threads currently in the team executing the parallel region from which the routine is called.</td>
</tr>
<tr>
<td>OMP_GET_MAX_THREADS</td>
<td>Gets the maximum value that can be returned by calls to the OMP_GET_NUM_THREADS function.</td>
</tr>
<tr>
<td>OMP_GET_THREAD_NUM</td>
<td>Gets the thread number, within the team, in the range from zero to OMP_GET_NUM_THREADS minus one.</td>
</tr>
<tr>
<td>OMP_GET_NUM_PROCS</td>
<td>Gets the number of processors that are available to the program.</td>
</tr>
<tr>
<td>OMP_IN_PARALLEL</td>
<td>Informs whether or not the current region is an active region (executing in parallel).</td>
</tr>
<tr>
<td>OMP_SET_DYNAMIC</td>
<td>Enables or disables dynamic adjustment of the number of threads available for execution of parallel regions.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------</td>

<tr>
<td>OMP_INIT_NEST_LOCK</td>
<td>Initializes a nested lock for use in subsequent calls.</td>
</tr>
<tr>
<td>OMPDESTROY_NEST_LOCK</td>
<td>Disassociates a lock variable from a nested lock.</td>
</tr>
<tr>
<td>OMP_SET_NEST_LOCK</td>
<td>Makes the executing thread wait until the specified nested lock is available, or if the thread already owns the lock, increments its nesting count.</td>
</tr>
<tr>
<td>OMP_UNSET_NEST_LOCK</td>
<td>Decrements the nesting count for the lock variable and releases the executing thread from ownership if the nesting count is zero.</td>
</tr>
<tr>
<td>OMP_TEST_NEST_LOCK</td>
<td>Tries to set the nested lock associated with a lock variable.</td>
</tr>
<tr>
<td>OMP_GET_WTIME</td>
<td>Returns a double-precision value equal to the elapsed wallclock time (in seconds) relative to an arbitrary reference time.</td>
</tr>
<tr>
<td>OMP_GETWTICK</td>
<td>Returns a double-precision value equal to the number of seconds between successive clock ticks.</td>
</tr>
</tbody>
</table>

**Intel® Fortran Extensions:**

- **KMP_PLACE_THREADS**
  Simplifies the specification of the number of cores and threads per core used by an OpenMP application, as an alternative to writing explicit affinity settings or a process affinity mask.

- **KMP_GET_STACKSIZE_S**
  Returns the number of bytes that will be allocated for each parallel thread to use as its private stack.

- **KMP_SET_STACKSIZE_S**
  Sets the number of bytes that will be allocated for each parallel thread to use as its private stack.

- **KMP_GET_BLOCKTIME**
  Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping.

- **KMP_SET_BLOCKTIME**
  Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_MALLOC</td>
<td>Allocates a memory block of a specified size (in bytes) from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_CALLOC</td>
<td>Allocates an array of a specified number of elements and size from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_REALLOC</td>
<td>Reallocates a memory block at a specified address and of a specified size from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_FREE</td>
<td>Frees a memory block at a specified address from the thread-local heap.</td>
</tr>
</tbody>
</table>

1 For backwards compatibility, this can also be specified as KMP_GET_STACKSIZE.
2 For backwards compatibility, this can also be specified as KMP_SET_STACKSIZE.

For more information on a specific routine, see the appropriate reference page; for example, for more information on OMP_SET_LOCK, see `omp_set_lock(3f)`.

Summary of Language Extensions

This appendix summarizes the Intel® Fortran language extensions to the ANSI/ISO Fortran 2003 Standard. Most extensions are available on all supported operating systems. However, some extensions are limited to one or more platforms. If an extension is limited, it is labeled.

Extensions related to the following topics are discussed:

- Source Forms
- Names
- Character Sets
- Intrinsic Data Types
- Constants
- Expressions and Assignment
- Specification Statements
- Execution Control
- Compilation Control Statements
- Built-In Functions
- I/O Statements
- I/O Formatting
- File Operation Statements
- Compiler Directives
- Intrinsic Procedures
- Additional Language Features
- Run-Time Library Routines

Language Extensions: Source Forms

The following are extensions to the methods and rules for source forms:

- Tab-formatting as a method to code lines
- The letter D as a debugging statement indicator in column 1 of fixed or tab source form
- An optional statement field width of 132 columns for fixed or tab source form
- An optional sequence number field for fixed source form
- Up to 511 continuation lines in a source program

Language Extensions: Names

As an extension, the dollar sign ($) is a valid character in names, and can be the first character.

Language Extensions: Character Sets

The following are extensions to the standard character set:

- The Tab (<Tab>) character (see Character Sets)
Language Extensions: Intrinsic Data Types

The following are data-type extensions:

<table>
<thead>
<tr>
<th>Type</th>
<th>INTEGER*1</th>
<th>INTEGER*2</th>
<th>INTEGER*4</th>
<th>INTEGER*8</th>
<th>INTEGER*16</th>
<th>INTEGER*32</th>
<th>COMPLEX*8</th>
<th>COMPLEX*16</th>
<th>COMPLEX*32</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COMPLEX*8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOGICAL*1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COMPLEX*16</td>
<td></td>
</tr>
<tr>
<td>LOGICAL*2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COMPLEX*32</td>
<td></td>
</tr>
<tr>
<td>LOGICAL*4</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>REAL*4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOGICAL*8</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>REAL*8</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Intrinsic Data Types

Language Extensions: Constants

Hollerith constants are allowed as an extension. C Strings are allowed as extensions in character constants.

Language Extensions: Expressions and Assignment

When operands of different intrinsic data types are combined in expressions, conversions are performed as necessary (see Data Type of Numeric Expressions).

Binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

The following are extensions allowed in logical expressions:

- .XOR. as a synonym for .NEQV.
- Integers as valid logical items
- Logical operators applied to integers bit-by-bit

Language Extensions: Specification Statements

The following specification attributes and statements are extensions:

- AUTOMATIC attribute and statement
- STATIC attribute and statement

Language Extensions: Execution Control

The following control statements are extensions:

- ASSIGN
- Assigned GO TO
- PAUSE
These are older Fortran features that have been deleted in Fortran 2003 and Fortran 95. Intel® Fortran fully supports these features.

**Language Extensions: Compilation Control Lines and Statements**
The following line option and statement are extensions that can influence compilation:
- \([/\[NO\]LIST\]), which can be specified in an INCLUDE line
- The OPTIONS statement

**Language Extensions: Built-In Functions**
The following built-in functions are extensions:
- %VAL, %REF, and %LOC, which facilitate references to non-Fortran procedures
- %FILL, which can be used in record structure type definitions

**Language Extensions: I/O Statements**
The following I/O statements are extensions:
- The ACCEPT statement
- The WRITE statement
- The TYPE statement, which is a synonym for the PRINT statement

**Language Extensions: I/O Formatting**
The following are extensions allowed in I/O Formatting:
- The Q edit descriptor
- The dollar sign (\$) edit descriptor and carriage-control character
- The backslash (\) edit descriptor
- The ASCII NUL carriage-control character
- Variable format expressions
- The H edit descriptor
  - This is an older Fortran feature that has been deleted in Fortran 95. Intel® Fortran fully supports this feature.

**Language Extensions: File Operation Statements**
The following statement specifiers and statements are extensions:
- CLOSED statement specifiers:
  - STATUS values: 'SAVE' (as a synonym for 'KEEP'), 'PRINT', 'PRINT/DELETE', 'SUBMIT', 'SUBMIT/DELETE'
  - DISPOSE (or DISP)
- DELETE statement
- INQUIRE statement specifiers:
  - BINARY (W*S)
  - BLOCKSIZE
  - BUFFERED
  - CARRIAGECONTROL
CONVERT
DEFAULTFILE
FORM values: 'UNKNOWN', 'BINARY' (W*S)
IOWOCUS (W*S)
MODE as a synonym for ACTION
ORGANIZATION
RECORDTYPE
SHARE (W*S)

See also INQUIRE Statement.

OPEN statement specifiers:

ACCESS values: 'APPEND'
ASSOCIATEVARIABLE
BLOCKSIZE
BUFFERCOUNT
BUFFERED
CARRIAGECONTROL
CONVERT
DEFAULTFILE
DISPOSE (or DISP)
FORM value: 'BINARY' (W*S)
IOWOCUS (W*S)
MAXREC
MODE as a synonym for ACTION
NAME as a synonym for FILE
NOSHARED
ORGANIZATION
READONLY
RECORDSIZE as a synonym for RECL
RECORDTYPE
SHARE (W*S)
SHARED
TITLE (W*S)
TYPE as a synonym for STATUS
USEROPEN

See also OPEN Statement.

Language Extensions: Compiler Directives

The following General Directives are extensions:

ALIAS
ASSUME
ASSUME_ALIGNED
ATTRIBUTES
BLOCK_LOOP and NOBLOCK_LOOP
DECLARE and NODECLARE
DEFINE and UNDEFINE
DISTRIBUTE POINT
FIXEDFORMLINESIZE
FMA and NOFMA
FORCEINLINE
FREEFORM and NOFREEFORM
The following OFFLOAD Compiler Directives are extensions:

- OFFLOAD
- BEGIN OFFLOAD and END OFFLOAD
- OFFLOAD_TRANSFER
- OFFLOAD_WAIT

### Language Extensions: Intrinsic Procedures

The following intrinsic procedures are extensions available on all platforms:

<table>

Language Extensions: Additional Language Features

The following are language extensions that facilitate compatibility with other versions of Fortran:

- **DEFINE FILE** statement
- **ENCODE** and **DECODE** statements
- **FIND** statement
- The **INTERFACE TO** statement
- **FORTRAN 66 Interpretation** of the EXTERNAL statement
An alternative syntax for the PARAMETER statement
VIRTUAL statement
AND, OR, XOR, IMAG, LSHIFT, RSHIFT intrinsics (see the A to Z Reference)
An alternative syntax for octal and hexadecimal constants
An alternative syntax for an I/O record specifier
An alternate syntax for the DELETE statement
An alternative form for namelist external records
The integer POINTER statement
Record structures

Language Extensions: Run-Time Library Routines

The following run-time library routines are available as extensions:

- Module routines
- OpenMP* Fortran routines
A to Z Reference Overview

This section contains the following:

- **Language Summary Tables**
  - This section organizes the Fortran functions, subroutines, and statements by the operations they perform. You can use the tables to locate a particular routine for a particular task.
  - The descriptions of all Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.
    - In the description of routines, pointers and handles are INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

The Fortran compiler understands statements and intrinsic functions in your program without any additional information, such as that provided in modules.

However, modules must be included in programs that contain the following routines:

- **Quickwin routines and graphics routines (W*S)**
  - These routines require a USE IFQWIN statement to include the library and graphics modules.

- **Portability routines**
  - It is recommended that you specify USE IFPORT when accessing routines in the portability library.

- **Serial port I/O routines**
  - These routines require a USE IFPORT statement to access the portability library. These routines are only available on Windows® systems.

- **NLS routines (W*S)**
  - These routines require a USE IFNLS statement to access the NLS library.

- **POSIX* routines**
  - These routines require a USE IFPOSIX statement to access the POSIX library.

- **Dialog routines (W*S)**
  - These routines require a USE IFLOGM statement to access the dialog library.

- **Component Object Module (COM) routines (W*S)**
  - These routines require a USE IFCOM statement to access the COM library.

- **Automation server routines (W*S)**
  - These routines require a USE IFAUTO statement to access the AUTO library.

- **Miscellaneous Run-Time Routines**
  - Most of these routines require a USE IFCORE statement to obtain the proper interfaces.

Whenever required, these USE module statements are prominent in the *A to Z Reference*.

In addition to the appropriate USE statement, for some routines you must specify the types of libraries to be used when linking.

Language Summary Tables

Statements for Program Unit Calls and Definitions

The following table lists statements used for program unit definition and procedure call and return.
### Statements Affecting Variables
The following table lists statements that affect variables.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>Declares a variable on the stack, rather than at a static memory location.</td>
</tr>
<tr>
<td>BYTE</td>
<td>Specifies variables as the BYTE data type; BYTE is equivalent to INTEGER(1).</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>Specifies variables as the CHARACTER data type.</td>
</tr>
<tr>
<td>CODIMENSION</td>
<td>Specifies that an entity is a coarray and specifies its corank and cobounds, if any.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Specifies variables as the COMPLEX data type.</td>
</tr>
<tr>
<td>DATA</td>
<td>Assigns initial values to variables.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>Specifies variables as the DOUBLE COMPLEX data type, equivalent to COMPLEX(8).</td>
</tr>
</tbody>
</table>
### Name List

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE PRECISION</td>
<td>Specifies variables as the DOUBLE-PRECISION real data type, equivalent to REAL(8).</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Specifies that two or more variables or arrays share the same memory location.</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>Specifies the default types for variables and functions.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Specifies variables as the INTEGER data type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Specifies variables as the LOGICAL data type.</td>
</tr>
<tr>
<td>MAP</td>
<td>Within a UNION statement, delimits a group of variable type declarations that are to be ordered contiguously within memory.</td>
</tr>
<tr>
<td>NAMELIST</td>
<td>Declares a group name for a set of variables to be read or written in a single statement.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>Equates a constant expression with a name.</td>
</tr>
<tr>
<td>PROTECTED</td>
<td>Specifies limitations on the use of module entities.</td>
</tr>
<tr>
<td>REAL</td>
<td>Specifies variables as the REAL data type.</td>
</tr>
<tr>
<td>RECORD</td>
<td>Declares one or more variables of a user-defined structure type.</td>
</tr>
<tr>
<td>SAVE</td>
<td>Causes variables to retain their values between invocations of the procedure in which they are defined.</td>
</tr>
<tr>
<td>STATIC</td>
<td>Declares a variable is in a static memory location, rather than on the stack.</td>
</tr>
<tr>
<td>STRUCTURE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>UNION</td>
<td>Within a structure, causes two or more maps to occupy the same memory locations.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Specifies that the value of an object is totally unpredictable based on information available to the current program unit.</td>
</tr>
</tbody>
</table>

### Statements for Input and Output

The following table lists statements used for input and output.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPT</td>
<td>Statement</td>
<td>Similar to a formatted, sequential READ statement.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Statement</td>
<td>Positions a file to the beginning of the previous record.</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Statement</td>
<td>Disconnects the specified unit.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DELETE</td>
<td>Statement</td>
<td>Deletes a record from a relative file.</td>
</tr>
<tr>
<td>ENDFILE</td>
<td>Statement</td>
<td>Writes an end-of-file record or truncates a file.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Statement</td>
<td>Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.</td>
</tr>
<tr>
<td>INQUIRE</td>
<td>Statement</td>
<td>Returns the properties of a file or unit.</td>
</tr>
<tr>
<td>OPEN</td>
<td>Statement</td>
<td>Associates a unit number with an external device or file.</td>
</tr>
<tr>
<td>PRINT(or TYPE)</td>
<td>Statement</td>
<td>Displays data on the screen.</td>
</tr>
<tr>
<td>READ</td>
<td>Statement</td>
<td>Transfers data from a file to the items in an I/O list.</td>
</tr>
<tr>
<td>REWIND</td>
<td>Statement</td>
<td>Repositions a file to its first record.</td>
</tr>
<tr>
<td>REWRITE</td>
<td>Statement</td>
<td>Rewrites the current record.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Statement</td>
<td>Transfers data from the items in an I/O list to a file</td>
</tr>
</tbody>
</table>

**Compiler Directives**

The following tables list available compiler directives.

Some directives may perform differently on Intel® microprocessors than on non-Intel microprocessors.

Each general directive name is preceded by the prefix cDIR$ (or cDEC$), where c is one of the following: !, C (or c), or *; for example, !DIR$ ALIAS).

Each OpenMP® Fortran directive name is preceded by the prefix c$OMP, where c is one of the following: !, C (or c), or *; for example, !$OMP ATOMIC.

Each OFFLOAD directive name is preceded by the prefix cDIR$, where c is one of the following: !, C (or c), or *; for example, !DIR$ OFFLOAD_TRANSFER.

**General Directives**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIAS</td>
<td>Specifies an alternate external name to be used when referring to an external subprogram.</td>
</tr>
<tr>
<td>ASSUME</td>
<td>Provides heuristic information to the compiler optimizer.</td>
</tr>
<tr>
<td>ASSUME_ALIGNED</td>
<td>Specifies that an entity in memory is aligned.</td>
</tr>
<tr>
<td>ATTRIBUTES</td>
<td>Applies attributes to variables and procedures.</td>
</tr>
<tr>
<td>BLOCK_LOOP</td>
<td>Enables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>DECLARE</td>
<td>Generates warning messages for undeclared variables.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DEFINE</td>
<td>Creates a variable whose existence can be tested during conditional compilation.</td>
</tr>
<tr>
<td>DISTRIBUTE POINT</td>
<td>Suggests a location at which a DO loop may be split.</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ELSEIF</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ENDIF</td>
<td>Marks the end of a conditional-compilation block.</td>
</tr>
<tr>
<td>FIXEDFORMLINESIZE</td>
<td>Sets fixed-form line length. This directive has no effect on freeform code.</td>
</tr>
<tr>
<td>FMA</td>
<td>Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>Specifies that a routine should be inlined whenever the compiler can do so.</td>
</tr>
<tr>
<td>FREEFORM</td>
<td>Uses freeform format for source code.</td>
</tr>
<tr>
<td>IDENT</td>
<td>Specifies an identifier for an object module.</td>
</tr>
<tr>
<td>IF</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>IF DEFINED</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>INLINE</td>
<td>Specifies that the routines can be inlined.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Selects default integer size.</td>
</tr>
<tr>
<td>IVDEP</td>
<td>Assists the compiler's dependence analysis of iterative DO loops.</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>Specifies the typical trip loop count for a DO loop; this assists the optimizer.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>Sends a character string to the standard output device.</td>
</tr>
<tr>
<td>NOBLOCK_LOOP</td>
<td>Disables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>NODEDECLARE</td>
<td>(Default) Turns off warning messages for undeclared variables.</td>
</tr>
<tr>
<td>NOFMA</td>
<td>Disables the generation of FMA instructions.</td>
</tr>
<tr>
<td>NOFREEFORM</td>
<td>(Default) Uses standard FORTRAN 77 code formatting column rules.</td>
</tr>
<tr>
<td>NOFUSION</td>
<td>Prevents a loop from fusing with adjacent loops.</td>
</tr>
<tr>
<td>NOINLINE</td>
<td>Specifies that a routine should not be inlined.</td>
</tr>
<tr>
<td>NOPARALLEL</td>
<td>Disables auto-parallelization for an immediately following DO loop.</td>
</tr>
</tbody>
</table>
### OpenMP* Fortran Directives

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC</td>
<td>Specifies that a specific memory location is to be updated atomically.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team.</td>
</tr>
</tbody>
</table>

---

To use the following directives, you must specify compiler option [q or Q]openmp. For more information, refer to the option description in the Compiler Options reference.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CANCEL</td>
<td>Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.</td>
</tr>
<tr>
<td>CANCELLATION POINT</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>Restricts access for a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>DECLARE SIMD</td>
<td>Generates a SIMD procedure.</td>
</tr>
<tr>
<td>DECLARE TARGET</td>
<td>Specifies that named variables, common blocks, functions, and subroutines are mapped to a device.</td>
</tr>
<tr>
<td>DISTRIBUTE</td>
<td>Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO SIMD</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DISTRIBUTE SIMD</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DO</td>
<td>Specifies that the iterations of the immediately following DO loop must be executed in parallel.</td>
</tr>
<tr>
<td>DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Specifies synchronization points where the implementation must have a consistent view of memory.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code to be executed sequentially.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Defines a parallel region.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Defines a parallel region that contains a single DO directive.</td>
</tr>
<tr>
<td>PARALLEL DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.</td>
</tr>
<tr>
<td>PARALLEL SECTIONS</td>
<td>Defines a parallel region that contains SECTIONS directives.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PARALLEL WORKSHARE</td>
<td>Defines a parallel region that contains a single WORKSHARE directive.</td>
</tr>
<tr>
<td>SECTION</td>
<td>Appears within a SECTIONS directive construct to indicate a block (section) of code. It is optional for the first block of code within the SECTIONS directive construct.</td>
</tr>
<tr>
<td>SECTIONS</td>
<td>Specifies a block of code to be divided among threads in a team (a worksharing area).</td>
</tr>
<tr>
<td>SIMD</td>
<td>Requires and controls SIMD vectorization of loops.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>Specifies a block of code to be executed by only one thread in a team.</td>
</tr>
<tr>
<td>TARGET</td>
<td>Creates a device data environment and executes the construct on the same device.</td>
</tr>
<tr>
<td>TARGET DATA</td>
<td>Creates a device data environment for the extent of the region.</td>
</tr>
<tr>
<td>TARGET ENTER DATA</td>
<td>Specifies that variables are mapped to a device data environment.</td>
</tr>
<tr>
<td>TARGET EXIT DATA</td>
<td>Specifies that variables are unmapped from a device data environment.</td>
</tr>
<tr>
<td>TARGET TEAMS</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE SIMD</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TARGET UPDATE</td>
<td>Makes the list items in the device data environment consistent with their corresponding original list items.</td>
</tr>
<tr>
<td>TASK</td>
<td>Defines a task region.</td>
</tr>
<tr>
<td>TASKGROUP</td>
<td>Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.</td>
</tr>
<tr>
<td>TASKWAIT</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>TASKYIELD</td>
<td>Specifies that the current task can be suspended in favor of execution of a different task.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE SIMD</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>THREADPRIVATE</td>
<td>Makes named common blocks private to a thread but global within the thread.</td>
</tr>
<tr>
<td>WORKSHARE</td>
<td>Divides the work of executing a block of statements or constructs into separate units.</td>
</tr>
</tbody>
</table>

**OFFLOAD Directives**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD</td>
<td>Enables statements to execute on the target.</td>
</tr>
<tr>
<td>OFFLOAD BEGIN and END OFFLOAD</td>
<td>Enables a group of statements to execute on the target.</td>
</tr>
</tbody>
</table>
**Program Control Statements**

The following table lists statements that affect program control.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Within a SELECT CASE structure, marks a block of statements that are executed if an associated value matches the SELECT CASE expression.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>Often used as the target of GOTO or as the terminal statement in a DO loop; performs no operation.</td>
</tr>
<tr>
<td>CYCLE</td>
<td>Advances control to the end statement of a DO loop; the intervening loop statements are not executed.</td>
</tr>
<tr>
<td>DO</td>
<td>Marks the beginning of a loop construct. Statements through and including the ending statement may be executed repeatedly.</td>
</tr>
<tr>
<td>DO WHILE</td>
<td>Evaluates statements in the DO WHILE loop, through and including the ending statement, until a logical condition becomes .FALSE..</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>ELSEWHERE</td>
<td>Marks an optional branch in a WHERE construct.</td>
</tr>
<tr>
<td>END</td>
<td>Marks the end of a program unit.</td>
</tr>
<tr>
<td>END DO</td>
<td>Marks the end of a series of statements following a DO or DO WHILE statement.</td>
</tr>
<tr>
<td>END FORALL</td>
<td>Marks the end of a series of statements following a block FORALL statement.</td>
</tr>
</tbody>
</table>

**Optimization Notice**

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**See Also**

qopenmp, Qopenmp
### Name | Description
--- | ---
END IF | Marks the end of a series of statements following a block IF statement.
END SELECT | Marks the end of a SELECT CASE statement.
END WHERE | Marks the end of a series of statements following a block WHERE statement.
EXIT | Terminates execution of a DO construct. Execution continues with the first statement that follows.
FORALL | Indicates a loop construct where the output from one iteration cannot change the input to another.
GOTO | Transfers control to a specified part of the program.
IF | Controls conditional execution of other statements.
PAUSE | Suspends program execution and, optionally, executes operating-system commands.
SELECT CASE | Transfers program control to a block of statements, determined by a controlling argument.
STOP | Terminates program execution.
WHERE | Controls conditional execution of array assignments and elemental function calls.

### Inquiry Intrinsic Functions

The following table lists inquiry intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Determines whether an allocatable variable is allocated.</td>
</tr>
<tr>
<td>ASSOCIATED</td>
<td>Determines if a pointer is associated or if two pointers are associated with the same target.</td>
</tr>
<tr>
<td>BIT_SIZE</td>
<td>Returns the number of bits in an integer type.</td>
</tr>
<tr>
<td>CACHESIZE</td>
<td>Returns the size of a level of the memory cache.</td>
</tr>
<tr>
<td>COMMAND_ARGUMENT_COUNT</td>
<td>Returns the number of command-line arguments.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EOF</td>
<td>Determines whether a file is at or beyond the end-of-file record.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns the largest number that can be represented by numbers of the type of the argument.</td>
</tr>
<tr>
<td>IARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INT_PTR_KIND</td>
<td>Returns the INTEGER KIND that will hold an address.</td>
</tr>
<tr>
<td>KIND</td>
<td>Returns the value of the kind parameter of the argument.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the length of a character expression.</td>
</tr>
<tr>
<td>LOC</td>
<td>Returns the address of the argument.</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NARGS</td>
<td>Returns the total number of command-line arguments, including the command.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>PRESENT</td>
<td>Determines whether an optional argument is present.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>SELECTED_INT_KIND</td>
<td>Returns the value of the kind parameter of integers in range $r$.</td>
</tr>
<tr>
<td>SELECTED_REAL_KIND</td>
<td>Returns the value of the kind parameter of reals with (optional) first argument digits and (optional) second argument exponent range. At least one optional argument is required.</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array or scalar argument.</td>
</tr>
<tr>
<td>SIZEOF</td>
<td>Returns the number of bytes of storage used by the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns the smallest positive number that can be represented by numbers of type the argument.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.</td>
</tr>
</tbody>
</table>

**Random Number Intrinsic Procedures**

The following table lists random number intrinsic procedures.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAN</td>
<td>Intrinsic function</td>
<td>Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1.</td>
</tr>
</tbody>
</table>
RANF

Intrinsic function
Generates a random number between 0.0 and RAND_MAX.

RANDOM_NUMBER

Intrinsic subroutine
Returns a pseudorandom real value greater than or equal to zero and less than one.

RANDOM_SEED

Intrinsic subroutine
Changes the starting point of RANDOM_NUMBER; takes one or no arguments.

RANDU

Intrinsic subroutine
Computes a pseudorandom number as a single-precision value.

The portability routines RANF, RANDOM, and SEED also supply this functionality.

Date and Time Intrinsic Subroutines
The following table lists date and time intrinsic subroutines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the processor time in seconds.</td>
</tr>
<tr>
<td>DATE</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current date (in dd-mmm-yy form).</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the date and time. This is the preferred procedure for date and time.</td>
</tr>
<tr>
<td>IDATE</td>
<td>Intrinsic subroutine</td>
<td>Returns three integer values representing the current month, day, and year.</td>
</tr>
<tr>
<td>SYSTEM_CLOCK</td>
<td>Intrinsic subroutine</td>
<td>Returns data from the system clock.</td>
</tr>
<tr>
<td>TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current time (in hh:mm:ss form).</td>
</tr>
</tbody>
</table>

The portability routines GETDAT, GETTIM, SETDAT, and SETTIM also supply this functionality.

Keyboard and Speaker Library Routines
The following table lists keyboard and speaker library routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETCHARQQ</td>
<td>Run-time Function</td>
<td>Returns the next keyboard keystroke.</td>
</tr>
<tr>
<td>BEEPQQ</td>
<td>Portability subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Run-time function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
</tbody>
</table>
### Statements and Intrinsic Procedures for Memory Allocation and Deallocation

The following table lists statements and intrinsic procedures that are used for memory allocation and deallocation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Statement</td>
<td>Dynamically establishes allocatable array dimensions.</td>
</tr>
<tr>
<td>ALLOCATED</td>
<td>Intrinsic Function</td>
<td>Determines whether an allocatable array is allocated.</td>
</tr>
<tr>
<td>DEALLOCATE</td>
<td>Statement</td>
<td>Frees the storage space previously reserved in an ALLOCATE statement.</td>
</tr>
<tr>
<td>FREE</td>
<td>Intrinsic Subroutine</td>
<td>Frees the memory block specified by the integer pointer argument.</td>
</tr>
<tr>
<td>MALLOC</td>
<td>Intrinsic Function</td>
<td>Allocates a memory block of size bytes and returns an integer pointer to the block.</td>
</tr>
<tr>
<td>MOVE_ALLOC</td>
<td>Intrinsic Subroutine</td>
<td>Moves an allocation from one allocatable object to another.</td>
</tr>
</tbody>
</table>

### Intrinsic Functions for Arrays

The following table lists intrinsic functions for arrays.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Determines whether all array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>ANY</td>
<td>Determines whether any array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>COUNT</td>
<td>Counts the number of array elements that meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>CSHIFT</td>
<td>Performs a circular shift along a (optional) dimension.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOT_PRODUCT</td>
<td>Performs dot-product multiplication on vectors (one-dimensional arrays).</td>
</tr>
<tr>
<td>EOSHIFT</td>
<td>Shifts elements off one end of array along a (optional) dimension and copies (optional) boundary values in other end.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns lower dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LCOBOUND</td>
<td>Returns the lower cobounds of a coarray.</td>
</tr>
<tr>
<td>MATMUL</td>
<td>Performs matrix multiplication on matrices (two-dimensional arrays).</td>
</tr>
<tr>
<td>MAXLOC</td>
<td>Returns the location of the maximum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MAXVAL</td>
<td>Returns the maximum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Merges two arrays according to conditions in a mask.</td>
</tr>
<tr>
<td>MINLOC</td>
<td>Returns the location of the minimum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MINVAL</td>
<td>Returns the minimum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>PACK</td>
<td>Packs an array into a vector (one-dimensional array) of a (optional) size using a mask.</td>
</tr>
<tr>
<td>PRODUCT</td>
<td>Returns product of elements of an array along a (optional) dimension that meet conditions in a (optional) mask.</td>
</tr>
<tr>
<td>RESHAPE</td>
<td>Reshapes an array with (optional) subscript order, padded with (optional) array elements.</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array.</td>
</tr>
<tr>
<td>SIZE</td>
<td>Returns the extent of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>SPREAD</td>
<td>Replicates an array by adding a dimension.</td>
</tr>
<tr>
<td>SUM</td>
<td>Sums array elements along a (optional) dimension that meet conditions of an (optional) mask.</td>
</tr>
<tr>
<td>TRANSPOSE</td>
<td>Transposes a two-dimensional array.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns upper dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>UCOBOUND</td>
<td>Returns the upper cobounds of a coarray.</td>
</tr>
<tr>
<td>UNPACK</td>
<td>Unpacks a vector (one-dimensional array) into an array under a mask padding with values from a field.</td>
</tr>
</tbody>
</table>

**Intrinsic Functions for Numeric and Type Conversion**

The following table lists intrinsic functions for numeric and type conversion.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Returns the absolute value of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>AIMAG</td>
<td>Returns imaginary part of complex number $z$.</td>
</tr>
<tr>
<td>AINT</td>
<td>Truncates the argument to a whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>AMAX0</td>
<td>Returns largest value among integer arguments as real.</td>
</tr>
<tr>
<td>AMIN0</td>
<td>Returns smallest value among integer arguments as real.</td>
</tr>
<tr>
<td>ANINT</td>
<td>Rounds to the nearest whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>CEILING</td>
<td>Returns smallest integer greater than the argument.</td>
</tr>
<tr>
<td>CMPLX</td>
<td>Converts the first argument and (optional) second argument to complex of a (optional) kind.</td>
</tr>
<tr>
<td>CONJG</td>
<td>Returns the conjugate of a complex number.</td>
</tr>
<tr>
<td>DBLE</td>
<td>Converts the argument to double precision type.</td>
</tr>
<tr>
<td>DCMPLX</td>
<td>Converts the argument to double complex type.</td>
</tr>
<tr>
<td>DFLOAT</td>
<td>Converts an integer to double precision type.</td>
</tr>
<tr>
<td>DIM</td>
<td>Returns the first argument minus the second argument if positive; else 0.</td>
</tr>
<tr>
<td>DPROD</td>
<td>Returns double-precision product of two single precision arguments.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>Converts the argument to REAL(4).</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Returns the greatest integer less than or equal to the argument.</td>
</tr>
<tr>
<td>IFIX</td>
<td>Converts a single-precision real argument to an integer argument by truncating.</td>
</tr>
<tr>
<td>IMAG</td>
<td>Same as AIMAG.</td>
</tr>
<tr>
<td>INT</td>
<td>Converts a value to integer type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Converts between logical arguments of (optional) kind.</td>
</tr>
<tr>
<td>MAX</td>
<td>Returns largest value among arguments.</td>
</tr>
<tr>
<td>MAX1</td>
<td>Returns largest value among real arguments as integer.</td>
</tr>
<tr>
<td>MIN</td>
<td>Returns smallest value among arguments.</td>
</tr>
<tr>
<td>MIN1</td>
<td>Returns smallest value among real arguments as integer</td>
</tr>
<tr>
<td>MOD</td>
<td>Returns the remainder of the first argument divided by the second argument.</td>
</tr>
<tr>
<td>MODULO</td>
<td>Returns the first argument modulo the second argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>NINT</td>
<td>Returns the nearest integer to the argument.</td>
</tr>
<tr>
<td>REAL</td>
<td>Converts a value to real type.</td>
</tr>
<tr>
<td>SIGN</td>
<td>Returns absolute value of the first argument times the sign of the second argument.</td>
</tr>
<tr>
<td>SNGL</td>
<td>Converts a double-precision argument to single-precision real type.</td>
</tr>
<tr>
<td>TRANSFER</td>
<td>Transforms first argument into type of second argument with (optional) size if an array.</td>
</tr>
<tr>
<td>ZEXT</td>
<td>Extends the argument with zeros.</td>
</tr>
</tbody>
</table>

**Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures**

The following table lists intrinsic procedures for trigonometric, exponential, root, and logarithmic operations.

**NOTE**
Many routines in the LIBM library (Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOS</td>
<td>Returns the arccosine of the argument, expressed in radians between 0 and pi.</td>
</tr>
<tr>
<td>ACOSD</td>
<td>Returns the arccosine of the argument, expressed in degrees between 0 and 180.</td>
</tr>
<tr>
<td>ALOG</td>
<td>Returns natural log of the argument.</td>
</tr>
<tr>
<td>ALOG10</td>
<td>Returns common log (base 10) of the argument.</td>
</tr>
<tr>
<td>ASIN</td>
<td>Returns the arcsine of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ASIND</td>
<td>Returns the arcsine of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN</td>
<td>Returns the arctangent of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ATAND</td>
<td>Returns the arctangent of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN2</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>ATAN2D</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>CCOS</td>
<td>Returns complex cosine of the argument.</td>
</tr>
<tr>
<td>CDCOS</td>
<td>Returns the double-precision complex cosine of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>CDEXP</td>
<td>Returns double-precision complex exponential value of the argument.</td>
</tr>
<tr>
<td>CDLOG</td>
<td>Returns the double-precision complex natural log of the argument.</td>
</tr>
<tr>
<td>CDSIN</td>
<td>Returns the double-precision complex sine of the argument.</td>
</tr>
<tr>
<td>CDSQRT</td>
<td>Returns the double-precision complex square root of the argument.</td>
</tr>
<tr>
<td>CEXP</td>
<td>Returns the complex exponential value of the argument.</td>
</tr>
<tr>
<td>CLOG</td>
<td>Returns the complex natural log of the argument.</td>
</tr>
<tr>
<td>COS</td>
<td>Returns the cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>COSD</td>
<td>Returns the cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>COSH</td>
<td>Returns the hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>COTAN</td>
<td>Returns the cotangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>COTAND</td>
<td>Returns the cotangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>CSIN</td>
<td>Returns the complex sine of the argument.</td>
</tr>
<tr>
<td>CSQRT</td>
<td>Returns the complex square root of the argument.</td>
</tr>
<tr>
<td>DACOS</td>
<td>Returns the double-precision arccosine of the argument radians between 0 and pi.</td>
</tr>
<tr>
<td>DACOSD</td>
<td>Returns the arccosine of the argument in degrees between 0 and 180.</td>
</tr>
<tr>
<td>DASIN</td>
<td>Returns the double-precision arcsine of the argument in radians between ±pi/2.</td>
</tr>
<tr>
<td>DASIND</td>
<td>Returns the double-precision arcsine of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN</td>
<td>Returns the double-precision arctangent of the argument radians between ±pi/2.</td>
</tr>
<tr>
<td>DATAND</td>
<td>Returns the double-precision arctangent of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN2</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>DATAN2D</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>DCOS</td>
<td>Returns the double-precision cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DCOSD</td>
<td>Returns the double-precision cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DCOSH</td>
<td>Returns the double-precision hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>Returns the double-precision cotangent of the argument.</td>
</tr>
<tr>
<td>DEXP</td>
<td>Returns the double-precision exponential value of the argument.</td>
</tr>
<tr>
<td>DLOG</td>
<td>Returns the double-precision natural log of the argument.</td>
</tr>
<tr>
<td>DLOG10</td>
<td>Returns the double-precision common log (base 10) of the argument.</td>
</tr>
<tr>
<td>DSIN</td>
<td>Returns the double-precision sin of the argument, which is in radians.</td>
</tr>
<tr>
<td>DSIND</td>
<td>Returns the double-precision sin of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DSINH</td>
<td>Returns the double-precision hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>DSQRT</td>
<td>Returns the double-precision square root of the argument.</td>
</tr>
<tr>
<td>DTAN</td>
<td>Returns the double-precision tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>DTAND</td>
<td>Returns the double-precision tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DTANH</td>
<td>Returns the double-precision hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>EXP</td>
<td>Returns the exponential value of the argument.</td>
</tr>
<tr>
<td>LOG</td>
<td>Returns the natural log of the argument.</td>
</tr>
<tr>
<td>LOG10</td>
<td>Returns the common log (base 10) of the argument.</td>
</tr>
<tr>
<td>SIN</td>
<td>Returns the sine of the argument, which is in radians.</td>
</tr>
<tr>
<td>SIND</td>
<td>Returns the sine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>SINH</td>
<td>Returns the hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>SQRT</td>
<td>Returns the square root of the argument.</td>
</tr>
<tr>
<td>TAN</td>
<td>Returns the tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>TAND</td>
<td>Returns the tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>TANH</td>
<td>Returns the hyperbolic tangent of the argument.</td>
</tr>
</tbody>
</table>
Intrinsic Functions for Floating-Point Inquiry and Control

The following table lists intrinsic functions for floating-point inquiry and control. Certain functions (EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, and SPACING) return values related to components of the model set of real numbers. For a description of this model, see the Model for Real Data.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>Returns the exponent part of the representation of x.</td>
</tr>
<tr>
<td>FRACTION</td>
<td>Returns the fractional part of the representation of the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns largest number that can be represented by data of type the argument.</td>
</tr>
<tr>
<td>MAXEXponent</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXponent</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NEAREST</td>
<td>Returns the nearest different machine representable number to the first argument in the direction of the sign of the second argument.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>RRSPACING</td>
<td>Returns the reciprocal of the relative spacing of numbers near the argument.</td>
</tr>
<tr>
<td>SCALE</td>
<td>Multiplies the first argument by 2 raised to the power of the second argument.</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>Returns a number whose fractional part is the first argument and whose exponential part is the second argument.</td>
</tr>
<tr>
<td>SPACING</td>
<td>Returns the absolute spacing of numbers near the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns smallest positive number that can be represented by data of type of the argument.</td>
</tr>
</tbody>
</table>

The portability routines GETCONTROLFPQQ, GETSTATUSFPQQ, LCWRQQ, SCWRQQ, SETCONTROLFPQQ, and SSWRQQ also supply this functionality.
### Character Intrinsic Functions

The following table lists character intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACHAR</td>
<td>Returns character in a specified position in the ASCII character set.</td>
</tr>
<tr>
<td>ADJUSTL</td>
<td>Adjusts left, removing leading blanks and inserting trailing blanks.</td>
</tr>
<tr>
<td>ADJUSTR</td>
<td>Adjusts right, removing trailing blanks and inserting leading blanks.</td>
</tr>
<tr>
<td>CHAR</td>
<td>Returns character in a specified position in the processor's character set.</td>
</tr>
<tr>
<td>IACHAR</td>
<td>Returns the position of the argument in the ASCII character set.</td>
</tr>
<tr>
<td>ICHAR</td>
<td>Returns the position of the argument in the processor's character set.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Returns the starting position of a substring in a string, leftmost or (optional) rightmost occurrence.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the size of the argument.</td>
</tr>
<tr>
<td>LEN_TRIM</td>
<td>Returns the number of characters in the argument, not counting trailing blanks.</td>
</tr>
<tr>
<td>LGE</td>
<td>Tests whether the first argument is greater than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LGT</td>
<td>Tests whether the first argument is greater than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLE</td>
<td>Tests whether the first argument is less than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLT</td>
<td>Tests whether the first argument is less than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>REPEAT</td>
<td>Concatenates multiple copies of a string.</td>
</tr>
<tr>
<td>SCAN</td>
<td>Scans a string for any characters in a set and returns leftmost or (optional) rightmost position where a match is found.</td>
</tr>
<tr>
<td>TRIM</td>
<td>Removes trailing blanks from a string.</td>
</tr>
<tr>
<td>VERIFY</td>
<td>Returns the position of the leftmost or (optional) rightmost character in the argument string not in a set, or zero if all characters in the set are present.</td>
</tr>
</tbody>
</table>

### Intrinsic Procedures for Bit Operation and Representation

The following tables list intrinsic procedures for bit operation and representation.
<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Intrinsic Function</td>
<td>Returns the number of bits in integers of the type the argument.</td>
</tr>
<tr>
<td>BTEST</td>
<td>Intrinsic Function</td>
<td>Tests a bit in a position of the argument; true if bit is 1.</td>
</tr>
<tr>
<td>IAND</td>
<td>Intrinsic Function</td>
<td>Performs a logical AND.</td>
</tr>
<tr>
<td>IBCHNG</td>
<td>Intrinsic Function</td>
<td>Reverses value of bit in a position of the argument.</td>
</tr>
<tr>
<td>IBCLR</td>
<td>Intrinsic Function</td>
<td>Clears the bit in a position of the argument to zero.</td>
</tr>
<tr>
<td>IBITS</td>
<td>Intrinsic Function</td>
<td>Extracts a sequence of bits of length from the argument starting in a position.</td>
</tr>
<tr>
<td>IBSET</td>
<td>Intrinsic Function</td>
<td>Sets the bit in a position of the argument to one.</td>
</tr>
<tr>
<td>IEOR</td>
<td>Intrinsic Function</td>
<td>Performs an exclusive OR.</td>
</tr>
<tr>
<td>IOR</td>
<td>Intrinsic Function</td>
<td>Performs an inclusive OR.</td>
</tr>
<tr>
<td>ISHA</td>
<td>Intrinsic Function</td>
<td>Shifts the argument arithmetically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from the right, ones shifted in from the left.</td>
</tr>
<tr>
<td>ISHC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the argument left or right by shift bits; left if shift positive, right if shift negative. No bits lost.</td>
</tr>
<tr>
<td>ISHFT</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>ISHFTC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the rightmost bits of (optional) size by shift bits. No bits lost.</td>
</tr>
</tbody>
</table>
### ISHL
- **Procedure Type**: Intrinsic Function
- **Description**: Shifts the argument logically left or right by shift bits. Zeros shifted in from opposite end.

### MVBITS
- **Procedure Type**: Intrinsic Subroutine
- **Description**: Copies a sequence of bits from one integer to another.

### NOT
- **Procedure Type**: Intrinsic Function
- **Description**: Performs a logical complement.

### Bit Representation

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEADZ</td>
<td>Intrinsic Function</td>
<td>Returns leading zero bits in an integer.</td>
</tr>
<tr>
<td>POPCNT</td>
<td>Intrinsic Function</td>
<td>Returns number of 1 bits in an integer.</td>
</tr>
<tr>
<td>POPPAR</td>
<td>Intrinsic Function</td>
<td>Returns the parity of an integer.</td>
</tr>
<tr>
<td>TRAILZ</td>
<td>Intrinsic Function</td>
<td>Returns trailing zero bits in an integer.</td>
</tr>
</tbody>
</table>

### QuickWin Library Routines (W*S)

The following table lists Quickwin library routines.

**Note**: Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABOUTBOXQQ</td>
<td>Function</td>
<td>Adds an About Box with customized text.</td>
</tr>
<tr>
<td>APPENDMENUQQ</td>
<td>Function</td>
<td>Appends a menu item.</td>
</tr>
<tr>
<td>CLICKMENUQQ</td>
<td>Function</td>
<td>Sends menu click messages to the application window.</td>
</tr>
<tr>
<td>DELETEMENUQQ</td>
<td>Function</td>
<td>Deletes a menu item.</td>
</tr>
<tr>
<td>FOCUSQQ</td>
<td>Function</td>
<td>Makes a child window active, and gives focus to the child window.</td>
</tr>
<tr>
<td>GETACTIVEQQ</td>
<td>Function</td>
<td>Gets the unit number of the active child window.</td>
</tr>
<tr>
<td>GETEXITQQ</td>
<td>Function</td>
<td>Gets the setting for a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>GETHWNDQQ</td>
<td>Function</td>
<td>Gets the true windows handle from window with the specified unit number.</td>
</tr>
<tr>
<td>GETWINDOWCONFIG</td>
<td>Function</td>
<td>Returns the current window's properties.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETWSIZEQQ</td>
<td>Function</td>
<td>Gets the size of the child or frame window.</td>
</tr>
<tr>
<td>GETUNITQQ</td>
<td>Function</td>
<td>Gets the unit number corresponding to the specified windows handle. Inverse of GETHWNDQQ.</td>
</tr>
<tr>
<td>INCHARRQQ</td>
<td>Function</td>
<td>Reads a keyboard input and return its ASCII value.</td>
</tr>
<tr>
<td>INITIALSETTINGS</td>
<td>Function</td>
<td>Controls initial menu settings and initial frame window settings.</td>
</tr>
<tr>
<td>INQFOCUSQQ</td>
<td>Function</td>
<td>Determines which window is active and has the focus.</td>
</tr>
<tr>
<td>INSERTMENUQQ</td>
<td>Function</td>
<td>Inserts a menu item.</td>
</tr>
<tr>
<td>INTEGRERTORGB</td>
<td>Subroutine</td>
<td>Converts a true color value into its red, green and blue components.</td>
</tr>
<tr>
<td>MESSAGEBOXQQ</td>
<td>Function</td>
<td>Displays a message box.</td>
</tr>
<tr>
<td>MODIFYMENUFLAGSQQ</td>
<td>Function</td>
<td>Modifies a menu item state.</td>
</tr>
<tr>
<td>MODIFYMENUROUTINEQQ</td>
<td>Function</td>
<td>Modifies a menu item's callback routine.</td>
</tr>
<tr>
<td>MODIFYMENUSTRINGQQ</td>
<td>Function</td>
<td>Changes a menu item's text string.</td>
</tr>
<tr>
<td>PASSDIRKEYSQQ</td>
<td>Function</td>
<td>Determines the behavior of direction and page keys.</td>
</tr>
<tr>
<td>REGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Registers the application-defined routines to be called on mouse events.</td>
</tr>
<tr>
<td>RGBTOINTEGER</td>
<td>Function</td>
<td>Converts a trio of red, green and blue values to a true color value for use with RGB functions and subroutines.</td>
</tr>
<tr>
<td>SETACTIVEQQ</td>
<td>Function</td>
<td>Makes the specified window the current active window without giving it the focus.</td>
</tr>
<tr>
<td>SETEXITQQ</td>
<td>Function</td>
<td>Sets a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>SETMESSAGEQQ</td>
<td>Subroutine</td>
<td>Changes any QuickWin message, including status bar messages, state messages and dialog box messages.</td>
</tr>
<tr>
<td>SETMOUSECURSOR</td>
<td>Function</td>
<td>Sets the mouse cursor for the window in focus.</td>
</tr>
<tr>
<td>SETWINDOWCONFIG</td>
<td>Function</td>
<td>Configures the current window's properties.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SETWINDOWMENUQQ</td>
<td>Function</td>
<td>Sets the Window menu to which current child window names will be appended.</td>
</tr>
<tr>
<td>SETWSIZEQQ</td>
<td>Function</td>
<td>Sets the size of the child or frame window.</td>
</tr>
<tr>
<td>UNREGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Removes the callback routine registered by REGISTERMOUSEEVENT.</td>
</tr>
<tr>
<td>WAITONMOUSEEVENT</td>
<td>Function</td>
<td>Blocks return until a mouse event occurs.</td>
</tr>
</tbody>
</table>

**Graphics Library Routines (W*S)**

The following table lists library routines for graphics. Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC, ARC_W</td>
<td>Functions</td>
<td>Draws an arc.</td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>Subroutine</td>
<td>Clears the screen, viewport, or text window.</td>
</tr>
<tr>
<td>DISPLAYCURSOR</td>
<td>Function</td>
<td>Turns the cursor off and on.</td>
</tr>
<tr>
<td>ELLIPSE, ELLIPSE_W</td>
<td>Functions</td>
<td>Draws an ellipse or circle.</td>
</tr>
<tr>
<td>FLOODFILL, FLOODFILL_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current color index, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB, FLOODFILLRGB_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current RGB color, using the current fill mask.</td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>Function</td>
<td>Determines the end points of the most recently drawn arc or pie.</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>Function</td>
<td>Returns the current background color index.</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>Function</td>
<td>Returns the current background RGB color.</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>Function</td>
<td>Returns the current color index.</td>
</tr>
<tr>
<td>GETCOLORRGB</td>
<td>Function</td>
<td>Returns the current RGB color.</td>
</tr>
<tr>
<td>GetCurrentPOSITION,</td>
<td>Subroutines</td>
<td>Returns the coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETFILLMASK</td>
<td>Subroutine</td>
<td>Returns the current fill mask.</td>
</tr>
<tr>
<td>GETFONTINFO</td>
<td>Function</td>
<td>Returns the current font characteristics.</td>
</tr>
<tr>
<td>GETGTEXTEXTENT</td>
<td>Function</td>
<td>Determines the width of the specified text in the current font.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETGTEXTROTATION</td>
<td>Function</td>
<td>Get the current text rotation angle.</td>
</tr>
<tr>
<td>GETIMAGE, GETIMAGE_W</td>
<td>Subroutines</td>
<td>Stores a screen image in memory.</td>
</tr>
<tr>
<td>GETLINESTYLE</td>
<td>Function</td>
<td>Returns the current line style.</td>
</tr>
<tr>
<td>GETLINEWIDTHQQ</td>
<td>Function</td>
<td>Returns the current line width or the line width set by the last call to SETLINEWIDTHQQ.</td>
</tr>
<tr>
<td>GETPHYSCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to physical coordinates.</td>
</tr>
<tr>
<td>GETPIXEL, GETPIXEL_W</td>
<td>Functions</td>
<td>Returns a pixel's color index.</td>
</tr>
<tr>
<td>GETPIXELRGB, GETPIXELRGB_W</td>
<td>Functions</td>
<td>Returns a pixel's RGB color.</td>
</tr>
<tr>
<td>GETPIXELS</td>
<td>Function</td>
<td>Returns the color indices of multiple pixels.</td>
</tr>
<tr>
<td>GETPIXELSRGB</td>
<td>Function</td>
<td>Returns the RGB colors of multiple pixels.</td>
</tr>
<tr>
<td>GETTEXTCOLOR</td>
<td>Function</td>
<td>Returns the current text color index.</td>
</tr>
<tr>
<td>GETTEXTCOLORRGB</td>
<td>Function</td>
<td>Returns the current text RGB color.</td>
</tr>
<tr>
<td>GETTEXTPOSITION</td>
<td>Subroutine</td>
<td>Returns the current text-output position.</td>
</tr>
<tr>
<td>GETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Returns the boundaries of the current text window.</td>
</tr>
<tr>
<td>GETVIEWCOORD, GETVIEWCOORD_W</td>
<td>Subroutines</td>
<td>Converts physical or window coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETWINDOWCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to window coordinates.</td>
</tr>
<tr>
<td>GETWRITEMODE</td>
<td>Function</td>
<td>Returns the logical write mode for lines.</td>
</tr>
<tr>
<td>GRSTATUS</td>
<td>Function</td>
<td>Returns the status (success or failure) of the most recently called graphics routine.</td>
</tr>
<tr>
<td>IMAGESIZE, IMAGESIZE_W</td>
<td>Functions</td>
<td>Returns image size in bytes.</td>
</tr>
<tr>
<td>INITIALIZEFONTS</td>
<td>Function</td>
<td>Initializes the font library.</td>
</tr>
<tr>
<td>LINETO, LINETO_W</td>
<td>Functions</td>
<td>Draws a line from the current position to a specified point.</td>
</tr>
<tr>
<td>LINETOAR</td>
<td>Function</td>
<td>Draws a line between points in one array and corresponding points in another array.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LINETOAREX</td>
<td>Function</td>
<td>Similar to LINETOAR, but also lets you specify color and line style.</td>
</tr>
<tr>
<td>LOADIMAGE, LOADIMAGE_W</td>
<td>Functions</td>
<td>Reads a Windows bitmap file (.BMP) and displays it at the specified location.</td>
</tr>
<tr>
<td>MOVETO, MOVETO_W</td>
<td>Subroutines</td>
<td>Moves the current position to the specified point.</td>
</tr>
<tr>
<td>OUTGTEXT</td>
<td>Subroutine</td>
<td>Sends text in the current font to the screen at the current position.</td>
</tr>
<tr>
<td>OUTTEXT</td>
<td>Subroutine</td>
<td>Sends text to the screen at the current position.</td>
</tr>
<tr>
<td>PIE, PIE_W</td>
<td>Functions</td>
<td>Draws a pie slice.</td>
</tr>
<tr>
<td>POLYBEZIER, POLYBEZIER_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYBEZIERTO, POLYBEZIERTO_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYGON, POLYGON_W</td>
<td>Functions</td>
<td>Draws a polygon.</td>
</tr>
<tr>
<td>POLYLINEQQ</td>
<td>Function</td>
<td>Draws a line between successive points in an array.</td>
</tr>
<tr>
<td>PUTIMAGE, PUTIMAGE_W</td>
<td>Subroutines</td>
<td>Retrieves an image from memory and displays it.</td>
</tr>
<tr>
<td>RECTANGLE, RECTANGLE_W</td>
<td>Functions</td>
<td>Draws a rectangle.</td>
</tr>
<tr>
<td>REMAPALLPALETTERGB</td>
<td>Function</td>
<td>Remaps a set of RGB color values to indices recognized by the current video configuration.</td>
</tr>
<tr>
<td>REMAPPALETTERGB</td>
<td>Function</td>
<td>Remaps a single RGB color value to a color index.</td>
</tr>
<tr>
<td>SAVEIMAGE, SAVEIMAGE_W</td>
<td>Functions</td>
<td>Captures a screen image and saves it as a Windows bitmap file.</td>
</tr>
<tr>
<td>SCROLLTEXTWINDOW</td>
<td>Subroutine</td>
<td>Scrolls the contents of a text window.</td>
</tr>
<tr>
<td>SETBKCOLOR</td>
<td>Function</td>
<td>Sets the current background color.</td>
</tr>
<tr>
<td>SETBKCOLORRRGB</td>
<td>Function</td>
<td>Sets the current background color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETCLIPRGN</td>
<td>Subroutine</td>
<td>Limits graphics output to a part of the screen.</td>
</tr>
<tr>
<td>SETCOLOR</td>
<td>Function</td>
<td>Sets the current color to a new color index.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SETCOLORRGB</td>
<td>Function</td>
<td>Sets the current color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETFILLMASK</td>
<td>Subroutine</td>
<td>Changes the current fill mask to a new pattern.</td>
</tr>
<tr>
<td>SETFONT</td>
<td>Function</td>
<td>Finds a single font matching the specified characteristics and assigns it to OUTGTEXT.</td>
</tr>
<tr>
<td>SETGTEXTROTATION</td>
<td>Subroutine</td>
<td>Sets the direction in which text is written to the specified angle.</td>
</tr>
<tr>
<td>SETLINESTYLE</td>
<td>Subroutine</td>
<td>Changes the current line style.</td>
</tr>
<tr>
<td>SETLINEWIDTHQQ</td>
<td>Subroutine</td>
<td>Sets the width of a solid line drawn using any of the supported graphics functions.</td>
</tr>
<tr>
<td>SETPIXEL, SETPIXEL_W</td>
<td>Functions</td>
<td>Sets color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELRGB, SETPIXELRGB_W</td>
<td>Functions</td>
<td>Sets RGB color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELS</td>
<td>Subroutine</td>
<td>Sets the color indices of multiple pixels.</td>
</tr>
<tr>
<td>SETPIXELSRGB</td>
<td>Subroutine</td>
<td>Sets the RGB color of multiple pixels.</td>
</tr>
<tr>
<td>SETTEXTCOLOR</td>
<td>Function</td>
<td>Sets the current text color to a new color index.</td>
</tr>
<tr>
<td>SETTEXTCOLORRGB</td>
<td>Function</td>
<td>Sets the current text color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETTEXTCURSOR</td>
<td>Function</td>
<td>Sets the height and width of the text cursor for the window in focus.</td>
</tr>
<tr>
<td>SETTEXTPosition</td>
<td>Subroutine</td>
<td>Changes the current text position.</td>
</tr>
<tr>
<td>SETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Sets the current text display window.</td>
</tr>
<tr>
<td>SETVIEWORG</td>
<td>Subroutine</td>
<td>Positions the viewport coordinate origin.</td>
</tr>
<tr>
<td>SETVIEWPORT</td>
<td>Subroutine</td>
<td>Defines the size and screen position of the viewport.</td>
</tr>
<tr>
<td>SETWINDOW</td>
<td>Function</td>
<td>Defines the window coordinate system.</td>
</tr>
<tr>
<td>SETWRITEMODE</td>
<td>Function</td>
<td>Changes the current logical write mode for lines.</td>
</tr>
<tr>
<td>WRAPON</td>
<td>Function</td>
<td>Turns line wrapping on or off.</td>
</tr>
</tbody>
</table>
Portability Library Routines

The following tables list library routines for portability.

If you have programs that use these routines, it is recommended that they access the portability library with USE IFPORT.

Some routines in this library can be called with different sets of arguments, and some can be used as a function or a subroutine. In these cases, the arguments and calling mechanism determine the meaning of the routine. The IFPORT module contains generic interface blocks that give procedure definitions for these routines.

## Information Retrieval

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR_IFCORE_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran run-time library (ifcore).</td>
</tr>
<tr>
<td>FOR_IFPORT_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran portability library (ifport).</td>
</tr>
<tr>
<td>FSTAT</td>
<td>Function</td>
<td>Returns information about a logical file unit.</td>
</tr>
<tr>
<td>GETCWD</td>
<td>Function</td>
<td>Returns the pathname of the current working directory.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Subroutine</td>
<td>Searches the environment for a given string and returns its value if found.</td>
</tr>
<tr>
<td>GETGID</td>
<td>Function</td>
<td>Returns the group ID of the user.</td>
</tr>
<tr>
<td>GETLOG</td>
<td>Subroutine</td>
<td>Returns the user's login name.</td>
</tr>
<tr>
<td>GETPID</td>
<td>Function</td>
<td>Returns the process ID of the process.</td>
</tr>
<tr>
<td>GETUID</td>
<td>Function</td>
<td>Returns the user ID of the user of the process.</td>
</tr>
<tr>
<td>HOSTNAM¹</td>
<td>Function</td>
<td>Returns the name of the user's host.</td>
</tr>
<tr>
<td>ISATTY</td>
<td>Function</td>
<td>Checks whether a logical unit number is a terminal.</td>
</tr>
<tr>
<td>LSTAT</td>
<td>Function</td>
<td>Returns information about a named file. STAT is the preferred form of this function.</td>
</tr>
<tr>
<td>RENAME</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>STAT</td>
<td>Function</td>
<td>Returns information about a named file.</td>
</tr>
<tr>
<td>UNLINK</td>
<td>Function</td>
<td>Deletes the file given by path.</td>
</tr>
</tbody>
</table>
### Process Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT</td>
<td>Subroutine</td>
<td>Stops execution of the current process, clears I/O buffers, and writes a string to external unit 0.</td>
</tr>
<tr>
<td>ALARM</td>
<td>Function</td>
<td>Executes an external subroutine after waiting a specified number of seconds.</td>
</tr>
<tr>
<td>KILL</td>
<td>Function</td>
<td>Sends a signal code to the process given by ID.</td>
</tr>
<tr>
<td>SIGNAL</td>
<td>Function</td>
<td>Changes the action for signal.</td>
</tr>
<tr>
<td>SLEEP</td>
<td>Subroutine</td>
<td>Suspends program execution for a specified number of seconds.</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Function</td>
<td>Executes a command in a separate shell.</td>
</tr>
</tbody>
</table>

### Numeric Values and Conversion

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN</td>
<td>Functions</td>
<td>Return single-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>BIC, BIS</td>
<td>Subroutines</td>
<td>Perform bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>BIT</td>
<td>Function</td>
<td>Performs bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>CDFLOAT</td>
<td>Function</td>
<td>Converts a COMPLEX(4) argument to DOUBLE PRECISION type.</td>
</tr>
<tr>
<td>COMPLINT, COMPLREAL, COMPLLOG</td>
<td>Functions</td>
<td>Return a BIT-WISE complement or logical .NOT. of the argument.</td>
</tr>
<tr>
<td>CSMG</td>
<td>Function</td>
<td>Performs an effective BIT-WISE store under mask.</td>
</tr>
<tr>
<td>DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN</td>
<td>Functions</td>
<td>Return double-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>DFLOATI, DFLOATJ, DFLOATK</td>
<td>Functions</td>
<td>Convert an integer to double-precision real type.</td>
</tr>
<tr>
<td>DRAND, DRANDM</td>
<td>Functions</td>
<td>Return random numbers between 0.0 and 1.0.</td>
</tr>
<tr>
<td>DRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>IDFLOAT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to double-precision real type.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>IFLOATI, IFLOATJ</td>
<td>Functions</td>
<td>Convert an integer to single-precision real type.</td>
</tr>
<tr>
<td>INMAX</td>
<td>Function</td>
<td>Returns the maximum positive value for an integer.</td>
</tr>
<tr>
<td>INTC</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>IRAND, IRANDM</td>
<td>Functions</td>
<td>Return a positive integer in the range 0 through 2<strong>31-1 or 2</strong>15-1 if called without an argument.</td>
</tr>
<tr>
<td>IRANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>IRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>JABS</td>
<td>Function</td>
<td>Computes an absolute value.</td>
</tr>
<tr>
<td>LONG</td>
<td>Function</td>
<td>Converts an INTEGER(2) argument to INTEGER(4) type.</td>
</tr>
<tr>
<td>QRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for a sequence of pseudo-random numbers.</td>
</tr>
<tr>
<td>RAND, RANDOM²</td>
<td>Functions</td>
<td>Return random values in the range 0 through 1.0.</td>
</tr>
<tr>
<td>RANF</td>
<td>Function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>RANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>SEED</td>
<td>Subroutine</td>
<td>Changes the starting point of RANDOM.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>SRAND</td>
<td>Subroutine</td>
<td>Seeds the random number generator used with IRAND and RAND.</td>
</tr>
</tbody>
</table>

**Input and Output**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>Function</td>
<td>Checks a file for accessibility according to mode.</td>
</tr>
<tr>
<td>CHMOD</td>
<td>Function</td>
<td>Changes file attributes.</td>
</tr>
<tr>
<td>FGETC</td>
<td>Function</td>
<td>Reads a character from an external unit.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Function</td>
<td>Flushes the buffer for an external unit to its associated file.</td>
</tr>
<tr>
<td>FPUTC</td>
<td>Function</td>
<td>Writes a character to an external unit.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
<td>-----------------------------------------</td>
</tr>
<tr>
<td>FSEEK</td>
<td>Subroutine</td>
<td>Repositions a file on an external unit.</td>
</tr>
<tr>
<td>FTELL, FTELLI8</td>
<td>Function</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>GETC</td>
<td>Function</td>
<td>Reads a character from unit 5.</td>
</tr>
<tr>
<td>GETPOS, GETPOSI8</td>
<td>Functions</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>PUTC</td>
<td>Function</td>
<td>Writes a character to unit 6.</td>
</tr>
</tbody>
</table>

**Date and Time**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOCK</td>
<td>Function</td>
<td>Returns current time in HH:MM:SS format using a 24-hour clock.</td>
</tr>
<tr>
<td>CLOCKX</td>
<td>Subroutine</td>
<td>Returns the processor clock to the nearest microsecond.</td>
</tr>
<tr>
<td>CTIME</td>
<td>Function</td>
<td>Converts system time to a 24-character ASCII string.</td>
</tr>
<tr>
<td>DATE³</td>
<td>Subroutine or Function</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DATE4</td>
<td>Subroutine</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DCLOCK</td>
<td>Function</td>
<td>Returns the elapsed time in seconds since the start of the current process.</td>
</tr>
<tr>
<td>DTIME</td>
<td>Function</td>
<td>Returns CPU time since later of (1) start of program, or (2) most recent call to DTIME.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Function</td>
<td>Returns elapsed CPU time since the start of program execution.</td>
</tr>
<tr>
<td>FDATE</td>
<td>Subroutine or Function</td>
<td>Returns the current date and time as an ASCII string.</td>
</tr>
<tr>
<td>GETDAT</td>
<td>Subroutine</td>
<td>Returns the date.</td>
</tr>
<tr>
<td>GETTIM</td>
<td>Subroutine</td>
<td>Returns the time.</td>
</tr>
<tr>
<td>GMTIME</td>
<td>Subroutine</td>
<td>Returns Greenwich Mean Time as a 9-element integer array.</td>
</tr>
<tr>
<td>IDATE³</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>IDATE4</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>ITIME</td>
<td>Subroutine</td>
<td>Returns current time as a 3-element array (hour, minute, second).</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>JDATE³</td>
<td>Function</td>
<td>Returns current date as an 8-character string with the Julian date.</td>
</tr>
<tr>
<td>JDATE⁴</td>
<td>Function</td>
<td>Returns current date as a 10-character string with the Julian date.</td>
</tr>
<tr>
<td>LTIME</td>
<td>Subroutine</td>
<td>Returns local time as a 9-element integer array.</td>
</tr>
<tr>
<td>RTC</td>
<td>Function</td>
<td>Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>SECONDS</td>
<td>Function</td>
<td>Returns number of seconds since midnight, less the value of its argument.</td>
</tr>
<tr>
<td>SETDAT</td>
<td>Function</td>
<td>Sets the date.</td>
</tr>
<tr>
<td>SETTIM</td>
<td>Function</td>
<td>Sets the time.</td>
</tr>
<tr>
<td>TIME</td>
<td>Subroutine or Function</td>
<td>As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>TIMEF</td>
<td>Function</td>
<td>Returns the number of seconds since the first time this function was called (or zero).</td>
</tr>
</tbody>
</table>

**Error Handling**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETLASTERROR</td>
<td>Function</td>
<td>Returns the last error set.</td>
</tr>
<tr>
<td>GETLASTERRORQQ</td>
<td>Function</td>
<td>Returns the last error set by a run-time function or subroutine.</td>
</tr>
<tr>
<td>IERRORNO</td>
<td>Function</td>
<td>Returns the last code error.</td>
</tr>
<tr>
<td>SETERRORMODEQQ</td>
<td>Subroutine</td>
<td>Sets the mode for handling critical errors.</td>
</tr>
</tbody>
</table>

**Program Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISEQQ</td>
<td>Function</td>
<td>Sends an interrupt to the executing program, simulating an interrupt from the operating system.</td>
</tr>
<tr>
<td>RUNQQ</td>
<td>Function</td>
<td>Calls another program and waits for it to execute.</td>
</tr>
<tr>
<td>SIGNALQQ</td>
<td>Function</td>
<td>Controls signal handling.</td>
</tr>
<tr>
<td>SLEEPQQ</td>
<td>Subroutine</td>
<td>Delays execution of the program for the specified time.</td>
</tr>
</tbody>
</table>
### System, Drive, and Directory

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHDIR</td>
<td>Function</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>CHANGEDIRQQ</td>
<td>Function</td>
<td>Makes the specified directory the current (default) directory.</td>
</tr>
<tr>
<td>CHANGEDRIVEQQ</td>
<td>Function</td>
<td>Makes the specified drive the current drive.</td>
</tr>
<tr>
<td>DELDIRQQ</td>
<td>Function</td>
<td>Deletes a specified directory.</td>
</tr>
<tr>
<td>GETDRIVEDIRQQ</td>
<td>Function</td>
<td>Returns the current drive and directory path.</td>
</tr>
<tr>
<td>GETDRIVESIZEQQ</td>
<td>Function</td>
<td>Gets the size of the specified drive.</td>
</tr>
<tr>
<td>GETDRIVESQQ</td>
<td>Function</td>
<td>Reports the drives available to the system.</td>
</tr>
<tr>
<td>GETENVQQ</td>
<td>Function</td>
<td>Gets a value from the current environment.</td>
</tr>
<tr>
<td>MADEDIRQQ</td>
<td>Function</td>
<td>Makes a directory with the specified directory name.</td>
</tr>
<tr>
<td>SETENVQQ</td>
<td>Function</td>
<td>Adds a new environment variable, or sets the value of an existing one.</td>
</tr>
<tr>
<td>SYSTEMQQ</td>
<td>Function</td>
<td>Executes a command by passing a command string to the operating system's command interpreter.</td>
</tr>
</tbody>
</table>

### Speaker

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>Subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
</tbody>
</table>

### File Management

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELFILESQQ</td>
<td>Function</td>
<td>Deletes the specified files in a specified directory.</td>
</tr>
<tr>
<td>FINDFILEQQ</td>
<td>Function</td>
<td>Searches for a file in the directories specified in the PATH environment variable.</td>
</tr>
<tr>
<td>FULLPATHQQ</td>
<td>Function</td>
<td>Returns the full path for a specified file or directory.</td>
</tr>
<tr>
<td>GETFILEINFOQQ</td>
<td>Function</td>
<td>Returns information about files with names that match a request string.</td>
</tr>
<tr>
<td>PACKTIMEQQ</td>
<td>Subroutine</td>
<td>Packs time values for use by SETFILETIMEQQ.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>RENAMEFILEQQ</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>SETFILEACCESSQQ</td>
<td>Function</td>
<td>Sets file-access mode for the specified file.</td>
</tr>
<tr>
<td>SETFILETIMEQQ</td>
<td>Function</td>
<td>Sets modification time for a given file.</td>
</tr>
<tr>
<td>SPLITPATHQQ</td>
<td>Function</td>
<td>Breaks a full path into four components.</td>
</tr>
<tr>
<td>UNPACKTIMEQQ</td>
<td>Subroutine</td>
<td>Unpacks a file's packed time and date value into its component parts.</td>
</tr>
</tbody>
</table>

**Arrays**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSEARCHQQ</td>
<td>Function</td>
<td>Performs a binary search for a specified element on a sorted one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
<tr>
<td>SORTQQ</td>
<td>Subroutine</td>
<td>Sorts a one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
</tbody>
</table>

**Floating-Point Inquiry and Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEARSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Clears the exception flags in the floating-point processor status word.</td>
</tr>
<tr>
<td>GETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>GETSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor status word.</td>
</tr>
<tr>
<td>LCWRQQ</td>
<td>Subroutine</td>
<td>Same as SETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SCWRQQ</td>
<td>Subroutine</td>
<td>Same as GETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Sets the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>SSWRQQ</td>
<td>Subroutine</td>
<td>Same as GETSTATUSFPQQ.</td>
</tr>
</tbody>
</table>

**IEEE Functionality**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_FLAGS</td>
<td>Function</td>
<td>Sets, gets, or clears IEEE flags.</td>
</tr>
<tr>
<td>IEEE_HANDLER</td>
<td>Function</td>
<td>Establishes a handler for IEEE exceptions.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SPORT_CANCEL_IO</td>
<td>Function</td>
<td>Cancels any I/O in progress to the specified port.</td>
</tr>
<tr>
<td>SPORT_CONNECT</td>
<td>Function</td>
<td>Establishes the connection to a serial port and defines certain usage parameters.</td>
</tr>
<tr>
<td>SPORT_CONNECT_EX</td>
<td>Function</td>
<td>Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.</td>
</tr>
<tr>
<td>SPORT_GET_HANDLE</td>
<td>Function</td>
<td>Returns the Windows* handle associated with the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits, and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE_EX</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_TIMEOUTS</td>
<td>Function</td>
<td>Returns the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_PEEK_DATA</td>
<td>Function</td>
<td>Returns information about the availability of input data.</td>
</tr>
<tr>
<td>SPORT_PEEK_LINE</td>
<td>Function</td>
<td>Returns information about the availability of input records.</td>
</tr>
<tr>
<td>SPORT_PURGE</td>
<td>Function</td>
<td>Executes a purge function on the specified port.</td>
</tr>
<tr>
<td>SPORT_READ_DATA</td>
<td>Function</td>
<td>Reads available data from the port specified.</td>
</tr>
<tr>
<td>SPORT_READ_LINE</td>
<td>Function</td>
<td>Reads a record from the port specified.</td>
</tr>
<tr>
<td>SPORT_RELEASE</td>
<td>Function</td>
<td>Releases a serial port that has previously been connected.</td>
</tr>
<tr>
<td>SPORT_SET_STATE</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_STATE_EX</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_TIMEOUTS</td>
<td>Function</td>
<td>Sets the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_SHOW_STATE</td>
<td>Function</td>
<td>Displays the state of a port.</td>
</tr>
</tbody>
</table>
### SPORT_SPECIAL_FUNC
- **Procedure Type**: Function
- **Description**: Executes a communications function on a specified port.

### SPORT_WRITE_DATA
- **Procedure Type**: Function
- **Description**: Outputs data to a specified port.

### SPORT_WRITE_LINE
- **Procedure Type**: Function
- **Description**: Outputs data to a specified port and follows it with a record terminator.

### Miscellaneous

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNBLNK</td>
<td>Function</td>
<td>Returns the index of the last non-blank character in a string.</td>
</tr>
<tr>
<td>QSORT</td>
<td>Subroutine</td>
<td>Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.</td>
</tr>
<tr>
<td>RINDEX</td>
<td>Function</td>
<td>Returns the index of the last occurrence of a substring in a string.</td>
</tr>
<tr>
<td>SCANENV</td>
<td>Subroutine</td>
<td>Scans the environment for the value of an environment variable.</td>
</tr>
<tr>
<td>TTYNAM</td>
<td>Subroutine</td>
<td>Checks whether a logical unit is a terminal.</td>
</tr>
</tbody>
</table>

1 This routine can also be specified as HOSTNM.
2 There is also a RANDOM subroutine in the portability library.
3 The two-digit year return value of DATE, IDATE, and JDATE may cause problems with the year 2000. Use the intrinsic subroutine DATE_AND_TIME instead.
4 W*S

### National Language Support Library Routines (W*S)

The following table lists library routines for National Language Support (NLS).

Programs that use these routines must access the NLS library with USE IFNLS. These routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBCharLen</td>
<td>Function</td>
<td>Returns the length of the first multibyte character in a string.</td>
</tr>
<tr>
<td>MBConvertMBToUnicode</td>
<td>Function</td>
<td>Converts a character string from a multibyte codepage to a Unicode string.</td>
</tr>
<tr>
<td>MBConvertUnicodeToMB</td>
<td>Function</td>
<td>Converts a Unicode string to a multibyte character string of the current codepage.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MBCurMax</td>
<td>Function</td>
<td>Returns the longest possible multibyte character for the current codepage.</td>
</tr>
<tr>
<td>MBINCHARQQ</td>
<td>Function</td>
<td>Same as INCHARQQ, but can read a single multibyte character at once.</td>
</tr>
<tr>
<td>MBINDEX</td>
<td>Function</td>
<td>Same as INDEX, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBJISToJMS</td>
<td>Function</td>
<td>Converts a Japan Industry Standard (JIS) character to a Kanji (Shift JIS or JMS) character.</td>
</tr>
<tr>
<td>MBJMSToJIS</td>
<td>Function</td>
<td>Converts a Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.</td>
</tr>
<tr>
<td>MBLead</td>
<td>Function</td>
<td>Determines whether a given character is the first byte of a multibyte character.</td>
</tr>
<tr>
<td>MBLen</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, including trailing spaces.</td>
</tr>
<tr>
<td>MBLen_Trim</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, not including trailing spaces.</td>
</tr>
<tr>
<td>MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE</td>
<td>Function</td>
<td>Same as LGE, LGT, LLE, and LLT, and the logical operators .EQ. and .NE., except that multibyte characters can be included in their arguments.</td>
</tr>
<tr>
<td>MBNext</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately after the given string position.</td>
</tr>
<tr>
<td>MBPrev</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately before the given string position.</td>
</tr>
<tr>
<td>MBSCAN</td>
<td>Function</td>
<td>Same as SCAN, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBStrLead</td>
<td>Function</td>
<td>Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.</td>
</tr>
<tr>
<td>MBVERIFY</td>
<td>Function</td>
<td>Same as VERIFY, except that multibyte characters can be included in its arguments.</td>
</tr>
</tbody>
</table>
**POSIX* Library Procedures**

The following table lists library procedures for POSIX*.

Programs that use POSIX procedures must access the appropriate libraries with USE IFPOSIX. The IPX nnnn routines are functions; the PXF nnnn routines are subroutines, except for the routines named PXFIS nnnn and PXFWIF nnnn.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NLSEnumCodepages</td>
<td>Function</td>
<td>Returns an array of valid codepages for the current console.</td>
</tr>
<tr>
<td>NLSEnumLocales</td>
<td>Function</td>
<td>Returns an array of locales (language/country combinations) installed on the system.</td>
</tr>
<tr>
<td>NLSFormatCurrency</td>
<td>Function</td>
<td>Formats a currency number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatDate</td>
<td>Function</td>
<td>Formats a date according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatNumber</td>
<td>Function</td>
<td>Formats a number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatTime</td>
<td>Function</td>
<td>Formats a time according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSGetEnvironmentCodepage</td>
<td>Function</td>
<td>Returns the current codepage for the system Window or console.</td>
</tr>
<tr>
<td>NLSGetLocale</td>
<td>Subroutine</td>
<td>Returns the current language, country, and/or codepage.</td>
</tr>
<tr>
<td>NLSGetLocaleInfo</td>
<td>Function</td>
<td>Returns information about the current locale.</td>
</tr>
<tr>
<td>NLSSetEnvironmentCodepage</td>
<td>Function</td>
<td>Sets the codepage for the console.</td>
</tr>
<tr>
<td>NLSSetLocale</td>
<td>Function</td>
<td>Sets the current language, country, and codepage.</td>
</tr>
</tbody>
</table>

**POSIX* Library Procedures**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPXFARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>IPXFCONST</td>
<td>Returns the value associated with a constant defined in the C POSIX standard.</td>
</tr>
<tr>
<td>IPXFLENTTRIM</td>
<td>Returns the index of the last non-blank character in an input string.</td>
</tr>
<tr>
<td>IPXFWEXITSTATUS¹</td>
<td>Returns the exit code of a child process.</td>
</tr>
<tr>
<td>IPXFWSTOPSIG¹</td>
<td>Returns the number of the signal that caused a child process to stop.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>IPXFWTERMSIG&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Returns the number of the signal that caused a child process to terminate.</td>
</tr>
<tr>
<td>PXF(type)GET</td>
<td>Gets the value stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXF(type)SET</td>
<td>Sets the value of a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)GET</td>
<td>Gets the array values stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)SET</td>
<td>Sets the value of an array component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFACCESS</td>
<td>Determines the accessibility of a file.</td>
</tr>
<tr>
<td>PXFALARM</td>
<td>Schedules an alarm.</td>
</tr>
<tr>
<td>PXFALLSUBHANDLE</td>
<td>Calls the associated subroutine.</td>
</tr>
<tr>
<td>PXFCFGETISPEED&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Returns the input baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFGETOSPEED&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Returns the output baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETISPEED&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Sets the input baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETOSPEED&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Sets the output baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>PXFCHMOD</td>
<td>Changes the ownership mode of the file.</td>
</tr>
<tr>
<td>PXFCHOWN&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Changes the owner and group of a file.</td>
</tr>
<tr>
<td>PXFCLEARENV</td>
<td>Clears the process environment.</td>
</tr>
<tr>
<td>PXFCLOSE</td>
<td>Closes the file associated with the descriptor.</td>
</tr>
<tr>
<td>PXFCLOSEDIR</td>
<td>Closes the directory stream.</td>
</tr>
<tr>
<td>PXFCNTL&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Manipulates an open file descriptor.</td>
</tr>
<tr>
<td>PXFCSTAT</td>
<td>Returns the value associated with a constant.</td>
</tr>
<tr>
<td>PXFCREAR</td>
<td>Creates a new file or rewrites an existing file.</td>
</tr>
<tr>
<td>PXFCTERMID&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Generates a terminal pathname.</td>
</tr>
<tr>
<td>PXFDUP, PXFDUP2</td>
<td>Duplicates an existing file descriptor.</td>
</tr>
<tr>
<td>PXFE(type)GET</td>
<td>Gets the value stored in an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFE(type)SET</td>
<td>Sets the value of an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFEXECV, PXFEXECVE, PXFEXECVP</td>
<td>Executes a new process by passing command-line arguments.</td>
</tr>
<tr>
<td>PXFEXIT, PXFFASTEXIT</td>
<td>Exits from a process.</td>
</tr>
<tr>
<td>PXFFDOPEN</td>
<td>Opens an external unit.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFFFLUSH</td>
<td>Flushes a file directly to disk.</td>
</tr>
<tr>
<td>PXFFGETC</td>
<td>Reads a character from a file.</td>
</tr>
<tr>
<td>PXFFILENO</td>
<td>Returns the file descriptor associated with a specified unit.</td>
</tr>
<tr>
<td>PXFFORK</td>
<td>Creates a child process that differs from the parent process only in its PID.</td>
</tr>
<tr>
<td>PXFFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFFPUTC</td>
<td>Writes a character to a file.</td>
</tr>
<tr>
<td>PXFFFSEEK</td>
<td>Modifies a file position.</td>
</tr>
<tr>
<td>PXFFSTAT</td>
<td>Gets a file's status information.</td>
</tr>
<tr>
<td>PXFFTELL</td>
<td>Returns the relative position in bytes from the beginning of the file.</td>
</tr>
<tr>
<td>PXFGETARG</td>
<td>Gets the specified command-line argument.</td>
</tr>
<tr>
<td>PXFGETC</td>
<td>Reads a character from standard input unit 5.</td>
</tr>
<tr>
<td>PXFGETCWD</td>
<td>Returns the path of the current working directory.</td>
</tr>
<tr>
<td>PXFGETEGID</td>
<td>Gets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETENV</td>
<td>Gets the setting of an environment variable.</td>
</tr>
<tr>
<td>PXFGETEUID</td>
<td>Gets the effective user ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGID</td>
<td>Gets the real group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGRGID</td>
<td>Gets group information for the specified GID.</td>
</tr>
<tr>
<td>PXFGETGRNAM</td>
<td>Gets group information for the named group.</td>
</tr>
<tr>
<td>PXFGETGROUPS</td>
<td>Gets supplementary group IDs.</td>
</tr>
<tr>
<td>PXFGETLOGIN</td>
<td>Gets the name of the user.</td>
</tr>
<tr>
<td>PXFGETPGRP</td>
<td>Gets the process group ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPID</td>
<td>Gets the process ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPPID</td>
<td>Gets the process ID of the parent of the calling process.</td>
</tr>
<tr>
<td>PXFGETPWNAM</td>
<td>Gets password information for a specified name.</td>
</tr>
<tr>
<td>PXFGETPWUID</td>
<td>Gets password information for a specified UID.</td>
</tr>
<tr>
<td>PXFGETSUBHANDLE</td>
<td>Returns a subroutine handle for a subroutine.</td>
</tr>
<tr>
<td>PXFGETUID</td>
<td>Gets the real user ID of the current process.</td>
</tr>
<tr>
<td>PXFISATTY</td>
<td>Tests whether a file descriptor is connected to a terminal.</td>
</tr>
<tr>
<td>PXFISBLK</td>
<td>Tests for a block special file.</td>
</tr>
<tr>
<td>PXFISCHR</td>
<td>Tests for a character file.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFISCONST</td>
<td>Tests whether a string is a valid constant name.</td>
</tr>
<tr>
<td>PXFISDIR</td>
<td>Tests whether a file is a directory.</td>
</tr>
<tr>
<td>PXFISFIFO</td>
<td>Tests whether a file is a special FIFO file.</td>
</tr>
<tr>
<td>PXFISREG</td>
<td>Tests whether a file is a regular file.</td>
</tr>
<tr>
<td>PXFKILL</td>
<td>Sends a signal to a specified process.</td>
</tr>
<tr>
<td>PXFLINK</td>
<td>Creates a link to a file or directory.</td>
</tr>
<tr>
<td>PXFLLOCALTIME</td>
<td>Converts a given elapsed time in seconds to local time.</td>
</tr>
<tr>
<td>PXFLSEEK</td>
<td>Positions a file a specified distance in bytes.</td>
</tr>
<tr>
<td>PXFMKDIR</td>
<td>Creates a new directory.</td>
</tr>
<tr>
<td>PXFMKFIFO</td>
<td>Creates a new FIFO.</td>
</tr>
<tr>
<td>PXFOPEN</td>
<td>Opens or creates a file.</td>
</tr>
<tr>
<td>PXFOPENDIR</td>
<td>Opens a directory and associates a stream with it.</td>
</tr>
<tr>
<td>PXFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFPAUSE</td>
<td>Suspends process execution.</td>
</tr>
<tr>
<td>PXFPIPE</td>
<td>Creates a communications pipe between two processes.</td>
</tr>
<tr>
<td>PXFPOSIXIO</td>
<td>Sets the current value of the POSIX I/O flag.</td>
</tr>
<tr>
<td>PXFPUTC</td>
<td>Outputs a character to logical unit 6 (stdout).</td>
</tr>
<tr>
<td>PXFREAD</td>
<td>Reads from a file.</td>
</tr>
<tr>
<td>PXFREADDIR</td>
<td>Reads the current directory entry.</td>
</tr>
<tr>
<td>PXFRENAME</td>
<td>Changes the name of a file.</td>
</tr>
<tr>
<td>PXFREWINDDIR</td>
<td>Resets the position of the stream to the beginning of the directory.</td>
</tr>
<tr>
<td>PXFRMDIR</td>
<td>Removes a directory.</td>
</tr>
<tr>
<td>PXFSETENV</td>
<td>Adds a new environment variable or sets the value of an environment variable.</td>
</tr>
<tr>
<td>PXFSETGID</td>
<td>Sets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFSETPGID</td>
<td>Sets the process group ID.</td>
</tr>
<tr>
<td>PXFSETSID</td>
<td>Creates a session and sets the process group ID.</td>
</tr>
<tr>
<td>PXFSETUID</td>
<td>Sets the effective user ID of the current process.</td>
</tr>
<tr>
<td>PXFSIGACTION</td>
<td>Changes the action associated with a specific signal.</td>
</tr>
<tr>
<td>PXFSIGADDSET</td>
<td>Adds a signal to a signal set.</td>
</tr>
<tr>
<td>PXFSIGDELSET</td>
<td>Deletes a signal from a signal set.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFSIGEMPTYSET</td>
<td>Empties a signal set.</td>
</tr>
<tr>
<td>PXFSIGFILLSET</td>
<td>Fills a signal set.</td>
</tr>
<tr>
<td>PXFSIGISMEMBER</td>
<td>Tests whether a signal is a member of a signal set.</td>
</tr>
<tr>
<td>PXFSIGPENDING</td>
<td>Examines pending signals.</td>
</tr>
<tr>
<td>PXFSIGPROCMASK</td>
<td>Changes the list of currently blocked signals.</td>
</tr>
<tr>
<td>PXFSIGSUSPEND</td>
<td>Suspends the process until a signal is received.</td>
</tr>
<tr>
<td>PXFSLEEP</td>
<td>Forces the process to sleep.</td>
</tr>
<tr>
<td>PXFSTAT</td>
<td>Gets a file's status information.</td>
</tr>
<tr>
<td>PXFSTRUCTCOPY</td>
<td>Copies the contents of one structure to another.</td>
</tr>
<tr>
<td>PXFSTRUCTCREATE</td>
<td>Creates an instance of the specified structure.</td>
</tr>
<tr>
<td>PXFSTRUCTFREE</td>
<td>Deletes the instance of a structure.</td>
</tr>
<tr>
<td>PXFSYSCONF</td>
<td>Gets values for system limits or options.</td>
</tr>
<tr>
<td>PXFTCDDRRAIN</td>
<td>Waits until all output written has been transmitted.</td>
</tr>
<tr>
<td>PXFTCFLOW</td>
<td>Suspends the transmission or reception of data.</td>
</tr>
<tr>
<td>PXFTCFLUSH</td>
<td>Discards terminal input data, output data, or both.</td>
</tr>
<tr>
<td>PXFTCGETATTR</td>
<td>Reads current terminal settings.</td>
</tr>
<tr>
<td>PXFTCGETPGRP</td>
<td>Gets the foreground process group ID associated with the terminal.</td>
</tr>
<tr>
<td>PXFTCSENDBREAK</td>
<td>Sends a break to the terminal.</td>
</tr>
<tr>
<td>PXFTCSETATTR</td>
<td>Writes new terminal settings.</td>
</tr>
<tr>
<td>PXFTCSETPGRP</td>
<td>Sets the foreground process group associated with the terminal.</td>
</tr>
<tr>
<td>PXFTIME</td>
<td>Gets the system time.</td>
</tr>
<tr>
<td>PXFTIMES</td>
<td>Gets process times.</td>
</tr>
<tr>
<td>PXFTTYNAM</td>
<td>Gets the terminal pathname.</td>
</tr>
<tr>
<td>PXFUCOMPARE</td>
<td>Compares two unsigned integers.</td>
</tr>
<tr>
<td>PXFUMASK</td>
<td>Sets a new file creation mask and gets the previous one.</td>
</tr>
<tr>
<td>PXFUNAME</td>
<td>Gets the operation system name.</td>
</tr>
<tr>
<td>PXFUNLINK</td>
<td>Removes a directory entry.</td>
</tr>
<tr>
<td>PXFUTIME</td>
<td>Sets file access and modification times.</td>
</tr>
<tr>
<td>PXFWAIT</td>
<td>Waits for a child process.</td>
</tr>
<tr>
<td>PXFWAITPID</td>
<td>Waits for a specific PID.</td>
</tr>
<tr>
<td>PXFWIFEXITED</td>
<td>Determines if a child process has exited.</td>
</tr>
<tr>
<td>PXFWIFSIGNALED</td>
<td>Determines if a child process has exited because of a signal.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------</td>
</tr>
<tr>
<td>PXFWIFSTOPPED¹</td>
<td></td>
</tr>
<tr>
<td>PXFWRITE</td>
<td></td>

**Dialog Library Routines (W*S)**

The following table lists routines from the dialog library.

Programs that use these routines must access the Dialog library with USE IFLOGM. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLGEXIT</td>
<td>Subroutine</td>
<td>Closes an open dialog.</td>
</tr>
<tr>
<td>DLGFLUSH</td>
<td>Subroutine</td>
<td>Updates the display of a dialog box.</td>
</tr>
<tr>
<td>DLGGET</td>
<td>Function</td>
<td>Retrieves values of dialog control variables.</td>
</tr>
<tr>
<td>DLGGETCHAR</td>
<td>Function</td>
<td>Retrieves values of dialog control variables of type Character.</td>
</tr>
<tr>
<td>DLGGETINT</td>
<td>Function</td>
<td>Retrieves values of dialog control variables of type Integer.</td>
</tr>
<tr>
<td>DLGGETLOG</td>
<td>Function</td>
<td>Retrieves values of dialog control variables of type Logical.</td>
</tr>
<tr>
<td>DLGINIT</td>
<td>Function</td>
<td>Initializes a dialog.</td>
</tr>
<tr>
<td>DLGINITWITHRESOURCEHANDLE</td>
<td>Function</td>
<td>Initializes a dialog.</td>
</tr>
<tr>
<td>DLGISDLGMESSAGE</td>
<td>Function</td>
<td>Determines whether a message is intended for a modeless dialog box and, if it is, processes it.</td>
</tr>
<tr>
<td>DLGISDLGMESSAGEWITHDLG</td>
<td>Function</td>
<td>Determines whether a message is intended for a specific modeless dialog box and, if it is, processes it.</td>
</tr>
<tr>
<td>DLMODAL</td>
<td>Function</td>
<td>Displays a dialog and processes dialog selections from user.</td>
</tr>
<tr>
<td>DLMODALWITHPARENT</td>
<td>Function</td>
<td>Displays a dialog in a specific parent window and processes dialog selections from user.</td>
</tr>
<tr>
<td>DLMODELESS</td>
<td>Function</td>
<td>Displays a modeless dialog box.</td>
</tr>
<tr>
<td>DLGSNDCTRLMESSAGE</td>
<td>Function</td>
<td>Sends a message to a dialog box control.</td>
</tr>
<tr>
<td>DLGSET</td>
<td>Function</td>
<td>Assigns values to dialog control variables.</td>
</tr>
<tr>
<td>DLGSETCHAR</td>
<td>Function</td>
<td>Assigns values to dialog control variables of type Character.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DLGSETCTRLEVENTHANDLER</td>
<td>Function</td>
<td>Assigns your own event handlers to ActiveX controls in a dialog box.</td>
</tr>
<tr>
<td>DLGSETINT</td>
<td>Function</td>
<td>Assigns values to dialog control variables of type Integer.</td>
</tr>
<tr>
<td>DLGSETLOG</td>
<td>Function</td>
<td>Assigns values to dialog control variables of type Logical.</td>
</tr>
<tr>
<td>DLGSETRETURN</td>
<td>Subroutine</td>
<td>Sets the return value for DLGMODAL.</td>
</tr>
<tr>
<td>DLGSETSUB</td>
<td>Function</td>
<td>Assigns procedures (callback routines) to dialog controls.</td>
</tr>
<tr>
<td>DLGSETTITLE</td>
<td>Subroutine</td>
<td>Sets the title of a dialog box.</td>
</tr>
<tr>
<td>DLGUNINIT</td>
<td>Subroutine</td>
<td>Deallocates memory occupied by an initialized dialog.</td>
</tr>
</tbody>
</table>

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features

**COM and Automation Library Routines (W*S)**

The following tables list COM and Automation library routines.

Programs that use COM routines must access the appropriate libraries with USE IFCOM. Programs that use automation routines must access the appropriate libraries with USE IFAUTO. Some procedures also require the USE IFWINTY module.

The COM and Automation routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

**Component Object Model (COM) Procedures (USE IFCOM)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMAddObjectReference</td>
<td>Function</td>
<td>Adds a reference to an object's interface.</td>
</tr>
<tr>
<td>COMCLSIDFromProgID¹</td>
<td>Subroutine</td>
<td>Passes a programmatic identifier and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCLSIDFromString¹</td>
<td>Subroutine</td>
<td>Passes a class identifier string and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCreateObject¹</td>
<td>Subroutine</td>
<td>A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.</td>
</tr>
<tr>
<td>COMCreateObjectByGUID¹</td>
<td>Subroutine</td>
<td>Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.</td>

<td>COMGetActiveObjectByGUID</td>
<td>Subroutine</td>
<td>Passes a class identifier and returns a pointer to the interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetActiveObjectByProgID</td>
<td>Subroutine</td>
<td>Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetFileObject</td>
<td>Subroutine</td>
<td>Passes a file name and returns a pointer to the IDispatch interface of an Automation object that can manipulate the file.</td>
</tr>
<tr>
<td>COMInitialize</td>
<td>Subroutine</td>
<td>Initializes the COM library.</td>
</tr>
<tr>
<td>COMIsEqualGUID</td>
<td>Function</td>
<td>Determines whether two GUIDs are the same.</td>
</tr>
<tr>
<td>COMQueryInterface</td>
<td>Subroutine</td>
<td>Passes an interface identifier and returns a pointer to an object's interface.</td>
</tr>
<tr>
<td>COMReleaseObject</td>
<td>Function</td>
<td>Indicates that the program is done with a reference to an object’s interface.</td>
</tr>
<tr>
<td>COMStringFromGUID</td>
<td>Subroutine</td>
<td>Passes a GUID and returns a string of printable characters.</td>
</tr>
<tr>
<td>COMUninitialize</td>
<td>Subroutine</td>
<td>Uninitializes the COM library.</td>
</tr>
</tbody>
</table>

**Automation Server Procedures (USE IFAUTO)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOAddArg</td>
<td>Subroutine</td>
<td>Passes an argument name and value and adds the argument to the argument list data structure.</td>
</tr>
<tr>
<td>AUTOAllocateInvokeArgs</td>
<td>Function</td>
<td>Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.</td>
</tr>
<tr>
<td>AUTOAllocateInvokeArgs</td>
<td>Subroutine</td>
<td>Deallocates an argument list data structure.</td>
</tr>
<tr>
<td>AUTODEallocateInvokeArgs</td>
<td>Subroutine</td>
<td></td>
</tr>
<tr>
<td>AUTOGGetExceptInfo</td>
<td>Subroutine</td>
<td>Retrieves the exception information when a method has returned an exception status.</td>
</tr>
<tr>
<td>AUTOGGetProperty</td>
<td>Function</td>
<td>Passes the name or identifier of the property and gets the value of the Automation object’s property.</td>
</tr>
</tbody>
</table>

1 Intel® Fortran Compiler 16.0 User and Reference Guide
<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOGetPropertyByID</td>
<td>Function</td>
<td>Passes the member ID of the property and gets the value of the Automation object’s property into the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOGetPropertyInvokeArgs</td>
<td>Function</td>
<td>Passes an argument list data structure and gets the value of the Automation object’s property specified in the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOInvoke</td>
<td>Function</td>
<td>Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments.</td>
</tr>
<tr>
<td>AUTOSetProperty</td>
<td>Function</td>
<td>Passes the name or identifier of the property and a value, and sets the value of the Automation object’s property.</td>
</tr>
<tr>
<td>AUTOSetPropertyByID</td>
<td>Function</td>
<td>Passes the member ID of the property and sets the value of the Automation object’s property, using the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOSetPropertyInvokeArgs</td>
<td>Function</td>
<td>Passes an argument list data structure and sets the value of the Automation object’s property specified in the argument list's first argument.</td>
</tr>
</tbody>
</table>

1These routines also require USE IFWINTY.

**Miscellaneous Run-Time Library Routines**

The following table lists miscellaneous run-time library routines.
Programs that use most of these routines should contain a USE IFCORE statement to obtain the proper interfaces to these routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMITQQ</td>
<td>Function</td>
<td>Forces the operating system to execute any pending write operations for a file.</td>
</tr>
<tr>
<td>FOR_DESCRIPTOR_ASSIGN</td>
<td>Subroutine</td>
<td>Creates an array descriptor in memory.</td>
</tr>
<tr>
<td>FOR_GET_FPE</td>
<td>Function</td>
<td>Returns the current settings of floating-point exception flags.</td>
</tr>
<tr>
<td>for_rtl_finish_</td>
<td>Function</td>
<td>Cleans up the Fortran run-time environment.</td>
</tr>
<tr>
<td>for_rtl_init_</td>
<td>Function</td>
<td>Initializes the Fortran run-time environment.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FOR_SET_FPE</td>
<td>Function</td>
<td>Sets the floating-point exception flags.</td>
</tr>
<tr>
<td>FOR__SET_FTN_ALLOC</td>
<td>Function</td>
<td>Tells the Fortran Run-Time Library (RTL) to use a user-defined routine to dynamically allocate commons.</td>
</tr>
<tr>
<td>FOR_SET_REENTRANCY</td>
<td>Function</td>
<td>Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits.</td>
</tr>
<tr>
<td>GERROR</td>
<td>Subroutine</td>
<td>Returns a message for the last error detected by a Fortran runtime routine.</td>
</tr>
<tr>
<td>GETCHARQQ</td>
<td>Function</td>
<td>Returns the next keystroke.</td>
</tr>
<tr>
<td>GETEXCEPTIONPTRSQQ</td>
<td>Function</td>
<td>Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal() routine.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Function</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
<tr>
<td>PERROR</td>
<td>Subroutine</td>
<td>Sends a message to the standard error stream, preceded by a specified string, for the last detected error.</td>
</tr>
<tr>
<td>TRACEBACKQQ</td>
<td>Subroutine</td>
<td>Provides traceback information.</td>
</tr>
</tbody>
</table>

1 W*S

2 You do not need a USE IFCORE statement for this routine.

---

### A to B

#### ABORT

**Portability Subroutine:** Flushes and closes I/O buffers, and terminates program execution.

**Module**

USE IFPORT

**Syntax**

CALL ABORT,[string]
string (Input; optional) Character(*). Allows you to specify an abort message at program termination. When ABORT is called, "abort:" is written to external unit 0, followed by string. If omitted, the default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the program that launched it.

Example

USE IFPORT
!The following prints "abort: Fortran Abort Called"
CALL ABORT
!The following prints "abort: Out of here!"
Call ABORT ("Out of here!")

ABOUTBOXQQ (W*S)

QuickWin Function: Specifies the information displayed in the message box that appears when the user selects the About command from a QuickWin application's Help menu.

Module
USE IFQWIN

Syntax
result=ABOUTBOXQQ(cstring)

cstring (Input; output) Character(*). Null-terminated C string.

Results
The value of the result is INTEGER(4). It is zero if successful; otherwise, nonzero.
If your program does not call ABOUTBOXQQ, the QuickWin run-time library supplies a default string.

Example

USE IFQWIN
INTEGER(4) dummy
! Set the About box message
dummy = ABOUTBOXQQ ('Matrix Multiplier\r\nVersion 1.0'C)

ABS

Elemental Intrinsic Function (Generic): Computes an absolute value.

Syntax
result=ABS(a)

a (Input) Must be of type integer, real, or complex.
Results

The result has the same type and kind type parameter as \( a \) except if \( a \) is complex value, the result type is real. If \( a \) is an integer or real value, the value of the result is \(| a|\); if \( a \) is a complex value \((X, Y)\), the result is the real value \(\text{SQRT}(X^2 + Y^2)\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BABS</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIABS(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>

<tr>
<td>CQABS</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)Or HABS.
\(^2\)Or JIABS. For compatibility with older versions of Fortran, IABS can also be specified as a generic function, which allows integer arguments of any kind and produces a result of type default INTEGER.
\(^3\)The setting of compiler options specifying real size can affect CABS, making CABS generic, which allows a complex argument of any kind to produce a result of default REAL.
\(^4\)This function can also be specified as ZABS.

Example

ABS (-7.4) has the value 7.4.

ABS ((6.0, 8.0)) has the value 10.0.

The following ABS.F90 program calculates two square roots, retaining the sign:

```fortran
REAL mag(2), sgn(2), result(2)
WRITE (*, '(A)') ' Enter two signed magnitudes: '
READ (*, *) mag
sgn = SIGN((/1.0, 1.0/), mag) ! transfer the signs to 1.0s
result = SQRT (ABS (mag)) ! Restore the sign by multiplying by -1 or +1:
result = result * sgn
WRITE (*, *) result
END
```

**ABSTRACT INTERFACE**

**Statement:** Defines an abstract interface.

**Syntax**

```
ABSTRACT INTERFACE
    [interface-body]...
END INTERFACE
```
interface-body

Is one or more function or subroutine subprograms or a procedure pointer. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

The subprogram must not contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name. The subprogram can contain a USE statement.

Description

An abstract interface block defines an interface whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics.

An abstract interface block cannot contain a PROCEDURE statement or a MODULE PROCEDURE statement. Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

Example

Previously, within an interface block, you needed to individually declare subroutines and functions that had the same argument keywords and characteristics. For example:

```fortran
INTERFACE
  SUBROUTINE SUB_ONE (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE SUB_ONE
  SUBROUTINE SUB_TWO (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE SUB_TWO
  ...
END INTERFACE
```

Now you can use an abstract interface to specify a subprogram name for these identical arguments and characteristics. For example:

```fortran
ABSTRACT INTERFACE
  SUBROUTINE TEMPLATE (X)
    REAL, INTENT(IN) :: X
  END SUBROUTINE TEMPLATE
END INTERFACE
```

You can then use the subprogram in the abstract interface as a template in a PROCEDURE statement to declare procedures. For example:

```fortran
PROCEDURE (TEMPLATE) :: SUB_ONE, SUB_TWO, ...
```

INTERFACE
PROCEDURE
FUNCTION
SUBROUTINE
Procedure Interfaces
Use and Host Association Overview

**ACCEPT**

**Statement:** Transfers input data.

**Syntax**

Formatted:

```
ACCEPT form[, io-list]
```

Formatted - List-Directed:

```
ACCEPT *[io-list]
```

Formatted - Namelist:

```
ACCEPT nml
```

- `form` Is the nonkeyword form of a format specifier (no FMT=).
- `io-list` Is an I/O list.
- `*` Is the format specifier indicating list-directed formatting.
- `nml` Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

The ACCEPT statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using environment variable FOR_ACCEPT.

**Example**

In the following example, character data is read from the implicit unit and binary values are assigned to each of the five elements of array CHARAR:

```
CHARACTER*10 CHARAR(5)
ACCEPT 200, CHARAR
200 FORMAT (5A10)
```

**ACCESS Function**

**Portability Function:** Determines if a file exists and how it can be accessed.

**Module**

USE IFPORT

**Syntax**

```
result = ACCESS(name, mode)
```

- `name` (Input) Character*(*). Name of the file whose accessibility is to be determined.
- `mode` (Input) Character*(*). Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Tests for read permission</td>
</tr>
<tr>
<td>Character</td>
<td>Meaning</td>
</tr>
<tr>
<td>-----------</td>
<td>---------</td>
</tr>
<tr>
<td>w</td>
<td>Tests for write permission</td>
</tr>
<tr>
<td>x</td>
<td>Tests for execute permission. On Windows* systems, the extension of name must be .COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.</td>
</tr>
<tr>
<td>(blank)</td>
<td>Tests for existence</td>
</tr>
</tbody>
</table>

The characters within mode can appear in any order or combination. For example, wrx and r are legal forms of mode and represent the same set of inquiries.

Results

The value of the result is INTEGER(4). It is zero if all inquiries specified by mode are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:

- EACCES: Access denied; the file's permission setting does not allow the specified access
- EINVAL: The mode argument is invalid
- ENOENT: File or path not found

For a list of error codes, see IERNO.

The name argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

Example

```fortran
use ifport
!
!
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J
!
!
J = ACCESS ("DATAFILE.TXT","x")
PRINT *, J
```

GETFILEINFO

ACHAR

**Elemental Intrinsic Function (Generic):** Returns the character in a specified position of the ASCII character set, even if the processor's default character set is different. It is the inverse of the IACHAR function. In Intel Fortran, ACHAR is equivalent to the CHAR function.

Syntax

```fortran
result = ACHAR (i [, kind])
```

i  
(Input) Is of type integer.
kind

(Input; optional) Must be a scalar integer initialization expression.

Results

The result type is character with length 1. If \textit{kind} is present, the kind parameter of the result is that specified by \textit{kind}; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \( i \) has a value within the range 0 to 127, the result is the character in position \( i \) of the ASCII character set; otherwise, it is processor defined. \textsc{achar} (\textsc{iachar}(C)) has the value C for any character C capable of representation in the default character set. For a complete list of ASCII character codes, see Character and Key Code Charts.

Example

\textsc{achar} (71) has the value 'G'.
\textsc{achar} (63) has the value '?'.

\textsc{iachar}
\textsc{ichar}

ACOS

\textbf{Elemental Intrinsic Function (Generic)}: Produces the arccosine of \( x \).

Syntax

\[
\text{result} = \text{ACOS} \ (x)
\]

\( x \)

(Input) Must be of type real. The \(| x |\) must be less than or equal to 1.

Results

The result type and \textit{kind} is the same as \( x \) and is expressed in radians. The value lies in the range 0 to \( \pi \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOS (^1)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DACOS (^1)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QACOS(^2)</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ACOS and DACOS.

\(^2\)Or QARCOS.

Example

ACOS (0.68032123) has the value .8225955.

ACOSD

\textbf{Elemental Intrinsic Function (Generic)}: Produces the arccosine of \( x \).

Syntax

\[
\text{result} = \text{ACOSD} \ (x)
\]
\( x \) (Input) Must be of type real. The \(|x|\) must be less than or equal to 1.

**Results**

The result type and kind is the same as \( x \) and is expressed in degrees. The value lies in the range \(-90\) to \(90\) degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOSD (^1)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DACOSD (^1)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QACOSD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ACOSD and DACOSD.

**Example**

ACOSD \((0.886579)\) has the value 27.55354.

**ACOSH**

*Elemental Intrinsic Function (Generic)*: Produces the hyperbolic arccosine of \( x \).

**Syntax**

\[
\text{result} = \text{ACOSH} (x)
\]

\( x \) (Input) Must be of type real and must be greater than or equal to 1.

**Results**

The result type and kind is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOSH (^1)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DACOSH (^1)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QACOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ACOSH and DACOSH.

**Example**

ACOSH \((1.0)\) has the value 0.0.

ACOSH \((180.0)\) has the value 5.8861.

**ADJUSTL**

*Elemental Intrinsic Function (Generic)*: Adjusts a character string to the left, removing leading blanks and inserting trailing blanks.

**Syntax**

\[
\text{result} = \text{ADJUSTL} (\text{string})
\]
string  (Input) Must be of type character.

Results
The result type is character with the same length and kind parameter as string. The value of the result is the same as string, except that any leading blanks have been removed and inserted as trailing blanks.

Example

```fortran
CHARACTER(16) STRING
STRING= ADJUSTL(' Fortran 90 ') ! returns 'Fortran 90
ADJUSTL (' SUMMERTIME') ! has the value 'SUMMERTIME
```

See Also
ADJUSTR

ADJUSTR

**Elemental Intrinsic Function (Generic):** Adjusts a character string to the right, removing trailing blanks and inserting leading blanks.

Syntax

```fortran
result = ADJUSTR (string)
```

string  (Input) Must be of type character.

Results
The result type is character with the same length and kind parameter as string.

The value of the result is the same as string, except that any trailing blanks have been removed and inserted as leading blanks.

Example

```fortran
CHARACTER(16) STRING
STRING= ADJUSTR(' Fortran 90 ') ! returns '     Fortran 90'
ADJUSTR (' SUMMERTIME ') ! has the value '    SUMMERTIME'
```

See Also
ADJUSTL

AIMAG

**Elemental Intrinsic Function (Generic):** Returns the imaginary part of a complex number. This function can also be specified as IMAG.

Syntax

```fortran
result = AIMAG (z)
```

z  (Input) Must be of type complex.

Results
The result type is real with the same kind parameter as z. If z has the value (x, y), the result has the value y.
Specific Name | Argument Type | Result Type |
--- | --- | --- |
AIMAG | COMPLEX(4) | REAL(4) |
DIMAG | COMPLEX(8) | REAL(8) |
QIMAG | COMPLEX(16) | REAL(16) |

1The setting of compiler options specifying real size can affect AIMAG.

To return the real part of complex numbers, use REAL.

Example

AIMAG ((4.0, 5.0)) has the value 5.0.

The program AIMAG.F90 applies the quadratic formula to a polynomial and allows for complex results:

```fortran
REAL a, b, c
COMPLEX ans1, ans2, d
WRITE (*, 100)
100 FORMAT (' Enter A, b, and c of the polynomial ax**2 + bx + c: ')
READ (*, *) a, b, c
d = CSQRT (CMPLX (b**2 - 4.0*a*c))  ! d is either:
   ! 0.0 + i root, or
   ! root + i 0.0
ans1 = (-b + d) / (2.0 * a)
ans2 = (-b + d) / (2.0 * a)
WRITE (*, 200)
200 FORMAT (/ ' The roots are:' /)
WRITE (*, 300) REAL(ans1), AIMAG(ans1), &
   REAL(ans2), AIMAG(ans2)
300 FORMAT (' X = ', F10.5, ' + i', F10.5)
END
```

See Also

CONJG
DBLE

AIMT

Elemental Intrinsic Function (Generic): Truncates a value to a whole number.

Syntax

```
result = AIMT (a [,kind])
```

- **a**  
  (Input) Must be of type real.

- **kind**  
  (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is real. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter is that of **a**.

The result is defined as the largest integer whose magnitude does not exceed the magnitude of **a** and whose sign is the same as that of **a**. If |a| is less than 1, AIMT(a) has the value zero.
Specific Name | Argument Type | Result Type |
---|---|---|
AINT \(^1\) | REAL(4) | REAL(4) |
DINT \(^1\) | REAL(8) | REAL(8) |
QINT | REAL(16) | REAL(16) |

\(^1\)The setting of compiler options specifying real size can affect AINT and DINT.

To round rather than truncate, use ANINT.

**Example**

AINT (3.678) has the value 3.0.

AINT (-1.375) has the value -1.0.

```fortran
REAL r1, r2
REAL(8) r3(2)
r1 = AINT(2.6) ! returns the value 2.0
r2 = AINT(-2.6) ! returns the value -2.0
r3 = AINT((/1.3, 1.9/), KIND = 8) ! returns the values
! (1.0D0, 1.0D0)
```

**See Also**

ANINT

**ALARM**

*Portability Function*: Causes a subroutine to begin execution after a specified amount of time has elapsed.

**Module**

USE IFPORT

**Syntax**

```fortran
result = ALARM (time, proc)
```

*result*  
(Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when *proc* is to begin execution. If *time* is 0, the alarm is turned off and no routine is called.

*time*  
(Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when *proc* is to begin execution. If *time* is 0, the alarm is turned off and no routine is called.

*proc*  
(Input) Name of the procedure to call. The procedure takes no arguments and must be declared EXTERNAL.

**Results**

The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After ALARM is called and the timer starts, the calling program continues for *time* seconds. The calling program then suspends and calls *proc*, which runs in another thread. When *proc* finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If *proc* performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries.

The thread that *proc* runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until *proc* terminates, or is blocked on some other event, such as I/O.
No alarms can occur after the main process ends. If the main program finishes or any thread executes an EXIT call, than any pending alarm is deactivated before it has a chance to run.

Example

USE IFPORT
INTEGER(4) numsec, istat
EXTERNAL subprog
numsec = 4
write *, "subprog will begin in ", numsec, " seconds"
ISTAT = ALARM (numsec, subprog)

See Also
RUNQQ

ALIAS Directive

**General Compiler Directive**: Declares alternate external names for external subprograms.

**Syntax**

```
!DIR$ ALIAS internal-name,external-name
```

- `internal-name`: The name of the entity as used in the current program unit. It can be a procedure name, a COMMON block name, a module variable that is initialized, or a PARAMETER in a module.
- `external-name`: A name or a character constant, delimited by apostrophes or quotation marks.

If a name is specified, the name (in uppercase) is used as the external name for the specified `internal-name`. If a character constant is specified, it is used as is; the string is not changed to uppercase, nor are blanks removed.

The ALIAS directive affects only the external name used for references to the specified `internal-name`. Names that are not acceptable to the linker will cause link-time errors.

**See Also**
ATTRIBUTES ALIAS
ATTRIBUTES DECORATE
ATTRIBUTES DEFAULT
General Compiler Directives
Syntax Rules for Compiler Directives

**ALIGNED Clause**

**Parallel Directive Clause**: Specifies that all variables in a list are aligned.

**Syntax**

```
ALIGNED (list [:n])
```

- `list`: Is the name of one or more variables. Each name must be separated by a comma. Any variable that appears in `list` cannot appear in more than one ALIGNED clause.
must be a constant positive integer expression; it indicates the number of bytes for the alignment. If \( n \) is not specified, the compiler uses the default alignment specified for SIMD instructions on the target platform.

The ALIGNED clause overrides efficiency heuristics in the optimizer. It instructs the compiler to use aligned data movement instructions for all array references. This clause disables all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

**NOTE**

Be careful when using the ALIGNED clause. Instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

### ALL

**Transformational Intrinsic Function (Generic):**

Determines if all values are true in an entire array or in a specified dimension of an array.

**Syntax**

\[
\text{result} = \text{ALL} \ (\text{mask} \ [,\ DIM])
\]

**mask**

(Input) Must be a logical array.

**dim**

(Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{mask} \).

**Results**

The result is an array or a scalar of type logical.

The result is a scalar if \( \text{dim} \) is omitted or \( \text{mask} \) has rank one. A scalar result is true only if all elements of \( \text{mask} \) are true, or \( \text{mask} \) has size zero. The result has the value false if any element of \( \text{mask} \) is false.

An array result has the same type and kind parameters as \( \text{mask} \), and a rank that is one less than \( \text{mask} \). Its shape is \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \( \text{mask} \).

Each element in an array result is true only if all elements in the one dimensional array defined by \( \text{mask}(s_1, s_2, \ldots, s_{\text{dim}-1}, : , s_{\text{dim}+1}, \ldots, s_n) \) are true.

**Example**

```fortran
LOGICAL mask( 2, 3), AR1(3), AR2(2)
mask = RESHAPE((/.TRUE., .TRUE., .FALSE., .TRUE., .FALSE., & .FALSE./),(/2,3/))

! mask is true false false
! true true false
AR1 = ALL(mask,DIM = 1) ! evaluates the elements column by column yielding [true false false]
AR2 = ALL(mask,DIM = 2) ! evaluates the elements row by row yielding [false false].
```

**ALL ((/TRUE., .FALSE., .TRUE./))** has the value false because some elements of MASK are not true.

**ALL ((/TRUE., .TRUE., .TRUE./))** has the value true because all elements of MASK are true.

**A is the array**

```
[ 1 5 7 ]
[ 3 6 8 ]
```
and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9 \\
\end{bmatrix}
\]

ALL (A .EQ. B, DIM=1) tests to see if all elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, false) because only the second column has elements that are all equal.

ALL (A .EQ. B, DIM=2) tests to see if all elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (false, false) because each row has some elements that are not equal.

ANY  
COUNT

**ALLOCATABLE**

**Statement and Attribute:** Specifies that an object is an allocatable array with a deferred shape. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array. Character objects may have deferred length which is determined when the object is allocated.

**Syntax**

The ALLOCATABLE attribute can be specified in a type declaration statement or an ALLOCATABLE statement, and takes one of the following forms:

**Type Declaration Statement:**

\[
type, [att-ls,] ALLOCATABLE [, att-ls] :: a[(d-spec)] [[coarray-spec]][, a[(d-spec)] [[coarray-spec]]...\]

**Statement:**

\[
ALLOCATABLE [::] a[(d-spec)] [[coarray-spec]][, a[(d-spec)] [[coarray-spec]]...\]

- **type**
  - Is a data type specifier.
- **att-ls**
  - Is an optional list of attribute specifiers.
- **a**
  - Is the name of the allocatable object.
- **d-spec**
  - Is a deferred-shape specification (:: [: , :] ...), where each colon represents a dimension of the array or a deferred-coshape specification.
- **coarray-spec**
  - Is a deferred-coshape specification. The left bracket and right bracket are required.

**Description**

A character object declaration uses LEN=: to indicate it is deferred length.

If the array is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

When the allocatable object is no longer needed, it can be deallocated by execution of a DEALLOCATE statement.

An allocatable object cannot be specified in a COMMON, EQUIVALENCE, DATA, or NAMELIST statement.
Allocatable objects are not saved by default. If you want to retain the values of an allocatable object across procedure calls, you must specify the SAVE attribute for the object.

**Example**

! Method for creating and allocating deferred-shape objects.

```fortran
INTEGER, ALLOCATABLE :: matrix(:,:)
REAL, ALLOCATABLE :: vector(:)
CHARACTER, ALLOCATABLE :: c1
CHARACTER(LEN=:), ALLOCATABLE :: c2, c3(:)

ALLOCATE(matrix(3,5),vector(-2:N+2))
ALLOCATE(c1)
ALLOCATE(character(len=5) :: c2)
ALLOCATE(character(len=3) :: c3(2:4))
...
```

The following example shows a type declaration statement specifying the ALLOCATABLE attribute:

```fortran
REAL, ALLOCATABLE :: Z(:, :, :)
```

The following is an example of the ALLOCATABLE statement:

```fortran
REAL A, B(:)
ALLOCATABLE :: A(:,:), B
```

**See Also**

Type Declarations  
Array Declarations  
DEALLOCATE  
Allocate of Allocatable Arrays  
Type Declarations

**ALLOCATE**

*Statement:* Dynamically creates storage for allocatable variables and pointer targets.

**Syntax**

```
ALLOCATE ([type::] object[(s-spec)] [, object[(s-spec,s-spec)...]] ... [[coarray-spec]...[, alloc-opt])
```

- **type**  
  Is a data type specifier. If specified, the kind type parameters of each object must be the same as the corresponding type parameter values.

- **object**  
  Is the object to be allocated. It is a variable name or structure component, and must be a pointer or an allocatable object. The object can be of type character with zero length.

- **s-spec**  
  Is an array shape specification in the form [lower-bound:]upper-bound. Each bound must be a scalar integer expression. The number of shape specifications must be the same as the rank of the object.

- **coarray-spec**  
  Is a coarray shape specification in the form:
  
  ```
  [[[lower-bound:] upper-bound, ] ... [lower-bound:] *
  ```
The brackets around coarray-spec are required. A coarray shape specification can only appear if the object is a coarray. The number of coarray specifications must be one less than the corank of the coarray object.

alloc-opt

(Output) Is one of the following:

STAT=stat-var  stat-var is a scalar integer variable in which the status of the allocation is stored.

ERRMSG=err-var err-var is a scalar default character value in which an error condition is stored if such a condition occurs.

SOURCE=source-expr  source-expr is an expression that is scalar or has the same rank as object. If source-expr is specified, type cannot be specified and each object must have the same rank as source-expr.

MOLD=source-expr

Description

The storage space allocated is uninitialized unless SOURCE= is specified.

A bound in s-spec must not be an expression containing an array inquiry function whose argument is any allocatable object in the same ALLOCATE statement; for example, the following is not permitted:

```fortran
INTEGER ERR
INTEGER, ALLOCATABLE :: A(:,), B(:)
...
ALLOCATE(A(10:25), B(SIZE(A)), STAT=ERR)  ! A is invalid as an argument to function SIZE
```

If object is an array, s-spec must appear or source-expr must appear and have the same rank as object. If object is scalar, no s-spec should appear.

If a STAT= variable, ERRMSG= variable, or source-expr is specified, it must not be allocated in the ALLOCATE statement in which it appears; nor can they depend on the value, bounds, length type parameters, allocation status, or association status of any object in the same ALLOCATE statement.

If the allocation is successful for STAT= or ERRMSG=, the variable is set to zero. If the allocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the ERRMSG= variable contains the error condition.

If no STAT= variable is specified and an error condition occurs, program execution terminates.

If the allocation is successful and source-expr is specified, the dynamic type and value of the allocated object becomes that of the source expression. If the value of a non-deferred length type parameter of object is different from the value of the corresponding type parameter of source-expr, an error condition occurs.

If any object has a deferred type parameter, is unlimited polymorphic, or is of ABSTRACT type, either type or source-expr must appear.

If object is a coarray, source-expr must not have a dynamic type of C_PTR, C_FUNPTR, or LOCK_TYPE, or have a subcomponent whose dynamic type is LOCK_TYPE. The object cannot be a coindexed object.

When an ALLOCATE statement is executed for an object that is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the same statement the same number of times.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images has initiated termination of execution, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.
If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT= variable becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE.

If MOLD= appears and source-expr is a variable, its value does not have to be defined.

To release the storage for an object, use DEALLOCATE.

To determine whether an allocatable object is currently allocated, use the ALLOCATED intrinsic function.

To determine whether a pointer is currently associated with a target, use the ASSOCIATED intrinsic function.

**Example**

```fortran
!Method for creating and allocating deferred shape arrays.
INTEGER, ALLOCATABLE:: matrix(:, :)
REAL, ALLOCATABLE:: vector(:)

... 
ALLOCATE (matrix(3, 5), vector(-2:N+2))

... 
```

The following shows another example of the ALLOCATE statement:

```fortran
INTEGER J, N, ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:, :)
...
ALLOCATE(A(0:80), B(-3:J+1, N), STAT = ALLOC_ERR)
```

The above example allocates the scalar objects s and t to be 15 by 25 matrices with the value of r.

Consider the following:

```fortran
REAL(KIND=8) :: r(15, 25)
REAL(KIND=8), ALLOCATABLE :: s(:, :), t(:, :)
...
ALLOCATE(s, SOURCE=r)
ALLOCATE(t, SOURCE=r)
```

The above example allocates s and t to be 15 by 25 arrays with the value of r.

### ALLOCATED

**Inquiry Intrinsic Function (Generic):** Indicates whether an allocatable array or allocatable scalar is currently allocated.

**Syntax**

```fortran
result = ALLOCATED ([ARRAY=]array)
result = ALLOCATED ([SCALAR=]scalar)
```

- **array** (Input) Must be an allocatable array.
- **scalar** (Input) Must be an allocatable scalar.
Results

The result is a scalar of type default logical.

The result has the value true if argument array or scalar is currently allocated, false if the argument is not currently allocated, or undefined if its allocation status is undefined.

NOTE

When the argument keyword ARRAY is used, array must be an allocatable array. When the argument keyword SCALAR is used, scalar must be an allocatable scalar.

Example

```fortran
REAL, ALLOCATABLE :: A(:)
...
IF (.NOT. ALLOCATED(A)) ALLOCATE (A (5))
```

Consider the following:

```fortran
REAL, ALLOCATABLE, DIMENSION (:,:,:) :: E
PRINT *, ALLOCATED (E)       ! Returns the value false
ALLOCATE (E (12, 15, 20))
PRINT *, ALLOCATED (E)       ! Returns the value true
```

Dynamic Allocation Overview

ANINT

Elemental Intrinsic Function (Generic): Calculates the nearest whole number.

Syntax

```
result = ANINT (a[,kind] )
```

- **a**  
  (Input) Must be of type real.

- **kind**  
  (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is real. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of a. If a is greater than zero, ANINT (a) has the value AINT (a + 0.5); if a is less than or equal to zero, ANINT (a) has the value AINT (a - 0.5).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANINT ¹</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DNINT ¹</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QNINT</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying real size can affect ANINT and DNINT.

To truncate rather than round, use AINT.
Example

ANINT (3.456) has the value 3.0.
ANINT (-2.798) has the value -3.0.

Consider the following:

```fortran
REAL r1, r2
r1 = ANINT(2.6)     ! returns the value 3.0
r2 = ANINT(-2.6)    ! returns the value -3.0
```

! Calculates and adds tax to a purchase amount.

```fortran
REAL amount, taxrate, tax, total

taxrate = 0.081
amount = 12.99

tax = ANINT (amount * taxrate * 100.0) / 100.0
total = amount + tax

WRITE (*, 100) amount, tax, total

100  FORMAT ( 1X, 'AMOUNT', F7.2 /
       + 1X, 'TAX ', F7.2 /
       + 1X, 'TOTAL ', F7.2)
END
```

See Also

NINT

ANY

**Transformational Intrinsic Function (Generic):** Determines if any value is true in an entire array or in a specified dimension of an array.

**Syntax**

```fortran
result = ANY (mask [, dim])
```

- **mask**
  - (Input) Must be a logical array.

- **dim**
  - (Input; optional) Must be a scalar integer expression with a value in the range 1 to n, where n is the rank of mask.

**Results**

The result is an array or a scalar of type logical.

The result is a scalar if dim is omitted or mask has rank one. A scalar result is true if any elements of mask are true. The result has the value false if no element of mask is true, or mask has size zero.

An array result has the same type and kind parameters as mask, and a rank that is one less than mask. Its shape is (d_1, d_2, ..., d_{dim-1}, d_{dim+1} ..., d_n), where (d_1, d_2, ..., d_n) is the shape of mask.

Each element in an array result is true if any elements in the one dimensional array defined by mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) are true.

**Example**

```fortran
LOGICAL mask( 2, 3), AR1(3), AR2(2)
logical, parameter :: T = .true.
logical, parameter :: F = .false.
DATA mask /T, T, F, T, F, F/
! mask is true false false
!
AR1 = ANY(mask,DIM = 1) ! evaluates the elements column by
```
ANY ($(./.FALSE., ./.FALSE., ./TRUE./)) has the value true because one element is true.

A is the array

```
[ 1  5  7 ]
[ 3  6  8 ]
```

and B is the array

```
[ 0  5  7 ]
[ 2  6  9 ]
```

ANY (A .EQ. B, DIM=1) tests to see if any elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, true) because the second and third columns have at least one element that is equal.

ANY (A .EQ. B, DIM=2) tests to see if any elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (true, true) because each row has at least one element that is equal.

ALL
COUNT

**APPENDMENUQQ (W*S)**

*QuickWin Function:* Appends a menu item to the end of a menu and registers its callback subroutine.

**Module**

USE IFQWIN

**Syntax**

```
result = APPENDMENUQQ (menuID, flags, text, routine)
```

- `menuID`  
  (Input) INTEGER(4). Identifies the menu to which the item is appended, starting with 1 as the leftmost menu.

- `flags`  
  (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:
  - $MENUGRAYED - Disables and grays out the menu item.
  - $MENUDISABLED - Disables but does not gray out the menu item.
  - $MENUENABLED - Enables the menu item.
  - $MENUSEPARATOR - Draws a separator bar.
  - $MENUCHECKED - Puts a check by the menu item.
  - $MENUUNCHECKED - Removes the check by the menu item.

- `text`  
  (Input) Character*(*) . Menu item name. Must be a null-terminated C string, for example, 'WORDS OF TEXT'.

- `routine`  
  (Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:
• WINPRINT - Prints the program.
• WINSAVE - Saves the program.
• WINEXIT - Terminates the program.
• WINSELECTTEXT - Selects text from the current window.
• WINSELECTGRAPHICS - Selects graphics from the current window.
• WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZETO FIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results
The result type is logical. It is .TRUE. if successful; otherwise, .FALSE..

You do not need to specify a menu item number, because APPENDMENUQQ always adds the new item to the bottom of the menu list. If there is no item yet for a menu, your appended item is treated as the top-level menu item (shown on the menu bar), and text becomes the menu title. APPENDMENUQQ ignores the callback routine for a top-level menu item if there are any other menu items in the menu. In this case, you can set routine to NUL.

If you want to insert a menu item into a menu rather than append to the bottom of the menu list, use INSERTMENUQQ.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to APPENDMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY (ALT+R in the example) as an alternative to selecting the item with the mouse.

Example

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
...
! Append two items to the bottom of the first (FILE) menu
```
str = '&Add to File Menu'! 'A' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
str = 'Menu Item &2b'! '2' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINCASCADE)
! Append an item to the bottom of the second (EDIT) menu
str = 'Add to Second &Menu'! 'M' is a quick-access key
result = APPENDMENUQQ(2, $MENUENABLED, str, WINTILE)

INSERTMENUQQ (W*S)
DELETEMENUQQ (W*S)
MODIFYMENUFLAGSQQ (W*S)
MODIFYMENUROUTINEQQ (W*S)
MODIFYMENUSTRINGQQ (W*S)
ARC, ARC_W (W*S)

Graphics Functions: Draw elliptical arcs using the
current graphics color.

Module
USE IFQWIN

Syntax
result = ARC (x1, y1, x2, y2, x3, y3, x4, y4)
result = ARC_W (wx1, wy1, wx2, wy2, wx3, wy3, wx4, wy4)

x1, y1  (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2  (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

x3, y3  (Input) INTEGER(2). Viewport coordinates of start vector.

x4, y4  (Input) INTEGER(2). Viewport coordinates of end vector.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

wx3, wy3 (Input) REAL(8). Window coordinates of start vector.

wx4, wy4 (Input) REAL(8). Window coordinates of end vector.

Results
The result type is INTEGER(2). It is nonzero if successful; otherwise, 0. If the arc is clipped or partially out of
bounds, the arc is considered successfully drawn and the return is 1. If the arc is drawn completely out of
bounds, the return is 0.

The center of the arc is the center of the bounding rectangle defined by the points (x1, y1) and (x2, y2) for
ARC and (wx1, wy1) and (wx2, wy2) for ARC_W.
The arc starts where it intersects an imaginary line extending from the center of the arc through \((x_3, y_3)\) for ARC and \((wx_3, wy_3)\) for ARC_W. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through \((x_4, y_4)\) for ARC and \((wx_4, wy_4)\) for ARC_W.

ARC uses the view-coordinate system. ARC_W uses the window-coordinate system. In each case, the arc is drawn using the current color.

**NOTE**

The ARC routine described here is a QuickWin graphics routine. If you are trying to use the Microsoft Platform SDK version of the Arc routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Arc.

**Example**

This program draws the arc shown below.

```
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4

x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 75
x4 = 90; y4 = 180
status = ARC( x1, y1, x2, y2, x3, y3, x4, y4 )
END
```

**ASIN**

*Elemental Intrinsic Function (Generic):* Produces the arcsine of an argument.

**Syntax**

\[
\text{result} = \text{ASIN}(\, x \,)
\]

*x*  
(Input) Must be of type real. The \(|x|\) must be less than or equal to 1.

**Results**

The result type and kind is the same as \(x\) and is expressed in radians. The value lies in the range \(-\pi/2\) to \(\pi/2\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>

<td>DASIN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>
Example

ASIN (0.79345021) has the value 0.9164571.

ASIND

*Elemental Intrinsic Function (Generic): Produces the arcsine of x.*

**Syntax**

\[
result = \text{ASIND} \ (x)
\]

\(x\) (Input) Must be of type real. The \(|x|\) must be less than or equal to 1.

**Results**

The result type and kind is the same as \(x\) and is expressed in degrees. The value lies in the range \(-90\) to \(90\) degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ASIND (0.2467590) has the value 14.28581.

ASINH

*Elemental Intrinsic Function (Generic): Produces the hyperbolic arcsine of x.*

**Syntax**

\[
result = \text{ASINH} \ (x)
\]

\(x\) (Input) Must be of type real.

**Results**

The result type and kind is the same as \(x\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASINH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<tr>
<td>DASINH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QASINH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ASINH (1.0) has the value -0.88137.

ASINH (180.0) has the value 5.88611.
**ASSIGN - Label Assignment**

**Statement:** Assigns a statement label value to an integer variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

```
ASSIGN label TO var
```

- `label` Is the label of a branch target or FORMAT statement in the same scoping unit as the ASSIGN statement.
- `var` Is a scalar integer variable.

When an ASSIGN statement is executed, the statement label is assigned to the integer variable. The variable is then undefined as an integer variable and can only be used as a label (unless it is later redefined with an integer value).

The ASSIGN statement must be executed before the statements in which the assigned variable is used.

Indirect branching through integer variables makes program flow difficult to read, especially if the integer variable is also used in arithmetic operations. Using these statements permits inconsistent usage of the integer variable, and can be an obscure source of error. The ASSIGN statement was used to simulate internal procedures, which now can be coded directly.

**Example**

The value of a label is not the same as its number; instead, the label is identified by a number assigned by the compiler. In the following example, 400 is the label number (not the value) of IVBL:

```
ASSIGN 400 TO IVBL
```

Variables used in ASSIGN statements are not defined as integers. If you want to use a variable defined by an ASSIGN statement in an arithmetic expression, you must first define the variable by a computational assignment statement or by a READ statement, as in the following example:

```
IVBL = 400
```

The following example shows ASSIGN statements:

```
INTEGER ERROR
...
ASSIGN 10 TO NSTART
ASSIGN 99999 TO KSTOP
ASSIGN 250 TO ERROR
```

Note that NSTART and KSTOP are integer variables implicitly, but ERROR must be previously declared as an integer variable.

The following statement associates the variable NUMBER with the statement label 100:

```
ASSIGN 100 TO NUMBER
```

If an arithmetic operation is subsequently performed on variable NUMBER (such as follows), the run-time behavior is unpredictable:

```
NUMBER = NUMBER + 1
```

To return NUMBER to the status of an integer variable, you can use the following statement:

```
NUMBER = 10
```

This statement dissociates NUMBER from statement 100 and assigns it an integer value of 10. Once NUMBER is returned to its integer variable status, it can no longer be used in an assigned GO TO statement.
Assignment(=) - Defined Assignment

**Statement:** An interface block that defines generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

**Syntax**
The initial line for such an interface block takes the following form:

```fortran
INTERFACE ASSIGNMENT (=)
```

**Description**
The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The `ASSIGNMENT` keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying `ELEMENTAL` in the `SUBROUTINE` statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

**Example**
The following is an example of a procedure interface block defining assignment:

```fortran
INTERFACE ASSIGNMENT (=)
   SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
      INTEGER, INTENT(OUT) :: NUM
      LOGICAL, INTENT(IN)  :: BIT(:)
   END SUBROUTINE BIT_TO_NUMERIC

   SUBROUTINE CHAR_TO_STRING (STR, CHAR)
      USE STRING_MODULE                    ! Contains definition of type STRING
      TYPE(STRING), INTENT(OUT) :: STR     ! A variable-length string
      CHARACTER(*), INTENT(IN)  :: CHAR
   END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```

The following example shows two equivalent ways to reference subroutine `BIT_TO_NUMERIC`:

```fortran
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine `CHAR_TO_STRING`:

```fortran
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```

The following is an example of a declaration and reference to a defined assignment:

```fortran
!Converting circle data to interval data.
module mod1
  TYPE CIRCLE
     REAL radius, center_point(2)
  END TYPE CIRCLE
END MODULE MOD1
```
TYPE INTERVAL
  REAL lower_bound, upper_bound
END TYPE INTERVAL
CONTAINS
  SUBROUTINE circle_to_interval(I,C)
    type (interval),INTENT(OUT)::I
    type (circle),INTENT(IN)::C
    !Project circle center onto the x=-axis
    !Note: the length of the interval is the diameter of the circle
    I%lower_bound = C%center_point(1) - C%radius
    I%upper_bound = C%center_point(1) + C%radius
  END SUBROUTINE circle_to_interval
end module mod1

PROGRAM assign
  use mod1
  TYPE(CIRCLE) circle1
  TYPE(INTERVAL) interval1
  INTERFACE ASSIGNMENT(=)
    module procedure circle_to_interval
  END INTERFACE
  !Begin executable part of program
  circle1%radius = 2.5
  circle1%center_point = (/3.0,5.0/)
  interval1 = circle1
  ...
END PROGRAM

See Also
INTERFACE
Assignments

Assignment - Intrinsic Computational

Statement: Assigns a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

Syntax
variable=expression

variable

expression

Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.

expression

Is of intrinsic type or the same derived type as variable. Its shape must conform with variable. If necessary, it is converted to the same type and kind as variable.

Description
Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.
NOTE
When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

If the IDIR$ NOSTRICT compiler directive (the default) is in effect, then you can assign a character expression to a noncharacter variable, and a noncharacter variable or array element (but not an expression) to a character variable.

Example

```fortran
REAL a, b, c
LOGICAL abigger
CHARACTER(16) assertion
  c  = .01
  a  = SQRT (c)
  b  = c**2
  assertion = 'a > b'
  abigger  = (a .GT. b)
  WRITE (*, 100) a, b
100 FORMAT (' a =', F7.4, ' b =', F7.4)
    IF (abigger) THEN
      WRITE (*, *) assertion, ' is true.'
    ELSE
      WRITE (*, *) assertion, ' is false.'
    END IF
END
```

The program above has the following output:
```
  a =    .1000     b =   .0001         a > b is true.
```

The following code shows legal and illegal assignment statements:
```
INTEGER i, j
REAL rone(4), rtwo(4), x, y
COMPLEX z
CHARACTER name6(6), name8(8)
  i    = 4
  x    = 2.0
  z    = (3.0, 4.0)
  rone(1) = 4.0
  rone(2) = 3.0
  rone(3) = 2.0
  rone(4) = 1.0
  name8 = 'Hello,'
  name8 = x + 1.0; int = name8//'test'; y = rone
```

! The following assignment statements are legal:
```
i    = rone(2); j = rone(i); j = x
y    = x; y = z; y = rone(3); rtwo = rone; rtwo = 4.7
name6 = name8
```

! The following assignment statements are illegal:
```
name6 = x + 1.0; int = name8//'test'; y = rone
END
```
ASSOCIATE

**Statement:** Marks the beginning of an ASSOCIATE construct. The ASSOCIATE construct creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.

**Syntax**

```
[name:] ASSOCIATE (assoc-entity[, assoc-entity]...)

    block

END ASSOCIATE [name]
```

- **name** (Optional) Is the name of the ASSOCIATE construct.
- **assoc-entity**
  - **associate-name** => **selector**
    - **associate-name** Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct.
    - **selector** Is an expression or variable. It becomes the associated entity.
- **block** Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified at the beginning of an ASSOCIATE statement, the same name must appear in the corresponding END ASSOCIATE statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of an ASSOCIATE statement, you cannot specify one following the END ASSOCIATE statement.

During execution of the block within the construct, each **associate-name** identifies an entity, which is associated with the corresponding **selector**. The associating entity assumes the declared type and type parameters of the selector.

You can only branch to an END ASSOCIATE statement from within its ASSOCIATE construct.

Within an ASSOCIATE construct, each associating entity has the same rank as its associated selector. The lower bound of each dimension is the result of the intrinsic function LBOUND applied to the corresponding dimension of selector. The upper bound of each dimension is one less than the sum of the lower bound and the extent.

If the selector has the ALLOCATABLE attribute, it must be allocated. The associating entity is associated with the associated entity and does not have the ALLOCATABLE attribute. If the selector has the POINTER attribute, it must be associated. The associating entity is associated with the target of the pointer and does not have the POINTER attribute. If the selector has the TARGET, VOLATILE, or ASYNCHRONOUS attribute, an associating entity that is a variable has those attributes.

This construct is useful when you want to simplify multiple accesses to a variable that has a lengthy description; for example, if the variable contains multiple subscripts and component names.
Example
The following shows an expression as a selector:

```
ASSOCIATE (O => (A-F)**2 + (B+G)**2)
  PRINT *, SQRT (O)
END ASSOCIATE
```

The following shows association with an array section:

```
ASSOCIATE (ARRAY => AB % D (I, :) % X)
  ARRAY (3) = ARRAY (1) + ARRAY (2)
END ASSOCIATE
```

Without the ASSOCIATE construct, this is what you would need to write:

```
AB % D (I, 3) % X = AB % D (I, 1) % X + AB % D (I, 2) % X
```

ASSOCIATED

**Inquiry Intrinsic Function (Generic):** Returns the association status of its pointer argument or indicates whether the pointer is associated with the target.

**Syntax**

```
result = ASSOCIATED (pointer [, target])
```

- `pointer` *(Input)* Must be a pointer. It can be of any data type. The pointer association status must be defined.
- `target` *(Input; optional)* Must be a pointer or target. If it is a pointer, the pointer association status must be defined.

**Results**

The result is a scalar of type default logical. The setting of compiler options specifying integer size can affect this function.

If only `pointer` appears, the result is true if it is currently associated with a target; otherwise, the result is false.

If `target` also appears and is a target, the result is true if `pointer` is currently associated with `target`; otherwise, the result is false.

If `target` is a pointer, the result is true if both `pointer` and `target` are currently associated with the same target; otherwise, the result is false. (If either `pointer` or `target` is disassociated, the result is false.)

Example

```
REAL C (:), D(:), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
C => E                       ! pointer assignment
D => E                       ! pointer assignment
STATUS = ASSOCIATED(C)       ! returns TRUE; C is associated
STATUS = ASSOCIATED(C, E)    ! returns TRUE; C is associated with E
STATUS = ASSOCIATED (C, D)   ! returns TRUE; C and D are associated
                             ! with the same target
```
Consider the following:

```fortran
REAL, TARGET, DIMENSION (0:50) :: TAR
REAL, POINTER, DIMENSION (:) :: PTR
PTR => TAR
PRINT *, ASSOCIATED (PTR, TAR)      ! Returns the value true
```

The subscript range for PTR is 0:50. Consider the following pointer assignment statements:

```fortran
(1) PTR => TAR (:)
(2) PTR => TAR (0:50)
(3) PTR => TAR (0:49)
```

For statements 1 and 2, ASSOCIATED (PTR, TAR) is true because TAR has not changed (the subscript range for PTR in both cases is 1:51, following the rules for deferred-shape arrays). For statement 3, ASSOCIATED (PTR, TAR) is false because the upper bound of TAR has changed.

Consider the following:

```fortran
REAL, POINTER, DIMENSION (:) :: PTR2, PTR3
ALLOCATE (PTR2 (0:15))
PTR3 => PTR2
PRINT *, ASSOCIATED (PTR2, PTR3)       ! Returns the value true
...
NULLIFY (PTR2)
NULLIFY (PTR3)
PRINT *, ASSOCIATED (PTR2, PTR3)       ! Returns the value false
```

ASSUME

**General Compiler Directive:** Provides heuristic information to the compiler optimizer.

**Syntax**

```fortran
!DIR$ ASSUME (scalar-Boolean-expression)
```

*scalar-Boolean-expression* is any expression that evaluates to .TRUE. or .FALSE. at run-time.

The *scalar-Boolean-expression* is presumed to be true and may be used by the optimizer to generate better code.

If the check assume option is specified and *scalar-Boolean-expression* does not evaluate to .TRUE. at run-time, an error message is displayed and execution is aborted.

**Example**

In the example below, the compiler is told that A is aligned on a 32-byte boundary using the ASSUME_ALIGNED directive. The ASSUME directive says that the length of the first dimension of A is a multiple of 8. Therefore the optimizer knows that A(I,J+1) and A(I,J-1) are 0 mod 64 bytes away from A(I,J) and are therefore also aligned on 32-byte boundaries. This information helps the optimizer in generating efficiently vectorized code for these loops.

```fortran
SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ ASSUME (MOD(NX,8) .EQ. 0) ! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
```
DO J=J1,J2
  DO I=I1,I2
    A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
  ENDDO
ENDDO
END SUBROUTINE F

See Also
General Compiler Directives
Syntax Rules for Compiler Directives
ASSUME_ALIGNED directive
check compiler option (setting assume)

ASSUME_ALIGNED
General Compiler Directive: Specifies that an entity in memory is aligned.

Syntax
!DIR$ ASSUME_ALIGNED address1:n1 [, address2:n2]...

address
A memory reference. It can be of any data type, kind, or rank. It cannot be any of the following:
  • An entity in COMMON (or an entity EQUIVALENCEd to something in COMMON)
  • A component of a variable of derived type or a record field reference
  • An entity accessed by use or host association

n
A positive integer initialization expression. Its value must be a power of 2 between 1 and 256, that is, 1, 2, 4, 8, 16, 32, 64, 128, 256. It specifies the memory alignment in bytes of address.

If you specify more than one address:n item, they must be separated by a comma.
If address is a Cray POINTER or it has the POINTER attribute, it is the POINTER and not the pointee or the TARGET that is assumed aligned.
If the check assume option is specified and address is not aligned on an n-byte boundary at run-time, an error message is displayed and execution is aborted.
For more information, see the example in the description of the ASSUME directive.

check compiler option

ASYNCRONOUS
Statement and Attribute: Specifies that a variable can be used for asynchronous input and output.

Syntax
The ASYNCRONOUS attribute can be specified in a type declaration statement or an ASYNCRONOUS statement, and takes one of the following forms:
Type Declaration Statement:

type, [att-ls,] ASYNCHRONOUS [, att-ls] :: var [, var] ...

Statement:

ASYNCHRONOUS [:] var [, var] ...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

var Is the name of a variable.

Description

Asynchronous I/O, or non-blocking I/O, allows a program to continue processing data while the I/O operation is performed in the background.

A variable can have the ASYNCHRONOUS attribute in a particular scoping unit without necessarily having it in other scoping units. If an object has the ASYNCHRONOUS attribute, then all of its subobjects also have the ASYNCHRONOUS attribute.

The ASYNCHRONOUS attribute can also be implied by use of a variable in an asynchronous READ or WRITE statement.

You can specify variables that are used for asynchronous communication, such as with Message Passing Interface Standard (MPI). Asynchronous communication has the following restrictions:

- For input, a pending communication affector must not be referenced, become defined, become undefined, become associated with a dummy argument that has the VALUE attribute, or have its pointer association status changed.
- For output, a pending communication affector must not be redefined, become undefined, or have its pointer association status changed.

Examples

The following example shows how the ASYNCHRONOUS attribute can be applied in an OPEN and READ statement.

```fortran
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1,file='asynch.dat',asynchronous='YES',&
    form='unformatted')
  write (1) (i,i=1,100)
  rewind (1)
  read (1,asynchronous='YES') array
  wait(1)
  write (*,*) array(1:10)
end
```

ATAN

Elemental Intrinsic Function (Generic): Produces the arctangent of an argument.

Syntax

result = ATAN (x)
(Input) Must be of type real.

Results
The result type and kind is the same as x and is expressed in radians. The value lies in the range -\pi/2 to \pi/2.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example
ATAN (1.5874993) has the value 1.008666.

**ATAN2**

Elemental Intrinsic Function (Generic): Produces an arctangent (inverse tangent). The result is the principal value of the argument of the nonzero complex number (x, y).

Syntax

\[
\text{result} = \text{ATAN2}(y, x)
\]

\(y\) (Input) Must be of type real.

\(x\) (Input) Must have the same type and kind parameters as y. If y has the value zero, x cannot have the value zero.

Results
The result type and kind is the same as x and is expressed in radians. The value lies in the range -\pi <= ATAN2 (y, x) <= \pi.

If x is not zero, the result is approximately equal to the value of arctan \((y/ x)\).

If y > zero, the result is positive.

If y < zero, the result is negative.

If y is zero and x > zero, the result is y (so for x>0, ATAN2 ((+0.0), x) is +0.0 and ATAN2 ((-0.0), x) is -0.0).

If y is a positive real zero and x < zero, the result is pi.

If y is a negative real zero and x < zero, the result is -pi.

If x is a positive real zero, the result is pi/2.

If y is a negative real zero, the result is -pi/2.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN2</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN2</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>
Example

ATAN2 (2.679676, 1.0) has the value 1.213623.

If Y is an array that has the value

\[
\begin{bmatrix}
  1 & 1 \\
  -1 & -1 \\
\end{bmatrix}
\]

and X is an array that has the value

\[
\begin{bmatrix}
  -1 & 1 \\
  -1 & 1 \\
\end{bmatrix},
\]

then ATAN2 (Y, X) is

\[
\begin{bmatrix}
  \frac{3\pi}{4} & \frac{\pi}{4} \\
  -\frac{3\pi}{4} & -\frac{\pi}{4} \\
\end{bmatrix}
\]

ATAN2D

Elemental Intrinsic Function (Generic): Produces an arctangent. The result is the principal value of the argument of the nonzero complex number (x, y).

Syntax

\[
\text{result} = \text{ATAN2D} (y, x)
\]

- \( y \) (Input) Must be of type real.
- \( x \) (Input) Must have the same type and kind parameters as \( y \). If \( y \) has the value zero, \( x \) cannot have the value zero.

Results

The result type and kind is the same as \( x \) and is expressed in degrees. The value lies in the range -180 degrees to 180 degrees. If \( x \) zero, the result is approximately equal to the value of arctan (y/ x).

If \( y > 0 \), the result is positive.
If \( y < 0 \), the result is negative.
If \( y = 0 \), the result is zero (if \( x > 0 \)) or 180 degrees (if \( x < 0 \)).
If \( x = 0 \), the absolute value of the result is 90 degrees.

<table>

<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN2D</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ATAN2D (2.679676, 1.0) has the value 69.53546.
**ATAND**

*Elemental Intrinsic Function (Generic):* Produces the arctangent of \( x \).

**Syntax**

\[ \text{result} = \text{ATAND} \ (x) \]

\( x \)  
(Input) Must be of type real and must be greater than or equal to zero.

**Results**

The result type and kind is the same as \( x \) and is expressed in degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<tr>
<td>DATAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATAND (0.0874679) has the value 4.998819.

**ATANH**

*Elemental Intrinsic Function (Generic):* Produces the hyperbolic arctangent of \( x \).

**Syntax**

\[ \text{result} = \text{ATANH} \ (x) \]

\( x \)  
(Input) Must be of type real, where \( |x| \) is less than or equal to 1.

**Results**

The result type and kind is the same as \( x \). The value lies in the range -1.0 to 1.0.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATANH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<td>DATANH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATANH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATANH (-0.77) has the value -1.02033.

ATANH (0.5) has the value 0.549306.

**ATOMIC**

*OpenMP* Fortran Compiler Directive: Ensures that a specific memory location is updated atomically; this prevents the possibility of multiple threads simultaneously reading and writing the specific memory location.
Syntax

!$OMP ATOMIC [type-clause[[,] clause]] -or- !$OMP ATOMIC [clause[[,] type-clause]]
    block
!$OMP END ATOMIC

type-clause  (Optional) Is one of the following:
    • CAPTURE
      If !$OMP ATOMIC CAPTURE is specified, block is either one update-statement and one capture-statement in either order, or one capture-statement followed by one write-statement in that order.
    • READ
      If !$OMP ATOMIC READ is specified, block is a capture-statement.
    • WRITE
      If !$OMP ATOMIC WRITE is specified, block is a write-statement.
    • UPDATE
      If !$OMP ATOMIC UPDATE is specified, block is an update-statement.

For details on the effects of these clauses, see the table in the Description section.

clause  (Optional) Is the following:
    • SEQ_CST
      Forces the atomically performed operation to include an implicit flush operation without a list. For details on the effects of this clause, see the table in the Description section.

capture-statement  Is an expression in the form \( v = x \).

write-statement  Is an expression in the form \( x = expr \).

update-statement  Is an expression with one of the following forms:

    - \( x = x \ \text{operator} \ expr \)
    - \( x = expr \ \text{operator} \ x \)
    - \( x = \text{intrinsic} \ (x, expr\text{-list}) \)
    - \( x = \text{intrinsic} \ (expr\text{-list}, x) \)

The following rules apply:

    - Operators in \( expr \) must have precedence equal to or greater than the precedence of operator.
    - \( x \ \text{operator} \ expr \) must be mathematically equivalent to \( x \ \text{operator} \ (expr) \). This requirement is satisfied if the operators in \( expr \) have precedence greater than \( operator \), or by using parentheses around \( expr \) or subexpressions of \( expr \).
    - \( expr \ \text{operator} x \) must be mathematically equivalent to \( (expr) \ \text{operator} x \). This requirement is satisfied if the operators in \( expr \) have precedence equal to or greater than \( operator \), or by using parentheses around \( expr \) or subexpressions of \( expr \).
    - All assignments must be intrinsic assignments.
$x, v$

Are scalar variables of intrinsic type. During execution of an atomic region, all references to storage location $x$ must specify the same storage location. $v$ must not access the same storage location as $x$.

$\text{expr, expr-list}$

The $\text{expr}$ is a scalar expression. The $\text{expr-list}$ is a comma-separated, non-empty list of scalar expressions. They must not access the same storage location as $x$.

If intrinsic is IAND, IOR, or IEOR, only one expression can appear in expr-list.

$\text{operator}$

Is one of the following intrinsic operators: $+, *, -, /, \text{AND}, \text{OR}, \text{EQV}$, or $\text{NEQV}$.

intrinsic

Is one of the following intrinsic procedures: MAX, MIN, IAND, IOR, or IEOR.

The binding thread set for an ATOMIC construct is all threads. Atomic regions enforce exclusive access with respect to other atomic regions that access the same storage location $x$ among all the threads in the program without regard to the teams to which the threads belong.

If !$OMP \text{ ATOMIC}$ is specified with no type-clause or no clause, it is the same as specifying !$OMP \text{ ATOMIC UPDATE}$.

If !$OMP \text{ ATOMIC CAPTURE}$ is specified, you must include an !$OMP \text{ END ATOMIC}$ directive following the block. Otherwise, the !$OMP \text{ END ATOMIC}$ directive is optional.

Note that the following restriction applies to the ATOMIC directive:

• All atomic accesses to the storage locations designated by $x$ throughout the program must have the same type and type parameters.

The following table describes what happens when you specify one of the clauses in an ATOMIC construct.

<table>
<thead>
<tr>
<th>Clause</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAPTURE</td>
<td>Causes an atomic update of the location designated by $x$ using the designated operator or intrinsic while also capturing the original or final value of the location designated by $x$ in $v$. The following rules also apply:</td>
</tr>
<tr>
<td></td>
<td>• The original or final value of the location designated by $x$ is written in the location designated by $v$, depending on the form of the ATOMIC construct, structured block, or statements, following the usual language semantics.</td>
</tr>
<tr>
<td></td>
<td>• Only the read and write of the location designated by $x$ are performed mutually atomically.</td>
</tr>
<tr>
<td></td>
<td>• The evaluation of $\text{expr}$ or $\text{expr-list}$, and the write to the location designated by $v$ do not need to be atomic with respect to the read or write of the location designated by $x$.</td>
</tr>
<tr>
<td></td>
<td>No task scheduling points are allowed between the read and the write of the location designated by $x$.</td>
</tr>
<tr>
<td>Clause</td>
<td>Result</td>
</tr>
<tr>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>READ</td>
<td>Causes an atomic read of the location designated by $x$ regardless of the native machine word size.</td>
</tr>
<tr>
<td>SEQ_CST</td>
<td>Causes the atomically performed operation to include an implicit flush operation without a list. If this clause is specified, the construct is a <em>sequentially consistent atomic construct</em>. Unlike non-sequentially consistent atomic constructs, sequentially consistent atomic constructs preserve the interleaving (sequentially consistent) behavior of correct, data-race-free programs. However, they are not designed to replace the FLUSH directive as a mechanism to enforce ordering for non-sequentially consistent atomic constructs, and attempts to do so require extreme caution. For example, a sequentially consistent atomic write construct may appear to be reordered with a subsequent non-sequentially consistent atomic write construct, since such reordering would not be observable by a correct program if the second write were outside an ATOMIC directive.</td>
</tr>
</tbody>
</table>
| UPDATE  | Causes an atomic update of the location designated by $x$ using the designated operator or intrinsic. The following rules also apply:  
• The evaluation of *expr* or *expr-list* need not be atomic with respect to the read or write of the location designated by $x$.  
• No task scheduling points are allowed between the read and the write of the location designated by $x$. |  |
| WRITE   | Causes an atomic write of the location designated by $x$ regardless of the native machine word size. |  |

Any combination of two or more of these atomic constructs enforces mutually exclusive access to the locations designated by $x$.

A race condition exists when two unsynchronized threads access the same shared variable with at least one thread modifying the variable; this can cause unpredictable results. To avoid race conditions, all accesses of the locations designated by $x$ that could potentially occur in parallel must be protected with an ATOMIC construct.

Atomic regions do not guarantee exclusive access with respect to any accesses outside of atomic regions to the same storage location $x$ even if those accesses occur during a CRITICAL or ORDERED region, while an OpenMP lock is owned by the executing task, or during the execution of a REDUCTION clause. However, other OpenMP* synchronization can ensure the desired exclusive access. For example, a BARRIER directive following a series of atomic updates to $x$ guarantees that subsequent accesses do not form a race condition with the atomic accesses.
Example

The following example shows a way to avoid race conditions by using ATOMIC to protect all simultaneous updates of the location by multiple threads.

Since the ATOMIC directive below applies only to the statement immediately following it, elements of Y are not updated atomically.

```fortran
REAL FUNCTION FOO1(I)
    INTEGER I
    FOO1 = 1.0 * I
    RETURN
END FUNCTION FOO1

REAL FUNCTION FOO2(I)
    INTEGER I
    FOO2 = 2.0 * I
    RETURN
END FUNCTION FOO2

SUBROUTINE SUB(X, Y, INDEX, N)
    REAL X(*), Y(*)
    INTEGER INDEX(*), N
    INTEGER I
    !$OMP PARALLEL DO SHARED(X, Y, INDEX, N)
    DO I=1,N
        !$OMP ATOMIC UPDATE
        X(INDEX(I)) = X(INDEX(I)) + FOO1(I)
        Y(I) = Y(I) + FOO2(I)
    ENDDO
    !$OMP END PARALLEL
END SUBROUTINE SUB

PROGRAM ATOMIC_DEMO
    REAL X(1000), Y(10000)
    INTEGER INDEX(10000)
    INTEGER I
    DO I=1,10000
        INDEX(I) = MOD(I, 1000) + 1
        Y(I) = 0.0
    ENDDO
    DO I = 1,1000
        X(I) = 0.0
    ENDDO
    CALL SUB(X, Y, INDEX, 10000)
END PROGRAM ATOMIC_DEMO
```

The following non-conforming example demonstrates the restriction on the ATOMIC construct:

```fortran
SUBROUTINE ATOMIC_INCORRECT()
    INTEGER:: I
    REAL:: R
    EQUIVALENCE(I,R)
    !$OMP PARALLEL
    !$OMP ATOMIC UPDATE
    I = I + 1
    !$OMP ATOMIC UPDATE
    R = R + 1.0
    !$OMP END PARALLEL
    ! The above is incorrect because I and R reference the same location
    ! but have different types
END SUBROUTINE ATOMIC_INCORRECT
```

**ATOMIC_DEFINE**

*Intrinsic Subroutine (Generic):* Defines a variable atomically.

**Syntax**

```fortran
CALL ATOMIC_DEFINE (atom, value)
```

*atom*  
(Output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND. If its kind is the same as that of value or its type is logical, it becomes defined with the value of value. Otherwise, it becomes defined with the value of INT(VALUE, ATOMIC_INT_KIND).

ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.

*value*  
(Input) Must be a scalar and of the same type as atom.

**Example**

Consider the following:

```fortran
CALL ATOMIC_DEFINE (N [9], 7)
```

This causes N on image 9 to become defined with the value 7.

**See Also**
ISO_FORTRAN_ENV Module

**ATOMIC_REF**

*Intrinsic Subroutine (Generic):* Lets you reference a variable atomically.

**Syntax**

```fortran
CALL ATOMIC_REF (value, atom)
```

*value*  
(Output) Must be a scalar and of the same type as atom. If its kind is the same as that of atom or its type is logical, it becomes defined with the value of atom. Otherwise, it is defined with the value of INT(ATOM, KIND (VALUE)).

*atom*  
(Input) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND.
Example
Consider the following:

```fortran
CALL ATOMIC_REF (SOL, I [9])
```

This causes SOL to become defined with the value of I on image 9.

See Also
ISO_FORTRAN_ENV Module

ATTRIBUTES

**General Compiler Directive:** Declares properties for specified variables.

**Syntax**

```fortran
!DIR$ ATTRIBUTES att[,att]...:: object[,object]...
```

**att**

Is one of the following options (or properties):

| att                              | ALIAS | DLLEXPORT | NOINLINE | ALIGN | DLLIMPORT | OFFLOAD | ALLOCATABLE | EXTERN | OPTIMIZATION_PARAMETER | ALLOW_NULL | FASTMEM | REFERENCE | ARRAY_VISUALIZER | FORCEINLINE | STDCALL | C | IGNORE_LOC | VALUE | CONCURRENCY_SAFE | INLINE | VARYING | CVF | MIXED_STR_LEN_ARG | VECTOR | DECORATE | NO_ARG_CHECK | DEFAULT | NOCLONE |
|---------------------------------|-------|-----------|----------|-------|-----------|---------|-------------|--------|------------------------|------------|---------|-----------|-----------------|-------------|---------|---|-----------|-------|----------|-----------|---------|---------|
| ALIAS                           |       |           |          | ALIGN |           |         | ALLOCATABLE  | EXTERN | OPTIMIZATION_PARAMETER | ALLOW_NULL | FASTMEM | REFERENCE | ARRAY_VISUALIZER | FORCEINLINE | STDCALL | C | IGNORE_LOC | VALUE | CONCURRENCY_SAFE | INLINE | VARYING | CVF | MIXED_STR_LEN_ARG | VECTOR | DECORATE | NO_ARG_CHECK | DEFAULT | NOCLONE |

¹A common block name is specified as [/]common-block-name[/]
²This option can only be applied to arrays.
³Module-level variables and arrays only.
⁴This option can only be applied to INTERFACE blocks.
⁵This option cannot be applied to EXTERNAL statements.
⁶This option can be applied to named main programs.
These options can be used in function and subroutine definitions, in type declarations, and with the INTERFACE and ENTRY statements.

Options applied to entities available through use or host association are in effect during the association. For example, consider the following:

```fortran
MODULE MOD1
  INTERFACE
    SUBROUTINE NEW_SUB
      !DIR$ ATTRIBUTES C, ALIAS:'othername' :: NEW_SUB
      END SUBROUTINE
  END INTERFACE

  CONTAINS
    SUBROUTINE SUB2
      CALL NEW_SUB
    END SUBROUTINE
  END MODULE
```

In this case, the call to NEW_SUB within SUB2 uses the C and ALIAS options specified in the interface block.

Options C, STDCALL, REFERENCE, VALUE, and VARYING affect the calling conventions of routines:

- You can specify C, STDCALL, REFERENCE, and VARYING for an entire routine.
- You can specify VALUE and REFERENCE for individual arguments.

### Examples

```fortran
INTERFACE
  SUBROUTINE For_Sub (I)
    !DIR$ ATTRIBUTES C, ALIAS:'_For_Sub' :: For_Sub
    INTEGER I
  END SUBROUTINE For_Sub
END INTERFACE
```

You can assign more than one option to multiple variables with the same compiler directive. All assigned options apply to all specified variables. For example:

```fortran
!DIR$ ATTRIBUTES REFERENCE, VARYING, C :: A, B, C
```

In this case, the variables `A`, `B`, and `C` are assigned the REFERENCE, VARYING, and C options. The only restriction on the number of options and variables is that the entire compiler directive must fit on one line.

The identifier of the variable or procedure that is assigned one or more options must be a simple name. It cannot include initialization or array dimensions. For example, the following is not allowed:

```fortran
!DIR$ ATTRIBUTES C :: A(10)  ! This is illegal.
```

The following shows another example:

```fortran
SUBROUTINE ARRAYTEST(arr)
  !DIR$ ATTRIBUTES DLLEXPORT :: ARRAYTEST
  REAL(4) arr(3, 7)
  INTEGER i, j
  DO i = 1, 3
    DO j = 1, 7
      arr (i, j) = 11.0 * i + j
    END DO
  END DO
END SUBROUTINE
```

ATTRIBUTES ALIAS

The ATTRIBUTES directive option ALIAS specifies an alternate external name to be used when referring to external subprograms.

Syntax

!DIR$ ATTRIBUTES ALIAS: external-name:: subprogram

external-name  Is a character constant delimited by apostrophes or quotation marks. The character constant is used as is; the string is not changed to uppercase, nor are blanks removed.

subprogram  Is an external subprogram.

The ALIAS option overrides the C (and STDCALL) option. If both C and ALIAS are specified for a subprogram, the subprogram is given the C calling convention, but not the C naming convention. It instead receives the name given for ALIAS, with no modifications.

ALIAS cannot be used with internal procedures, and it cannot be applied to dummy arguments.

The following example gives the subroutine happy the name "_OtherName@4" outside this scoping unit:

```
INTERFACE
  SUBROUTINE happy(i)
    !DIR$ ATTRIBUTES STDCALL, DECORATE, ALIAS:'OtherName' :: happy
    INTEGER i
  END SUBROUTINE
END INTERFACE
```

!DIR$ ATTRIBUTES ALIAS has the same effect as the !DIR$ ALIAS directive.

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES ALIGN

The ATTRIBUTES directive option ALIGN specifies the byte alignment for variables and for allocatable or pointer components of derived types.

Syntax

!DIR$ ATTRIBUTES ALIGN: n:: object

n  Is the number of bytes for the minimum alignment boundary.

For allocatable objects, the boundary value must be a power of 2 between 1 and 16384, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.

For non-allocatable objects, the boundary value must be a power of 2 between 1 and 64 on Windows* systems, between 1 and 2**16 on Linux* systems, or between 1 and 2**12 on OS X* systems.

object  Is the variable or the allocatable or pointer component of a derived type to be aligned.

Objects that can be aligned by this directive include static local variables, automatic variables, module variables, dynamically allocated arrays, allocatable array components of derived types, and the start of common blocks. This directive cannot be used to align variables within common blocks.

If you specify directive !DIR$ ATTRIBUTES ALIGN on an object with the ALLOCATABLE or POINTER attribute, an ALLOCATE statement will attempt to use that alignment when the memory is allocated.
For allocatable or pointer components of derived types, the directive must appear within the derived-type TYPE...END TYPE block.

If the TYPE is an extended type, the directive cannot reference a component in the parent type.

**Example**

Consider the following:

```fortran
TYPE EXAMPLE
  !DIR$ ATTRIBUTES ALIGN : 64 :: R_alloc
  REAL, ALLOCATABLE :: R_alloc ( : )
  REAL :: R_scalar
  INTEGER :: I_nonalloc(25)
END TYPE EXAMPLE

TYPE (EXAMPLE) :: MyVar

ALLOCATE (MyVar%R_alloc(1000)) ! Memory is allocated aligned at a 64-byte boundary
```

Note that it is valid to give the ALIGN:64 attribute to component R_alloc, but not to component R_scalar or to component I_nonalloc.

The following example shows that the name of a common block may optionally be enclosed in slashes:

```fortran
!DIR$ ATTRIBUTES ALIGN: n :: /common_name/
```

ATTRIBUTES

ASSUMEAligned

align compiler option (see setting array|byte)

**Syntax Rules for Compiler Directives**

**ATTRIBUTES ALLOCATABLE**

The ATTRIBUTES directive option ALLOCATABLE is provided for compatibility with older programs. It lets you delay allocation of storage for a particular declared entity until some point at run time when you explicitly call a routine that dynamically allocates storage for the entity.

**Syntax**

```fortran
!DIR$ ATTRIBUTES ALLOCATABLE :: entity
```

entity Is the name of the entity that should have allocation delayed.

The recommended method for dynamically allocating storage is to use the ALLOCATABLE statement or attribute.

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives

**ATTRIBUTES ALLOW_NULL**

The ATTRIBUTES directive option ALLOW_NULL enables a corresponding dummy argument to pass a NULL pointer (defined by a zero or the NULL intrinsic) by value for the argument.

**Syntax**

```fortran
!DIR$ ATTRIBUTES ALLOW_NULL :: arg
```
ARG

Is the name of the argument.

ALLOW_NULL is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES ARRAY_VISUALIZER (W*S)
The ATTRIBUTES directive option ARRAY_VISUALIZER enables more efficient memory sharing between the application and the Intel® Array Visualizer library.

Syntax

!DIR$ ATTRIBUTES ARRAY_VISUALIZER :: array

array

Is the array to be used with the Intel® Array Visualizer library.

The following example shows a way to use this directive option to improve the performance of the call:

```
real(4), allocatable :: MyArray(:, :)
!DIR$ ATTRIBUTES array_visualizer :: MyArray
```

Syntax Rules for Compiler Directives

ATTRIBUTES C and STDCALL
The ATTRIBUTES directive options C and STDCALL specify procedure calling, naming, and argument passing conventions.

Syntax

!DIR$ ATTRIBUTES C :: object[, object] ...

!DIR$ ATTRIBUTES STDCALL :: object[, object] ...

object

Is the name of a data object or procedure.

On Windows* systems on IA-32 architecture, C and STDCALL have slightly different meanings; on all other platforms, STDCALL is treated as C.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions. The effects depend on whether or not the subprogram is interoperable (has the BIND attribute).

For interoperable subprograms with the BIND attribute, ATTRIBUTES STDCALL has the following effects for subprograms in applications targeting Windows systems on IA-32 architecture:

- The STDCALL calling convention is used where the called subprogram cleans up the stack at exit.
- The external name has @n appended, where n is the number of bytes of arguments pushed on the stack.

No other effects of ATTRIBUTES STDCALL are applied for interoperable subprograms. If pass-by-value is desired for a dummy argument to an interoperable subprogram, the Fortran standard VALUE attribute should be specified for that argument.

For platforms other than Windows systems on IA-32 architecture, ATTRIBUTES STDCALL has no effect on interoperable subprograms. You should not specify ATTRIBUTES C for interoperable subprograms.

The following table and subsequent text summarizes the differences between the calling conventions for subprograms that are not interoperable:
<table>
<thead>
<tr>
<th>Convention</th>

</tbody>
</table>

¹ STDCALL is treated as C on Linux* OS, OS X*, and on Windows* OS on Intel® 64 architecture.
² The Intel® Fortran calling convention
³ On Linux* OS, if there are one or more underscores in the external name, two trailing underscores are added; if there are no underscores, one is added.
⁴ IA-32 architecture only

If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore (_ ) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:
- By default, hidden lengths are put at the end of the argument list.
  - On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.
- If C or STDCALL (only) is specified:
  - On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).
- If C or STDCALL is specified, and REFERENCE is specified for the argument:
  - On all systems, the string is passed with no length.
- If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is not specified for the argument, if any):
  - On all systems, the string is passed with the length.
ATTRIBUTES CONCURRENCY_SAFE
The ATTRIBUTES directive option
CONCURRENCY_SAFE specifies that there are no
unacceptable side effects and no illegal (or improperly
synchronized) memory access interferences among
multiple invocations of a routine or between an
invocation of the specified routine and other
statements in the program if they were executed
concurrently.

Syntax

!DIR$ ATTRIBUTES CONCURRENCY_SAFE [(: clause) :: routine-name-list

clause
Is one of the following:

• profitable
• cost (int-cycle-count)

int-cycle-count
Is an integer scalar constant expression.

routine-name-list
Is a comma-separated list of function and subroutine names.

When a CONCURRENCY_SAFE routine is called from parallelized code, you can ignore assumed cross-block or
cross-iteration dependencies and side effects of calling the specified routine from parallelized code.

The profitable clause indicates that the loops or blocks that contain calls to the routine can be safely
executed in parallel if the loop or blocks are legal to be parallelized; that is, if it is profitable to parallelize
them.

The cost clause indicates the execution cycles of the routine where the compiler can perform parallelization
profitability analysis while compiling its enclosing loops or blocks.

The attribute can appear in the declaration of the routine; for example:

function f(x)
!DIR$ attributes concurrency_safe :: f

The attribute can also appear in the code of the caller; for example:

main m
integer f
external f
!dir$ attributes concurrency_safe :: f   ! or it could be in an interface block describing f
...
Print *, f(x)

NOTE
For every routine named in routine-name-list, you should ensure that any possible side effects are
acceptable or expected, and the memory access interferences are properly synchronized.
ATTRIBUTES CVF
The ATTRIBUTES direction option CVF tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation.

Syntax
!DIR$ ATTRIBUTES CVF :: object[, object] ...

object Is the name of a data object or procedure.

The conventions that are used are as follows:

• The calling mechanism: STDCALL on Windows* systems using IA-32 architecture
• The argument passing mechanism: by reference
• Character-length argument passing: following the argument address
• The external name case: uppercase
• The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where n is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES DECORATE
The ATTRIBUTES directive option DECORATE specifies that the external name used in !DIR$ ALIAS or !DIR$ ATTRIBUTES ALIAS should have the prefix and postfix decorations performed on it that are associated with the platform and calling mechanism that is in effect. These are the same decorations performed on the procedure name when ALIAS is not specified, except that, on Linux* and OS X* systems, DECORATE does not add a trailing underscore signifying a Fortran procedure.

Syntax
!DIR$ ATTRIBUTES DECORATE :: exname

exname Is an external name.

The case of the ALIAS external name is not modified.

If ALIAS is not specified, this option has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES ALIAS
ATTRIBUTES C and STDCALL
ATTRIBUTES DEFAULT
The ATTRIBUTES directive option DEFAULT overrides certain compiler options that can affect external routine and COMMON block declarations.

Syntax

```
c!DIR$ ATTRIBUTES DEFAULT :: entity
```

`entity` Is an external procedure, a COMMON block, a module variable that is initialized, or a PARAMETER in a module.

It specifies that the compiler should ignore compiler options that change the default conventions for external symbol naming and argument passing for routines and COMMON blocks (such as names, assume underscore, assume 2underscores on Linux systems, and iface on Windows* systems).

This option can be combined with other ATTRIBUTES options, such as STDCALL, C, REFERENCE, ALIAS, etc. to specify properties different from the compiler defaults.

This option is useful when declaring INTERFACE blocks for external routines, since it prevents compiler options from changing calling or naming conventions.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives
iface
names
assume

ATTRIBUTES DLLEXPORT and DLLIMPORT
The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library's interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. These directive options are available on Windows* and OS X* systems.

Syntax

```
!DIR$ ATTRIBUTES DLLEXPORT :: object[, object] ...
!DIR$ ATTRIBUTES DLLIMPORT :: object[, object] ...
```

`object` Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.

DLLEXPORT and DLLIMPORT define the interface for the following dynamic-link libraries:

- DLL on Windows* OS
- DYLIB on OS X*

DLLEXPORT specifies that procedures or data are being exported to other applications or dynamic libraries. This causes the compiler to produce efficient code; for example, eliminating the need on Windows OS for a module definition (.def) file to export symbols.

DLLEXPORT should be specified in the routine to which it applies. If the routine's implementation is in a submodule, specify DLLEXPORT in the parent module's INTERFACE block for the routine. If MODULE PROCEDURE is used in the submodule, the DLLEXPORT attribute will be inherited; otherwise you must also specify DLLEXPORT in the submodule routine.

Symbols defined in a DLL are imported by programs that use them. On Windows* OS, the program must link with the DLL import library (.lib).
The DLLIMPORT option is used inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

**See Also**

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES EXTERN
The ATTRIBUTES directive option EXTERN specifies that a variable is allocated in another source file. EXTERN can be used in global variable declarations, but it must not be applied to dummy arguments.

**Syntax**

```fortran
!DIR$ ATTRIBUTES EXTERN :: var
```

*var* is the variable to be allocated.

This option must be used when accessing variables declared in other languages.

**See Also**

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES FASTMEM
The ATTRIBUTES directive option FASTMEM enables High Band Width (HBW) memory allocation for an allocated object. This directive option only applies to Intel® MIC Architecture and it is only available for Linux® OS.

**Syntax**

```fortran
!DIR$ ATTRIBUTES FASTMEM :: object
```

*object* is an allocatable array. It cannot be a local variable, a common block, or an array that will be allocated on the stack.

FASTMEM enables High Band Width (HBW) memory allocation for an allocated object at runtime.

When the specified object is allocated using the ALLOCATE statement at runtime, the Fortran Run-Time Library (RTL) allocates the memory in HBW memory. When the specified object is deallocated using the DEALLOCATE statement at runtime, the Fortran RTL deallocates the memory in HBW memory.

If the hardware is not available to allocate the object to High Band Width (HBW) memory, or if enough HBW memory is not available to satisfy the allocation, then allocation is performed using non-HBW memory.

When you use this directive in a program, you must specify the following on the compiler or linker command line:

```
-lmemkind
```

If the libraries required for HBW memory support are not linked successfully, no warning will be given but the application will still run correctly using non-HBW memory in place of HBW memory.

The following example shows a way to use this directive option to allocate High Band Width (HBW) memory:

```fortran
real, allocatable :: X (:,:)
!dir$ attributes fastmem :: X
...
allocate (X(100,100))
```
You can use ATTRIBUTES option ALIGN with FASTMEM, for example:

```fortran
!DIR$ ATTRIBUTES FASTMEM, ALIGN:64 :: A
ALLOCATE ( A(1000), STAT= integer-variable )
...
DEALLOCATE ( A )
```

**See Also**

Syntax Rules for Compiler Directives

ATTRIBUTES ALIGN

Using HBW Memory

**ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE**

The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

**Syntax**

The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

```fortran
!DIR$ ATTRIBUTES INLINE :: procedure
```

*procedure* is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function.

```fortran
!DIR$ ATTRIBUTES NOINLINE :: procedure
```

*procedure* is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors.

```fortran
!DIR$ ATTRIBUTES FORCEINLINE :: procedure
```

*procedure* is the function or subroutine that must be inlined.

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives

**ATTRIBUTES IGNORE_LOC**

The ATTRIBUTES directive option IGNORE_LOC enables %LOC to be stripped from an argument.

**Syntax**

```fortran
!DIR$ ATTRIBUTES IGNORE_LOC :: arg
```

*arg* is the name of an argument.

IGNORE_LOC is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

**See Also**

ATTRIBUTES
**ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG**

These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed. MIXED_STR_LEN_ARG specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list. NOMIXED_STR_LEN_ARG specifies that these hidden lengths should be placed in sequential order at the end of the argument list.

**Syntax**

```
!DIR$ ATTRIBUTES MIXED_STR_LEN_ARG :: args
!DIR$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: args
```

`args` Is a list of arguments.

The default is NOMIXED_STR_LEN_ARG. However, if you specify compiler option `/iface:CVF` or `/iface:mixed_str_len_arg` (Windows* OS), or compiler option `-mixed-str-len-arg` (Linux* OS and OS X*), the default is MIXED_STR_LEN_ARG.

**See Also**

ATTRIBUTES directive

Syntax Rules for Compiler Directives

iface compiler option

**ATTRIBUTES NO_ARG_CHECK**

The ATTRIBUTES directive option NO_ARG_CHECK specifies that type and shape matching rules related to explicit interfaces are to be ignored. This permits the construction of an INTERFACE block for an external procedure or a module procedure that accepts an argument of any type or shape; for example, a memory copying routine.

**Syntax**

```
!DIR$ ATTRIBUTES NO_ARG_CHECK :: object
```

`object` Is the name of an argument or procedure.

NO_ARG_CHECK can appear only in an INTERFACE block for a non-generic procedure or in a module procedure. It can be applied to an individual dummy argument name or to the routine name, in which case the option is applied to all dummy arguments in that interface.

NO_ARG_CHECK cannot be used for procedures with the PURE or ELEMENTAL prefix.

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives
ATTRIBUTES NOCLONE

The ATTRIBUTES directive option NOCLONE can be used to prevent a procedure from being considered for cloning, which is a mechanism performed by interprocedural constant propagation that produces specialized copies of the procedure.

Syntax

!DIR$ ATTRIBUTES NOCLONE :: procedure

procedure Is a function or subroutine that can be inlined.

Note that if you specify ATTRIBUTES NOINLINE, it does not prevent this cloning.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE

ATTRIBUTES OFFLOAD

The ATTRIBUTES directive option OFFLOAD ensures that variables, COMMON blocks, and procedures are available on the target. This directive option only applies to Intel® MIC Architecture.

Syntax

!DIR$ ATTRIBUTES OFFLOAD: target-name:: object-name

target-name Is a specific target. The only supported value for this argument is MIC.

object-name Is the name of a procedure, or a variable, or a COMMON block name (enclosed in slashes).

The statement following an OFFLOAD directive is converted into an outlined function that runs on the coprocessor. This code is permitted to call other procedures. To ensure that these called procedures are also available on the coprocessor, they should also include the ATTRIBUTES OFFLOAD:MIC directive.

All procedures in the program are always compiled for the CPU and are available to be called on the CPU. However, only procedures that include the ATTRIBUTES OFFLOAD:MIC directive are available to be called by offloaded code, and only these procedures can be called on the coprocessor.

Global variables and COMMON blocks are treated in a similar fashion. All global variables are always present in the CPU code. But only global variables and COMMON blocks declared with the ATTRIBUTES OFFLOAD:MIC directive are compiled into the code offloaded to the coprocessor. If an data object in a named COMMON block is given the OFFLOAD:MIC attribute, the entire named COMMON block is given the OFFLOAD:MIC attribute.

Compiling only procedures and data explicitly marked with the ATTRIBUTES OFFLOAD:MIC directive into the Intel® MIC Architecture binary ensures that the code on the coprocessor is as small as possible.

The compiler issues warnings for procedures and data referenced within offloaded code that do not include the ATTRIBUTES OFFLOAD:MIC directive.

NOTE

The definition and all declarations of a variable or procedure with the ATTRIBUTES OFFLOAD:MIC directive must be consistent with each other across all compilation units.
Example

```fortran
module m
   !dir$ attributes offload:mic :: global
   integer :: global = 55
end module m

!dir$ attributes offload:mic :: foo
function foo ()
   use m
   integer :: foo
   global = global + 1
   foo = global
end function foo

program main
   use m
   integer :: i

   !dir$ attributes offload:mic :: foo
   integer :: foo

   !dir$ offload target(mic) in(global) out(i, global)
   i = foo()

   write(*, '( " global = ", i0, " I = ", i0)' )  global, i
end program main
```

Calling function foo() within an offloaded construct requires adding the ATTRIBUTES OFFLOAD:MIC directive within both the calling routine's scope and the function definition/scope for foo() itself.

OFFLOAD_WAIT
OFFLOAD

ATTRIBUTES OPTIMIZATION_PARAMETER

The ATTRIBUTES directive option

OPTIMIZATION_PARAMETER passes certain information about a procedure or main program to the optimizer.

Syntax

```
!DIR$ ATTRIBUTES OPTIMIZATION_PARAMETER: string::{ procedure-name | named-main-program}
```

string

Is a character constant that is passed to the optimizer. The constant must be delimited by apostrophes or quotation marks, and it may have one of the following values:

- **TARGET_ARCH= cpu**
  
  Tells the compiler to generate code specialized for a particular processor. For the list of cpus you can specify, see option [Q|x].

- **INLINE_MAX_PER_ROUTINE= n**
  
  Specifies the maximum number of times the inliner may inline into the procedure. The n is one of the following:
• A non-negative scalar integer constant (>=0) that specifies the maximum number of times the inliner may inline into the procedure. If you specify zero, no inlining is done into the routine.
• The keyword UNLIMITED, which means that there is no limit to the number of times the inliner may inline into the procedure.

For more information, see option \[Q\]inline-max-per-routine.

• \[Q\]inline-max-total-size= \(n\)

Specifies how much larger a routine can normally grow when inline expansion is performed. The \(n\) is one of the following:

• A non-negative scalar integer constant (>=0) that specifies the permitted increase in the routine's size when inline expansion is performed. If you specify zero, no inlining is done into the routine.
• The keyword UNLIMITED, which means that there is no limit to the size a routine may grow when inline expansion is performed.

For more information, see option \[Q\]inline-max-total-size.

procedure-name
Is the name of a procedure.

named-main-program
Is the name of a main program

Description
The characters in string can appear in any combination of uppercase and lowercase. The following rules also apply to string:

• If string does not contain an equal sign (=), then the entire value of string is converted to lowercase before being passed to the optimizer.
• If string contains an equal sign, then all characters to the left of the equal sign are converted to lowercase before all of string is passed to the optimizer.

Characters to the right of the equal sign are not converted to lowercase since their value may be case sensitive to the optimizer, for example "target_arch=AVX".

You can specify multiple ATTRIBUTES OPTIMIZATION_PARAMETER directives for one procedure or one main program.

For the named procedure or main program, the values specified for ATTRIBUTES OPTIMIZATION_PARAMETER override any settings specified for the following compiler options:

• \[Q\]x, \(-m\), and \(/arch\)
• \[Q\]inline-max-per-routine
• \[Q\]inline-max-total-size

Example
Consider the two attributes optimization_parameter directives in the following code:

```fortran
function f (x)
!dir$ attributes optimization_parameter: "inline_max_per_routine=10" :: f
!dir$ attributes optimization_parameter: "inline_max_total_size=2000" :: f
real :: f, x
...
```

The two directives have the same effect as if the function F had been compiled with "/Qinline-max-per-routine:10 /Qinline-max-total-size:2000" on Windows* or with "-inline-max-per-routine=10 -inline-max-total-size=2000" on Linux* or OS X*, that is, inlining will not increase the size of F by more than 2000 and the inliner will not inline routines into F more than 10 times.

Syntax Rules for Compiler Directives
x, Qx compiler option
inline-max-per-routine, Qinline-max-per-routine compiler option
inline-max-total-size, Qinline-max-total-size compiler option

ATTRIBUTES REFERENCE and VALUE
The ATTRIBUTES directive options REFERENCE and VALUE specify how a dummy argument is to be passed.

Syntax
!DIR$ ATTRIBUTES REFERENCE :: arg
!DIR$ ATTRIBUTES VALUE :: arg

arg Is the name of a dummy argument.

REFERENCE specifies a dummy argument's memory location is to be passed instead of the argument's value.

VALUE specifies a dummy argument's value is to be passed instead of the argument's memory location.

When VALUE is specified for a dummy argument, the actual argument passed to it can be of a different type. If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, two floating-point arguments (one containing the real part, the other containing the imaginary part) are passed by immediate value.

Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by value.

If REFERENCE (only) is specified for a character argument, the string is passed with no length.

If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified for the routine, the string is passed with no length. This is true even if REFERENCE is also specified for the routine.

If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has not been specified for the argument, the string is passed with the length.

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.

In the following example integer x is passed by value:

```fortran
SUBROUTINE Subr (x)
INTEGER x
!DIR$ ATTRIBUTES VALUE :: x
```

See Also
ATTRIBUTES C and STDCALL
ATTRIBUTES
Syntax Rules for Compiler Directives

Mixed Language Programming: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES VARYING
The ATTRIBUTES directive option VARYING allows a Fortran routine to call a C/C++ routine with a variable number of arguments.

Syntax
!DIR$ ATTRIBUTES VARYING :: var[, var] ...
**var**

Is a variable representing a C/C++ routine that takes a variable number of arguments.

This attribute can be used in an interface block to create an explicit interface for a C/C++ routine or it can be used on a variable declared EXTERN that represents a C/C++ routine. When the routine is called from the Fortran code, a variable number of arguments can be specified.

This attribute cannot be used with a Fortran routine declaration.

If ATTRIBUTES VARYING is specified, the C calling convention must also be used, either implicitly or explicitly.

All actual arguments in the routine call are passed to the called routine, regardless of the number of dummy arguments specified in the interface. If the called routine tries to access a dummy argument that has no matching actual argument, it causes a user error and the program may fail unpredictably.

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives

**ATTRIBUTES VECTOR**

The ATTRIBUTES directive option VECTOR tells the compiler to vectorize the specified function or subroutine.

**Syntax**

```
!DIR$ ATTRIBUTES [att [, att]...] VECTOR [:clause] [, att]...] :: routine-name
```

- **att**
  
  Is an ATTRIBUTES directive option. For a list of possible directive options, see the description of argument att in ATTRIBUTES.

- **clause**
  
  Is one or more of the following optional clauses:

  - **LINEAR** (`var1:step1 [, var2:step2]...`)
    
    - **var**
      
      Is a scalar variable that is a dummy argument in the specified routine.
    
    - **step**
      
      Is a compile-time positive, integer constant expression.

    Tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of var1 is incremented by step1, var2 is incremented by step2, and so on.

    If more than one step is specified for a particular var, a compile-time error occurs.

    Multiple LINEAR clauses are merged as a union.

  - **[NO]MASK**

    Determines whether the compiler generates a masked vector version of the routine.

  - **PROCESSOR (cpuid)** (an Intel® language extension)

  - **UNIFORM** (`arg [, arg]...`)

   - **arg**
     
     Is a scalar variable that is a dummy argument in the specified routine.
Tells the compiler that the values of the specified arguments can be broadcasted to all iterations as a performance optimization.

Multiple UNIFORM clauses are merged as a union.

- **VECTORLENGTH \((n, n)\)...**

  \(n\) is a vector length (VL). It must be an integer, scalar constant expression that is a power of 2; the value must be 2, 4, 8, or 16. If you specify more than one \(n\), the compiler will choose the VL from the values specified.

Tells the compiler that each routine invocation at the call site should execute the computation equivalent to \(n\) times the scalar function execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- **VECTORLENGTHFOR (data-type)**

  data-type is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
<tr>
<td>REAL</td>
<td>Default REAL</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>REAL (KIND=4)</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>REAL (KIND=8)</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Default COMPLEX</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>COMPLEX (KIND=4)</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>COMPLEX (KIND=8)</td>
</tr>
</tbody>
</table>

Causes each iteration in the vector loop to execute the computation equivalent to \(n\) iterations of scalar loop execution where \(n\) is computed from size_of_vector_register/sizeof(data_type).

For example, VECTORLENGTHFOR (REAL (KIND=4)) results in \(n=4\) for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and \(n=8\) for AVX target (packed float operations available on 256-bit YMM registers). VECTORLENGTHFOR(INTEGER (KIND=4)) results in \(n=4\) for SSE2 to AVX targets.
The VECTORLENGTHFOR and VECTORLENGTH clauses are mutually exclusive. You cannot use the VECTORLENGTHFOR clause with the VECTORLENGTH clause, and vice versa.

Multiple VECTORLENGTHFOR clauses cause a syntax error.

Without explicit VECTORLENGTH and VECTORLENGTHFOR clauses, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

*routine-name* is the name of a routine (a function or subroutine). It must be the enclosing routine or the routine immediately following the directive.

If you specify more than one clause, they must be separated by commas and enclosed in parentheses.

When you specify the ATTRIBUTES VECTOR directive, the compiler provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. If you specify one or more clauses, they affect the data parallel semantics provided by the compiler.

If you specify the ATTRIBUTES VECTOR directive with no VECTORLENGTH clause, a default VECTORLENGTH is computed based on efficiency heuristics of the vectorizer and the following:

- The return type of the function, if the function has a return type.
- The data type of the first non-scalar argument (that is, the first argument that is specified in the scalar clause), if any.
- Default integer type, if neither of the above is supplied.

If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model.

If you specify the ATTRIBUTES VECTOR directive with no clause, the compiler will generate vector code based on compiler efficiency heuristics and whatever processor compiler options are specified.

The VECTOR attribute implies the C attribute, so that when you specify the VECTOR attribute on a routine, the C attribute is automatically also set on the same routine. This changes how the routine name is decorated and how arguments are passed.

**NOTE**

You should ensure that any possible side effects for the specified routine-name are acceptable or expected, and the memory access interferences are properly synchronized.

The Fortran Standard keyword ELEMENTAL specifies that a procedure written with scalar arguments can be extended to conforming array arguments by processing the array elements one at a time in any order. The ATTRIBUTES VECTOR directive tells the optimizer to produce versions of the procedure *routine-name* that execute with contiguous slices of the array arguments as defined by the VECTORLENGTH clause in an "elemental" fashion. *routine-name* does not need to be defined as ELEMENTAL to be given the VECTOR attribute.

The VECTOR attribute causes the compiler to generate a short vector form of the procedure, which can perform the procedure's operation on multiple elements of its array arguments in a single invocation. The short vector version may be able to perform multiple operations as fast as the regular implementation performs a single operation by using the vector instruction set in the CPU.
In addition, when invoked from an OMP construct, the compiler may assign different copies of the elemental procedures to different threads, executing them concurrently. The end result is that your data parallel operation executes on the CPU using both the parallelism available in the multiple cores and the parallelism available in the vector instruction set. If the short vector procedure is called inside a parallel loop or an auto-parallelized loop that is vectorized, you can achieve both vector-level and thread-level parallelism.

The INTENT(OUT) or INTENT(INOUT) attribute is not allowed for arguments of a procedure with the VECTOR attribute since the VECTOR attribute forces the procedure to receive its arguments by value.

The Intel C/C++ compiler built-in function __intel_simd_lane() may be helpful in removing certain performance penalties caused by non-unit stride vector access. Consider the following:

```fortran
interface
! returns a number between 0 and vectorlength - 1 that reflects the current "lane id" within the SIMD vector
! __intel_simd_lane() will return zero if the loop is not vectorized
  function for_simd_lane () bind (C, name = "__intel_simd_lane")
    integer (kind=4) :: for_simd_lane
    !DEC$ attributes known_intrinsic, default :: for_simd_lane
    end function for_simd_lane
end interface
```

For more details, see the Intel C++ documentation.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

---

**Example**

The ATTRIBUTES VECTOR directive must be accessible in the caller, either via an INTERFACE block or by USE association.

The following shows an example of an external function with an INTERFACE block:

```fortran
The ATTRIBUTES VECTOR directive can be brought into the caller by USE association if the vector function is a module procedure; for example:

You can specify more than one SCALAR or LINEAR clause in an ATTRIBUTES VECTOR directive. For example, all of the following are valid:

The three directives above are equivalent to specifying a single, continued, directive in fixed-form source, as follows:

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives

**AUTOAddArg (W*S)**

**AUTO Subroutine:** Passes an argument name and value and adds the argument to the argument list data structure.
Module
USE IFAUTO
USE IFWINTY

Syntax
CALL AUTOAddArg (invoke_args, name, value [, intent_arg ] [, type ])

invoke_args
The argument list data structure. Must be of type INTEGER(INT_PTR_KIND( )).

name
The argument's name of type CHARACTER(*)..

value
The argument's value. Must be of type INTEGER(1), INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), CHARACTER(*), or a single dimension array of one of these types. Can also be of type VARIANT, which is defined in the IFWINTY module.

intent_arg
Indicates the intended use of the argument by the called method. Must be one of the following constants defined in the IFAUTO module:

- AUTO_ARG_IN: The argument's value is read by the called method, but not written. This is the default value if intent_arg is not specified.
- AUTO_ARG_OUT: The argument's value is written by the called method, but not read.
- AUTO_ARG_INOUT: The argument's value is read and written by the called method.

When the value of intent_arg is AUTO_ARG_OUT or AUTO_ARG_INOUT, the variable used in the value argument should be declared using the VOLATILE attribute. This is because the value of the variable will be changed by the subsequent call to AUTOInvoke. The compiler's global optimizations need to know that the value can change unexpectedly.

type
The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VARIANT Type</td>
<td>Value Type</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------</td>
</tr>
<tr>
<td>VT_VARIANT</td>
<td>TYPE(VARIANT)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Example**

See the example in COMInitialize.

**AUTOAllocateInvokeArgs (W*S)**

**AUTO Function**: Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.

**Module**

USE IFAUTO

**Syntax**

```plaintext
result = AUTOAllocateInvokeArgs( )
```

**Results**

The value returned is an argument list data structure of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.

**AUTODeallocateInvokeArgs (W*S)**

**AUTO Subroutine**: Deallocates an argument list data structure.

**Module**

USE IFAUTO

**Syntax**

```plaintext
CALL AUTODeallocateInvokeArgs (invoke_args)
```

`invoke_args` The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.

**AUTOGetExceptInfo (W*S)**

**AUTO Subroutine**: Retrieves the exception information when a method has returned an exception status.

**Module**

USE IFAUTO
Syntax

CALL AUTOGetExceptInfo (invoke_args, code, source, description, h_file, h_context, scode)

invoke_args The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

code An output argument that returns the error code. Must be of type INTEGER(2).

source An output argument that returns a human-readable name of the source of the exception. Must be of type CHARACTER(*)

description An output argument that returns a human-readable description of the error. Must be of type CHARACTER(*)

h_file An output argument that returns the fully qualified path of a Help file with more information about the error. Must be of type CHARACTER(*)

h_context An output argument that returns the Help context of the topic within the Help file. Must be of type INTEGER(4).

scode An output argument that returns an SCODE describing the error. Must be of type INTEGER(4).

AUTOGetProperty (W*S)

AUTO Function: Passes the name or identifier of the property and gets the value of the automation object's property.

Module

USE IFAUTO
USE IFWINTY

Syntax

result = AUTOGetProperty (idispatch, id, value[, type])

idispatch The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

id The argument’s name of type CHARACTER(*), or its member ID of type INTEGER(4).

value An output argument that returns the argument’s value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER(*), or a single dimension array of one of these types.

type The variant type of the requested argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>
### VARIANT Type

<table>
<thead>
<tr>
<th>VT_R4</th>
<th>REAL(4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*))</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

### Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

---

**AUTOGetPropertyByID (W*S)**

**AUTO Function:** Passes the member ID of the property and gets the value of the automation object’s property into the argument list’s first argument.

#### Module

USE IFAUTO

#### Syntax

```plaintext
result = AUTOGetPropertyByID (idispatch, memid, invoke_args)
```

- **idispatch**
  The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

- **memid**
  Member ID of the property. Must be of type INTEGER(4).

- **invoke_args**
  The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

#### Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

---

**AUTOGetPropertyInvokeArgs (W*S)**

**AUTO Function:** Passes an argument list data structure and gets the value of the automation object’s property specified in the argument list’s first argument.

#### Module

USE IFAUTO
Syntax

Result = AUTOGetPropertyInvokeArgs (idispatch, invoke_args)

idispatch            The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

invoke_args         The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(INT_PTR_KIND()).

AUTOInvoke (W*S)

**AUTO Function:** Passes the name or identifier of an object’s method and an argument list data structure and invokes the method with the passed arguments.

Module

USE IFAUTO

Syntax

Result = AUTOInvoke (idispatch, id, invoke_args)

idispatch            The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

id               The argument’s name of type CHARACTER*(*) or its member ID of type INTEGER(4).

invoke_args         The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

Example

See the example in COMInitialize.

AUTOMATIC

**Statement and Attribute:** Controls the storage allocation of variables in subprograms (as does STATIC). Variables declared as AUTOMATIC and allocated in memory reside in the stack storage area, rather than at a static memory location.

Syntax

The AUTOMATIC attribute can be specified in a type declaration statement or an AUTOMATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

type, [att-ls,] AUTOMATIC [, att-ls] :: v[, v] ...

**Statement:**

AUTOMATIC [::] v[, v] ...
**type**

Is a data type specifier.

**att-1s**

Is an optional list of attribute specifiers.

**v**

Is the name of a variable or an array specification. It can be of any type.

AUTOMATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

Automatic variables can reduce memory use because only the variables currently being used are allocated to memory.

Automatic variables allow possible recursion. With recursion, a subprogram can call itself (directly or indirectly), and resulting values are available upon a subsequent call or return to the subprogram. For recursion to occur, RECURSIVE must be specified in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

By default, the compiler allocates local scalar variables on the stack. Other non-allocatable variables of non-recursive subprograms are allocated in static storage by default. This default can be changed through compiler options. Appropriate use of the SAVE attribute may be required if your program assumes that local variables retain their definition across subprogram calls.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE (in one of the ways mentioned above).

To override any compiler option that may affect variables, explicitly specify the variables as AUTOMATIC.

**NOTE**

Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as AUTOMATIC more than once in the same scoping unit.

If the variable is a pointer, AUTOMATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as AUTOMATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>AUTOMATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>No</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

If a variable is in a module's outer scope, it cannot be specified as AUTOMATIC.

**Example**

The following example shows a type declaration statement specifying the AUTOMATIC attribute:

```plaintext
REAL, AUTOMATIC :: A, B, C
```
The following example uses an AUTOMATIC statement:

```fortran
... CONTAINS
INTEGER FUNCTION REDO_FUNC
  INTEGER I, J(10), K
  REAL C, D, E(30)
  AUTOMATIC I, J, K(20)
  STATIC C, D, E
...
END FUNCTION
... C       In this example, all variables within the program unit
C       are saved, except for "var1" and "var3". These are
C       explicitly declared in an AUTOMATIC statement, and thus have
C       memory locations on the stack:
  SUBROUTINE DoIt (arg1, arg2)
    INTEGER(4) arg1, arg2
    INTEGER(4) var1, var2, var3, var4
    SAVE
    AUTOMATIC var1, var3
  C       var2 and var4 are saved
```

**AUTOSetProperty (W*S)**

**AUTO Function**: Passes the name or identifier of the property and a value, and sets the value of the automation object’s property.

**Module**

USE IFAUTO
USE IFWINTY

**Syntax**

```fortran
result = AUTOSetProperty (idispatch, id, value[, type])
```

- **idispatch**: The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **id**: The argument’s name of type CHARACTER(*) or its member ID of type INTEGER(4).
- **value**: The argument’s value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER(*), or a single dimension array of one of these types.
**type**

The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOSetPropertyByID (W*S)**

**AUTO Function:** Passes the member ID of the property and sets the value of the automation object's property into the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOSetPropertyByID} (\text{idispatch, memid, invoke_args})
\]

**idispatch**

The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**memid**

Member ID of the property. Must be of type INTEGER(4).

**invoke_args**

The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).
**AUTOSetPropertyInvokeArgs (W*S)**

**AUTO Function:** Passes an argument list data structure and sets the value of the automation object's property specified in the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

result = AUTOSetPropertyInvokeArgs (idispatch, invoke_args)

idispatch The object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

invoke_args The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**BACKSPACE**

**Statement:** Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing. It takes one of the following forms:

**Syntax**

BACKSPACE ([UNIT=] io-unit[, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])

BACKSPACE io-unit

io-unit (Input) Is an external unit specifier.

label Is the label of the branch target statement that receives control if an error occurs.

msg-var (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

The I/O unit number must specify an open file on disk or magnetic tape.

Backspacing from the current record \( n \) is performed by rewinding to the start of the file and then performing \( n - 1 \) successive READs to reach the previous record.

A BACKSPACE statement must not be specified for a file that is open for direct or append access, because \( n \) is not available to the Fortran I/O system.

BACKSPACE cannot be used to skip over records that have been written using list-directed or namelist formatting.

If a file is already positioned at the beginning of a file, a BACKSPACE statement has no effect.
If the file is positioned between the last record and the end-of-file record, BACKSPACE positions the file at the start of the last record.

### Example

```plaintext
BACKSPACE 5  
BACKSPACE (5)  
BACKSPACE lunit  
BACKSPACE (UNIT = lunit, ERR = 30, IOSTAT = ios)
```

The following statement repositions the file connected to I/O unit 4 back to the preceding record:

```plaintext
BACKSPACE 4
```

Consider the following statement:

```plaintext
BACKSPACE (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 back to the preceding record. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

ENDFILE  
Data Transfer I/O Statements Overview  
Branch Specifiers (END=, EOR=, ERR=)

### BADDRESS

**Inquiry Intrinsic Function (Generic):** Returns the address of an argument. This function cannot be passed as an actual argument. This function can also be specified as IADDR.

#### Syntax

```plaintext
result = BADDRESS (x)
```

- `x` is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

#### Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

### Example

```plaintext
PROGRAM batest  
   INTEGER X(5), I  
   DO I=1, 5  
      PRINT *, BADDRESS(X(I))  
   END DO  
END
```
BARRIER

OpenMP* Fortran Compiler Directive:
Synthesizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.

Syntax

 !$OMP BARRIER

The binding thread set for a BARRIER construct is the current team. A barrier region binds to the innermost enclosing parallel region.

Each barrier region must be encountered by all threads in a team or by none at all, unless cancellation has been requested for the innermost enclosing parallel region.

The barrier region must also be encountered in the same order by all threads in a team.

Example

INTEGER K
K = 17

 !$OMP PARALLEL SHARED (K) NUM_THREADS (2)
 IF (OMP_GET_THREAD_NUM() == 0) THEN
   X = 5
 ELSE
   ! The following read access of K creates a race condition
   PRINT *,"1: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
 ENDIF

 ! This barrier contains implicit flushes on all threads, as well as a thread 
 ! synchronization: this guarantees that the value 5 will be printed by 
 ! both PRINT 2 and PRINT 3 below.

 !$OMP BARRIER

 IF (OMP_GET_THREAD_NUM() == 0) THEN
   PRINT *,"2: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
 ELSE
   PRINT *,"3: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
 ENDIF
 !$OMP END PARALLEL

BEEPQ

Portability Subroutine: Sounds the speaker at the specified frequency for the specified duration in milliseconds.

Module

USE IFPORT
Syntax
CALL BEEPQQ (frequency, duration)

frequency (Input) INTEGER(4). Frequency of the tone in Hz.
duration (Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Example
USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration = 1000
CALL BEEPQQ(frequency, duration)

See Also
SLEEPQQ
BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

Portability Functions: Compute the single-precision values of Bessel functions of the first and second kinds.

Module
USE IFPORT

Syntax
result = BESJ0 (value)
result = BESJ1 (value)
result = BESJN (n, value)
result = BESY0 (posvalue)
result = BESY1 (posvalue)
result = BESYN (n, value)

value (Input) REAL(4). Independent variable for a Bessel function.
n (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.
posvalue (Input) REAL(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results
BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and n, respectively, with the independent variable posvalue.
BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and n, respectively, with the independent variable posvalue.

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.
Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

---

**BESSEL_J0**

*Elemental Intrinsic Function (Generic): Computes a Bessel function of the first kind, order 0.*

**Syntax**

\[
\text{result} = \text{BESSEL}_J0 (x)
\]

- \( x \) (Input) Must be of type real.

**Results**

The result type and kind is the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order zero of \( x \).

**Example**

BESSEL_J0 (1.0) has the approximate value 0.765.

---

**BESSEL_J1**

*Elemental Intrinsic Function (Generic): Computes a Bessel function of the first kind, order 1.*

**Syntax**

\[
\text{result} = \text{BESSEL}_J1 (x)
\]

- \( x \) (Input) Must be of type real.

**Results**

The result type and kind is the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order 1 of \( x \).

**Example**

BESSEL_J1 (1.0) has the approximate value 0.440.

---

**BESSEL_JN**

*Elemental and Transformational Intrinsic Functions (Generic): Compute Bessel functions of the first kind.*

**Syntax**

- Elemental function: \( \text{result} = \text{BESSEL}_JN (n, x) \)
- Transformational function: \( \text{result} = \text{BESSEL}_JN (n1, n2, x) \)
$n$, $n_1$, $n_2$  
(Input) Must be of type integer and nonnegative.

$x$  
(Input) Must be of type real.

**Results**

The result type and kind is the same as $x$.

The result of `BESSEL_JN (n, x)` is scalar. The result value of `BESSEL_JN (n, x)` is a processor-dependent approximation to the Bessel function of the first kind and order $n$ of $x$.

The result of `BESSEL_JN (n1, n2, x)` is a rank-one array with extent MAX ($n_2 - n_1 + 1$, 0). Element $i$ of the result value of `BESSEL_JN (n1, n2, x)` is a processor-dependent approximation to the Bessel function of the first kind and order $n_1 + i - 1$ of $x$.

**Example**

`BESSEL_JN (2, 1.0)` has the approximate value 0.115.

Consider the following program `Bessel.f90`:

```fortran
real :: z (6) = [0:5]/5.          ! 0.0 through 1.0 by 0.2
print *, z
print *, bessel_jn (2, 1.0)      ! scalar argument, answer about 0.115
print *, bessel_jn (1, z)          ! elemental
print *, bessel_jn (1, 4, 1.0)  ! orders 1 thru 4 on a scalar
end
```

Compile `bessel.f90` and execute the result:

```
> ifort Bessel.f90 -o Bessel
> bessel
```

The above commands produce the following result:

```
0.0000000E+00  0.2000000      0.4000000      0.6000000      0.8000000      1.000000
0.1149035
0.0000000E+00  9.9500835E-02  0.1960266      0.2867010      0.3688421      0.4400506
0.4400506      0.1149035      1.9563355E-02  2.4766389E-03
```

**BESSEL_Y0**

*Elemental Intrinsic Function (Generic): Computes a Bessel function of the second kind, order 0.*

**Syntax**

```fortran
result = BESSEL_Y0 (x)
```

$x$  
(Input) Must be of type real with a value greater than zero.

**Results**

The result type and kind is the same as $x$.

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order zero of $x$.

**Example**

`BESSEL_Y0 (1.0)` has the approximate value 0.088.
BESSEL_Y1

Elemental Intrinsic Function (Generic): Computes a Bessel function of the second kind, order 1.

Syntax

\[
\text{result} = \text{BESSEL_Y1} \ (x)
\]

\(x\) (Input) Must be of type real with a value greater than zero.

Results

The result type and kind is the same as \(x\).
The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order 1 of \(x\).

Example

BESSEL_Y1 (1.0) has the approximate value -0.781.

BESSEL_YN

Elemental and Transformational Intrinsic Functions (Generic): Compute Bessel functions of the second kind.

Syntax

Elemental function: \[
\text{result} = \text{BESSEL_YN} \ (n, x)
\]

Transformational function: \[
\text{result} = \text{BESSEL_YN} \ (n1, n2, x)
\]

\(n, n1, n2\) (Input) Must be of type integer and nonnegative.

\(x\) (Input) Must be of type real with a value greater than zero.

Results

The result type and kind is the same as \(x\).
The result of BESSEL_YN \((n, x)\) is scalar. The result value of BESSEL_YN \((n, x)\) is a processor-dependent approximation to the Bessel function of the second kind and order \(n\) of \(x\).
The result of BESSEL_YN \((n1, n2, x)\) is a rank-one array with extent \(\text{MAX}(n2 - n1 + 1, 0)\). Element \(i\) of the result value of BESSEL_YN \((n1, n2, x)\) is a processor-dependent approximation to the Bessel function of the second kind and order \(n1 + i - 1\) of \(x\).

Example

BESSEL_YN (2, 1.0) has the approximate value -1.651.

BGE

Elemental Intrinsic Function (Generic): Performs a bitwise greater than or equal to on its arguments.

Syntax

\[
\text{result} = \text{BGE} \ (i, j)
\]
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of $i$ and $j$ do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by $i$ is greater than or equal to the sequence of bits represented by $j$, according to the method of bit sequence comparison in *Bit Sequence Comparisons*; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in *Binary, Octal, Hexadecimal, and Hollerith Constants*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**Example**

If BIT_SIZE ($J$) has the value 8, BGE (Z'FF', $J$) has the value true for any value of $J$. BGE (0, -1) has the value false.

**See Also**

BIT_SIZE

**BGT**

**Elemental Intrinsic Function (Generic):** Performs a bitwise greater than on its arguments.

**Syntax**

```fortran
result = BGT (i, j)
```

$i$  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

$j$  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of $i$ and $j$ do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by $i$ is greater than the sequence of bits represented by $j$, according to the method of bit sequence comparison in *Bit Sequence Comparisons*; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in *Binary, Octal, Hexadecimal, and Hollerith Constants*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**Example**

BGT (Z'FF', Z'FC') has the value true. BGT (0, -2) has the value false.
**BIC, BIS**

*Portability Subroutines:* Perform a bit-level set and clear for integers.

**Module**

USE IFPORT

**Syntax**

CALL BIC (bitnum, target)
CALL BIS (bitnum, target)

**Example**

Consider the following:

```fortran
USE IFPORT
integer(4) bitnum, target_i4
integer(8) target_i8

target_i4 = Z'AAAA'
bitnum = 1
call BIC(bitnum, target_i4)
target_i8 = Z'FFFFFFFF00000000'
bitnum = 40
call BIC(bitnum, target_i8)
bitnum = 0
call BIS(bitnum, target_i4)
bitnum = 1
call BIS(bitnum, target_i8)
print '(" integer*4 result ",Z)', target_i4
print '(" integer*8 result ",Z)', target_i8
end
```

**See Also**

BIT

**BIND**

*Statement and Attribute:* Specifies that an object is interoperable with C and has external linkage.

**Syntax**

The BIND attribute can be specified in a type declaration statement or a BIND statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
  type, [att-ls, ] BIND (C [, NAME=ext-name]) [ , att-ls ] :: object
```

**Statement:**

```fortran
  BIND (C [, NAME=ext-name]) [ :: ] object
```
**Type**

Is a data type specifier.

**att-ls**

Is an optional list of attribute specifiers.

**ext-name**

Is a character scalar initialization expression that can be used to construct the external name.

**object**

Is the name of a variable or common block.

**Description**

If a common block is specified in a BIND statement, it must be specified with the same binding label in each scoping unit in which it is declared.

For variables and common blocks, BIND also implies the SAVE attribute, which may be explicitly confirmed with SAVE.

A variable given the BIND attribute (or declared in a BIND statement) must appear in the specification part of a module. You cannot specify BIND for a subroutine local variable or a variable in a main program.

The BIND attribute is similar to directive !DIR$ ATTRIBUTES C as follows:

- The compiler applies the same naming rules, that is, names are lowercase (unless NAME= specifies otherwise).
- The compiler applies the appropriate platform decoration, such as a leading underscore.

However, procedure argument passing differs. When BIND is specified, procedure arguments are passed by reference unless the VALUE attribute is also specified.

The BIND attribute can optionally be used in a PROCEDURE, SUBROUTINE, or FUNCTION declaration. It must be used in an ENUM declaration.

**Example**

The following example shows the BIND attribute used in a type declaration statement, a statement, and a SUBROUTINE statement.

```fortran
INTEGER, BIND(C) :: SOMEVAR
BIND(C,NAME='SharedCommon') :: /SHAREDCOMMON/
SUBROUTINE FOOBAR, BIND(C, NAME='FooBar')
...
END SUBROUTINE
```

**BIT**

*Portability Function:* Performs a bit-level test for integers.
Module
USE IFPORT

Syntax
result = BIT (bitnum, source)

bitnum (Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).

source (Input) INTEGER(4) or INTEGER(8). Variable being tested.

Results
The result type is logical. It is .TRUE. if bit bitnum of source is 1; otherwise, .FALSE..

See Also
BIC, BIS

BIT_SIZE
Inquiry Intrinsic Function (Generic): Returns the number of bits in an integer type.

Syntax
result = BIT_SIZE (i)

i (Input) Must be of type integer or of type logical (which is treated as an integer).

Results
The result is a scalar integer with the same kind parameter as i. The result value is the number of bits (s) defined by the bit model for integers with the kind parameter of the argument. For information on the bit model, see Model for Bit Data.

Example
BIT_SIZE (1_2) has the value 16 because the KIND=2 integer type contains 16 bits.

See Also
BTEST IBCLR IBITS IBSET

BLE
Elemental Intrinsic Function (Generic): Performs a bitwise less than or equal to on its arguments.

Syntax
result = BLE (i,j)

i (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j  (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by i is less than or equal to the sequence of bits represented by j, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

BLE (0, J) has the value true for any value of J. BLE (-2, 0) has the value false.

**BLOCK**

* Marks the beginning of a BLOCK construct. The BLOCK construct executes a block of statements or constructs that can contain declarations.

**Syntax**

```
[name:] BLOCK
  [specification-part]
  block
END BLOCK [name]
```

* name  (Optional) Is the name of the BLOCK construct.

* specification-part  (Optional) Is one or more specification statements, except for the following:
  * COMMON
  * FUNCTION (outside of an INTERFACE block)
  * EQUIVALENCE
  * IMPLICIT
  * INTENT (or its equivalent attribute)
  * MODULE
  * NAMELIST
  * OPTIONAL (or its equivalent attribute)
  * SUBROUTINE (outside of an INTERFACE block)
  * VALUE (or its equivalent attribute)
  * Statement functions

* block  Is a sequence of zero or more statements or constructs, except for the following:
  * CONTAINS (outside of a TYPE definition)
  * ENTRY
  * IMPORT (outside of a TYPE definition)
  * Statement functions
Description

A BLOCK construct is itself a scoping unit. Entities declared in a BLOCK construct are local to the BLOCK construct and are accessible only in that construct and in any contained constructs. A local entity in a block construct hides any entity with the same name in its host scope. No transfer of control into a block from outside the block is allowed, except for the return from a procedure call. Transfers within a block or out of the block are allowed.

If a construct name is specified at the beginning of a BLOCK statement, the same name must appear in the corresponding END BLOCK statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a BLOCK statement, you cannot specify one following the END BLOCK statement.

You can only branch to an END BLOCK statement from within its BLOCK construct.

A BLOCK construct cannot appear inside a structured block of an OpenMP* directive.

The SAVE attribute specifies that a local variable of a BLOCK construct retains its association status, allocation status, definition status, and value after termination of the construct unless it is a pointer and its target becomes undefined. If the BLOCK construct contains a SAVE statement, the SAVE statement cannot specify the name of a common block. A SAVE statement outside a BLOCK construct does not affect variables local to the BLOCK construct, because a SAVE statement affects variables in its scoping unit which excludes nested scoping units in it.

The statements specified within the specification-part are evaluated in a processor-dependent order, followed by execution of block. When execution exits block, all non-SAVEd automatic and allocatable local variables are deallocated.

Example

The following shows a BLOCK construct:

```
block
  integer :: i
  real :: a(n)
  do i = 1,n
    a(i) = i
  end do
  ...
end block
```

When control exits the bottom of the BLOCK, local variables i and a revert to their meaning outside the block.

The following example shows two nested BLOCK constructs where the inner BLOCK construct has the construct name INNER and the outer one does not have a name:

```
BLOCK
  ...
INNER: BLOCK
  ...
END BLOCK INNER
  ...
END BLOCK
```

In the following example, the appearance and the reference of the FORMAT statement are legal:

```
PROGRAM MAIN
  WRITE(6, FMT=10)
  ...
  BLOCK
    10 FORMAT("Hello")
```

Implicit typing is not affected by BLOCK constructs. In the following example, even if NSQP only appears in the two BLOCK constructs, the scope of NSQP is the whole subroutine S:

```
SUBROUTINE S(N)
  ...
  IF (N>0) THEN
    BLOCK
      NSQP = CEILING(SQRT(DBLE(N)))
    END BLOCK
  END IF
  ...
  IF (N>0) THEN
    BLOCK
      PRINT *,NSQP
    END BLOCK
  END IF
END SUBROUTINE S
```

**BLOCK DATA**

**Statement:** Identifies a block-data program unit, which provides initial values for variables in named common blocks.

**Syntax**

```
BLOCK DATA [name]
  [specification-part]
END [BLOCK DATA[name]]
```

- `name` is the name of the block data program unit.
- `specification-part` is one or more of the following statements:
  - COMMON
  - DATA
  - Derived-type definition
  - DIMENSION
  - EQUIVALENCE
  - IMPLICIT
  - INTRINSIC
  - PARAMETER
  - POINTER
  - RECORD
  - SAVE
  - STATIC
  - TARGET
  - USE

<table>
<thead>
<tr>
<th>COMMON</th>
<th>INTRINSIC</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>PARAMETER</td>
<td>TARGET</td>
</tr>
<tr>
<td>Derived-type definition</td>
<td>POINTER</td>
<td>Type declaration ²</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>RECORD¹</td>
<td>USE ³</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Record structure declaration¹</td>
<td></td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>SAVE</td>
<td></td>
</tr>
</tbody>
</table>

¹ For more information, see RECORD statement and record structure declarations.

² Can only contain attributes: DIMENSION, INTRINSIC, PARAMETER, POINTER, SAVE, STATIC, or TARGET.

³ Allows access to only named constants.
Description

A block data program unit need not be named, but there can only be one unnamed block data program unit in an executable program.

If a name follows the END statement, it must be the same as the name specified in the BLOCK DATA statement.

An interface block must not appear in a block data program unit and a block data program unit must not contain any executable statements.

If a DATA statement initializes any variable in a named common block, the block data program unit must have a complete set of specification statements establishing the common block. However, all of the variables in the block do not have to be initialized.

A block data program unit can establish and define initial values for more than one common block, but a given common block can appear in only one block data program unit in an executable program.

The name of a block data program unit can appear in the EXTERNAL statement of a different program unit to force a search of object libraries for the block data program unit at link time.

Example

The following shows a block data program unit:

```
BLOCK DATA BLKDAT
   INTEGER S,X
   LOGICAL T,W
   DOUBLE PRECISION U
   DIMENSION R(3)
   COMMON /AREA1/R,S,U,T /AREA2/W,X,Y
   DATA R/1.0,2*2.0/, T/.FALSE./, U/0.214537D-7/, W/.TRUE./, Y/3.5/
END
```

The following shows another example:

```
C     Main Program
CHARACTER(LEN=10) family
INTEGER a, b, c, d, e
REAL X(10), Y(4)
COMMON/Lakes/a,b,c,d,e,family/Blk2/x,y
...
C     The following block-data subprogram initializes
C     the named common block /Lakes/: 
C
BLOCK DATA InitLakes
   COMMON /Lakes/ erie, huron, michigan, ontario, +
       superior, fname
   DATA erie, huron, michigan, ontario, superior /1, 2, 3, 4, 5/
   CHARACTER(LEN=10) fname/'GreatLakes'/
   INTEGER erie, huron, michigan, ontario, superior
END
```

EXTERNAL
Program Units and Procedures Overview
**BLOCK_LOOP and NOBLOCK_LOOP**

**General Compiler Directives:** Enables or disables loop blocking for the immediately following nested DO loops. BLOCK_LOOP enables loop blocking for the nested loops. NOBLOCK_LOOP disables loop blocking for the nested loops.

**Syntax**

```
!DIR$ BLOCK_LOOP [clause [,] clause]...
```

```
!DIR$ NOBLOCK_LOOP
```

clause  

<table>
<thead>
<tr>
<th>Is one or more of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• FACTOR(expr)</td>
</tr>
<tr>
<td>expr</td>
</tr>
<tr>
<td>Is a positive scalar constant integer expression representing the blocking factor for the specified loops.</td>
</tr>
</tbody>
</table>

This clause is optional. If the FACTOR clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the directive.

At most only one FACTOR clause can appear in a BLOCK_LOOP directive.

<table>
<thead>
<tr>
<th>• LEVEL(level [, level]...)</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
</tr>
<tr>
<td>Is specified in the form:</td>
</tr>
<tr>
<td>const1 or const1:const2</td>
</tr>
<tr>
<td>where const1 is a positive integer constant $m \leq 8$ representing the loop at level $m$, where the immediate following loop is level 1.</td>
</tr>
<tr>
<td>The const2 is a positive integer constant $n \leq 8$ representing the loop at level $n$, where $n &gt; m$: const1:const2 represents the nested loops from level const1 through const2.</td>
</tr>
</tbody>
</table>

This clause is optional. If the LEVEL clause is not present, the specified blocking factor is applied to all levels of the immediately following nested loops.

At most only one LEVEL clause can appear in a BLOCK_LOOP directive.

The clauses can be specified in any order. If you do not specify any clause, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.

The BLOCK_LOOP directive lets you exert greater control over optimizations on a specific DO loop inside a nested DO loop.

Using a technique called loop blocking, the BLOCK_LOOP directive separates large iteration counted DO loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no LEVEL and FACTOR clause, the blocking factor will be determined based on the processor's type and memory access patterns and it will apply to all the levels in the nested loops following this directive.
You can use the NOBLOCK_LOOP directive to tune the performance by disabling loop blocking for nested loops.

**NOTE**
The loop-carried dependence is ignored during the processing of BLOCK_LOOP directives.

### Example

```
!dir$ block_loop factor(256) level(1)       ! applies blocking factor 256 to
!dir$ block_loop factor(512) level(2)       ! the top level loop in the following
 !dir$ block_loop factor(256) level(2)      ! nested loop and blocking factor 512 to
 !dir$ block_loop factor(512) level(1)       ! the 2nd level (1st nested) loop

!dir$ block_loop factor(256) level(2)       ! levels can be specified in any order
!dir$ block_loop factor(512) level(1)       ! adjacent loops can be specified as a range

!dir$ block_loop factor (256)     ! the blocking factor applies to all levels of loop nest
!dir$ block_loop                  ! the blocking factor will be determined based on
 !dir$ noblock_loop                ! None of the levels in the nested loop following this
 !None of the levels in the nested loop following this
 ! directive will have a blocking factor applied
```

**Consider the following:**

```
!dir$ block_loop factor(256) level(1:2)
do  j = 1,n
   f = 0
   do  i =1,n
      f = f + a (i) * b (i)
   enddo
   c(j) = c(j) + f
enddo

The above code produces the following result after loop blocking:
do jj=1,n/256+1
   do ii = 1,n/256+1
      do j = (jj-1)*256+1, min(jj*256, n)
         f = 0
         do i = (ii-1)*256+1, min(ii*256,n)
            f = f + a(i) * b(i)
         enddo
         c(j) = c(j) + f
      enddo
   enddo
enddo
```

**BLT**

*Elemental Intrinsic Function (Generic): Performs a bitwise less than on its arguments.*

**Syntax**

\[ \text{result} = \text{BLT} \(i, j\) } \]

\(i\)  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

\(j\)  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of \(i\) and \(j\) do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by \(i\) is less than the sequence of bits represented by \(j\), according to the method of bit sequence comparison in *Bit Sequence Comparisons*; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in *Binary, Octal, Hexadecimal, and Hollerith Constants*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**Example**

BLT \((0, 2)\) has the value true. BLT \((Z'FF', Z'FC')\) has the value false.

**BSEARCHQQ**

*Portability Function: Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.*

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{BSEARCHQQ} \(\text{adrkey}, \text{adrarray}, \text{length}, \text{size}\) } \]

\(\text{adrkey}\)  
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the variable containing the element to be found (returned by LOC).

\(\text{adrarray}\)  
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

\(\text{length}\)  
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in the array.

\(\text{size}\)  
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in *IFPORT.F90*, specify type and kind for numeric arrays:
<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**Results**

The result type is INTEGER(4). It is an array index of the matched entry, or 0 if the entry is not found.

The array must be sorted in ascending order before being searched.

---

**CAUTION**

The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the `length` and `size` arguments are correct, and that `size` is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

---

**Example**

```fortran
USE IFPORT
INTEGER(4) array(10), length
INTEGER(4) result, target
length = SIZE(array)
...
result = BSEARCHQQ(LOC(target),LOC(array),length,SRT$INTEGER4)
```

**See Also**

SORTQQ
LOC

**BTEST**

*Elemental Intrinsic Function (Generic): Tests a bit of an integer argument.*

**Syntax**

```fortran
result = BTEST (i,pos)
```

*i*  
(Input) Must be of type integer or of type logical (which is treated as an integer).
pos

(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(i).

The rightmost (least significant) bit of i is in position 0.

Results

The result type is default logical.

The result is true if bit pos of i has the value 1. The result is false if pos has the value zero. For more information, see Bit Functions.

For information on the model for the interpretation of an integer value as a sequence of bits, see Model for Bit Data.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBTEST</td>
<td>INTEGER(1)</td>
<td>LOGICAL(1)</td>
</tr>
<tr>
<td>BITEST(^1)</td>
<td>INTEGER(2)</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>BTEST (^2)</td>
<td>INTEGER(4)</td>
<td>LOGICAL(4)</td>
</tr>
<tr>
<td>BKTEST</td>
<td>INTEGER(8)</td>
<td>LOGICAL(8)</td>
</tr>
</tbody>
</table>

\(^1\) Or HTEST

\(^2\) Or BJTEST

Example

BTEST (9, 3) has the value true.

If A has the value

\[
\begin{bmatrix}
  1 & 2 \\
  3 & 4 \\
\end{bmatrix}
\]

the value of BTEST (A, 2) is

\[
\begin{bmatrix}
  \text{false} & \text{false} \\
  \text{false} & \text{true} \\
\end{bmatrix}
\]

and the value of BTEST (2, A) is

\[
\begin{bmatrix}
  \text{true} & \text{false} \\
  \text{false} & \text{false} \\
\end{bmatrix}
\]

The following shows more examples:

<table>
<thead>
<tr>
<th>Function reference</th>
<th>Value of (i)</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTEST ((i,2))</td>
<td>00011100 01111000</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>BTEST ((i,3))</td>
<td>00011100 01111000</td>
<td>.TRUE.</td>
</tr>
</tbody>
</table>

The following shows another example:

INTEGER(1) i(2)
LOGICAL result(2)
i(1) = 2#10101010
i(2) = 2#01010101
result = BTEST(i, (/3,2/)) ! returns (.TRUE.,.TRUE.)
write(*,*) result
BYTE

**Statement:** Specifies the BYTE data type, which is equivalent to INTEGER(1).

**Example**

```fortran
BYTE count, matrix(4, 4) / 4*1, 4*2, 4*4, 4*8 /
BYTE num  / 10 /
```

C to D

---

C_ASSOCIATED

**Intrinsic Module Inquiry function (Generic):** Indicates the association status of one argument, or whether two arguments are associated with the same entity.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```fortran
result = C_ASSOCIATED(c_ptr_1[, c_ptr_2])
```

- **c_ptr_1** (Input) Is a scalar of derived type C_PTR or C_FUNPTR.
- **c_ptr_2** (Optional; input) Is a scalar of the same type as **c_ptr_1**.

**Results**

The result is a scalar of type default logical. The result value is one of the following:

- If only **c_ptr_1** is specified, the result is false if **c_ptr_1** is a C null pointer; otherwise, the result is true.
- If **c_ptr_2** is specified, the result is false if **c_ptr_1** is a C null pointer. The result is true if **c_ptr_1** is equal to **c_ptr_2**; otherwise, the result is false.

**See Also**

Intrinsic Modules
ISO_C_BINDING Module
**C_F_POINTER**

**Intrinsic Module Subroutine:** Associates a pointer with the target of a C pointer and specifies its shape.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

CALL C_F_POINTER(cptr, fptr [,shape])

- **cptr** (Input) Is a scalar of derived type C_PTR. Its value is the C address of an interoperable data entity, or the result of a reference to function C_LOC with a noninteroperable argument. If the value of **cptr** is the C address of a Fortran variable, it must have the TARGET attribute.

- **fptr** (Output) Is a pointer. If it is an array, **shape** must be specified.

- **shape** (Optional, input) Must be of type integer and rank one. Its size equals the rank of **fptr**.

If the value of **cptr** is the C address of an interoperable data entity, **fptr** must be a pointer with type and type parameters interoperable with the type of the entity. In this case, **fptr** becomes pointer-associated with the target of **cptr**.

If **fptr** is an array, it has the shape specified by **shape** and each lower bound is 1.

If the value of **cptr** is the result of a reference to C_LOC with a noninteroperable argument **x**, the following rules apply:

- C_LOC argument **x** (or its target) must not have been deallocated or have become undefined due to the execution of a RETURN or END statement since the reference to C_LOC.
- **fptr** is a scalar pointer with the same type and type parameters as **x**. **fptr** becomes pointer-associated with **x**, or it becomes pointer-associated with its target if **x** is a pointer.

**See Also**

Intrinsic Modules
ISO_C_BINDING Module
C_LOC

**C_F_PROCPOINTER**

**Intrinsic Module Subroutine:** Associates a Fortran procedure pointer with the target of a C function pointer.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

CALL C_F_POINTER(cptr, fptr)

- **cptr** (Input) Is a scalar of derived type C_FUNPTR. Its value is the C address of a procedure.

- **fptr** (Output) Is a Fortran procedure pointer. It becomes pointer-associated with the target of **cptr**.
Example

The following Fortran subroutine can be called from a C program that passes a pointer to a C function to be called:

```fortran
SUBROUTINE CallIt (cp) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
TYPE(C_FUNPTR), INTENT(IN) :: cp
ABSTRACT INTERFACE
  SUBROUTINE Add_Int (i) BIND(C)
  IMPORT
  INTEGER(C_INT), INTENT(INOUT) :: i
  END SUBROUTINE Add_Int
END INTERFACE
PROCEDURE(Add_Int), POINTER :: fp
INTEGER(C_INT) :: j
CALL C_F_PROCPOINTER (cp, fp)
j = 1
CALL fp(j)
...
```

ISO_C_BINDING Module
Procedure Pointers
PROCEDURE

**C_FUNLOC**

*Intrinsic Module Inquiry function (Generic):*

*Returns the C address of a function pointer.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```fortran
result = C_FUNLOC(x)
```

*x*  
(Input) Is a procedure or a Fortran pointer of type INTEGER associated with a procedure. If *x* is a procedure pointer, it must be associated. *x* cannot be a coindexed object.

**Results**

The result is a scalar of derived type C_FUNPTR. The result value represents the C address of the argument.

See Also

Intrinsic Modules
ISO_C_BINDING Module

**C_LOC**

*Intrinsic Module Inquiry function (Generic):*

*Returns the C address of an argument.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING
Syntax

```fortran
result = C_LOC(x)
```

- **x** (Input) Is one of the following:
  - An interoperable variable that has the TARGET attribute; if the variable is an array, it does not have to be interoperable
  - An interoperable, allocatable, variable that is allocated, has the TARGET attribute, and is not an array of size zero; if the variable is an array, it does not have to be interoperable
  - An associated, interoperable scalar pointer
  - A scalar that has no length type parameters and is one of the following:
    - A nonallocatable, nonpointer variable that has the TARGET attribute
    - An allocatable variable that is allocated and has the TARGET attribute
    - An associated pointer

Results

The result is a scalar of derived type C_PTR. The result value represents the C address of the argument.

The result is a value that can be used as an actual CPTR argument in a call to procedure C_F_POINTER where `fptr` has attributes that allow the pointer assignment `fptr=>x`. Such a call to C_F_POINTER has the effect of the pointer assignment `fptr=>x`.

If `x` is a scalar, the result is determined as if C_PTR were a derived type containing a scalar pointer component `PX` of the type and type parameters of `x` and the pointer assignment CPTR%PX=>x were executed.

If `x` is an array, the result is determined as if C_PTR were a derived type containing a scalar pointer component `PX` of the type and type parameters of `x` and the pointer assignment CPTR%PX to the first element of `x` were executed.

C_F_POINTER

C_SIZEOF

**Intrinsic Module Inquiry function (Generic):**

`Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument nor used in a constant expression.`

Module

```fortran
USE, INTRINSIC :: ISO_C_BINDING
```

Syntax

```fortran
result = C_SIZEOF(x)
```

- **x** (Input) Is an interoperable data entity of any type. It must not be an assumed-size array.

Results

The result is a scalar of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. If `x` is scalar, the result value is the size of `x` in bytes. If `x` is an array, the result value is the size of a single element of `x` multiplied by the number of elements in `x`. 
Example
Consider the following:

```fortran
INTEGER(4) :: S
INTEGER(4) :: T(3)
C_SIZEOF(S) ! has the value 4
C_SIZEOF(T) ! has the value 12
```

SIZEOF

CACHESIZE

**Inquiry Intrinsic Function (Generic): Returns the size of a level of the memory cache.**

**Syntax**

```fortran
result = CACHESIZE (n)
```

*n* (Input) Must be scalar and of type integer.

**Results**

The result type and kind is the same as *n*. The result value is the number of kilobytes in the level *n* memory cache.

*n* = 1 specifies the first level cache; *n* = 2 specifies the second level cache; etc. If cache level *n* does not exist, the result value is 0.

Example

CACHESIZE(1) returns 16 for a processor with a 16KB first level memory cache.

CALL

**Statement:** Transfers control to a subroutine subprogram.

**Syntax**

```fortran
CALL sub([ (a-arg[,a-arg]... ] )]
```

$sub$ Is the name of the subroutine subprogram or other external procedure, or a dummy argument associated with a subroutine subprogram or other external procedure.

*a-arg* Is an actual argument optionally preceded by [keyword=], where keyword is the name of a dummy argument in the explicit interface for the subroutine. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, the name of a procedure, or an alternate return specifier. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)
An alternate return specifier is an asterisk (*), or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement. (An alternate return is an obsolescent feature in Standard Fortran.)

**Description**

When the CALL statement is executed, any expressions in the actual argument list are evaluated, then control is passed to the first executable statement or construct in the subroutine. When the subroutine finishes executing, control returns to the next executable statement following the CALL statement, or to a statement identified by an alternate return label (if any).

If an argument list appears, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures Overview).

The procedure invoked by the CALL statement must be a subroutine subprogram and not a function. Calling a function as if it were a subroutine can cause unpredictable results.

**Example**

The following example shows valid CALL statements:

```fortran
CALL CURVE(BASE,3.14159+X,Y,LIMIT,R(LT+2))
CALL PNTOUT(A,N,'ABCD')
CALL EXIT
CALL MULT(A,B,*10,*20,C) ! The asterisks and ampersands denote alternate returns
CALL SUBA(X,&30,&50,Y)
```

The following example shows a subroutine with argument keywords:

```fortran
PROGRAM KEYWORD_EXAMPLE

INTERFACE
  SUBROUTINE TEST_C(I, L, J, KYWD2, D, F, KYWD1)
  INTEGER I, L(20), J, KYWD1
  REAL, OPTIONAL :: D, F
  COMPLEX KYWD2
  ...
  END SUBROUTINE TEST_C
END INTERFACE

INTEGER I, J, K
INTEGER L(20)
COMPLEX Z1
CALL TEST_C(I, L, J, KYWD1 = K, KYWD2 = Z1)
...
```

The first three actual arguments are associated with their corresponding dummy arguments by position. The argument keywords are associated by keyword name, so they can appear in any order.

Note that the interface to subroutine TEST has two optional arguments that have been omitted in the CALL statement.

The following shows another example of a subroutine call with argument keywords:

```fortran
CALL TEST(X, Y, N, EQUALITIES = Q, XSTART = X0)
```
The first three arguments are associated by position.

The following shows another example:

```fortran
!Variations on a subroutine call
REAL S,T,X
INTRINSIC NINT
S=1.5
T=2.5
X=14.7
!This calls SUB1 using keywords. NINT is an intrinsic function.
CALL SUB1(B=X,C=S*T,FUNC=NINT,A=4.0)
!Here is the same call using an implicit reference
CALL SUB1(4.0,X,S*T,NINT)
CONTAINS
  SUBROUTINE sub1(a,b,c,func)
  INTEGER func
  REAL a,b,c
  PRINT *, a,b,c, func(b)
  END SUBROUTINE
END
```

Program Units and Procedures Overview

**CANCEL**

*OpenMP Fortran Compiler Directive*: Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

**Syntax**

```fortran
!$OMP CANCEL construct-clause [[,] if-clause]
```

- **construct-clause**: Is one of the following:
  - DO
  - PARALLEL
  - SECTIONS
  - TASKGROUP

- **if-clause**: (Optional) IF (expression)

The binding thread set of a CANCEL construct is the current team. The cancel region binds to the innermost enclosing construct of the type corresponding to the `construct-clause` specified in the directive specifying the innermost DO, PARALLEL, SECTIONS, or TASKGROUP construct.

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.
If `construct-clause` is TASKGROUP, the CANCEL construct must be closely nested inside a TASK construct. Otherwise, the CANCEL construct must be closely nested inside an OpenMP construct that matches the type specified in `construct-clause`.

The CANCEL construct requests cancellation of the innermost enclosing region of the type specified. The request is checked at a cancellation point. When a cancellation is observed, execution jumps to the end of the canceled region.

Cancellation points are implied at certain locations, as follows:

- Implicit barriers
- BARRIER regions
- CANCEL regions
- CANCELLATION POINT regions

When cancellation of tasks occurs with a CANCEL TASKGROUP construct, the encountering task jumps to the end of its task region and is considered complete. Any task that belongs to the innermost enclosing taskgroup and has already begun execution, must run to completion or run until a cancellation point is reached. Any task that belongs to the innermost enclosing taskgroup and has not begun execution may be discarded and considered completed.

When cancellation occurs for a PARALLEL region, each thread of the binding thread set resumes execution at the end of the canceled region and any tasks that have been created by a TASK construct and their descendants are canceled according to the above taskgroup cancellation semantics.

When cancellation occurs for a DO or SECTIONS region, each thread of the binding thread set resumes execution at the end of the canceled region but no task cancellation occurs.

A DO construct that is being canceled must not have a NOWAIT or an ORDERED clause. A SECTIONS construct that is being canceled must not have a NOWAIT clause.

The behavior for concurrent cancellation of a region and a region nested within it is unspecified.

**NOTE**

You must release locks and similar data structures that can cause a deadlock when a CANCEL construct is encountered; blocked threads cannot be canceled.

If the canceled construct contains a REDUCTION or LASTPRIVATE clause, the final value of the REDUCTION or LASTPRIVATE variable is undefined.

All private objects or subobjects with the ALLOCATABLE attribute that are allocated inside the canceled construct are deallocated.

CANCELLATION POINT
Parallel Processing Model for information about Binding Sets

CANCELLATION POINT

OpenMP* Fortran Compiler Directive: Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.

**Syntax**

```fortran
!$OMP CANCELLATION POINT construct-clause
```
construct-clause is one of the following:

- **DO**
- **PARALLEL**
- **SECTIONS**
- **TASKGROUP**

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

A CANCELLATION POINT region binds to the current task region.

If `construct-clause` is TASKGROUP, the CANCELLATION POINT construct must be closely nested inside a TASK construct. Otherwise, the CANCELLATION POINT construct must be closely nested inside an OpenMP construct that matches the type specified by the `construct-clause`.

When an implicit or explicit task reaches a user-defined cancellation point, the task immediately checks for cancellation of the region specified in the clause and performs cancellation of this region if cancellation is observed. If the clause specified is TASKGROUP then the current task region is canceled.

An OpenMP program with orphaned CANCELLATION POINT constructs is non-conforming.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
CANCEL

**CASE**

**Statement:** Marks the beginning of a CASE construct. A CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.

**Syntax**

```
[name:] SELECT CASE (expr)
[CASE (case-value [, case-value] ...) [name]]
   block]...
[CASE DEFAULT [name]]
   block]
END SELECT [name]
```

- `name` is the name of the CASE construct.
- `expr` is a scalar expression of type integer, logical, or character (enclosed in parentheses). Evaluation of this expression results in a value called the case index.
- `case-value` is one or more scalar integer, logical, or character initialization expressions enclosed in parentheses. Each `case-value` must be of the same type and kind parameter as `expr`. If the type is character, `case-value` and `expr` can be of different lengths, but their kind parameter must be the same.
Integer and character expressions can be expressed as a range of case values, taking one of the following forms:

\[
\text{low:high} \\
\text{low:} \\
\text{:high}
\]

Case values must not overlap.

**block**

Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified in a SELECT CASE statement, the same name must appear in the corresponding END SELECT statement. The same construct name can optionally appear in any CASE statement in the construct. The same construct name must not be used for different named constructs in the same scoping unit.

The case expression (\( expr \)) is evaluated first. The resulting case index is compared to the case values to find a matching value (there can only be one). When a match occurs, the block following the matching case value is executed and the construct terminates.

The following rules determine whether a match occurs:

- When the case value is a single value (no colon appears), a match occurs as follows:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>A Match Occurs If:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logical</td>
<td>case-index \ .EQV. case-value</td>
</tr>
<tr>
<td>Integer or Character</td>
<td>case-index = = case-value</td>
</tr>
</tbody>
</table>

- When the case value is a range of values (a colon appears), a match depends on the range specified, as follows:

<table>
<thead>
<tr>
<th>Range</th>
<th>A Match Occurs If:</th>
</tr>
</thead>
<tbody>
<tr>
<td>low : high</td>
<td>case-index \ &gt;= low</td>
</tr>
<tr>
<td>: high</td>
<td>case-index \ &lt;= high</td>
</tr>
<tr>
<td>low : : high</td>
<td>low \ &lt;= case-index \ &lt;= high</td>
</tr>
</tbody>
</table>

The following are all valid case values:

\[
\begin{align*}
\text{CASE (1, 4, 7, 11:14, 22)} & \quad \text{! Individual values as specified:} \quad 1, 4, 7, 11, 12, 13, 14, 22 \\
\text{CASE (-1)} & \quad \text{! All values less than zero} \\
\text{CASE (0)} & \quad \text{! Only zero} \\
\text{CASE (1:) & \quad \text{! All values above zero}
\end{align*}
\]

If no match occurs but a CASE DEFAULT statement is present, the block following that statement is executed and the construct terminates.

If no match occurs and no CASE DEFAULT statement is present, no block is executed, the construct terminates, and control passes to the next executable statement or construct following the END SELECT statement.
The following figure shows the flow of control in a CASE construct:

**Flow of Control in CASE Constructs**

You cannot use branching statements to transfer control to a CASE statement. However, branching to a SELECT CASE statement is allowed. Branching to the END SELECT statement is allowed only from within the CASE construct.

**Example**

The following are examples of CASE constructs:

```fortran
INTEGER FUNCTION STATUS_CODE (I)
   INTEGER I
   CHECK_STATUS: SELECT CASE (I)
   CASE (:-1)
      STATUS_CODE = -1
   CASE (0)
      STATUS_CODE = 0
   CASE (1:)
      STATUS_CODE = 1
   END SELECT CHECK_STATUS
END FUNCTION STATUS_CODE

SELECT CASE (J)
   CASE (1, 3:7, 9) ! Values: 1, 3, 4, 5, 6, 7, 9
      CALL SUB_A
   CASE DEFAULT
      CALL SUB_B
   END SELECT

The following three examples are equivalent:

1. SELECT CASE (ITEST .EQ. 1)
   CASE (.TRUE.)
      CALL SUB1()
   CASE (.FALSE.)
      CALL SUB2()
   END SELECT

2. SELECT CASE (ITEST)
   CASE DEFAULT
      CALL SUB2()
   CASE (1)
      CALL SUB1()
   END SELECT

3. IF (ITEST .EQ. 1) THEN
   CALL SUB1()
   ELSE
      CALL SUB2()
   END IF

The following shows another example:

CHARACTER*1 cmdchar
GET_ANSWER: SELECT CASE (cmdchar)
   CASE ('0')
      WRITE (*, *) "Must retrieve one to nine files"
   CASE ('1':'9')
      CALL RetrieveNumFiles (cmdchar)
   CASE ('A', 'a')
```
CALL AddEntry
CASE ('D', 'd')
   CALL DeleteEntry
CASE ('H', 'h')
   CALL Help
CASE DEFAULT
   WRITE (*, *) "Command not recognized; please use H for help"
END SELECT GET_ANSWER

Execution Control Overview

CDFLOAT

**Portability Function:** Converts a COMPLEX(4) argument to double-precision real type.

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{CDFLOAT} \left( \text{input} \right) \]

**input** (Input) COMPLEX(4). The value to be converted.

**Results**

The result type is REAL(8).

CEILING

**Elemental Intrinsic Function (Generic):** Returns the smallest integer greater than or equal to its argument.

**Syntax**

\[ \text{result} = \text{CEILING} \left( a[,kind] \right) \]

**a** (Input) Must be of type real.

**kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the smallest integer greater than or equal to **a**.

The setting of compiler options specifying integer size can affect this function.

**Example**

CEILING (4.8) has the value 5.
CEILING (-2.55) has the value -2.0.
The following shows another example:

```fortran
INTEGER I, IARRAY(2)
I = CEILING(8.01) ! returns 9
I = CEILING(-8.01) ! returns -8
IARRAY = CEILING((/8.01,-5.6/)) ! returns (9, -5)
```

**See Also**
FLOOR

**CFI_address**

*C function prototype:* Returns the C address of an object described by a C descriptor.

**Syntax**

```c
void *CFI_address (const CFI_cdesc_t *dv,
                     const CFI_index_t subscripts[]);
```

**Formal Parameters:**

- **dv**
  - The address of a C descriptor describing the object. The object must not be an unallocated allocatable variable or a pointer that is not associated.

- **subscripts**
  - A null pointer or the address of an array of type `CFI_index_t`. If the object is an array, `subscripts` must be the address of an array of type `CFI_index_t` with at least `n` elements, where `n` is the rank of the object. The value of `subscripts[i]` must be within the bounds of dimension `i` specified by the `dim` member of the C descriptor.

**Result Value**

If the object is an array of rank `n`, the result is the C address of the element of the object that the first `n` elements of the `subscripts` argument would specify if used as subscripts. If the object is scalar, the result is its C address.

**Example**

If `dv` is the address of a C descriptor for the Fortran array `A` declared as follows:

```fortran
REAL(C_FLOAT) :: A(100, 100)
```

then the following code calculates the C address of `A(5, 10)`:

```c
CFI_index_t subscripts[2];
float *address;
subscripts[0] = 4;
subscripts[1] = 9;
address = (float *) CFI_address(dv, subscripts);
```

**See Also**
C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

**CFI_allocate**

*C function prototype:* Allocates memory for an object described by a C descriptor.
Syntax

```c
int CFI_allocate (CFI_cdesc_t *dv,
    const CFI_index_t lower_bounds[],
    const CFI_index_t upper_bounds[],
    size_t elem_len);
```

Formal Parameters:

dv  
The address of a C descriptor specifying the rank and type of the object. The base_addr member of the C descriptor is a null pointer. If the type is not a character type, the `elem_len` member must specify the element length. The attribute member must have a value of `CFI_attribute_allocatable` or `CFI_attribute_pointer`.

lower_bounds  
The address of an array with at least `dv->rank` elements. The first `dv->rank` elements of `lower_bounds` provide the lower Fortran bounds for each corresponding dimension of the object.

upper_bounds  
The address of an array with at least `dv->rank` elements. The first `dv->rank` elements of `upper_bounds` provide the upper Fortran bounds for each corresponding dimension of the object.

elem_len  
If the type specified in the C descriptor type is a Fortran character type, the value of `elem_len` is the storage size in bytes of an element of the object; otherwise, `elem_len` is ignored.

Description

Successful execution of CFI_allocate allocates memory for the object described by the C descriptor with the address `dv` using the same mechanism as the Fortran ALLOCATE statement, and assigns the address of that memory to `dv->base_addr`.

The first `dv->rank` elements of the `lower_bounds` and `upper_bounds` arguments provide the lower and upper Fortran bounds, respectively, for each corresponding dimension of the object. The supplied lower and upper bounds override any current dimension information in the C descriptor. If the rank is zero, the `lower_bounds` and `upper_bounds` arguments are ignored.

If the type specified in the C descriptor is a character type, the supplied element length overrides the current element-length information in the descriptor.

If an error is detected, the C descriptor is not modified.

Result Value

The result is an error indicator.

Example

If `dv` is the address of a C descriptor for the Fortran array A declared as follows:

```
REAL, ALLOCATABLE :: A(:, :)
```

and the array is not allocated, the following code allocates it to be of shape [100, 500]:

```c
cfi_index_t lower[2], upper[2];
int ind;
lower[0] = 1; lower[1] = 1;
upper[0] = 100; upper[1] = 500;
ind = CFI_allocate(dv, lower, upper, 0);
```

See Also

ALLOCATE
C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

**CFI_deallocate**

*C function prototype:* Deallocates memory for an object described by a C descriptor.

### Syntax

```c
int CFI_deallocate (CFI_cdesc_t *dv);
```

### Formal Parameters:

- **dv**
  
  The address of a C descriptor describing the object. It must have been allocated using the same mechanism as the Fortran ALLOCATE statement. If the object is a pointer, it must be associated with a target satisfying the conditions for successful deallocation by the Fortran DEALLOCATE statement.

### Description

Successful execution of CFI_deallocate deallocates memory for the object using the same mechanism as the Fortran DEALLOCATE statement, and the `base_addr` member of the C descriptor becomes a null pointer.

If an error is detected, the C descriptor is not modified.

### Result Value

The result is an error indicator.

### Example

If `dv` is the address of a C descriptor for the Fortran array `A` declared as follows:

```fortran
REAL, ALLOCATABLE :: A(:, :)
```

and the array is allocated, the following code deallocates it:

```c
int ind;
ind = CFI_deallocate(dv);
```

### See Also

- ALLOCATE
- DEALLOCATE
- Interoperating with arguments using C descriptors

**CFI_establish**

*C function prototype:* Establishes a C descriptor.

### Syntax

```c
int CFI_establish(CFI_cdesc_t *dv, void *base_addr, CFI_attribute_t attribute, CFI_type_t type, size_t elem_len, CFI_rank_t rank, const CFI_index_t extents[]);
```

### Formal Parameters:

- **dv**
  
  The address of a C descriptor describing the object. It must have been allocated using the same mechanism as the Fortran ALLOCATE statement. If the object is a pointer, it must be associated with a target satisfying the conditions for successful deallocation by the Fortran DEALLOCATE statement.
**dv**

The address of a data object large enough to hold a C descriptor of the rank specified by `rank`. It must not have the same value as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument. It must not be the address of a C descriptor that describes an allocated allocatable object.

**base_addr**

A null pointer or the base address of the object to be described. If it is not a null pointer, it must be the address of a contiguous storage sequence that is appropriately aligned for an object of the type specified by `type`.

**attribute**

One of the attribute codes in Table "Macros for attribute codes" in C Typedefs and Macros for interoperability. If it is `CFI_attribute_allocatable`, `base_addr` must be a null pointer.

**type**

One of the type codes in Table "Macros for type codes" in C Typedefs and Macros for interoperability.

**elem_len**

If the type is `CFI_type_struct`, `CFI_type_other`, or a Fortran character type code, `elem_len` must be greater than zero and equal to the storage size in bytes of an element of the object. Otherwise, `type` is ignored.

**rank**

A value in the range $0 \leq rank \leq CFI_MAX_RANK$. It specifies the rank of the object.

**extents**

This is ignored if rank is equal to zero or if `base_addr` is a null pointer. Otherwise, it must be the address of an array with rank elements; the value of each element must be nonnegative, and `extents[i]` specifies the extent of dimension $i$ of the object.

**Description**

Successful execution of `CFI_establish` updates the object with the address `dv` to be an established C descriptor for a nonallocatable nonpointer data object of known shape, an unallocated allocatable object, or a data pointer.

If `base_addr` is not a null pointer, it is the address for a nonallocatable entity that is a scalar or a contiguous array. If the attribute argument has the value `CFI_attribute_pointer`, the lower bounds of the object described by `dv` are set to zero. If `base_addr` is a null pointer, the established C descriptor is for an unallocated allocatable, a disassociated pointer, or is a C descriptor that has the attribute `CFI_attribute_other` but does not describe a data object. If `base_addr` is the C address of a Fortran data object, the `type` and `elem_len` arguments must be consistent with the type and type parameters of the Fortran data object.

The remaining properties of the object are given by the other arguments.

`CFI_establish` is used to initialize a C descriptor declared in C with `CFI_CDESC_T` before passing it to any other functions as an actual argument, in order to set the rank, attribute, type and element length.

A C descriptor with attribute `CFI_attribute_other` and a `base_addr` that is a null pointer can be used as the argument result in calls to `CFI_section` or `CFI_select_part`, which will produce a C descriptor for a nonallocatable nonpointer data object.

If an error is detected, the object with the address `dv` is not modified.

**Result Value**

The result is an error indicator.
Example

The following code fragment establishes a C descriptor for an unallocated rank-one allocatable array that can be passed to Fortran for allocation there:

```c
CFI_rank_t rank;
CFI_CDESC_T(1) field;
int ind;
rank = 1;
ind = CFI_establish((CFI_cdesc_t *)&field, NULL,
CFI_attribute_allocatable,
CFI_type_double, 0, rank, NULL);
```

If the following Fortran type definition is specified:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
```

and a Fortran subprogram that has an assumed-shape dummy argument of type T, the following code fragment creates a descriptor `a_fortran` for an array of size 100 that can be used as the actual argument in an invocation of the subprogram from C:

```c
typedef struct {double x; double _Complex y;} t;
t a_c[100];
CFI_CDESC_T(1) a_fortran;
int ind;
CFI_index_t extent[1];
extent[0] = 100;
ind = CFI_establish((CFI_cdesc_t *)&a_fortran, a_c,
CFI_attribute_other,
CFI_type_struct, sizeof(t), 1, extent);
```

See Also

C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

**CFI_is_contiguous**

*C function prototype:* Tests contiguity of an array.

**Syntax**

```
int CFI_is_contiguous(const CFI_cdesc_t *dv);
```

**Formal Parameters:**

- `dv` The address of a C descriptor describing an array. The `base_addr` member of the C descriptor must not be a null pointer.

**Result Value**

The value of the result is 1 if the array described by `dv` is contiguous; otherwise, 0.

Since assumed-size and allocatable arrays are always contiguous, the result of CFI_is_contiguous on a C descriptor for such an array is 1.

See Also

C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

**CFI_section**

**C function prototype:** Updates a C descriptor for an array section for which each element is an element of a given array.

**Syntax**

```c
int CFI_section(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                 const CFI_index_t lower_bounds[],
                 const CFI_index_t upper_bounds[],
                 const CFI_index_t strides[]);
```

**Formal Parameters:**

- **result**
  
  The address of a C descriptor with rank equal to the rank of `source` minus the number of zero `strides`. The attribute member must have the value `CFI_attribute_other` or `CFI_attribute_pointer`. If the value of `result` is the same as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument, the attribute member must have the value `CFI_attribute_pointer`.

  Successful execution of `CFI_section` updates the `base_addr` and `dim` members of the C descriptor with the address result to describe the array section determined by `source`, `lower_bounds`, `upper_bounds`, and `strides`, as follows:

  - The array section is equivalent to the Fortran array section `SOURCE(sectsub1, sectsub2, ... sectsubn)`, where `SOURCE` is the array described by `source`, `n` is the rank of that array, and `sectsubi` is the subscript `loweri` if `stridesi` is zero, and the section subscript `loweri : upperi : stridesi` otherwise.
  
  - The value of `loweri` is the lower bound of dimension `i` of `SOURCE` if `lower_bounds` is a null pointer and `lower_bounds[i]` otherwise.
  
  - The value of `upperi` is the upper bound of dimension `i` of `SOURCE` if `upper_bounds` is a null pointer and `upper_bounds[i]` otherwise.
  
  - The value of `stridesi` is 1 if `strides` is a null pointer and `strides[i]` otherwise. If `strides` has the value zero, `loweri` must have the same value as `upperi`.

- **source**

  The address of a C descriptor that describes a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer. The `elem_len` and `type` members of `source` must have the same values as the corresponding members of `result`.

- **lower_bounds**

  A null pointer or the address of an array with at least `source->rank` elements. If it is not a null pointer, and `stridesi` is zero or `(upperi - lower_bounds[i] + stridesi)/stridesi > 0`, the value of `lower_bounds[i]` must be within the bounds of dimension `i` of `SOURCE`.

- **upper_bounds**

  A null pointer or the address of an array with at least `source->rank` elements. If `source` describes an assumed-size array, `upper_bounds` must not be a null pointer. If it is not a null pointer and `stridesi` is zero or `(upper_bounds[i] - loweri + stridesi)/stridesi > 0`, the value of `upper_bounds[i]` must be within the bounds of dimension `i` of `SOURCE`. 

strides

A null pointer or the address of an array with at least source->rank elements.

If an error is detected, the C descriptor with the address result is not modified.

**Result Value**

The result is an error indicator.

**Example**

If source is already the address of a C descriptor for the rank-one Fortran array A, the lower bounds of A are equal to 1, and the lower bounds in the C descriptor are equal to 0, the following code fragment establishes a new C descriptor section and updates it to describe the array section A(3::5):

```c
CFI_index_t lower[1], strides[1];
CFI_CDESC_T(1) section;
int ind;
lower[0] = 2;
strides[0] = 5;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, NULL, strides);
```

If source is already the address of a C descriptor for a rank-two Fortran assumed-shape array A with lower bounds equal to 1, the following code fragment establishes a C descriptor and updates it to describe the rank-one array section A(:, 42):

```c
CFI_index_t lower[2], upper[2], strides[2];
CFI_CDESC_T(1) section;
int ind;
lower[0] = source->dim[0].lower_bound;
upper[0] = source->dim[0].lower_bound + source->dim[0].extent - 1;
strides[0] = 1;
strides[1] = 0;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, upper, strides);
```

**See Also**

C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

**CFI_select_part**

*C function prototype:* Updates a C descriptor for an array section for which each element is a part of the corresponding element of an array.

**Syntax**

```c
int CFI_select_part(CFI_cdesc_t *result, const CFI_cdesc_t *source,
size_t displacement, size_t elem_len);
```

**Formal Parameters:**
result

The address of a C descriptor; result->rank must have the same value as source->rank and result->attribute must have the value CFI_attribute_other or CFI_attribute_pointer. If the address specified by result is the value of a C formal parameter that corresponds to a Fortran actual argument or of a C actual argument that corresponds to a Fortran dummy argument, result->attribute must have the value CFI_attribute_pointer. The value of result->type specifies the type of the array section.

source

The address of a C descriptor for a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer.

displacement

A value \(0 \leq \text{displacement} < \text{source}->\text{elem_len} - 1\), and the sum of the displacement and the size in bytes of an element of the array section must be less than or equal to source->elem_len. The address displacement bytes greater than the value of source->base_addr is the base of the array section and must be appropriately aligned for an object of the type of the array section.

elem_len

A value equal to the storage size in bytes of an element of the array section if result->type specifies a Fortran character type; otherwise, elem_len is ignored.

Description

Successful execution of CFI_select_part updates the base_addr, dim, and elem_len members of the C descriptor with the address result for an array section for which each element is a part of the corresponding element of the array described by the C descriptor with the address source. The part must be a component of a structure, a substring, or the real or imaginary part of a complex value.

If an error is detected, the C descriptor with the address result is not modified.

Result Value

The result is an error indicator.

Example

If source is already the address of a C descriptor for the Fortran array A declared as follows:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
TYPE(T) A(100)
```

then the following code fragment establishes a C descriptor for the array A%Y:

```c
typedef struct {
  double x; double _Complex y;
} t;
CFI_CDESC_T(1) component;
CFI_cdesc_t * comp_cdesc = (CFI_cdesc_t *)&component;
CFI_index_t extent[] = {100};
(void)CFI_establish(comp_cdesc, NULL, CFI_attribute_other,
  CFI_type_double_Complex,
  sizeof(double _Complex), 1, extent);
(void)CFI_select_part(comp_cdesc, source, offsetof(t,y), 0);
```

C Structures, Typedefs, and Macros for Interoperability
Interoperating with arguments using C descriptors

CFI_setpointer

**C function prototype:** Updates a C descriptor for a Fortran pointer to be associated with the whole of a given object or to be disassociated.

**Syntax**

```c
int CFI_setpointer(CFI_cdesc_t *result, CFI_cdesc_t *source, const CFI_index_t lower_bounds[]);
```

**Formal Parameters:**

- `result`:
  The address of a C descriptor for a Fortran pointer. It is updated using information from the `source` and `lower_bounds` arguments.

- `source`:
  A null pointer or the address of a C descriptor for a nonallocatable nonpointer data object, an allocated allocatable object, or a data pointer object. If `source` is not a null pointer, the corresponding values of the `elem_len`, `rank`, and `type` members must be the same in the C descriptors with the addresses `source` and `result`.

- `lower_bounds`:
  If `source` is not a null pointer and `source->rank` is nonzero, `lower_bounds` must be a null pointer or the address of an array with at least `source->rank` elements.

**Description**

Successful execution of `CFI_setpointer` updates the `base_addr` and `dim` members of the C descriptor with the address result as follows:

- If `source` is a null pointer or the address of a C descriptor for a disassociated pointer, the updated C descriptor describes a disassociated pointer.
- Otherwise, the C descriptor with the address result becomes a C descriptor for the object described by the C descriptor with the address source, except that if `source->rank` is nonzero and `lower_bounds` is not a null pointer, the lower bounds are replaced by the values of the first `source->rank` elements of the `lower_bounds` array.

**Result Value**

The result is an error indicator.

**Example**

If `ptr` is already the address of a C descriptor for an array pointer of rank 1, the following code updates it to be a C descriptor for a pointer to the same array with lower bound 0:

```c
CFI_index_t lower_bounds[1];
int ind;
lower_bounds[0] = 0;
ind = CFI_setpointer(ptr, ptr, lower_bounds);
```

CHANGEDIRQQ

*Portability Function:* Makes the specified directory the current, default directory.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{CHANGEDIRQQ} (\text{dir})
\]

\[
\text{dir} \quad \text{(Input) Character*(*). Directory to be made the current directory.}
\]

**Results**

The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..

If you do not specify a drive in the \texttt{dir} string, the named directory on the current drive becomes the current directory. If you specify a drive in \texttt{dir}, the named directory on the specified drive becomes the current directory.

**Example**

```fortran
USE IFPORT
LOGICAL(4) status
status = CHANGEDIRQQ('d:\fps90\bin'))
! We are now CCed to 'd:\fps90\bin'
status = CHANGEDIRQQ('bessel'))
! We are now CCed to 'd:\fps90\bin\bessel'
```

**See Also**

GETDRIVEDIRQQ
MAKEDIRQQ
DELDIRQQ
CHANGEDRIVEQQ

CHANGEDRIVEQQ

*Portability Function:* Makes the specified drive the current, default drive.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{CHANGEDRIVEQQ} (\text{drive})
\]

\[
\text{drive} \quad \text{(Input) Character*(*). String beginning with the drive letter.}
\]

**Results**

The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE.

On Linux* and OS X* systems, the result is always .FALSE..

Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of \texttt{drive}. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.
Example

```fortran
USE IFPORT
LOGICAL(4) status
status = CHANGEDRIVEQQ('d')
```

CHAR

**Elemental Intrinsic Function (Generic):** Returns the character in the specified position of the processor's character set. It is the inverse of the function ICHAR.

**Syntax**

```fortran
result = CHAR (i[,kind])
```

- **i** (Input) Must be of type integer with a value in the range 0 to \( n - 1 \), where \( n \) is the number of characters in the processor's character set.
- **kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is of type character with length 1. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is the character in position \( i \) of the processor's character set. ICHAR(CHAR( \( i, \) **kind**( c ))) has the value \( I \) for 0 to \( n - 1 \) and CHAR(ICHAR( c ), **kind**( c )) has the value \( c \) for any character \( c \) capable of representation in the processor.

<table>
<thead>
<tr>
<th>Specific Name</th>

**CHARACTER**

**Statement:** Specifies the CHARACTER data type.

**Syntax**

```
CHARACTER
CHARACTER([KIND=] n)
CHARACTER*len
```

- **n** Is kind 1.
- **len** Is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

**Example**

```
C
C   Length of wt and vs is 10, city is 80, and ch is 1
C
CHARACTER wt*10, city*80, ch
CHARACTER (LEN = 10), PRIVATE :: vs
CHARACTER(*), private :: arg !declares a dummy argument
C   name and plume are ten-element character arrays
C   of length 20
   CHARACTER name(10)*20
   CHARACTER(len=20), dimension(10):: plume
C
C   Length of susan, patty, and dotty are 2, alice is 12, jane is a 79-member array of length 2
C
   CHARACTER(2) susan, patty, alice*12, dotty, jane(79)
```

**CHDIR**

**Portability Function:** Changes the default directory.

**Module**

```
USE IFPORT
```

**Syntax**

```
result = CHDIR(dir_name)
```

- **dir_name** (Input) Character*(*) . Name of a directory to become the default directory.

**Results**

The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:
**ENOENT**: The named directory does not exist.

**ENOTDIR**: The `dir_name` parameter is not a directory.

### Example

```fortran
use ifport
integer(4) istatus, enoent, enotdir
character(255) newdir
character(300) prompt, errmsg

prompt = 'Please enter directory name: '
10   write(*,*) TRIM(prompt)
read *, newdir
ISTATUS = CHDIR(newdir)
select case (istatus)
  case (2)  ! ENOENT
    errmsg = 'The directory '//TRIM(newdir)//' does not exist'
  case (20) ! ENOTDIR
    errmsg = TRIM(newdir)//' is not a directory'
  case (0) ! NO error
    goto 40
  case default
    write (errmsg,*) 'Error with code ', istatus
  end select
write(*,*) TRIM(errmsg)
goto 10
40    write(*,*) 'Default directory successfully changed.'
end
```

CHANGEDIRQQ

**CHMOD**

**Portability Function**: Changes the access mode of a file.

**Module**

USE IFPORT

**Syntax**

```fortran
result = CHMOD (name, mode)
```

*name* (Input) Character*(*)

Name of the file whose access mode is to be changed. Must have a single path.

*mode* (Input) Character*(*)

File permission: either Read, Write, or Execute. The `mode` parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

<table>
<thead>
<tr>
<th>Permission bit</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
</table>
| 4000           | Set user ID on execution | W*S: Ignored; never true  
<p>|                |             | L<em>X, M</em>X: Settable |</p>
<table>
<thead>
<tr>
<th>Permission bit</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Set group ID on execution</td>
<td>W*S: Ignored; never true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>1000</td>
<td>Sticky bit</td>
<td>W*S: Ignored; never true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0400</td>
<td>Read by owner</td>
<td>W*S: Ignored; always true</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0200</td>
<td>Write by owner</td>
<td>Settable</td>
</tr>
<tr>
<td>0100</td>
<td>Execute by owner</td>
<td>W*S: Ignored; based on file name extension</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0040, 0020, 0010</td>
<td>Read, Write, Execute by group</td>
<td>W*S: Ignored; assumes owner permissions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0004, 0002, 0001</td>
<td>Read, Write, Execute by others</td>
<td>W*S: Ignored; assumes owner permissions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: Settable</td>
</tr>
</tbody>
</table>

The following regular expression represents a symbolic mode:

```
[ugoa][+-=] [rwxXst]*
```

On Windows* systems, "[ugoa]" is ignored. On Linux* and OS X* systems, a combination of the letters "ugoa" control which users' access to the file will be changed:

- **u**: The user who owns the file
- **g**: Other users in the group that owns the file
- **o**: Other users not in the group that owns the file
- **a**: All users

"[+ - =]" indicates the operation to carry out:

- **+**: Add the permission
- **-**: Remove the permission
- **=**: Absolutely set the permission

"[rwxXst]" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux and OS X systems, all letters are significant.
Results

The result type is INTEGER(4). It is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The specified file was not found.
- EINVAL: The mode argument is invalid.
- EPERM: Permission denied; the file’s mode cannot be changed.

Example

USE IFPORT

integer(4) I,Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (i) then
   ISTATUS = CHMOD ("datafile.txt", "+w")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, i

See Also
SETFILEACCESSQQ

CLASS

Statement: Declares a polymorphic object. It takes one of the following forms:

Syntax

CLASS (name) att-list :: v-list
CLASS (*) att-list :: v-list

name

att-list

Is the name of the extensible derived data type.

v-list

Is one or more attribute specifiers. These are the same attribute specifiers allowed for a derived-type TYPE statement.

Is the name of one or more data objects or functions. The name can optionally be followed by any of the following:

- An array specification, if the object is an array.
  In a function declaration, an array must be a deferred-shape array if it has the POINTER attribute; otherwise, it must be an explicit-shape array.
- A character length, if the object is of type character.
- A coarray specification, if the object is a coarray.
- An initialization expression preceded by an = or, for pointer objects, => NULL( ).

Description

A polymorphic object can have differing types during program execution.

The type of the object at a particular point during execution of a program is its dynamic type.

The declared type of a data entity is the type that it is declared to have, either explicitly or implicitly.

If CLASS (*) is specified, it denotes an unlimited polymorphic object. An unlimited polymorphic entity is not declared to have a type. It is not considered to have the same declared type as any other entity, including another unlimited polymorphic entity.
An entity declared with the CLASS keyword must be a dummy argument or have the ALLOCATABLE or POINTER attribute.

A polymorphic entity that is not an unlimited polymorphic entity is type compatible with entities of the same declared type or any of its extensions. Even though an unlimited polymorphic entity is not considered to have a declared type, it is type compatible with all entities. An entity is said to be type compatible with a type if it is type compatible with entities of that type.

A polymorphic allocatable object can be allocated to be of any type with which it is type compatible. During program execution, a polymorphic pointer or dummy argument can be associated with objects with which it is type compatible.

TYPE Statement (Derived Types)

CLEARSCREEN (W*S)

*Graphics Subroutine: Erases the target area and fills it with the current background color.*

**Module**

USE IFQWIN

**Syntax**

CALL CLEARSCREEN (area)

area  
(Input) INTEGER(4). Identifies the target area. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- $GCLEARSCREEN - Clears the entire screen.
- $GVIEWPORT - Clears only the current viewport.
- $GWINDOW - Clears only the current text window (set with SETTEXTWINDOW).

All pixels in the target area are set to the color specified with SETBKCOLORRGB. The default color is black.

**Example**

USE IFQWIN
CALL CLEARSCREEN($GCLEARSCREEN)

GETBKCOLORRGB (W*S)  
SETBKCOLORRGB (W*S)  
SETTEXTWINDOW (W*S)  
SETVIEWPORT (W*S)

CLEARSTATUSFPQQ

*Portability Subroutine: Clears the exception flags in the floating-point processor status word.*

**Module**

USE IFPORT

**Syntax**

CALL CLEARSTATUSFPQQ()
Description

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see *Floating-Point Operations*: Floating-Point Environment.

Example

```
! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a
! floating-point exception has occurred.
! So, build this console application with the default
! floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows)
! or -O0 (Linux) to get the correct results.
!
! PROGRAM CLEARFP

USE IFPORT

REAL*4 A,B,C
INTEGER*2 STS

A = 2.0E0
B = 0.0E0

! Poll and display initial floating point status
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS

! Cause a divide-by-zero exception
! Poll and display the new floating-point status
C = A/B
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS

! If a divide by zero error occurred, clear the floating-point
! status register so future exceptions can be detected.
IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
   CALL CLEARSTATUSFPQQ()
   CALL GETSTATUSFPQQ(STS)
   WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
ENDIF

END
```

This program is available in the online samples.

SIGNALQQ
CLICKMENUQQ (W*S)

**QuickWin Function:** Simulates the effect of clicking or selecting a menu command. The QuickWin application responds as though the user had clicked or selected the command.

**Module**
USE IFQWIN

**Syntax**

```fortran
result = CLICKMENUQQ (item)
```

**item** (Input) INTEGER(4). Constant that represents the command selected from the Window menu. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- QWIN$STATUS - Status command
- QWIN$TILE - Tile command
- QWIN$CASCADE - Cascade command
- QWIN$ARRANGE - Arrange Icons command

**Results**
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

**See Also**
REGISTERMOUSEEVENT (W*S)
UNREGISTERMOUSEEVENT (W*S)
WAITONMOUSEEVENT (W*S)

CLOCK

**Portability Function:** Converts a system time into an 8-character ASCII string.

**Module**
USE IFPORT

**Syntax**

```fortran
result = CLOCK()
```

**Results**
The result type is character with a length of 8. The result is the current time in the form hh:mm:ss, using a 24-hour clock.

**Example**

```fortran
USE IFPORT
character(8) whatimeisit
whatimeisit = CLOCK()
pdint *, 'The current time is ',whatimeisit
```

**See Also**
DATE_AND_TIME
CLOCKX

*Portability Subroutine:* Returns the processor clock in units of microseconds.

**Module**

USE IFPORT

**Syntax**

CALL CLOCKX (clock)

clock  

(Input) REAL(8). The current time.

On Windows systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

CLOSE

*Statement:* Disconnects a file from a unit.

**Syntax**

CLOSE ( [UNIT=] io-unit[, {STATUS | DISPOSE | DISP} = p] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])

io-unit

(Input) an external unit specifier.

p

(Input) a scalar default character expression indicating the status of the file after it is closed. It has one of the following values:

- 'KEEP' or 'SAVE' - Retains the file after the unit closes.
- 'DELETE' - Deletes the file after the unit closes (unless OPEN(READONLY) is in effect).
- 'PRINT' - Submits the file to the line print spooler, then retains it (sequential files only).
- 'PRINT/DELETE' - Submits the file to the line print spooler, then deletes it (sequential files only).
- 'SUBMIT' - Forks a process to execute the file.
- 'SUBMIT/DELETE' - Forks a process to execute the file, then deletes the file after the fork is completed.

The default is 'DELETE' for Windows* QuickWin applications and for scratch files. For all other files, the default is 'KEEP'.

Scratch files are temporary and are always deleted upon normal program termination; specifying STATUS='KEEP' for scratch files causes a run-time error.

For Windows* QuickWin applications, STATUS='KEEP' causes the child window to remain on the screen even after the unit closes. The default status is 'DELETE', which removes the child window from the screen.

label

Is the label of the branch target statement that receives control if an error occurs.

msg-var

(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
i-var

(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The CLOSE statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The status specified in the CLOSE statement supersedes the status specified in the OPEN statement, except that a file opened as a scratch file cannot be saved, printed, or submitted, and a file opened for read-only access cannot be deleted.

If a CLOSE statement is specified for a unit that is not open, it has no effect.

You do not need to explicitly close open files. Normal program termination closes each file according to its default status. The CLOSE statement does not have to appear in the same program unit that opened the file.

Closing unit 0 automatically reconnects unit 0 to the keyboard and screen. Closing units 5 and 6 automatically reconnects those units to the keyboard or screen, respectively. Closing the asterisk (*) unit causes a compile-time error. In Windows QuickWin applications, use CLOSE with unit 0, 5, or 6 to close the default window. If all of these units have been detached from the console (through an explicit OPEN), you must close one of these units beforehand to reestablish its connection with the console. You can then close the reconnect unit to close the default window.

If a parameter of the CLOSE statement is an expression that calls a function, that function must not cause an I/O operation or the EOF intrinsic function to be executed, because the results are unpredictable.

NOTE

You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures/USEROPEN Specifier.

Example

C    Close and discard file:

    CLOSE (7, STATUS = 'DELETE')

Consider the following statement:

    CLOSE (UNIT=J, STATUS='DELETE', ERR=99)

This statement closes the file connected to unit J and deletes it. If an error occurs, control is transferred to the statement labeled 99.

See Also

Data Transfer I/O Statements Overview
Branch Specifiers (END=, EOR=, ERR=)

CMPLX

Elemental Intrinsic Function (Specific): Converts the argument to complex type. This function cannot be passed as an actual argument.

Syntax

result = CMPLX (x[,y] [,kind])
x  (Input) Must be of type integer, real, or complex.

y  (Input; optional) Must be of type integer or real. It must not be present if x is of type complex.

kind  (Input; optional) Must be a scalar integer initialization expression.

Results
The result type is complex. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default real type.

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If y is not specified and x is complex, the result value is CMPLX(REAL(x), AIMAG(x)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

CMPLX(x, y, kind) has the complex value whose real part is REAL(x, kind) and whose imaginary part is REAL(y, kind).

The setting of compiler options specifying real size can affect this function.

If the argument is a boz-constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

Example
CMPLX (-3) has the value (-3.0, 0.0).
CMPLX (4.1, 2.3) has the value (4.1, 2.3).

The following shows another example:

```
COMPLEX z1, z2
COMPLEX(8) z3
z1 = CMPLX(3) ! returns the value 3.0 + i 0.0
z2 = CMPLX(3,4) ! returns the value 3.0 + i 4.0
z3 = CMPLX(3,4,8) ! returns a COMPLEX(8) value 3.0D0 + i 4.0D0
```

CODIMENSION
Statement and Attribute: Specifies that an entity is a coarray, and specifies its corank and cobounds, if any.

Syntax
The CODIMENSION attribute can be specified in a type declaration statement or a CODIMENSION statement, and takes one of the following forms:
Type Declaration Statement:

type, [att-ls,] CODIMENSION [coarray-spec] :: var-list [(array-spec)]...

type, [att-ls,] var-list [(array-spec)] [coarray-spec]...

Statement:
CODIMENSION [:] var-list [coarray-spec]...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

coarray-spec Is an allocatable (deferred-coshape) coarray or an explicit-coshape coarray.

var-list Is a list of variable names, separated by commas.

Description

In Intel® Fortran, the sum of the rank and corank of an entity must not exceed 31. The Fortran 2008 Standard allows a combined rank of up to 15.

A coarray must be a component or a variable that is not a function result.

A coarray must not be of type C_PTR or C_FUNPTR.

An entity whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar, must not be a coarray, and must not be a function result.

A coarray or an object with a coarray ultimate component must be a dummy argument or have the ALLOCATABLE or SAVE attribute.

A coarray must not be a dummy argument of a procedure that has a BIND attribute.

A coarray can be a derived type with pointer or allocatable components. The target of such a pointer component is always on the same image as the pointer.

Examples

Explicit-shape coarrays that are not dummy arguments must have the SAVE attribute. Because of this, automatic coarrays are not allowed. For example, coarray TASK in the following code is not valid:

```fortran
SUBROUTINE SUBA(I,C,D)
INTEGER :: I
REAL :: C(I)*, D(I)
REAL :: TASK(I)* ! Not permitted
```

The following lines show valid examples of CODIMENSION attribute specifications:

```fortran
REAL, CODIMENSION[3,*] :: B(:, ) ! Assumed-shape coarray
REAL R(50,50)[0:5,*] ! Explicit-shape coarray
REAL, CODIMENSION[*] :: A ! Scalar coarray
REAL, CODIMENSION[*,],ALLOCATABLE :: C(:, :) ! Allocatable coarray
```

COLLAPSE Clause

**Parallel Directive Clause:** Specifies how many loops are associated with a loop construct.

Syntax

```
COLLAPSE (n)
```

n Must be a constant positive scalar integer expression.
If \( n \) is greater than one, the iterations of all associated loops are collapsed into one larger iteration, which is then divided according to the SCHEDULE clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration. The associated loops must be perfectly nested, that is, there must be no intervening code or any OpenMP* directive between any two loops.

The iteration count for each associated loop is computed before entry to the outermost loop. If execution of any associated loop changes any of the values used to compute any of the iteration counts, then the behavior is unspecified. The integer kind used to compute the iteration count for the collapsed loop is implementation defined.

If COLLAPSE is not specified, the only loop that is associated with the loop construct is the one that immediately follows the construct.

At most one COLLAPSE clause can appear in a directive that allows the clause.

See Nested DO Constructs for restrictions on perfectly nested loops using COLLAPSE.

**COMAddObjectReference (W*S)**

**COM Function:** Adds a reference to an object’s interface.

**Module**

USE IFCOM

**Syntax**

```fortran
result = COMAddObjectReference (iunknown)
```

- `iunknown` An IUnKnown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

The result type is INTEGER(4). It is the object's current reference count.

**See Also**

IUnknown::AddRef in the Microsoft* Platform SDK

**COMCLSIDFromProgID (W*S)**

**COM Subroutine:** Passes a programmatic identifier and returns the corresponding class identifier.

**Module**

USE IFCOM
USE IFWINTY

**Syntax**

```fortran
CALL COMCLSIDFromProgID (prog_id, clsid, status)
```

- `prog_id` The programmatic identifier of type CHARACTER*(*)
- `clsid` The class identifier corresponding to the programmatic identifier. Must be of type GUID, which is defined in the IFWINTY module.
status

The status of the operation. It can be any status returned by CLSIDFromProgID. Must be of type INTEGER(4).

See Also

CLSIDFromProgID in the Microsoft* Platform SDK

COMCLSIDFromString (W*S)

COM Subroutine: Passes a class identifier string and returns the corresponding class identifier.

Module

USE IFCOM
USE IFWINTY

Syntax

CALL COMCLSIDFromString (string, clsid, status)

string

The class identifier string of type CHARACTER*(*)

clsid

The class identifier corresponding to the identifier string. Must be of type GUID, which is defined in the IFWINTY module.

status

The status of the operation. It can be any status returned by CLSIDFromString. Must be of type INTEGER(4).

See Also

CLSIDFromString in the Microsoft* Platform SDK

COMCreateObject (W*S)

COM Subroutine: A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.

Module

USE IFCOM
USE IFWINTY

Description

Your application obtains its first pointer to an object’s interface by calling COMCreateObject. It creates a new instance of an object class and returns a pointer to it.

See Also

COMCreateObjectByGUID (W*S)
COMCreateObjectByProgID (W*S)

COMCreateObjectByGUID (W*S)

COM Subroutine: Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.

Module

USE IFCOM
USE IFWINTY

Syntax
CALL COMCreateObjectByGUID (clsid, clsctx, iid, interface, status)

clsid
The class identifier of the class of object to be created. Must be of type
GUID, which is defined in the IFWINTY module.

clsctx
Lets you restrict the types of servers used for the object. Must be of type
INTEGER(4). Must be one of the CLSCTX_* constants defined in the
IFWINTY module.

iid
The interface identifier of the interface being requested. Must be of type
GUID, which is defined in the IFWINTY module.

interface
An output argument that returns the object’s interface pointer. Must be of
type INTEGER(INT_PTR_KIND()).

status
The status of the operation. It can be any status returned by
CoCreateInstance. Must be of type INTEGER(4).

See Also
CoCreateInstance in the Microsoft® Platform SDK
Using the Intel(R) Fortran Module Wizard (COM Client) in Key Features: Fortran Language Extensions

COMCreateObjectByProgID (W*S)

COM Subroutine: Passes a programmatic identifier,
creates an instance of an object, and returns a pointer
to the object’s IDispatch interface.

Module
USE IFCOM

Syntax
CALL COMCreateObjectByProgID (prog_id, idispatch, status)

prog_id
The programmatic identifier of type CHARACTER*(*)

idispatch
An output argument that returns the object’s IDispatch interface pointer.
Must be of type INTEGER(INT_PTR_KIND()).

status
The status of the operation. It can be any status returned by
CLSIDFromProgID or CoCreateInstance. Must be of type INTEGER(4).

See Also
COMCLSIDFromProgID (W*S)
CoCreateInstance in the OLE section of the Microsoft® Platform SDK
Using the Intel(R) Fortran Module Wizard (COM Client) in Key Features: Fortran Language Extensions

COMGetActiveObjectByGUID (W*S)

COM Subroutine: Passes a class identifier and
returns a pointer to the interface of a currently active
object.
Module
USE IFCOM
USE IFWINTY

Syntax
CALL COMGetActiveObjectByGUID (clsid, iid, interface, status)

clsid
The class identifier of the class of object to be found. Must be of type GUID, which is defined in the IFWINTY module.

iid
The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

interface
An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

status
The status of the operation. It can be any status returned by GetActiveObject. Must be of type INTEGER(4).

See Also
GetActiveObject in the Microsoft* Platform SDK

COMGetActiveObjectByProgID (W*S)

COM Subroutine: Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.

Module
USE IFCOM

Syntax
CALL COMGetActiveObjectByProgID (prog_id, idispatch, status)

prog_id
The programmatic identifier of type CHARACTER*(*)

idispatch
An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

status
The status of the operation. It can be any status returned by CLSIDFromProgID or GetActiveObject. Must be of type INTEGER(4).

Example
See the example in COMInitialize.

See Also
CLSIDFromProgID and GetActiveObject in the Microsoft* Platform SDK

COMGetFileObject (W*S)

COM Subroutine: Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file.

Module
USE IFCOM
CALL COMGetFileObject (filename, idispatch, status)

filename       The path of the file of type CHARACTER(*).
idispatch      An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
status         The status of the operation. It can be any status returned by the CreateBindCtx or MkParseDisplayName routines, or the IMoniker::BindToObject method. Must be of type INTEGER(4).

See Also
CreateBindCtx, MkParseDisplayName, and IMoniker::BindToObject in the Microsoft* Platform SDK

COMInitialize (W*S)
COM Subroutine: Initializes the COM library.

Module
USE IFCOM

Syntax
CALL COMInitialize (status)

status       The status of the operation. It can be any status returned by OleInitialize. Must be of type INTEGER(4).

You must use this routine to initialize the COM library before calling any other COM or AUTO routine.

Example
Consider the following:

program COMInitExample
  use ifwin
  use ifcom
  use ifauto
  implicit none

  ! Variables
  integer(4) word_app
  integer(4) status
  integer(INT_PTR_KIND()) invoke_args

  call COMInitialize(status)

  ! Call GetActiveObject to get a reference to a running MS WORD application
  call COMGetActiveObjectByProgID("Word.Application", word_app, status)
  if (status >= 0) then
    ! Print the active document
    invoke_args = AutoAllocateInvokeArgs()
    call AutoAddArg(invoke_args, "Copies", 2)
    status = AutoInvoke(word_app, "PrintOut", invoke_args)
    call AutoDeallocateInvokeArgs(invoke_args)
    ! Release the reference
    status = COMReleaseObject(word_app)
See Also
OleInitialize in the Microsoft* Platform SDK

COMIsEqualGUID (W*S)
COM Function: Determines whether two globally unique identifiers (GUIDs) are the same.

Module
USE IFCOM
USE IFWINTY

Syntax
result = COMIsEqualGUID (guid1, guid2)

guid1 The first GUID. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

guid2 The second GUID, which will be compared to guid1. It must be the same type of GUID as guid1. For example, if guid1 is a CLSID, guid2 must also be a CLSID.

Results
The result type is LOGICAL(4). The result is .TRUE. if the two GUIDs are the same; otherwise, .FALSE.

See Also
IsEqualGUID in the Microsoft* Platform SDK

COMMAND_ARGUMENT_COUNT
Inquiry Intrinsic Function (Generic): Returns the number of command arguments.

Syntax
result = COMMAND_ARGUMENT_COUNT ()

Results
The result is a scalar of type default integer. The result value is equal to the number of command arguments available. If there are no command arguments available, the result is 0. The command name does not count as one of the command arguments.

Example
Consider the following:

program echo_command_line
integer i, cnt, len, status
character c*30, b*100

call get_command (b, len, status)
if (status .ne. 0) then
If the above program is invoked with the command line "echo_command_line.exe -o 42 -a hello b", the following is displayed:

```fortran
command line = echo_command_line.exe -o 42 -a hello b
command name = echo_command_line.exe
number of command arguments = 5
command arg 1 = -o
command arg 2 = 42
command arg 3 = -a
command arg 4 = hello
command arg 5 = b
command line processed
```

GET_COMMAND_ARGUMENT

COMMITQQ

**Run-Time Function:** Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file's physical device.

**Module**
USE IFCORE

**Syntax**
```
result = COMMITQQ (unit)
```
**unit**  
(Input) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

**Results**

The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initially written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.

COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

**Example**

```fortran
USE IFCORE
INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff
OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')
DO WHILE (.TRUE.)
    WRITE (*, '(A, \)') 'Enter some data (Hit RETURN to &
    exit): '
    len = GETSTRQQ (stuff)
    IF (len .EQ. 0) EXIT
    WRITE (unit, *) stuff
    IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
END DO
CLOSE (unit)
END
```

**See Also**

PRINT  
WRITE Statement

**COMMON**

**Statement:** Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items.

**Syntax**

```fortran
COMMON [ /[cname]/ ] var-list[[,] /[cname]/ var-list]...
```

**cname**  
(Optional) Is the name of the common block. The name can be omitted for blank common (//).

**var-list**  
Is a list of variable names, separated by commas.
The variable must not be a dummy argument, allocatable array, automatic object, function, function result, a variable with the BIND attribute, or entry to a procedure. It must not have the PARAMETER attribute. If an object of derived type is specified, it must be a sequence type or a type with the BIND attribute.

**Description**

Common blocks can be named or unnamed (a *blank common*).

A common block is a global entity, and must not have the same name as any other global entity in the program, such as a subroutine or function.

Any common block name (or blank common) can appear more than once in one or more COMMON statements in a program unit. The list following each successive appearance of the same common block name is treated as a continuation of the list for the block associated with that name. Consider the following COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin
COMMON /     / shepard, grissom, carpenter
COMMON /glenn/ borman, anders
COMMON /young/ mcdiivitt, white, conrad
COMMON schirra, cooper
```

They are equivalent to these COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin, borman, anders
COMMON         shepard, grissom, carpenter, schirra, cooper
COMMON /young/ mcdiivitt, white, conrad
```

A variable can appear in only one common block within a scoping unit.

A common block object must **not** be one of the following:

- A dummy argument
- A result variable
- An allocatable variable
- A derived-type object with an ultimate component that is allocatable
- A procedure pointer
- An automatic object
- A variable with the BIND attribute
- An unlimited polymorphic pointer
- A coarray

If an array is specified, it can be followed by an explicit-shape array specification, each bound of which must be a constant specification expression. Such an array must not have the POINTER attribute.

A pointer can only be associated with pointers of the same type and kind parameters, and rank.

An object with the TARGET attribute can only be associated with another object with the TARGET attribute and the same type and kind parameters.

A nonpointer can only be associated with another nonpointer, but association depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Variable</th>
<th>Type of Associated Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric (^1) or numeric sequence (^2)</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence (^2)</td>
<td>Can be of either of these types</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Type of Variable</td>
<td>Type of Associated Variable</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

1. Default integer, default real, double precision real, default complex, double complex, or default logical.
2. If an object of numeric sequence or character sequence type appears in a common block, it is as if the individual components were enumerated directly in the common list.

So, variables can be associated if they are of different numeric type. For example, the following is valid:

```plaintext
INTEGER A(20)
REAL Y(20)
COMMON /QUANTA/ A, Y
```

When common blocks from different program units have the same name, they share the same storage area when the units are combined into an executable program.

Entities are assigned storage in common blocks on a one-for-one basis. So, the data type of entities assigned by a COMMON statement in one program unit should agree with the data type of entities placed in a common block by another program unit. For example:

<table>
<thead>
<tr>
<th>Program Unit A</th>
<th>Program Unit B</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON CENTS</td>
<td>INTEGER(2) MONEY</td>
</tr>
<tr>
<td></td>
<td>COMMON MONEY</td>
</tr>
</tbody>
</table>

When these program units are combined into an executable program, incorrect results can occur if the 2-byte integer variable MONEY is made to correspond to the lower-addressed two bytes of the real variable CENTS.

Named common blocks must be declared to have the same size in each program unit. Blank common can have different lengths in different program units.

**NOTE**

If a common block is initialized by a DATA statement, the module containing the initialization must declare the common block to be its maximum defined length.

This limitation does not apply if you compile all source modules together.

**Example**

```plaintext
PROGRAM MyProg
COMMON i, j, x, k(10)
COMMON /mycom/ a(3)
... END 
SUBROUTINE MySub
COMMON ps, mn, z, idum(10)
COMMON /mycom/ a(3)
... END
```

In the following example, the COMMON statement in the main program puts HEAT and X in blank common, and KILO and Q in a named common block, BLK1:
The COMMON statement in the subroutine makes ALFA and BET share the same storage location as HEAT and X in blank common. It makes LIMA and R share the same storage location as KILO and Q in BLK1.

The following example shows how a COMMON statement can be used to declare arrays:

```
COMMON / MIXED / SPOTTED(100), STRIPED(50,50)
```

The following example shows a valid association between subroutines in different program units. The object lists agree in number, type, and kind of data objects:

```
SUBROUTINE unit1
  REAL(8) x(5)
  INTEGER J
  CHARACTER str*12
  TYPE(member) club(50)
  COMMON / blocka / x, j, str, club
...
SUBROUTINE unit2
  REAL(8) z(5)
  INTEGER m
  CHARACTER chr*12
  TYPE(member) myclub(50)
  COMMON / blocka / z, m, chr, myclub
...
```

See also the example for BLOCK DATA.

Specification Expressions

**COMPLEX Statement**

*Statement:* Specifies the COMPLEX data type.

**Syntax**

- `COMPLEX`
- `COMPLEX([KIND=] n)`
- `COMPLEX* s`
- `DOUBLE COMPLEX`
n Is kind 4, 8, or 16.
s Is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

DOUBLE COMPLEX is COMPLEX(8). No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

Example

```
COMPLEX ch
COMPLEX (KIND=4),PRIVATE :: zz, yy !equivalent to COMPLEX*8 zz, yy
COMPLEX(8) ax, by !equivalent to COMPLEX*16 ax, by
COMPLEX (kind(4)) y(10)
complex (kind=8) x, z(10)
```

See Also

Data Types, Constants, and Variables Overview

**COMPLINT, COMPLREAL, COMPLLOG**

*Portability Functions:* Return a BIT-WISE complement or logical .NOT. of the argument.

**Module**

USE IFPORT

**Syntax**

```
result = COMPLINT (intval)
result = COMPREAL (realval)
result = COMPLLOG (logval)
```

*intval* (Input) INTEGER(4).

*realval* (Input) REAL(4).

*logval* (Input) LOGICAL(4).

**Results**

The result is INTEGER(4) for COMPLINT, REAL(4) for COMPREAL and LOGICAL(4) for COMPLLOG with a value that is the bitwise complement of the argument.

**COMQueryInterface (W*S)**

*COM Subroutine:* Passes an interface identifier and returns a pointer to an object's interface.

**Module**

USE IFCOM
CALL COMQueryInterface (iunknown, iid, interface, status)

**iunknown**
An IUnknown interface pointer. Must be of type INTEGER(4).

**iid**
The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

**interface**
An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**status**
The status of the operation. It can be any status returned by the IUnknown method QueryInterface. Must be of type INTEGER(4).

**See Also**
IUnknown::QueryInterface in the Microsoft* Platform SDK
Using the Intel(R) Fortran Module Wizard (COM Client) in Key Features: Fortran Language Extensions

**COMReleaseObject (W*S)**

**COM Function**: Indicates that the program is done with a reference to an object's interface.

**Module**
USE IFCOM

**Syntax**
result = COMReleaseObject (iunknown)

**iunknown**
An IUnknown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

**Results**
The result type is INTEGER(4). It is the object's current reference count.

**Example**
See the example in COMInitialize.

**COMStringFromGUID (W*S)**

**COM Subroutine**: Passes a globally unique identifier (GUID) and returns a string of printable characters.

**Module**
USE IFCOM
USE IFWINTY

**Syntax**
CALL COMStringFromGUID (guid,string,status)
The GUID to be converted. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

A character variable of type CHARACTER*(*) that receives the string representation of the GUID. The length of the character variable should be at least 38.

The status of the operation. If the string is too small to contain the string representation of the GUID, the value is zero. Otherwise, the value is the number of characters in the string representation of the GUID. Must be of type INTEGER(4).

The string representation of a GUID has a format like that of the following:
[c200e360-38c5-11ce-ae62-08002b2b79ef]
where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-WORD.DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

See Also
StringFromGUID2 in the Microsoft* Platform SDK

COMUninitialize (W*S)

COM Subroutine: Uninitializes the COM library.

Module
USE IFCOM

Syntax
CALL COMUninitialize( )
When using COM routines, this must be the last routine called.

Example
See the example in COMInitialize.

CONJG

Elemental Intrinsic Function (Generic): Calculates the conjugate of a complex number.

Syntax
result = CONJG (z)

z (Input) Must be of type complex.

Results
The result type and kind is the same as z. If z has the value (x, y), the result has the value (x, -y).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONJG</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>DCONJG</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>Specific Name</td>
<td>Argument Type</td>
<td>Result Type</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>QCONJG</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

**Example**

CONJG ((2.0, 3.0)) has the value (2.0, -3.0).

CONJG ((1.0, -4.2)) has the value (1.0, 4.2).

The following shows another example:

```fortran
COMPLEX z1
COMPLEX(8) z2
z1 = CONJG((3.0, 5.6))  ! returns (3.0, -5.6)
z2 = DCONJG((3.0D0, 5.6D0))  ! returns (3.0D0, -5.6D0)
```

**See Also**

AIMAG

**CONTAINS**

**Statement:** Separates the body of a main program, module, submodule, or external subprogram from any internal or module procedures it may contain, or it introduces the type-bound procedure part of a derived-type definition. It is not executable.

**Syntax**

```fortran
CONTAINS
```

Any number of internal procedures can follow a CONTAINS statement, but a CONTAINS statement cannot appear in the internal procedures themselves.

An empty CONTAINS section is allowed.

**Example**

```fortran
PROGRAM OUTER
  REAL, DIMENSION(10) :: A
  . . .
  CALL INNER (A)
CONTAINS
  SUBROUTINE INNER (B)
  REAL, DIMENSION(10) :: B
  . . .
  END SUBROUTINE INNER
END PROGRAM OUTER
```

**See Also**

Internal Procedures
Modules and Module Procedures
Main Program

**CONTIGUOUS**

**Statement and Attribute:** Specifies that the target of a pointer or an assumed-sized array is contiguous.

**Syntax**

The CONTIGUOUS attribute can be specified in a type declaration statement or an CONTIGUOUS statement, and takes one of the following forms:
Type Declaration Statement:

type, [att-ls], CONTIGUOUS [, att-ls] :: object [, object] ...

Statement:

CONTIGUOUS [:] object [, object] ...

type
Is a data type specifier.

att-ls
Is an optional list of attribute specifiers.

object
Is an assumed-shape array or an array pointer.

Description

This attribute explicitly indicates that an assumed-shape array is contiguous or that a pointer will only be associated with a contiguous object.

An entity can be contiguous even if CONTIGUOUS is not specified. An object is contiguous if it is one of the following:

• An object with the CONTIGUOUS attribute
• A nonpointer whole array that is not assumed-shape
• An assumed-shape array that is argument associated with an array that is contiguous
• An array allocated by an ALLOCATE statement
• An pointer associated with a contiguous target
• A nonzero-sized array section in which the following is true:
  • Its base object is contiguous.
  • It does not have a vector subscript.
  • The elements of the section, in array element order, are a subset of the base object elements that are consecutive in array element order.
  • If the array is of type character and a substring-range appears, the substring-range specifies all of the characters of the parent-string.
  • Only its final reference to a structure component, if any, has nonzero rank
  • It is not the real or imaginary part of an array of type complex.

An object is not contiguous if it is an array subobject, and all of the following are true:

• The object has two or more elements.
• The elements of the object in array element order are not consecutive in the elements of the base object.
• The object is not of type character with length zero.
• The object is not of a derived type that has no ultimate components other than zero-sized arrays and characters with length zero.

The CONTIGUOUS attribute can make it easier to enable optimizations that rely on the memory layout of an object occupying a contiguous block of memory.

Examples

The following examples show valid CONTIGUOUS statements:

REAL, CONTIGUOUS, DIMENSION(:, :) :: A
REAL, POINTER, CONTIGUOUS :: MY_POINTER(:)

Compatible Attributes
CONTINUE

**Statement:** Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.

**Syntax**

```fortran
CONTINUE
```

The statement by itself does nothing and has no effect on program results or execution sequence.

**Example**

The following example shows a CONTINUE statement:

```fortran
DO 150 I = 1,40
  40  Y = Y + 1
      Z = COS(Y)
      PRINT *, Z
      IF (Y .LT. 30) GO TO 150
      GO TO 40
150  CONTINUE
```

The following shows another example:

```fortran
DIMENSION narray(10)
DO 100 n = 1, 10
  narray(n) = 120
100  CONTINUE
```

**See Also**

END DO

DO Statement

Execution Control Overview

**COPYIN Clause**

**Parallel Directive Clause:** Specifies that the data in the master thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.

**Syntax**

```fortran
COPYIN (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The COPYIN clause applies only to common blocks declared as THREADPRIVATE.

You do not need to specify the whole THREADPRIVATE common block; you can specify named variables within the common block.
COPYPRIVATE Clause

Parallel Directive Clause: Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.

Syntax

COPYPRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables in the list must not appear in a PRIVATE or FIRSTPRIVATE clause for the SINGLE directive construct. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a COPYPRIVATE clause.

If the directive is encountered in the dynamic extent of a parallel region, variables in the list must be private in the enclosing context.

If a common block is specified, it must be declared as THREADPRIVATE; the effect is the same as if the variable names in its common block object list were specified.

The effect of the COPYPRIVATE clause on the variables in its list occurs after the execution of the code enclosed within the SINGLE construct, and before any threads in the team have left the barrier at the end of the construct.

COS

Elemental Intrinsic Function (Generic): Produces the cosine of an argument.

Syntax

result = COS (x)

x

(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

If x is of type complex, its real part is regarded as a value in radians.

Results

The result type and kind is the same as x.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COS</td>

<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQCOS</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>
The setting of compiler options specifying real size can affect CCOS.

This function can also be specified as ZCOS.

Example

COS (2.0) has the value -0.4161468.

COS (0.567745) has the value 0.8431157.

COSD

*Elemental Intrinsic Function (Generic): Produces the cosine of x.*

**Syntax**

```
result = COSD (x)
```

*x*  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind is the same as *x*.

<table>
<thead>
<tr>
<th>Specific Name</th>

</tr>
</tbody>
</table>

Example

COSD (2.0) has the value 0.9993908.

COSD (30.4) has the value 0.8625137.

COSH

*Elemental Intrinsic Function (Generic): Produces a hyperbolic cosine.*

**Syntax**

```
result = COSH (x)
```

*x*  
(Input) Must be of type real.

**Results**

The result type and kind is the same as *x*.

<table>
<thead>
<tr>

<tr>
<td>QCOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COSH (2.0) has the value 3.762196.
COSH (0.65893) has the value 1.225064.

**COTAN**

*Elemental Intrinsic Function (Generic):* Produces the cotangent of \( x \).

**Syntax**

\[
\text{result} = \text{COTAN} \ (\text{x})
\]

\( x \)  
(Input) Must be of type real; it cannot be zero. It must be in radians and is treated as modulo \( 2\pi \).

**Results**

The result type and kind is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>

<tr>
<td>DCOTAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAN (2.0) has the value -4.576575E-01.
COTAN (0.6) has the value 1.461696.

**COTAND**

*Elemental Intrinsic Function (Generic):* Produces the cotangent of \( x \).

**Syntax**

\[
\text{result} = \text{COTAND} \ (\text{x})
\]

\( x \)  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COTAND</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<td>DCOTAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>
Example
COTAND (2.0) has the value 0.2863625E+02.
COTAND (0.6) has the value 0.9548947E+02.

COUNT
Transformational Intrinsic Function (Generic):
Counts the number of true elements in an entire array or in a specified dimension of an array.

Syntax
result = COUNT (mask[,dim][, kind])

mask (Input) Must be a logical array.
dim (Input; optional) Must be a scalar integer expression with a value in the range 1 to n, where n is the rank of mask.
kind (Input; optional) Must be a scalar integer initialization expression.

Results
The result is an array or a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is a scalar if dim is omitted or mask has rank one. A scalar result has a value equal to the number of true elements of mask. If mask has size zero, the result is zero.

An array result has a rank that is one less than mask, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of mask.

Each element in an array result equals the number of elements that are true in the one dimensional array defined by mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n).

Example
COUNT ((/ .TRUE., .FALSE., .TRUE./)) has the value 2 because two elements are true.
COUNT ((/ .TRUE., .TRUE., .TRUE./)) has the value 3 because three elements are true.

A is the array

\[
\begin{bmatrix}
1 & 5 & 7 \\
3 & 6 & 8 \\
\end{bmatrix}
\]

and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9 \\
\end{bmatrix}
\]

COUNT (A .NE. B, DIM=1) tests to see how many elements in each column of A are not equal to the elements in the corresponding column of B. The result has the value (2, 0, 1) because:

- The first column of A and B have 2 elements that are not equal.
- The second column of A and B have 0 elements that are not equal.
- The third column of A and B have 1 element that is not equal.

COUNT (A .NE. B, DIM=2) tests to see how many elements in each row of A are not equal to the elements in the corresponding row of B. The result has the value (1, 2) because:

- The first row of A and B have 1 element that is not equal.
• The second row of A and B have 2 elements that are not equal.

The following shows another example:

```fortran
LOGICAL mask (2, 3)
INTEGER AR1(3), AR2(2), I
mask = RESHAPE((/ .TRUE., .TRUE., .FALSE., .TRUE., &
                .FALSE., .FALSE./), (/2,3/))
!
! mask is the array   true false false
!                     true true false
AR1 = COUNT(mask,DIM=1) ! counts true elements by
! column yielding [2 1 0]
AR2 = COUNT(mask,DIM=2) ! counts true elements by row
! yielding [1 2]
I = COUNT( mask)        ! returns 3
```

ALL
ANY

**CPU_TIME**

**Intrinsic Subroutine (Generic):** Returns a processor-dependent approximation of the processor time in seconds. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL CPU_TIME (time)
```

time (Output) Must be scalar and of type real.

The time returned is summed over all active threads. The result is the sum (in units of seconds) of the current process's user time and the user and system time of all its child processes, if any.

If a meaningful time cannot be returned, a processor-dependent negative value is returned.

**NOTE**

If you want to estimate performance or scaling of multithreaded applications, you should use intrinsic subroutine SYSTEM_CLOCK or portability function DCLOCK. Both of these routines return the elapsed time from a single clock.

**Example**

Consider the following:

```fortran
REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
! task to be timed
!
CALL CPU_TIME ( time_end )
WRITE (*,*) 'Time of operation was ', time_end - time_begin, ' seconds'
```

See Also
DCLOCK
SYSTEM_CLOCK
CRITICAL Directive

OpenMP* Fortran Compiler Directive: Restricts access to a block of code to only one thread at a time.

Syntax

```fortran
!$OMP CRITICAL [(name)]
   block
!$OMP END CRITICAL [(name)]
```

- **name**: Is the name of the critical section.
- **block**: Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for a CRITICAL construct is all threads in the contention group. Region execution is restricted to a single thread at a time among all threads in the contention group, without regard to the teams to which the threads belong.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name. All unnamed CRITICAL directives map to the same name.

If a name is specified in the CRITICAL directive, the same name must appear in the corresponding END CRITICAL directive. If no name appears in the CRITICAL directive, no name can appear in the corresponding END CRITICAL directive.

Critical section names are global entities of the program. If the name specified conflicts with any other entity, the behavior of the program is undefined.

Example

The following example shows a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation is placed in a critical section.

Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, XAXIS and YAXIS, respectively:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,Y)
   !$OMP CRITICAL(XAXIS)
   CALL DEQUEUE(IX_NEXT, X)
   !$OMP END CRITICAL(XAXIS)
   CALL WORK(IX_NEXT, X)
   !$OMP CRITICAL(YAXIS)
   CALL DEQUEUE(IY_NEXT,Y)
   !$OMP END CRITICAL(YAXIS)
   CALL WORK(IY_NEXT,Y)
!$OMP END PARALLEL
```

Parallel Processing Model for information about Binding Sets

CRITICAL Statement

**Statement**: Marks the beginning of a CRITICAL construct. A CRITICAL construct limits execution of a block to one image at a time.

Syntax

```
[name:] CRITICAL
```
END CRITICAL [name]

(name) Is the name of the CRITICAL construct.

block

Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified in a CRITICAL statement, the same name must appear in the corresponding END CRITICAL statement. If no name is specified at the beginning of a CRITICAL statement, you cannot specify one following the END CRITICAL statement. The same construct name must not be used for different named constructs in the same scoping unit.

The block of a CRITICAL construct must not contain a RETURN statement or an image control statement.

A branch within a CRITICAL construct must not have a branch target that is outside the construct.

Execution of the CRITICAL construct is completed when execution of its block is completed. A procedure that is invoked, directly or indirectly, from a CRITICAL construct must not execute an image control statement.

The processor ensures that once an image has commenced executing block, no other image can start executing block until this image has completed executing block. The image must not execute an image control statement during the execution of block. The sequence of executed statements is therefore a segment. If image S is the next to execute the construct after image N, the segment on image N precedes the segment on image S.

If more than one image executes the block of a CRITICAL construct, its execution by one image always precedes or succeeds its execution by another image. Normally no other statement ordering is needed.

**Example**

Consider the following example:

```fortran
CONA: CRITICAL
END CRITICAL CONA
```

The definition of MY_COUNTER [1] by a particular image will always precede the reference to the same variable by the next image to execute the block.

The following example shows a way to share a large number of tasks among images:

```fortran
INTEGER :: NUMBER_TASKS[*], TASK
IF (THIS_IMAGE() == 1) READ(*,*) NUMBER_TASKS
SYNC ALL
DO
    CRITICAL
        TASK = NUMBER_TASKS[1]
        NUMBER_TASKS[1] = TASK - 1
    END CRITICAL
    IF (TASK > 0) THEN
        ELSE
            EXIT
    END IF
END DO
SYNC ALL
```

Coarrays
Using Coarrays
**CSHIFT**

Transformational Intrinsic Function (Generic):
Performs a circular shift on a rank-one array, or performs circular shifts on all the complete rank-one sections (vectors) along a given dimension of an array of rank two or greater.

**Syntax**
Elements shifted off one end are inserted at the other end. Different sections can be shifted by different amounts and in different directions.

```
result = CSHIFT (array, shift [,dim])
```

- **array** (Input) Array whose elements are to be shifted. It can be of any data type.
- **shift** (Input) The number of positions shifted. Must be a scalar integer or an array with a rank that is one less than `array`, and shape `(d1, d2, ..., d_{dim-1}, d_{dim+1}, ..., dn)`, where `(d1, d2, ..., dn)` is the shape of `array`.
- **dim** (Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer with a value in the range 1 to n, where n is the rank of `array`. If `dim` is omitted, it is assumed to be 1.

**Results**
The result is an array with the same type and kind parameters, and shape as `array`.

If `array` has rank one, element i of the result is `array(1 + MODULO (i + shift - 1, SIZE (array)))`. (The same shift is applied to each element.)

If `array` has rank greater than one, each section `(s_1, s_2, ..., s_{dim-1}, : , s_{dim+1}, ..., s_n)` of the result is shifted as follows:
- By the value of `shift`, if `shift` is scalar
- According to the corresponding value in `shift(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)`, if `shift` is an array

The value of `shift` determines the amount and direction of the circular shift. A positive `shift` value causes a shift to the left (in rows) or up (in columns). A negative `shift` value causes a shift to the right (in rows) or down (in columns). A zero `shift` value causes no shift.

**Example**

V is the array `(1, 2, 3, 4, 5, 6).

CSHIFT (V, SHIFT=2) shifts the elements in V circularly to the left by 2 positions, producing the value `(3, 4, 5, 6, 1, 2)`. 1 and 2 are shifted off the beginning and inserted at the end.

CSHIFT (V, SHIFT= -2) shifts the elements in V circularly to the right by 2 positions, producing the value `(5, 6, 1, 2, 3, 4)`. 5 and 6 are shifted off the end and inserted at the beginning.

M is the array

```
[ 1 2 3 ]
[ 4 5 6 ]
[ 7 8 9 ]
```

CSHIFT (M, SHIFT = 1, DIM = 2) produces the result

```
[ 2 3 1 ]
[ 5 6 4 ]
[ 8 9 7 ]
```

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. The elements shifted off the beginning are inserted at the end.
CSHIFT (M, SHIFT = -1, DIM = 1) produces the result

\[
\begin{bmatrix}
7 & 8 & 9 \\
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. The elements shifted off the end are inserted at the beginning.

CSHIFT (M, SHIFT = (/1, -1, 0/), DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & 1 \\
6 & 4 & 5 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position; each element in row 2 is shifted to the right by 1 position; no element in row 3 is shifted at all.

The following shows another example:

INTEGER array (3, 3), AR1(3, 3), AR2 (3, 3)
DATA array /1, 4, 7, 2, 5, 8, 3, 6, 9/

! array is  
! 1 2 3  
! 4 5 6  
! 7 8 9  
!AR1 = CSHIFT(array, 1, DIM = 1) ! shifts all columns  
! by 1 yielding  
! 4 5 6  
! 7 8 9  
! 1 2 3  

AR2=CSHIFT(array,shift=/-1, 1, 0/),DIM=2) ! shifts each row separately  
! by the amount in  
! shift yielding  
! 3 1 2  
! 5 6 4  
! 7 8 9

CSMG

**Portability Function:** Performs an effective **BIT-WISE** store under mask.

**Module**
USE IFPORT

**Syntax**
result = CSMG (x, y, z)

\[x, y, z\] (Input) INTEGER(4).

**Results**
The result type is INTEGER(4). The result is equal to the following expression:

\[(x \& z) \mid (y \& \neg z)\]
where "&" is a bitwise AND operation, | - bitwise OR, ~ - bitwise NOT.

The function returns the value based on the following rule: when a bit in \( z \) is 1, the output bit is taken from \( x \). When a bit in \( z \) is zero, the corresponding output bit is taken from \( y \).

### CTIME

**Portability Function:** Converts a system time into a 24-character ASCII string.

**Module**

USE IFPORT

**Syntax**

```fortran
result = CTIME (stime)
```

**stime**

(Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

**Results**

The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.

The value of \( stime \) can be determined by calling the TIME function. CTIME(TIME( )) returns the current time and date.

**Example**

```fortran
USE IFPORT
character (24) systime
systime = CTIME (TIME( ))
p想办法 *, 'Current date and time is ',systime
```

**See Also**

DATE_AND_TIME

### CYCLE

**Statement:** Interrupts the current execution cycle of the innermost (or named) DO construct.

**Syntax**

```fortran
CYCLE [name]
```

**name**

(Optional) Is the name of the DO construct.

**Description**

When a CYCLE statement is executed, the following occurs:

1. The current execution cycle of the named (or innermost) DO construct is terminated. If a DO construct name is specified, the CYCLE statement must be within the range of that construct.
2. The iteration count (if any) is decremented by 1.
3. The DO variable (if any) is incremented by the value of the increment parameter (if any).

Any executable statements following the CYCLE statement (including a labeled terminal statement) are not executed.

A CYCLE statement can be labeled, but it cannot be used to terminate a DO construct.
Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

**Example**

The following example shows a CYCLE statement:

```fortran
DO I = 1, 10
   A(I) = C + D(I)
   IF (D(I) < 0) CYCLE    ! If true, the next statement is omitted
   A(I) = 0               ! from the loop and the loop is tested again.
END DO
```

The following shows another example:

```fortran
sample_loop: do i = 1, 5
   print *, i
   if (i .gt. 3) cycle sample_loop
   print *, i
end do sample_loop
print *,'done!'
```

!output:

```
!     1
!     1
!     2
!     2
!     3
!     3
!     4
!     5
!     done!
```

DO Statement

DO WHILE

Execution Control Overview

**DATA**

**Statement**: Assigns initial values to variables before program execution.

**Syntax**

```
DATA var-list /clist/ [[,] var-list /clist/]...
```

- **var-list**: Is a list of variables or implied-DO lists, separated by commas.
  
  Subscript expressions and expressions in substring references must be initialization expressions.

  An implied-DO list in a DATA statement takes the following form:
  
  `( do-list, var= expr1, expr2[, expr3] )`

- **do-list**: Is a list of one or more array elements, substrings, scalar structure components, or implied-DO lists, separated by commas. Any array elements or scalar structure components must not have a constant parent.

- **var**: Is the name of a scalar integer variable (the implied-DO variable).

- **expr**: Is a list of variables or implied-DO lists, separated by commas.
clist

Is a list of variables or implied-DO lists, separated by commas.

A constant can be specified in the form r*constant, where r is a repeat specification. It is a nonnegative scalar integer constant (with no kind parameter). If it is a named constant, it must have been declared previously in the scoping unit or made accessible through use or host association. If r is omitted, it is assumed to be 1.

Description

A variable can be initialized only once in an executable program. A variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration which may change the implicit typing.

The number of constants in c-list must equal the number of variables in var-list. The constants are assigned to the variables in the order in which they appear (from left to right).

The following objects cannot be initialized in a DATA statement:

- A dummy argument
- A function
- A function result
- An automatic object
- An allocatable array
- A variable that is accessible by use or host association
- A variable in a named common block (unless the DATA statement is in a block data program unit)
- A variable in blank common

Except for variables in named COMMON blocks, a named variable has the SAVE attribute if any part of it is initialized in a DATA statement. You can confirm this property by specifying the variable in a SAVE statement or a type declaration statement containing the SAVE attribute.

When an unsubscripted array name appears in a DATA statement, values are assigned to every element of that array in the order of subscript progression. If the associated constant list does not contain enough values to fill the array, a warning is issued and the remaining array elements become undefined.

Array element values can be initialized in three ways: by name, by element, or by an implied-DO list (interpreted in the same way as a DO construct).

The following conversion rules and restrictions apply to variable and constant list items:

- If the constant and the variable are both of numeric type, the following conversion occurs:
  - The constant value is converted to the data type of the variable being initialized, if necessary.
  - When a binary, octal, or hexadecimal constant is assigned to a variable or array element, the number of digits that can be assigned depends on the data type of the data item. If the constant contains fewer digits than the capacity of the variable or array element, the constant is extended on the left with zeros. If the constant contains more digits than can be stored, the constant is truncated on the left. An error results if any nonzero digits are truncated.
  - If the constant and the variable are both of character type, the following conversion occurs:
    - If the length of the constant is less than the length of the variable, the rightmost character positions of the variable are initialized with blank characters.
    - If the length of the constant is greater than the length of the variable, the character constant is truncated on the right.
  - If the constant is of numeric type and the variable is of character type, the following restrictions apply:
    - The character variable must have a length of one character.
    - The constant must be an integer, binary, octal, or hexadecimal constant, and must have a value in the range 0 through 255.
When the constant and variable conform to these restrictions, the variable is initialized with the character that has the ASCII code specified by the constant. (This lets you initialize a character object to any 8-bit ASCII code.)

- If the constant is a Hollerith or character constant, and the variable is a numeric variable or numeric array element, the number of characters that can be assigned depends on the data type of the data item.
  
  If the Hollerith or character constant contains fewer characters than the capacity of the variable or array element, the constant is extended on the right with blank characters. If the constant contains more characters than can be stored, the constant is truncated on the right.

**Example**

The following example shows the three ways that DATA statements can initialize array element values:

```plaintext
DIMENSION A(10,10)
DATA A/100*1.0/    ! initialization by name
DATA A(1,1), A(10,1), A(3,3) /2*2.5, 2.0/ ! initialization by element
DATA ((A(I,J), I=1,5,2), J=1,5) /15*1.0/  ! initialization by implied-DO list
```

The following example shows DATA statements containing structure components:

```plaintext
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE

TYPE(EMPLOYEE) MAN_NAME, CON_NAME
DATA MAN_NAME / EMPLOYEE(417, 'Henry Adams') /
DATA CON_NAME%ID, CON_NAME%NAME /891, "David James"
```

In the following example, the first DATA statement assigns zero to all 10 elements of array A, and four asterisks followed by two blanks to the character variable STARS:

```plaintext
INTEGER A(10,10), B(10)
CHARACTER BELL, TAB, LF, FF, STARS*6
DATA A,STARS /10*0,'****'/
DATA BELL,TAB,LF,FF /7,9,10,12/
DATA (B(I), I=1,10,2) /5*1/
```

In this case, the second DATA statement assigns ASCII control character codes to the character variables BELL, TAB, LF, and FF. The last DATA statement uses an implied-DO list to assign the value 1 to the odd-numbered elements in the array B.

The following shows another example:

```plaintext
INTEGER n, order, alpha, list(100)
REAL coef(4), eps(2),
  pi(5), x(5,5)
CHARACTER*12 help
COMPLEX*8 cstuff
DATA  n /0/, order /3/
DATA  alpha '/'A'/
DATA  coef /1.0, 2*3.0, 1.0/, eps(1) /.00001/
DATA  cstuff /(-1.0, -1.0)/
!  The following example initializes diagonal and below in
!  a 5x5 matrix:
DATA  ((x(j,i), i=1,j), j=1,5) / 15*1.0 / 
DATA  pi / 5*3.14159 / 
DATA  list / 100*0 / 
DATA  help(1:4), help(5:8), help(9:12) /3*'HELP'/
```

Consider the following:

```plaintext
CHARACTER (LEN = 10) NAME
INTEGER, DIMENSION (0:9) :: MILES
REAL, DIMENSION (100, 100) :: SKEW
TYPE (MEMBER) MYNAME, YOURS
```
In this example, the character variable NAME is initialized with the value JOHN DOE with two trailing blanks to fill out the declared length of the variable. The ten elements of MILES are initialized to zero. The two-dimensional array SKEW is initialized so that its lower triangle is zero and its upper triangle is one. The structures MYNAME and YOURS are declared using the derived type MEMBER. The derived-type variable MYNAME is initialized by a structure constructor. The derived-type variable YOURS is initialized by supplying a separate value for each component.

The first DATA statement in the previous example could also be written as:

```fortran
DATA name / 'JOHN DOE' /  
DATA miles / 10*0 / 
```

A pointer can be initialized as disassociated by using a DATA statement. For example:

```fortran
INTEGER, POINTER :: P  
DATA P/NULL( )/ 
END 
```

### DATE Intrinsic Procedure

**Intrinsic Subroutine (Generic):** Returns the current date as set within the system. DATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```
CALL DATE (buf) 
```  

**buf**

(Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least nine bytes of storage.

The date is returned as a 9-byte ASCII character string taking the form dd-mmm-yy, where:

- dd is the 2-digit date
- mmm is the 3-letter month
- yy is the last two digits of the year

If **buf** is of numeric type and smaller than 9 bytes, data corruption can occur.
If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 9 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

CAUTION
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```fortran
CHARACTER*1 DAY(9)
...
CALL DATE (DAY)
```

The length of the first array element in CHARACTER array *DAY* is passed to the DATE subroutine. The subroutine then truncates the date to fit into the 1-character element, producing an incorrect result.

See Also

DATE_AND_TIME

DATE Portability Routine

**DATE Portability Routine**

*Portability Function or Subroutine:* Returns the current system date. DATE can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

**Function Syntax:**

```fortran
result = DATE( )
```

**Subroutine Syntax:**

```fortran
CALL DATE (dstring)
```

*dstring* (Output) CHARACTER. Is a variable or array containing at least nine bytes of storage.

DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where mm, dd, and yy are two-digit representations of the month, day, and year, respectively. DATE in its subroutine form returns *dstring* in the form dd-mmm-yy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yy are the last two digits of the current year.

CAUTION
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.
Example

USE IFPORT
!If today's date is March 02, 2000, the following
!code prints "02-Mar-00"
CHARACTER(9) TODAY
CALL DATE(TODAY)
PRINT *, TODAY
!The next line prints "03/02/00"
PRINT *, DATE( )

See Also
DATE_AND_TIME
DATE Intrinsic Procedure

DATE4

Portability Subroutine: Returns the current system
date.

Module
USE IFPORT

Syntax
CALL DATE4 (datestr)

Output) CHARACTER. Is a variable or array containing at least eleven bytes of storage.

This subroutine returns datestr in the form dd-mmm-yyyy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yyyy are the four digits of the current year.

DATE_AND_TIME

Intrinsic Subroutine (Generic): Returns character and binary data on the real-time clock and date.
Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL DATE_AND_TIME ( [date] [,time] [,zone] [,values] )

Date
(Output; optional) Must be scalar and of type default character; its length must be at least 8 to contain the complete value. Its leftmost 8 characters are set to a value of the form CCYMMDD, where:

<table>
<thead>
<tr>
<th>CC</th>
<th>YY</th>
<th>MM</th>
<th>DD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the century</td>
<td>Is the year within the century</td>
<td>Is the month within the year</td>
<td>Is the day within the month</td>
</tr>
</tbody>
</table>

Time
(Output; optional) Must be scalar and of type default character; its length must be at least 10 to contain the complete value. Its leftmost 10 characters are set to a value of the form hhmmss.sss, where:
<table>
<thead>
<tr>
<th>hh</th>
<th>Is the hour of the day</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm</td>
<td>Is the minutes of the hour</td>
</tr>
<tr>
<td>ss.sss</td>
<td>Is the seconds and milliseconds of the minute</td>
</tr>
</tbody>
</table>

**zone**

(Output; optional) Must be scalar and of type default character; its length must be at least 5 to contain the complete value. Its leftmost 5 characters are set to a value of the form +hhmm or -hhmm, where *hh* and *mm* are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively.

UTC is also known as Greenwich Mean Time.

**values**

(Output; optional) Must be of type integer. One-dimensional array with size of at least 8. The values returned in `values` are as follows:

| values(1) | Is the 4-digit year |
| values(2) | Is the month of the year |
| values(3) | Is the day of the month |
| values(4) | Is the time difference with respect to Coordinated Universal Time (UTC) in minutes |
| values(5) | Is the hour of the day (range 0 to 23) - local time |
| values(6) | Is the minutes of the hour (range 0 to 59) - local time |
| values(7) | Is the seconds of the minute (range 0 to 59) - local time |
| values(8) | Is the milliseconds of the second (range 0 to 999) - local time |

**Example**

Consider the following example executed on 2000 March 28 at 11:04:14.5:

```fortran
INTEGER DATE_TIME (8)
CHARACTER (LEN = 12) REAL_CLOCK (3)
CALL DATE_AND_TIME (REAL_CLOCK (1), REAL_CLOCK (2), &
                     REAL_CLOCK (3), DATE_TIME)
```

This assigns the value "20000328" to REAL_CLOCK (1), the value "110414.500" to REAL_CLOCK (2), and the value "-0500" to REAL_CLOCK (3). The following values are assigned to DATE_TIME: 2000, 3, 28, -300, 11, 4, 14, and 500.

The following shows another example:

```fortran
CHARACTER(10) t
CHARACTER(5) z
CALL DATE_AND_TIME(TIME = t, ZONE = z)
```

DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN

Portability Functions: Compute the double-precision values of Bessel functions of the first and second kinds.

Module
USE IFPORT

Syntax
result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)

value (Input) REAL(8). Independent variable for a Bessel function.

n (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.

posvalue (Input) REAL(8). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results
DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and n, respectively, with the independent variable value.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and n, respectively, with the independent variable posvalue.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the Handbook of Mathematical Functions (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

Example
USE IFPORT
real(8) besnum, besout
10 read *, besnum
besout = dbesj0(besnum)
print *, 'result is ',besout
goto 10
end
**See Also**
BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

**DBLE**

**Elemental Intrinsic Function (Generic):** Converts a number to double-precision real type.

**Syntax**

\[ \text{result} = \text{DBLE} \left( \text{a} \right) \]

\( \text{a} \)  \hspace{1cm} \text{(Input) Must be of type integer, real, or complex.}

**Results**

The result type is double precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If \( \text{a} \) is of type double precision, the result is the value of the \( \text{a} \) with no conversion (DBLE( \( \text{a} \) ) = \( \text{a} \)).

If \( \text{a} \) is of type integer or real, the result has as much precision of the significant part of \( \text{a} \) as a double precision value can contain.

If \( \text{a} \) is of type complex, the result has as much precision of the significant part of the real part of \( \text{a} \) as a double precision value can contain.

<table>
<thead>
<tr>
<th>Specific Name (^1)</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(1)</td>
<td></td>
<td>REAL(8)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td></td>
<td>REAL(8)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td></td>
<td>REAL(8)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td></td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DBLE(^2)</td>
<td>REAL(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DBLEQ</td>
<td>REAL(16)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(16)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

\(^1\) These specific functions cannot be passed as actual arguments.

\(^2\) The setting of compiler options specifying double size can affect DBLE.

If the argument is a boz-constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

DBLE (4) has the value 4.0.

DBLE ((3.4, 2.0)) has the value 3.4.

**See Also**
FLOAT
SNGL
REAL Function
CMPLX

DCLOCK
**Portability Function:** Returns the elapsed time in seconds since the start of the current process.

**Module**
USE IFPORT

**Syntax**
result = DCLOCK()

**Results**
The result type is REAL(8). This routine provides accurate timing to the nearest millisecond (Windows* OS) or to the nearest microsecond (Linux* OS and OS X*), taking into account the frequency of the processor where the current process is running.

Note that the first call to DCLOCK performs calibration.

**Example**
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME
START_CLOCK = DCLOCK()
CALL FOO()
STOP_CLOCK = DCLOCK()
PRINT *, 'foo took:', STOP_CLOCK - START_CLOCK, 'seconds.'

**See Also**
DATE_AND_TIME
CPU_TIME

DCMPLX
**Elemental Intrinsic Function (Specific):** Converts the argument to double complex type. This function cannot be passed as an actual argument.

**Syntax**
result = DCMPLX (x[,y])

- **x**
  (Input) Must be of type integer, real, or complex.

- **y**
  (Input; optional) Must be of type integer or real. It must not be present if x is of type complex.

**Results**
The result type is double complex (COMPLEX(8) or COMPLEX*16).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If y is not specified and x is complex, the result value is CMPLX(REAL( x), AIMAG( x)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.
DCMPLX( x, y) has the complex value whose real part is REAL( x, KIND=8) and whose imaginary part is REAL( y, KIND=8).

Example

DCMPLX (-3) has the value (-3.0, 0.0).
DCMPLX (4.1, 2.3) has the value (4.1, 2.3).

DEALLOCATE

Statement: Frees the storage allocated for allocatable variables and nonprocedure pointer targets (and causes the pointers to become disassociated).

Syntax

DEALLOCATE (object[], object)...[, dealloc-opt])

object

Is a structure component or the name of a variable, and must be a pointer or allocatable variable.

dealloc-opt

(Output) Is one of the following:

STAT=stat-var  stat-var is a scalar integer variable in which the status of the deallocation is stored.

ERRMSG=err-var  err-var is a scalar default character value in which an error condition is stored if such a condition occurs.

Description

If a STAT= variable or ERRMSG= variable is specified, it must not be deallocated in the DEALLOCATE statement in which it appears. If the deallocation is successful, the variable is set to zero. If the deallocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the ERRMSG= variable contains the error condition. If no STAT= variable is specified and an error condition occurs, program execution terminates.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images has initiated termination of execution, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT= variable becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE.

It is recommended that all explicitly allocated storage be explicitly deallocated when it is no longer needed.

To disassociate a pointer that was not associated with the ALLOCATE statement, use the NULLIFY statement.

For a list of run-time errors, see Error Handling in the Compiler Reference.
Example

The following example shows deallocation of an allocatable array:

```
INTEGER ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)
...
ALLOCATE (A(10), B(-2:8,1:5))
...
DEALLOCATE(A, B, STAT = ALLOC_ERR)
```

The following shows another example:

```
INTEGER, ALLOCATABLE :: dataset(:,:,)
INTEGER reactor, level, points, error
DATA reactor, level, points / 10, 50, 10 /
ALLOCATE (dataset(1:reactor,1:level,1:points), STAT = error)
DEALLOCATE (dataset, STAT = error)
```

NULLIFY
Arrays
Dynamic Allocation Overview

DECLARE and NODEDECLARE

**General Compiler Directives:** DECLARE generates warnings for variables that have been used but have not been declared (like the IMPLICIT NONE statement). NODEDECLARE (the default) disables these warnings.

Syntax

```
!DIR$ DECLARE

!DIR$ NODECLARE
```

The DECLARE directive is primarily a debugging tool that locates variables that have not been properly initialized, or that have been defined but never used.

See Also

IMPLICIT
General Compiler Directives
Syntax Rules for Compiler Directives
Equivalent Compiler Options

DECLARE SIMD

**OpenMP* Fortran Compiler Directive:** Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.

Syntax

```
!$OMP DECLARE SIMD(routine-name) [clause[,, clause]... ]
```
**routine-name**

Is the name of a routine (a function or subroutine). It cannot be a generic name; it must be a specific name. It also cannot be a procedure pointer or an entry name.

**clause**

Is an optional vectorization clause. It can be one or more of the following:

- **ALIGNED (list [:n])**
- **INBRANCH | NOTINBRANCH**

The **INBRANCH** clause specifies that the routine must always be called from inside a conditional statement of a SIMD loop.

The **NOTINBRANCH** clause specifies that the routine must never be called from inside a conditional statement of a SIMD loop.

If neither clause is specified, then the routine may or may not be called from inside a conditional statement of a SIMD loop.

You can only specify **INBRANCH** or **NOTINBRANCH**; you cannot specify both.

- **LINEAR (linear-list[: linear-step])**
- **PROCESSOR (cpuid) (an Intel® language extension)**
- **SIMDLEN(n)**

Specifies the number of concurrent arguments \( n \) for the SIMD version of **routine-name**. The \( n \) must be a constant positive integer expression.

If **SIMDLEN** is not specified, the number of concurrent arguments for the **routine-name** is implementation defined.

Only one **SIMDLEN** clause can appear in a **DECLARE SIMD** directive.

- **UNIFORM(list)**

Tells the compiler that the values of the specified arguments have an invariant value for all concurrent invocations of the routine in the execution of a single SIMD loop.

The **list** is one or more scalar variables that are dummy arguments in the specified routine.

Multiple **UNIFORM** clauses are merged as a union.

The **DECLARE SIMD** construct enables the creation of SIMD versions of the specified subroutine or function. You can use multiple **DECLARE SIMD** constructs in a single procedure to produce more than one SIMD version of a procedure. These versions can be used to process multiple arguments from a single invocation from a SIMD loop concurrently.

When **routine-name** is executed, it cannot have any side-effects that would change its execution for concurrent iterations of a SIMD chunk. When the routine is called from a SIMD loop, it cannot cause the execution of any OpenMP® Fortran construct.

If a **DECLARE SIMD** directive is specified for a routine name with explicit interface and for the definition of the routine, they must match. Otherwise, the result is unspecified.

You cannot use procedure pointers to access routines created by the **DECLARE SIMD** directive.

You can only specify a particular variable in at most one instance of a **UNIFORM** or **LINEAR** clause.

**See Also**

OpenMP® Fortran Compiler Directives  
Syntax Rules for Compiler Directives
DECLARE TARGET

OpenMP* Fortran Compiler Directive: Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This directive only applies to Intel® MIC Architecture.

Syntax

```fortran
!$OMP DECLARE TARGET [(list)]
```

*list* is a list of one or more variables, functions, subroutines, or common blocks. If you specify more than one *list* item, they must be separated by commas. A common block name must appear between slashes (/ /); you cannot specify a blank common block. The specified *list* items can be used inside a target region that executes on the device.

If the *list* item is a function or subroutine, it must not be a generic name, procedure pointer, or entry name. A device-specific version of the routine is created that can be called from a target region.

If the *list* item is a variable:

- It is mapped to a corresponding variable in the device data environment. If the variable is initialized, the corresponding variable in the device data environment is initialized with the same value.
- It can only appear in the scope in which it is declared.
- It must be declared in the Fortran scope of a module, or it must have the SAVE attribute (explicitly or implicitly).

You cannot specify the following variables in the DECLARE TARGET directive:

- A THREADPRIVATE variable
- A variable that is part of another variable (for example, an element in an array or a field of a structure)
- A variable that is an element of a common block
- A variable that appears in an EQUIVALENCE statement

If the *list* item is a common block:

- It must be declared to be a common block in the same scoping unit in which the DECLARE TARGET directive appears.
- If the DECLARE TARGET directive specifying the common block name appears in one program unit, a DECLARE TARGET directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. The directive must appear after the last relevant COMMON statement in the program unit.

If you specify *list*, this directive can only appear in a specification part of a subroutine, function, program, or module.

If you do not specify *list*, the directive must appear in the specification part of the relevant subroutine, function, or interface block.

If a DECLARE TARGET directive is specified in an interface block for a procedure, it must match a DECLARE TARGET directive in the definition of the procedure.

If a procedure is declared in a procedure declaration statement, any DECLARE TARGET directive containing the procedure name must appear in the same specification part.

The following additional rules apply to variables and common blocks:
• The DECLARE TARGET directive must appear in the declaration section of a scoping unit in which the common block or variable is declared.
• If a variable or common block is declared with the BIND attribute, the corresponding C entities must also be specified in a DECLARE TARGET directive in the C program.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

DECODE
Statement: Translates data from character to internal form. It is comparable to using internal files in formatted sequential READ statements.

Syntax

```
DECODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]
```

- **c**
  Is a scalar integer expression. It is the number of characters to be translated to internal form.

- **f**
  Is a format identifier. An error occurs if more than one record is specified.

- **b**
  Is a scalar or array reference. If b is an array reference, its elements are processed in the order of subscript progression. b contains the characters to be translated to internal form.

- **i-var**
  Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).

- **label**
  Is the label of an executable statement that receives control if an error occurs.

- **io-list**
  Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list receives the data after translation to internal form.

The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the DECODE statement can translate depends on the data type of b. For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

Example

In the following example, the DECODE statement translates the 12 characters in A to integer form (as specified by the FORMAT statement):

```
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
```
The 12 characters are stored in array K:

K(1) = 1234  
K(2) = 5678  
K(3) = 9012

See Also
READ Statement
WRITE Statement
ENCODE

DEFAULT Clause

**Parallel Directive Clause:** Lets you specify a scope for all variables in the lexical extent of a parallel region.

**Syntax**

```
DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
```

The specifications have the following effects:

- **PRIVATE** - Makes all named objects in the lexical extent of the parallel region, including common block variables but excluding THREADPRIVATE variables, private to a thread as if you explicitly listed each variable in a PRIVATE clause.
- **FIRSTPRIVATE** - Makes all variables in the construct that have implicitly determined data-sharing attributes firstprivate as if you explicitly listed each variable in a FIRSTPRIVATE clause.
- **SHARED** - Makes all named objects in the lexical extent of the parallel region shared among the threads in a team, as if you explicitly listed each variable in a SHARED clause. If you do not specify a DEFAULT clause, this is the default.
- **NONE** - Specifies that there is no implicit default as to whether variables are PRIVATE or SHARED. In this case, you must specify the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION property of each variable you use in the lexical extent of the parallel region.

You can specify only one DEFAULT clause in a PARALLEL directive. You can exclude variables from a defined default by using the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clauses.

Variables in THREADPRIVATE common blocks are not affected by this clause.

**DEFINE and UNDEFINE**

**General Compiler Directives:** DEFINE creates a symbolic variable whose existence or value can be tested during conditional compilation. UNDEFINE removes a defined symbol.

**Syntax**

```
!DIR$ DEFINE name[ = val]  
!DIR$ UNDEFINE name
```

- `name` is the name of the variable.
- `val` is an INTEGER(4). The value assigned to `name`.

DEFINE creates and UNDEFINE removes symbols for use with the IF (or IF DEFINED) compiler directive. Symbols defined with DEFINE directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.
To test whether a symbol has been defined, use the IF DEFINED (name) directive. You can assign an integer value to a defined symbol. To test the assigned value of name, use the IF directive. IF test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The DEFINE and UNDEFINE directives can appear anywhere in a program, enabling and disabling symbol definitions.

Example

```plaintext
!DIR$ DEFINE testflag
!DIR$ IF DEFINED (testflag)
   write (*,*) 'Compiling first line'
!DIR$ ELSE
   write (*,*) 'Compiling second line'
!DIR$ ENDIF
!DIR$ UNDEFINE testflag
```

Syntax Rules for Compiler Directives

**DEFINE FILE**

*Statement:* Establishes the size and structure of files with relative organization and associates them with a logical unit number.

**Syntax**

```
DEFINE FILE u(m,n,U,asv) [,u(m,n,U,asv)] ...
```

- **u**
  - Is a scalar integer constant or variable that specifies the logical unit number.

- **m**
  - Is a scalar integer constant or variable that specifies the number of records in the file.

- **n**
  - Is a scalar integer constant or variable that specifies the length of each record in 16-bit words (2 bytes).

- **U**
  - Specifies that the file is unformatted (binary); this is the only acceptable entry in this position.

- **asv**
  - Is a scalar integer variable, called the associated variable of the file. At the end of each direct access I/O operation, the record number of the next higher numbered record in the file is assigned to asv; asv must not be a dummy argument.

The DEFINE FILE statement is comparable to the OPEN statement. In situations where you can use the OPEN statement, OPEN is the preferable mechanism for creating and opening files.

The DEFINE FILE statement specifies that a file containing m fixed-length records, each composed of n 16-bit words, exists (or will exist) on the specified logical unit. The records in the file are numbered sequentially from 1 through m.
A DEFINE FILE statement does not itself open a file. However, the statement must be executed before the first direct access I/O statement referring to the specified file. The file is opened when the I/O statement is executed.

If this I/O statement is a WRITE statement, a direct access sequential file is opened, or created if necessary.

If the I/O statement is a READ or FIND statement, an existing file is opened, unless the specified file does not exist. If a file does not exist, an error occurs.

The DEFINE FILE statement establishes the variable asv as the associated variable of a file. At the end of each direct access I/O operation, the Fortran I/O system places in asv the record number of the record immediately following the one just read or written.

The associated variable always points to the next sequential record in the file (unless the associated variable is redefined by an assignment, input, or FIND statement). So, direct access I/O statements can perform sequential processing on the file by using the associated variable of the file as the record number specifier.

Example

```
DEFINE FILE 3(1000,48,U,NREC)
```

In this example, the DEFINE FILE statement specifies that the logical unit 3 is to be connected to a file of 1000 fixed-length records; each record is forty-eight 16-bit words long. The records are numbered sequentially from 1 through 1000 and are unformatted.

After each direct access I/O operation on this file, the integer variable NREC will contain the record number of the record immediately following the record just processed.

**See Also**

OPEN

DELDIRQQ

**Portability Function:** Deletes a specified directory.

**Module**

USE IFPORT

**Syntax**

```
result = DELDIRQQ (dir)
```

```
dir (Input) Character*(*). String containing the path of the directory to be deleted.
```

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

**Example**

See the example for GETDRIVEDIRQQ.

**See Also**

GETDRIVEDIRQQ
GETDRIVEDIRQQ
MAKEDIRQQ
CHANGEDIRQQ
CHANGEDRIVEQQ
UNLINK
DELETE

**Statement:** Deletes a record from a relative file.

**Syntax**

```
DELETE ([UNIT=] io-unit[, REC=r][, ERR=label] [, IOSTAT=i-var])
```

- **io-unit**
  - Is an external unit specifier.

- **r**
  - Is a scalar numeric expression indicating the record number to be deleted.

- **label**
  - Is the label of the branch target statement that receives control if an error occurs.

- **i-var**
  - Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

In a relative file, the DELETE statement deletes the direct access record specified by `r`. If `REC=r` is omitted, the current record is deleted. When the direct access record is deleted, any associated variable is set to the next record number.

The DELETE statement logically removes the appropriate record from the specified file by locating the record and marking it as a deleted record. It then frees the position formerly occupied by the deleted record so that a new record can be written at that position.

**NOTE**

You must use compiler option vms for READs to detect that a record has been deleted.

**Example**

The following statement deletes the fifth record in the file connected to I/O unit 10:

```
DELETE (10, REC=5)
```

Suppose the following statement is specified:

```
DELETE (UNIT=9, REC=10, IOSTAT=IOS, ERR=20)
```

The tenth record in the file connected to unit 9 is deleted. If an error occurs, control is transferred to the statement labeled 20, and a positive integer is stored in the variable IOS.

vms

**DELETEMENUQQ (W*S)**

**QuickWin Function:** Deletes a menu item from a QuickWin menu.

**Module**

USE IFQWIN

**Syntax**

```
result = DELETEMENUQQ (menuID, itemID)
```
**menuID**
(Input) INTEGER(4). Identifies the menu that contains the menu item to be deleted, starting with 1 as the leftmost menu.

**itemID**
(Input) INTEGER(4). Identifies the menu item to be deleted, starting with 0 as the top menu item.

**Results**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

**Example**

```fortran
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
str = 'Add to EDIT Menu'C  ! Append to 2nd menu
result = APPENDMENUQQ(2, $MENUENABLED, str, WINSTATUS)
! Delete third item (EXIT) from menu 1 (FILE)
result = DELETEMENUQQ(1, 3)
! Delete entire fifth menu (WINDOW)
result = DELETEMENUQQ(5, 0)
END
```

**See Also**
APPENDMENUQQ (W*S)
INSERTMENUQQ (W*S)
MODIFYMENUFLAGSQQ (W*S)
MODIFYMENUROUTINEQQ (W*S)
MODIFYMENUSTRINGQQ (W*S)

**DELFFILESQQ**

**Portability Function:** Deletes all files matching the name specification, which can contain wildcards (* and ?).

**Module**
USE IFPORT

**Syntax**

```fortran
result = DELFILESQQ (files)
```

**files**
(Input) Character*(*) . Files to be deleted. Can contain wildcards (* and ?).

**Results**
The result type is INTEGER(2). The result is the number of files deleted.

You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

**Example**

```fortran
USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: 
```
len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
  WRITE(*,*) "Are you sure (Y/N)?"
  ch = GETCHARQQ()
  IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END

FINDFILEQQ

DEPEND Clause

Parallel Directive Clause: Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.

Syntax

DEPEND (dependence-type : list)

dependence-type

Can be any one of the following clauses: IN, OUT, or INOUT.

For IN, the generated task will be a dependent task of all previously generated sibling tasks that reference at least one of the list items in an OUT or INOUT clause.

For OUT and INOUT, the generated task will be a dependent task of all previously generated sibling tasks that reference at least one of the list items in an IN, OUT, or INOUT clause.

list

Is one or more variables or non-zero length array sections. Any list items used in a DEPEND clause of the same task or sibling tasks must indicate identical storage or disjoint storage.

Note that this enforced task dependence establishes a synchronization of accesses to each list item performed by a dependent task, with respect to accesses to the same list item performed by any previous tasks. You must properly synchronize access with respect to other concurrent accesses to each list item.

If a DEPEND clause appears in a TARGET or TARGET UPDATE directive, it is treated as if it had appeared on the implicit task construct that encloses the TARGET construct.

DEVICE Clause

Parallel Directive Clause: Specifies the target device for a coprocessor control directive like TARGET.

Syntax

DEVICE (integer-expression)

integer-expression

Is an integer expression. It must evaluate to a positive scalar integer value.

At most one DEVICE clause can appear in a directive that allows the clause.

If DEVICE is not specified, the default device is determined by the internal control variable (ICV) named device-num-var.
**DFLOAT**

*Elemental Intrinsic Function (Generic):* Converts an integer to double-precision real type.

**Syntax**

\[
\text{result} = \text{DFLOAT} (a)
\]

\[a\] (Input) Must be of type integer.

**Results**

The result type is double-precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

<table>
<thead>

<td>INTEGER(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLOATKI</td>
<td>INTEGER(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1 These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying double size can affect DFLOAT.

**Example**

DFLOAT (-4) has the value -4.0.

**See Also**

REAL Function

**DFLOATI, DFLOATJ, DFLOATK**

*Portability Functions:* Convert an integer to double-precision real type.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{DFLOATI} (i)
\]

\[
\text{result} = \text{DFLOATJ} (j)
\]

\[
\text{result} = \text{DFLOATK} (k)
\]

\[i\] (Input) Must be of type INTEGER(2).

\[j\] (Input) Must be of type INTEGER(4).

\[k\] (Input) Must be of type INTEGER(8).

**Results**

The result type is double-precision real (REAL(8) or REAL*8).
See Also
DFLOAT

DIGITS
Inquiry Intrinsic Function (Generic): Returns the number of significant digits for numbers of the same type and kind parameters as the argument.

Syntax
result = DIGITS (x)

x  (Input) Must be of type integer or real; it can be scalar or array valued.

Results
The result is a scalar of type default integer.
The result has the value $q$ if $x$ is of type integer; it has the value $p$ if $x$ is of type real. Integer parameter $q$ is defined in Model for Integer Data; real parameter $p$ is defined in Model for Real Data.

Example
If $x$ is of type REAL(4), DIGITS(x) has the value 24.

EXPONENT
RADIX
FRACTION
Data Representation Models

DIM
Elemental Intrinsic Function (Generic): Returns the difference between two numbers (if the difference is positive).

Syntax
result = DIM (x, y)

x  (Input) Must be of type integer or real.

y  (Input) Must have the same type and kind parameters as x.

Results
The result type and kind is the same as $x$. The value of the result is $x - y$ if $x$ is greater than $y$; otherwise, the value of the result is zero.
The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

1Or HDIM.
2Or JIDIM. For compatibility, IDIM can also be specified as a generic function for integer types.

**Example**

DIM (6, 2) has the value 4.

DIM (-4.0, 3.0) has the value 0.0.

The following shows another example:

```fortran
INTEGER i
REAL r
REAL(8) d
i = IDIM(10, 5)  ! returns 5
r = DIM (-5.1, 3.7)  ! returns 0.0
d = DDIM (10.0D0, -5.0D0)  ! returns 15.0D0
```

**See Also**

Argument Keywords in Intrinsic Procedures

**DIMENSION**

*Statement and Attribute:* Specifies that an object is an array, and defines the shape of the array.

**Syntax**

The DIMENSION attribute can be specified in a type declaration statement or a DIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```
| type, [att-ls], DIMENSION (a-spec) [, att-ls] :: a[(a-spec)][, a[(a-spec)] ] ... |
```

**Statement:**

```
| DIMENSION [::]a(a-spec) [, a(a-spec) ] ... |
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `a-spec` Is an array specification. It can be any of the following:
  - An explicit-shape specification; for example, a(10,10)
  - An assumed-shape specification; for example, a(:)
  - A deferred-shape specification; for example, a(:,;)
  - An assumed-size specification; for example, a(10,*)
  - An assumed-rank specification; for example, a(..)

For more information on array specifications, see Declaration Statements for Arrays.

In a type declaration statement, any array specification following an array overrides any array specification following DIMENSION.

---

39 Intel® Fortran Compiler 16.0 User and Reference Guide

1300
Description

The DIMENSION attribute allocates a number of storage elements to each array named, one storage element to each array element in each dimension. The size of each storage element is determined by the data type of the array.

The total number of storage elements assigned to an array is equal to the number produced by multiplying together the number of elements in each dimension in the array specification. For example, the following statement defines ARRAY as having 16 real elements of 4 bytes each and defines MATRIX as having 125 integer elements of 4 bytes each:

```
DIMENSION ARRAY(4,4), MATRIX(5,5,5)
```

An array can also be declared in the following statements: ALLOCATABLE, AUTOMATIC, COMMON, POINTER, STATIC, TARGET.

Example

The following examples show type declaration statements specifying the DIMENSION attribute:

```fortran
REAL, DIMENSION(10, 10) :: A, B, C(10, 15)  ! Specification following C
                      ! overrides the one following
                      ! DIMENSION
REAL(8), DIMENSION(5,-2:2) :: A,B,C
```

The following are examples of the DIMENSION statement:

```
DIMENSION BOTTOM(12,24,10)
DIMENSION X(5,5,5), Y(4,85), Z(100)
DIMENSION MARK(4,4,4)
SUBROUTINE APROC(A1,A2,N1,N2,N3)
                   DIMENSION A1(N1:N2), A2(N3:*)
CHARACTER(LEN = 20) D
DIMENSION A(15), B(15, 40), C(-5:8, 7), D(15)
```

You can also declare arrays by using type and ALLOCATABLE statements, for example:

```fortran
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:,;)
REAL(8), ALLOCATABLE, DIMENSION( :, :, : ) :: E
```

You can specify both the upper and lower dimension bounds. If, for example, one array contains data from experiments numbered 28 through 112, you could dimension the array as follows:

```
DIMENSION experiment(28:112)
```

Then, to refer to the data from experiment 72, you would reference experiment(72).

Array elements are stored in column-major order: the leftmost subscript is incremented first when the array is mapped into contiguous memory addresses. For example, consider the following statements:

```
INTEGER(2) a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

These are equivalent to:

```
INTEGER(2) a
DIMENSION a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

If a is placed at location 1000 in memory, the preceding DATA statement produces the following mapping.
The following DIMENSION statement defines an assumed-size array in a subprogram:

```fortran
DIMENSION data (19,*
```

At execution time, the array data is given the size of the corresponding array in the calling program.

The following program fragment dimensions two arrays:

```fortran
SUBROUTINE Subr (matrix, rows, vector)
REAL MATRIX, VECTOR
INTEGER ROWS
DIMENSION MATRIX (ROWS,*), VECTOR (10),
+  LOCAL (2,4,8)
MATRIX (1,1) = VECTOR (5)
```

#### DISPLAYCURSOR (W'S)

**Graphics Function:** Controls cursor visibility.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = DISPLAYCURSOR (toggle)
```

`toggle` (Input) INTEGER(2). Constant that defines the cursor state. Has two possible values:

- `$GCURSOROFF` - Makes the cursor invisible regardless of its current shape and mode.
- `$GCURSORON` - Makes the cursor always visible in graphics mode.

**Results**

The result type is INTEGER(2). The result is the previous value of `toggle`.

Cursor settings hold only for the currently active child window. You need to call DISPLAYCURSOR for each window in which you want the cursor to be visible.

A call to SETWINDOWCONFIG turns off the cursor.
**See Also**

SETTEXTCURSOR (W*S)

SETWINDOWCONFIG (W*S)

**DISTRIBUTE**

*OpenMP* Fortran Compiler Directive: Specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a `teams` construct.

**Syntax**

```
!$OMP DISTRIBUTE [clause[, clause]...]  
   do-loop  
   !$OMP END DISTRIBUTE
```

clause Is one of the following:

- `COLLAPSE (n)`
- `DIST_SCHEDULE (kind [, chunk-size])`

Specifies how iterations are divided.

The `kind` must be `STATIC` (see `SCHEDULE` in DO Directive).

The `chunk-size` must be a positive scalar integer expression. If specified, iterations are divided into chunks of size `chunk-size`. Chunks are assigned round-robin to the teams of the parallel region in the order of the team numbers.

When no `chunk-size` is specified, iterations are divided into chunks that are approximately equal in size. In this case, at most one chunk is distributed to each team of the parallel region.

- `FIRSTPRIVATE (list)`
- `PRIVATE (list)`

do-loop Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

If an END DO directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The DISTRIBUTE construct inherits the restrictions of the loop construct.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If more than one loop is associated with the DISTRIBUTE construct, then the iteration s of all associated loops are collapsed into one larger iteration space. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

You cannot branch out of a DO loop associated with a DISTRIBUTE directive.
The binding thread set for a DISTRIBUTE construct is the set of master threads created by a TEAMS construct. A DISTRIBUTE region binds to the innermost enclosing team's parallel region. Only the threads that execute the binding team's parallel region participate in the execution of the loop iterations. A DISTRIBUTE construct must be closely nested in a team's region.

If used, the END DISTRIBUTE directive must appear immediately after the end of the loop. If you do not specify an END DISTRIBUTE directive, an END DISTRIBUTE directive is assumed at the end of the do-loop.

The DISTRIBUTE construct is associated with loop iterations that follow the directive. The iterations are distributed across the master threads of all teams that execute the team's parallel region to which the DISTRIBUTE region binds.

Parallel Processing Model for information about Binding Sets

DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

Syntax

```
!$OMP DISTRIBUTE PARALLEL DO [clause[[,] clause]... ]
        do-loop
[!$OMP END DISTRIBUTE PARALLEL DO]
```

clause

Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO directive is not specified, an END DISTRIBUTE PARALLEL DO directive is assumed at the end of do-loop.

See Also
OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
DISTRIBUTE PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.

Syntax

```fortran
$OMP DISTRIBUTE PARALLEL DO SIMD [clause[,] clause]...
```

do-loop

```fortran
$OMP END DISTRIBUTE PARALLEL DO SIMD
```

clause

Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO SIMD directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of do-loop.

See Also

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

DISTRIBUTE POINT

General Compiler Directive: Specifies loop distribution. It suggests a location at which a DO loop can be split.

Syntax

```fortran
!DIR$ DISTRIBUTE POINT
```

Loop distribution causes large loops to be distributed (split) into smaller ones. The resulting loops contain a subset of the instructions from the initial loop. Loop distribution can enable software pipelining to be applied to more loops. It can also reduce register pressure and improve both instruction and data cache use.

If the directive is placed before a loop, the compiler will determine where to distribute; data dependencies are observed.

If the directive is placed inside a loop, the distribution is performed after the directive and any loop-carried dependencies are ignored. Currently only one distribute directive is supported if the directive is placed inside the loop.

Example

```fortran
!DIR$ DISTRIBUTE POINT
  do i = 1, m
```
b(i) = a(i) + 1 
.....
c(i) = a(i) + b(i) ! Compiler will decide
! where to distribute.
! Data dependencies are
! observed
.....
d(i) = c(i) + 1 
enddo 
do i = 1, m 
b(i) = a(i) + 1 
.....
!DIR$ DISTRIBUTE POINT
  call sub(a, n)! Distribution will start here,
  ! ignoring all loop-carried
  ! dependencies
c(i) = a(i) + b(i) 
.....
d(i) = c(i) + 1 
enddo

Rules for General Directives that Affect DO Loops

DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.

Syntax

!$OMP DISTRIBUTE SIMD [clause[, clause]... ]
do-loop
![$OMP END DISTRIBUTE SIMD]

clause
Can be any of the clauses accepted by the DISTRIBUTE or SIMD directives with identical meanings and restrictions.

do-loop
Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE SIMD directive is not specified, an END DISTRIBUTE SIMD directive is assumed at the end of do-loop.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DLGEXIT (W*S)**

Dialog Subroutine: Closes an open dialog box.

**Module**

USE IFLOGM

**Syntax**

CALL DLGEXIT (dlg)

*dlg*  
(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

If you want to exit a dialog box on a condition other than the user selecting the OK or Cancel button, you need to include a call to DLGEXIT from within your callback routine. DLGEXIT saves the data associated with the dialog box controls and then closes the dialog box. The dialog box is exited after DLGEXIT has returned control back to the dialog manager, not immediately after the call to DLGEXIT.

**Example**

SUBROUTINE EXITSUB (dlg, exit_button_id, callbacktype)
USE IFLOGM
TYPE (DIALOG) dlg
INTEGER exit_button_id, callbacktype
...
CALL DLGEXIT (dlg)

**See Also**

DLGSETRETURN (W*S)  
DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)  
DLGMODAL, DLGMODALWITHPARENT (W*S)  
DLGMODELESS (W*S)  

**DLGFLUSH (W*S)**

Dialog Subroutine: Updates the display of a dialog box.

**Module**

USE IFLOGM

**Syntax**

CALL DLGFLUSH (dlg[, flushall])

*dlg*  
(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

*flushall*  
(Input; optional) Logical. If .FALSE. (the default), then only the controls that the dialog routines have marked as changed are updated. If .TRUE., all controls are updated with the state of the controls as known by the dialog routines. Normally, you would not set flushall to .TRUE..

When your application calls DLGSET to change a property of a control in a dialog box, the change is not immediately reflected in the displayed dialog box. Changes are applied when the dialog box is first displayed, and then after every dialog callback to the user’s code.
This design expects that, after a call to DLGMODAL or DLGMODELESS, every call to DLGSET will be made from within a callback routine, and that the callback routine finishes quickly. This is true most of the time.

However, there may be cases where you want to change a control outside of a dialog callback, or from within a loop in a dialog callback.

In these cases, DLGFLUSH is required, but is not always sufficient, to update the dialog display. DLGFLUSH sends pending Windows* system messages to the dialog box and the controls that it contains. However, many display changes do not appear until after the program reads and processes these messages. A loop that processes the pending messages may be required; for example:

```fortran
use IFWINTY
use USER32
use IFLOGM
logical lNotQuit, lret
integer iret
TYPE (T_MSG) mesg
lNotQuit = .TRUE.
do while (lNotQuit .AND. (PeekMessage(mesg, 0, 0, 0, PM_NOREMOVE) <> 0))
   lNotQuit = GetMessage(mesg, NULL, 0, 0)
   if (lNotQuit) then
      if (DLGISDLGMESSAGE(mesg) .EQV. .FALSE) then
         lret = TranslateMessage(mesg)
         iret = DispatchMessage(mesg)
      end if
   end if
end do
```

DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR (W*S)
DLGSETSUB (W*S)

**DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR (W*S)**

*Dialog Functions*: Return the state of the dialog control variable.

**Module**

USE IFLOGM

**Syntax**

```fortran
result = DLGGET (dlg, controlid, value[, index])
result = DLGGETINT (dlg, controlid, value[, index])
result = DLGGETLOG (dlg, controlid, value[, index])
result = DLGGETCHAR (dlg, controlid, value[, index])
```

**dlg**

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

**controlid**

(Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).
value  (Output) Integer, logical, or character. The value of the control's variable.

index  (Input; optional) Integer. Specifies the control variable whose value is retrieved. Necessary if the control has more than one variable of the same data type and you do not want to get the value of the default for that type.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGGET functions to retrieve the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variable associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see Additional Documentation: Creating Fortran Applications that Use Windows* OS Features.

You can use DLGGET to retrieve the value of any variable. You can also use DLGGETINT to retrieve an integer value, or DLGGETLOG and DLGGETCHAR to retrieve logical and character values, respectively. If you use DLGGET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to retrieve a variable type that is not available, the DLGGET functions return .FALSE..

If two or more controls have the same controlid, you cannot use these controls in a DLGGET operation. In this case the function returns .FALSE..

The dialog box does not need to be open to access its control variables.

Example
USE IFLOGM
INCLUDE "THISDLG.FD"
TYPE (DIALOG)  dlg
INTEGER        val
LOGICAL        retlog, is_checked
CHARACTER(256) text ...
retlog = DLGGET (dlg, IDC_CHECKBOX1, is_checked, dlg_status)
retlog = DLGGET (dlg, IDC_SCROLLBAR2, val, dlg_range)
retlog = DLGGET (dlg, IDC_STATIC_TEXT1, text, dlg_title)
...

DLGSETSUB (W*S)
DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
DLGMODAL, DLGMODALWITHPARENT (W*S)
DLGMODELESS (W*S)

DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
Dialog Functions: Initialize a dialog box.

Module
USE IFLOGM

Syntax
result = DLGINIT (id, dlg)
result = DLGINITWITHRESOURCEHANDLE (id, hinst, dlg)
id (Input) INTEGER(4). Dialog identifier. Can be either the symbolic name for the dialog or the identifier number, both listed in the Include file (with extension .FD).

dlg (Output) Derived type dialog. Contains dialog box parameters.

hinst (Input) INTEGER(HANDLE). Handle of the module instance in which the dialog resource can be found. INTEGER(HANDLE) is INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

DLGINIT must be called to initialize a dialog box before it can be used with DLGMODAL, DLGMODELESS, or any other dialog function.

DLGINIT will only search for the dialog box resource in the main application. For example, it will not find a dialog box resource that has been built into a dynamic link library.

DLGINITWITHRESOURCEHANDLE can be used when the dialog resource is not in the main application. If the dialog resource is in a dynamic link library (DLL), hinst must be the value passed as the first argument to the DLLMAIN procedure.

Dialogs can be used from any application, including console, QuickWin, and Windows* applications.

Example

USE IFLOGM
INCLUDE 'DLG1.FD'
LOGICAL retlog
type (DIALOG) thisdlg
...
retlog = DLGINIT (IDD_DLG3, thisdlg)
IF (.not. retlog) THEN
  WRITE (*,*), 'ERROR: dialog not found'
ELSE
  ...

DLGEXIT (W*S)
DLGMODAL, DLGMODALWITHPARENT (W*S)
DLGMODELESS (W*S)
DLGUNINIT (W*S)

DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG (W*S)

Dialog Functions: Determine whether the specified message is intended for one of the currently displayed modeless dialog boxes, or a specific dialog box.

Module
USE IFLOGM

Syntax
result = DLGISDLGMESSAGE (msg)
result = DLGISDLGMESSAGEWITHDLG (msg, dlg)

msg (Input) Derived type T_MSG. Contains a Windows message.
Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the message is processed by the dialog box. Otherwise, the result is .FALSE. and the message should be further processed.

`DLGISDLGMESSAGE` must be called in the message loop of Windows applications that display a modeless dialog box using `DLGMODELESS`. `DLGISDLGMESSAGE` determines whether the message is intended for one of the currently displayed modeless dialog boxes. If it is, it passes the message to the dialog box to be processed.

`DLGISDLGMESSAGEWITHDLG` specifies a particular dialog box to check. Use `DLGISDLGMESSAGEWITHDLG` when the message loop is in a main application and the currently active modeless dialog box was created by a DLL.

**Example**

```fortran
use IFLOGM
include 'resource.fd'
type (DIALOG) dlg
type (T_MSG) mesg
integer*4 ret
logical*4 lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) /= 0 )
! Note that DlgIsDlgMessage must be called in order to give
! the dialog box first chance at the message.
if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
  lret = TranslateMessage( mesg )
  ret  = DispatchMessage( mesg )
end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return
```

**See Also**

`DLGMODELESS (W*S)`

`DLGMODAL, DLGMODALWITHPARENT (W*S)`

**Dialog Functions:** Display a dialog box and process user control selections made within the box.

**Module**

USE IFLOGM

**Syntax**

```fortran
result = DLGMODAL (dlg)
```
result = DLGMODAL (dlg, hwndParent)

dlg

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

hwndParent

(Input) Integer. Specifies the parent window for the dialog box. If omitted, the value is determined in this order:

1. If DLGMODAL is called from the callback of a modal or modeless dialog box, then that dialog box is the parent window.
2. If it is a QuickWin or Standard Graphics application, then the frame window is the parent window.
3. The Windows* desktop window is the parent window.

Results

The result type is INTEGER(4). By default, if successful, it returns the identifier of the control that caused the dialog to exit; otherwise, it returns -1. The return value can be changed with the DLGSETRETURN subroutine.

During execution, DLGMODAL displays a dialog box and then waits for user control selections. When a control selection is made, the callback routine, if any, of the selected control (set with DLGSETSUB) is called. The dialog remains active until an exit control is executed: either the default exit associated with the OK and Cancel buttons, or DLGEXIT within your own control callbacks. DLGMODAL does not return a value until the dialog box is exited.

The default return value for DLGMODAL is the identifier of the control that caused it to exit (for example, IDOK for the OK button and IDCANCEL for the Cancel button). You can specify your own return value with DLGSETRETURN from within one of your dialog control callback routines. You should not specify -1 as your return value, because this is the error value DLGMODAL returns if it cannot open the dialog.

Use DLGMODALWITHPARENT when you want the parent window to be other than the default value (see argument hwndParent above). In particular, in an SDI or MDI Windows application, you may want the parent window to be the main application window. The parent window is disabled for user input while the modal dialog box is displayed.

Example

USE IFLOGM
INCLUDE "MYDLG.FD"
INTEGER return
TYPE (DIALOG) mydialog
...
return = DLGMODAL (mydialog)
...

See Also

DLGSETSUB (W*S)
DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
DLGEXIT (W*S)

DLGMODELESS (W*S)

*Dialog Function: Displays a modeless dialog box.*

Module

USE IFLOGM
Syntax

result = DLGMODELESS (dlg[, nCmdShow, hwndParent])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user. The variable passed to this function must remain in memory for the duration of the dialog box, that is from the DLGINIT call through the DLGUNINIT call.

The variable can be declared as global data in a module, as a variable with the STATIC attribute, or in a calling procedure that is active for the duration of the dialog box. It must not be an AUTOMATIC variable in the procedure that calls DLGMODELESS.

nCmdShow (Input) Integer. Specifies how the dialog box is to be shown. It must be one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the dialog box.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the dialog box.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
<tr>
<td>SW_SHOW</td>
<td>Activates the dialog box and displays it in its current size and position.</td>
</tr>
<tr>
<td>SW_SHOWMAXIMIZED</td>
<td>Activates the dialog box and displays it as a maximized window.</td>
</tr>
<tr>
<td>SW_SHOWMINIMIZED</td>
<td>Activates the dialog box and displays it as an icon.</td>
</tr>
<tr>
<td>SW_SHOWMINNOACTIVE</td>
<td>Displays the dialog box as an icon. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNA</td>
<td>Displays the dialog box in its current state. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNOACTIVATE</td>
<td>Displays the dialog box in its most recent size and position. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNORMAL</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
</tbody>
</table>

The default value is SW_SHOWNORMAL.
39

Intel® Fortran Compiler 16.0 User and Reference Guide

hwndParent

(Input) Integer. Specifies the parent window for the dialog box. The default
value is determined in this order:
1.
2.

If DLGMODELESS is called from a callback of a modeless dialog box,
then that dialog box is the parent window.
The Windows desktop window is the parent window.

Results
The result type is LOGICAL(4). The value is .TRUE. if the function successfully displays the dialog box.
Otherwise the result is .FALSE..
During execution, DLGMODELESS displays a modeless dialog box and returns control to the calling
application. The dialog box remains active until DLGEXIT is called, either explicitly or as the result of the
invocation of a default button callback.
DLGMODELESS is typically used in a Windows application. The application must contain a message loop that
processes Windows messages. The message loop must call DLGISDLGMESSAGE for each message. See the
example below in the Example section. Multiple modeless dialog boxes can be displayed at the same time. A
modal dialog box can be displayed from a modeless dialog box by calling DLGMODAL from a modeless dialog
callback. However, DLGMODELESS cannot be called from a modal dialog box callback.
DLGMODELESS also can be used in a Console, DLL, or LIB project. However, the requirements remain that
the application must contain a message loop and must call DLGISDLGMESSAGE for each message. For an
example of calling DLGMODELESS in a DLL project, see the Dllprgrs sample in the ...\SAMPLES
\DIALOGfolder.
Use the DLG_INIT callback with DLGSETSUB to perform processing immediately after the dialog box is
created and before it is displayed, and to perform processing immediately before the dialog box is destroyed.

Example
use IFLOGM
include 'resource.fd'
type (DIALOG) dlg
type (T_MSG)
mesg
integer*4 ret
logical*4 lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messsages
do while( GetMessage (mesg, NULL, 0, 0) )
! Note that DlgIsDlgMessage must be called in order to give
! the dialog box first chance at the message.
if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
lret = TranslateMessage( mesg )
ret = DispatchMessage( mesg )
end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return

DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
DLGEXIT (W*S)
DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG (W*S)

**DLGSENDCTRLMESSAGE (W*S)**

*Dialog Function:* Sends a Windows message to a dialog box control.

**Module**

USE IFLOGM

**Syntax**

```fortran
result = DLGSENDCTRLMESSAGE (dlg, controlid, msg, wparam, lparam)
```

- **dlg** *(Input)* Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

- **controlid** *(Input)* Integer. Specifies the identifier of the control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

- **msg** *(Input)* Integer. Derived type `T_MSG`. Specifies the message to be sent.

- **wparam** *(Input)* Integer. Specifies additional message specific information.

- **lparam** *(Input)* Integer. Specifies additional message specific information.

**Results**

The result type is INTEGER(4). The value specifies the result of the message processing and depends upon the message sent.

The dialog box must be currently active by a call to DLGMODAL or DLGMODELESS. This function does not return until the message has been processed by the control.

**Example**

```fortran
use IFLOGM
include 'resource.fd'
type (dialog)    dlg
integer          callbacktype
integer          cref
integer          iret
if (callbacktype == dlg_init) then
    ! Change the color of the Progress bar to red
    ! NOTE: The following message succeeds only if Internet Explorer 4.0
    ! or later is installed
    cref = Z'FF'   ! Red
    iret = DlgSendCtrlMessage(dlg, IDC_PROGRESS1, PBM_SETBARCOLOR, 0, cref)
endif
```

**See Also**

DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
DLGSETSUB (W*S)
DLGMODAL, DLGMODALWITHPARENT (W*S)
DLGMODELESS (W*S)
DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR (WS)

Dialog Functions: Set the values of dialog control variables.

Module

USE IFLOGM

Syntax

result = DLGSET (dlg, controlid, value[, index])
result = DLGSETINT (dlg, controlid, value[, index])
result = DLGSETLOG (dlg, controlid, value[, index])
result = DLGSETCHAR (dlg, controlid, value[, index])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid (Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

value (Input) Integer, logical, or character. The value of the control's variable.

index (Input; optional) Integer. Specifies the control variable whose value is set. Necessary if the control has more than one variable of the same data type and you do not want to set the value of the default for that type.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGSET functions to set the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variables associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see Additional Documentation: Creating Fortran Applications that Use Windows* OS Features.

You can use DLGSET to set any control variable. You can also use DLGSETINT to set an integer variable, or DLGSETLOG and DLGSETCHAR to set logical and character values, respectively. If you use DLGSET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to set a variable type that is not available, the DLGSET functions return .FALSE..

Calling DLGSET does not cause a callback routine to be called for the changing value of a control. In particular, when inside a callback, performing a DLGSET on a control does not cause the associated callback for that control to be called. Callbacks are invoked automatically only by user action on the controls in the dialog box. If the callback routine needs to be called, you can call it manually after the DLGSET is executed.

If two or more controls have the same controlid, you cannot use these controls in a DLGSET operation. In this case the function returns .FALSE..

Example

USE IFLOGM
INCLUDE "DLGRADAR.FD"
TYPE (DIALOG) dlg
LOGICAL retlog
...
retlog = DLGSET (dlg, IDC_SCROLLBAR1, 400, dlg_range)
retlog = DLGSET (dlg, IDC_CHECKBOX1, .FALSE., dlg_status)
retlog = DLGSET (dlg, IDC_RADIOBUTTON1, "Hot Button", dlg_title)

DLGSETSUB (W*S)
DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR (W*S)

DLGSETCTRLEVENTHANDLER (W*S)

Dialog Function: Assigns user-written event handlers to ActiveX controls in a dialog box.

Module
USE IFLOGM

Syntax
result = DLGSETCTRLEVENTHANDLER (dlg, controlid, handler, dispid[, iid])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid (Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file.

handler (Input) Name of the routine to be called when the event occurs. It must be declared EXTERNAL.

dispid (Input) Integer. Specifies the member id of the method in the event interface that identifies the event.

iid (Input; optional) Derived type GUID, which is defined in the IFWINTY module. Specifies the interface identifier of the source (event) interface. If omitted, the default source interface of the ActiveX control is used.

Results
The result type is INTEGER(4). The result is an HRESULT describing the status of the operation.

When the ActiveX control event occurs, the handler associated with the event is called. You call DLGSETCTRLEVENTHANDLER to specify the handler to be called.

The events supported by an ActiveX control and the interfaces of the handlers are determined by the ActiveX control.

You can find this information in one of the following ways:

- By reading the documentation of the ActiveX control.
- By using a tool that lets you examine the type information of the ActiveX control; such as the OLE-COM Object Viewer.
- By using the Fortran Module Wizard to generate a module that contains Fortran interfaces to the ActiveX control, and examining the generated module.

The handler that you define in your application must have the interface that the ActiveX control expects, including calling convention and parameter passing mechanisms. Otherwise, your application will likely crash in unexpected ways because of the application's stack getting corrupted.
Note that an object is always the first parameter in an event handler. This object value is a pointer to the control’s source (event) interface, not the IDispatch pointer of the control. You can use DLGGET with the DLG_IDDISPATCH index to retrieve the control’s IDispatch pointer.

Example

USE IFLOGM
ret = DlgSetCtrlEventHandler(             &
dlg,                         & ! Identifies the control
IDC_ACTIVEMOVIECONTROL1,     & ! Identifies the control
ReadyStateChange,            & ! Name of the event handling routine
-609,                        & ! Member id of the ActiveMovie's
& !   control ReadyStateChange event.
IID_DActiveMovieEvents2 )          & ! Identifier of the source (event) interface.

DLGMOELESS (W*S)
DLGSETSUB (W*S)

DLGSETRETURN (W*S)

Dialog Subroutine: Sets the return value for the DLGMODAL function from within a callback subroutine.

Module
USE IFLOGM

Syntax
CALL DLGSETRETURN (dlg, retval)

dlg                        (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

retval                    (Input) Integer. Specifies the return value for DLGMODAL upon exiting.

DLGSETRETURN overrides the default return value with retval. You can set your own value as a means of determining the condition under which the dialog box was closed. The default return value for an error condition is -1, so you should not use -1 as your return value.

DLGSETRETURN should be called from within a callback routine, and is generally used with DLGEXIT, which causes the dialog box to be exited from a control callback rather than the user selecting the OK or Cancel button.

Example

SUBROUTINE SETRETSUB (dlg, button_id, callbacktype)
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) dlg
LOGICAL     is_checked, retlog
INTEGER     return, button_id, callbacktype
...
retlog = DLGGET(dlg, IDC_CHECKBOX4, is_checked, dlg_state)
IF (is_checked) THEN
   return = 999
ELSE
    return = -999
END IF
CALL DLGSETRETURN (dlg, return)
CALL DLGEXIT (dlg)
END SUBROUTINE SETRETSUB

See Also
DLGEXIT (W*S)
DLGMODAL, DLGMODALWITHPARENT (W*S)

DLGSETSUB (W*S)
Dialog Function: Assigns your own callback subroutines to dialog controls and to the dialog box.

Module
USE IFLOGM

Syntax
result = DLGSETSUB (dlg, controlid, value[, index])

dlg
    (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid
    (Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file, or it can be the identifier of the dialog box.

value
    (Input) EXTERNAL. Name of the routine to be called when the callback event occurs.

index
    (Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

When a callback event occurs (for example, when you select a control), the callback routine associated with that callback event is called. You use DLGSETSUB to specify the subroutine to be called. All callback routines should have the following interface:

SUBROUTINE callbackname( dlg, control_id, callbacktype)

!DIR$ ATTRIBUTES DEFAULT :: callbackname

callbackname
    Is the name of the callback routine.

dlg
    Refers to the dialog box and allows the callback to change values of the dialog controls.

control_id
    Is the name of the control that caused the callback.
**callbacktype**

(Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

The *control_id* and *callbacktype* parameters let you write a single subroutine that can be used with multiple callbacks from more than one control. Typically, you do this for controls comprising a logical group. You can also associate more than one callback routine with the same control, but you must use then use *index* parameter to indicate which callback routine to use.

The *control_id* can also be the identifier of the dialog box. The dialog box supports two *callbacktypes*, DLG_INIT and DLG_SIZECHANGE. The DLG_INIT callback is executed immediately after the dialog box is created with *callbacktype* DLG_INIT, and immediately before the dialog box is destroyed with *callbacktype* DLG_DESTROY. DLG_SIZECHANGE is called when the size of a dialog is changed.

Callback routines for a control are called after the value of the control has been updated based on the user's action.

If two or more controls have the same *controlid*, you cannot use these controls in a DLGSETSUB operation. In this case, the function returns .FALSE..

**Example**

```
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (dialog) mydialog
LOGICAL retlog
INTEGER return
EXTERNAL RADIOSUB
retlog = DLGINIT(IDD_mydlg, mydialog)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON1, RADIOSUB)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON2, RADIOSUB)
return = DLGMODAL(mydialog)
END

SUBROUTINE RADIOSUB( dlg, id, callbacktype )
  !DIR$ ATTRIBUTES DEFAULT :: radiosub
  USE IFLOGM
  TYPE (dialog) dlg
  INTEGER id, callbacktype
  INCLUDE 'MYDLG.FD'
  CHARACTER(256) text
  LOGICAL retlog
  SELECT CASE (id)
    CASE (IDC_RADIO_BUTTON1)
      ! Radio button 1 selected by user so
      ! change text accordingly
      text = 'Statistics Package A'
      retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
    CASE (IDC_RADIO_BUTTON2)
      ! Radio button 2 selected by user so
      ! change text accordingly
      text = 'Statistics Package B'
      retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
  END SELECT
END SUBROUTINE RADIOSUB
```

DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR (W*S)
DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR (W*S)
DLGSETTITLE (W*S)

*Dialog Subroutine: Sets the title of a dialog box.*

**Module**

USE IFLOGM

**Syntax**

CALL DLGSETTITLE (dlg, title)

*dlg* 
(Input) Derived type *dialog*. Contains dialog box parameters. The components of the type *dialog* are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

*title* 
(Input) Character*(*). Specifies text to be the title of the dialog box.

Use this routine when you want to specify the title for a dialog box.

**Example**

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGSETTITLE(mydialog, "New Title")
...

**See Also**

DLGINIT, DLGINITWITHRESOURCEHANDLE (W*S)
DLGMODAL, DLGMODALWITHPARENT (W*S)
DLGMODELESS (W*S)

DLGUNINIT (W*S)

*Dialog Subroutine: Deallocates memory associated with an initialized dialog.*

**Module**

USE IFLOGM

**Syntax**

CALL DLGUNINIT (dlg)

*dlg* 
(Input) Derived type *dialog*. Contains dialog box parameters. The components of the type *dialog* are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

You should call DLGUNINIT when a dialog that was successfully initialized by DLGINIT is no longer needed. DLGUNINIT should only be called on a dialog initialized with DLGINIT. If it is called on an uninitialized dialog or one that has already been deallocated with DLGUNINIT, the result is undefined.

**Example**

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL          retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGUNINIT (mydialog)
END

DNUM

Elemental Intrinsic Function (Specific): Converts a character string to a REAL(8) value. This function cannot be passed as an actual argument.

Syntax
result = DNUM (i)

i             (Input) Must be of type character.

Results
The result type is REAL(8). The result value is the double-precision real value represented by the character string i.

Example
DNUM ("3.14159") has the value 3.14159 of type REAL(8).

The following sets x to 311.0:

CHARACTER(3) i
DOUBLE PRECISION x
i = "311"
x = DNUM(i)

DO Statement

Statement: Marks the beginning of a DO construct. The DO construct controls the repeated execution of a block of statements or constructs. This repeated execution is called a loop.

Syntax
A DO construct takes one of the following forms:

Block Form:
[name:] DO [label[, ] ] [loop-control]
    block
[label] term-stmt

Nonblock Form:
DO label [,] [loop-control]
    block
[label] ex-term-stmt
**name**  
(Optional) Is the name of the DO construct.

**label**  
(Optional) Is a statement label identifying the terminal statement.

**loop-control**  
Is one of the following:
- a loop iteration (see Iteration Loop Control)
- WHILE (see the DO WHILE statement)
- CONCURRENT (see the DO CONCURRENT statement)

**block**  
Is a sequence of zero or more statements or constructs that make up the DO range.

**term-stmt**  
Is the terminal statement for the block form of the construct.

**ex-term-stmt**  
Is the terminal statement for the nonblock form of the construct.

**Description**
The terminal statement (**term-stmt**) for a block DO construct is an END DO or CONTINUE statement. If the block DO statement contains a label, the terminal statement must be identified with the same label. If no label appears, the terminal statement must be an END DO statement.

If a construct name is specified in a block DO statement, the same name must appear in the terminal END DO statement. If no construct name is specified in the block DO statement, no name can appear in the terminal END DO statement.

The terminal statement (**ex-term-stmt**) for a nonblock DO construct is an executable statement (or construct) that is identified by the label specified in the nonblock DO statement. A nonblock DO construct can share a terminal statement with another nonblock DO construct. A block DO construct cannot share a terminal statement.

The following cannot be terminal statements for nonblock DO constructs:
- CONTINUE (allowed if it is a shared terminal statement)
- CYCLE
- END (for a program or subprogram)
- EXIT
- GO TO (unconditional or assigned)
- Arithmetic IF
- RETURN
- STOP

The nonblock DO construct is an obsolescent feature in Standard Fortran.

**Example**
The following example shows a simple block DO construct (contains no iteration count or DO WHILE statement):

```fortran
DO
    READ *, N
    IF (N == 0) STOP
    CALL SUBN
END DO
```

The DO block executes repeatedly until the value of zero is read. Then the DO construct terminates.
The following example shows a named block DO construct:

```
LOOP_1: DO I = 1, N
    A(I) = C * B(I)
END DO LOOP_1
```

The following example shows a nonblock DO construct with a shared terminal statement:

```
DO 20 I = 1, N
    DO 20 J = 1 + I, N
    20 RESULT(I,J) = 1.0 / REAL(I + J)
```

The following two program fragments are also examples of DO statements:

```
C   Initialize the even elements of a 20-element real array
C      DIMENSION array(20)
      DO j = 2, 20, 2
          array(j) = 12.0
      END DO
C
C   Perform a function 11 times
C      DO k = -30, -60, -3
          int = j / 3
          isb = -9 - k
          array(isb) = MyFunc(int)
      END DO
```

The following shows the final value of a DO variable (in this case 11):

```
DO j = 1, 10
    WRITE (*, '(I5)') j
END DO
WRITE (*, '(I5)') j
```

Execution Control Overview

**DO Directive**

**OpenMP* Fortran Compiler Directive:** Specifies that the iterations of the immediately following DO loop must be executed in parallel.

**Syntax**

```
!$OMP DO [clause[, ] clause] ... ]
    do_loop
[!$OMP END DO [NOWAIT]]
```

clause Is one of the following:
- COLLAPSE (n)
- FIRSTPRIVATE (list)
- LASTPRIVATE (list)
- ORDERED
Must be used if ordered sections are contained in the dynamic extent of
the DO directive. For more information about ordered sections, see the
ORDERED directive.

- PRIVATE (list)
- REDUCTION (operator | intrinsic : list)
- SCHEDULE (type[, chunk])

Specifies how iterations of the DO loop are divided among the threads of
the team. chunk must be a positive scalar integer expression. The
following four types are permitted, three of which allow the optional
parameter chunk:

<table>
<thead>
<tr>
<th>Type</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Divides iterations into contiguous pieces by dividing the number of</td>
</tr>
<tr>
<td></td>
<td>iterations by the number of threads in the team. Each piece is then</td>
</tr>
<tr>
<td></td>
<td>dispatched to a thread before loop execution begins.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, iterations are divided into pieces of a size</td>
</tr>
<tr>
<td></td>
<td>specified by chunk. The pieces are statically dispatched to threads</td>
</tr>
<tr>
<td></td>
<td>in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>Can be used to get a set of iterations dynamically. It defaults to 1</td>
</tr>
<tr>
<td></td>
<td>unless chunk is specified.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, the iterations are broken into pieces of a size</td>
</tr>
<tr>
<td></td>
<td>specified by chunk. As each thread finishes a piece of the iteration</td>
</tr>
<tr>
<td></td>
<td>space, it dynamically gets the next set of iterations.</td>
</tr>
<tr>
<td>GUIDED</td>
<td>Can be used to specify a minimum number of iterations. It defaults to 1</td>
</tr>
<tr>
<td></td>
<td>unless chunk is specified.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, the chunk size is reduced exponentially with</td>
</tr>
<tr>
<td></td>
<td>each succeeding dispatch. The chunk specifies the minimum number of</td>
</tr>
<tr>
<td></td>
<td>iterations to dispatch each time. If there are less than chunk</td>
</tr>
<tr>
<td></td>
<td>iterations remaining, the rest are dispatched.</td>
</tr>
<tr>
<td>AUTO(^1)</td>
<td>Delegates the scheduling decision until compile time or run time.</td>
</tr>
<tr>
<td></td>
<td>The schedule is processor</td>
</tr>
</tbody>
</table>
**Type** | **Effect**
---|---
| dependent. The programmer gives the implementation the freedom to choose any possible mapping of iterations to threads in the team. | RUNTIME

Defers the scheduling decision until run time. You can choose a schedule type and chunk size at run time by using the environment variable OMP_SCHEDULE.

1No chunk is permitted for this type.

If the SCHEDULE clause is not used, the default schedule type is STATIC.

**do_loop**

Is a DO iteration (an iterative DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO directive.

The binding thread set for a DO construct is the current team. A DO loop region binds to the innermost enclosing parallel region.

If used, the END DO directive must appear immediately after the end of the loop. If you do not specify an END DO directive, an END DO directive is assumed at the end of the DO loop.

If you specify NOWAIT in the END DO directive, threads do not synchronize at the end of the parallel loop. Threads that finish early proceed straight to the instruction following the loop without waiting for the other members of the team to finish the DO directive.

Parallel DO loop control variables are block-level entities within the DO loop. If the loop control variable also appears in the LASTPRIVATE list of the parallel DO, it is copied out to a variable of the same name in the enclosing PARALLEL region. The variable in the enclosing PARALLEL region must be SHARED if it is specified in the LASTPRIVATE list of a DO directive.

Only a single SCHEDULE, COLLAPSE, or ORDERED clause can appear in a DO directive.

DO directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

**Example**

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END DO directive is optional:

```
!$OMP PARALLEL
!$OMP DO
   DO I=1,N
      B(I) = (A(I) + A(I-1)) / 2.0
   END DO
!$OMP END DO
!$OMP END PARALLEL
```
If there are multiple independent loops within a parallel region, you can use the NOWAIT option to avoid the implied BARRIER at the end of the DO directive, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO
DO I=2,N
   B(I) = (A(I) + A(I-1)) / 2.0
END DO
!$OMP END DO NOWAIT
!$OMP DO
DO I=1,M
   Y(I) = SQRT(Z(I))
END DO
!$OMP END DO NOWAIT
!$OMP END PARALLEL
```

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. Such programs must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO LASTPRIVATE(I)
DO I=1,N
   A(I) = B(I) + C(I)
END DO
!$OMP END PARALLEL
CALL REVERSE(I)
```

In this case, the value of I at the end of the parallel region equals N+1, as in the sequential case.

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
END DO
... 
SUBROUTINE WORK(K)
!$OMP ORDERED
   WRITE(*,*) K
!$OMP END ORDERED
```

In the next example, the loops over J1 and J2 are collapsed and their iteration space is executed by all threads of the current team:

```fortran
!$OMP DO COLLAPSE(2) PRIVATE(J1, J2, J3)
DO J1 = J1_L, J1_U, J1_S
   DO J2 = J2_L, J2_U, J2_S
      DO J3 = J3_L, J3_U, J3_S
         CALL BAR(A, J1, J2, J3)
      ENDDO
   ENDDO
ENO.DO
!$OMP END DO
```

DO CONCURRENT

**Statement:** Specifies that there are no data dependencies between the iterations of a DO loop. It takes the following form:

**Syntax**

```
[name:] DO[, ] CONCURRENT forall-header
   block
[END DO [name]]
```

- **name** (Optional) Is the name of the DO CONCURRENT construct.
- **forall-header**
  - Is ( [ type :: ] forall-spec [, mask-expr ] )
- **type** (Optional) Is an integer data type.
- **forall-spec** Is an assignment using a triplet specification in the form `index-name = forall-limit : forall-limit [ : forall-step]`
- **index-name** Is a named scalar variable of type integer. It becomes defined when the index-name value set is evaluated. It has the scope of the construct.
- **forall-limit** Is a scalar integer expression.
- **forall-step** (Optional) Is a scalar integer expression.
- **mask-expr** (Optional) Is a mask expression that is scalar and of type logical.
- **block** Is a sequence of zero or more statements or constructs that make up the DO range.

If a construct name is specified in a DO CONCURRENT statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO CONCURRENT statement, no name can appear in the terminal END DO statement, if one is specified.

The DO CONCURRENT range is executed for every active combination of the `index-name` values.

Each execution of the range is an iteration. The executions can occur in any order.

If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive.

When the DO CONCURRENT construct terminates, a variable that is defined or becomes undefined during more than one iteration of the construct becomes undefined.

Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

A branch within a DO CONCURRENT construct must not have a branch target that is outside the construct.

If **type** appears, the `index-name` has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If **type** does not appear, the `index-name` must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.

The `index-name` of a contained FORALL or DO CONCURRENT construct must not be the same as an `index-name` of any of its containing FORALL or DO CONCURRENT constructs.
The following cannot appear in a DO CONCURRENT construct:

- A RETURN statement
- An image control statement
- A reference to a nonpure procedure
- A reference to module IEEE_EXCEPTIONS procedure IEEE_GET_FLAG, IEEE_SET_HALTING_MODE, or IEEE_GET_HALTING_MODE

An EXIT statement must not appear within a DO CONCURRENT construct if it belongs to that construct or an outer construct.

The following are additional rules for DO CONCURRENT constructs:

- A variable that is referenced in an iteration must be previously defined during that iteration, or it must not be defined or become undefined during any other iteration.
  
  A variable that is defined or becomes undefined by more than one iteration becomes undefined when the loop terminates.
- An allocatable object that is allocated in more than one iteration must be subsequently deallocated during the same iteration in which it was allocated.
  
  An object that is allocated or deallocated in only one iteration must not be referenced, allocated, deallocated, defined, or become undefined in a different iteration.
- A pointer that is referenced in an iteration must have been pointer associated previously during that iteration, or it must not have its pointer association changed during any iteration.
  
  A pointer that has its pointer association changed in more than one iteration has an association status of undefined when the construct terminates.
- An input/output statement must not write data to a file record or position in one iteration and read from the same record or position in a different iteration.
- Records written by output statements in the range of the loop to a sequential-access file appear in the file in an indeterminate order.

The restrictions on referencing variables defined in an iteration of a DO CONCURRENT construct also apply to any procedure invoked within the loop.

These restrictions ensure no interdependencies occur that might affect code optimizations.

Note that if compiler option -parallel (Linux* OS and OS X*) or /Qparallel (Windows* OS) is specified, the compiler will attempt to parallelize the construct.

**Example**

The following shows a DO CONCURRENT construct:

```fortran
REAL :: Q
DO CONCURRENT (I = 1:N)
  Q = B(I) + C(I)
  D(I) = Q + SIN(Q) + 2
END DO
```

**DO SIMD**

*OpenMP* Fortran Compiler Directive: Specifies a loop that can be executed concurrently using SIMD instructions.

**Syntax**

```
!$OMP DO SIMD [clause[, clause] ... ]
  do-loop
  [!$OMP END DO SIMD[NOWAIT]]
```
Can be any of the clauses accepted by the **DO** or **SIMD** directives.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END DO SIMD directive is not specified, an END DO SIMD directive is assumed at the end of *do-loop*. You can specify the NOWAIT clause to avoid the implied barrier at the end of a loop construct.

The DO SIMD construct converts the associated DO loop to a SIMD loop in a way that is consistent with any clauses that apply to the SIMD construct. The resulting SIMD chunks and any remaining iterations will be distributed across the implicit tasks of the parallel region in a way that is consistent with any clauses that apply to the DO construct.

**See Also**

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DO WHILE**

*Statement:* Executes the range of a DO construct while a specified condition remains true.

**Syntax**

```
[name:] DO [label[, ]] WHILE (expr)
   block
[END DO [name]]
```

*name* (Optional) Is the name of the DO WHILE construct.

*label* (Optional) Is a label specifying an executable statement in the same program unit.

*expr* Is a scalar logical (test) expression enclosed in parentheses.

*block* Is a sequence of zero or more statements or constructs that make up the DO range.

**Description**

If a construct name is specified in a DO WHILE statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO WHILE statement, no name can appear in the terminal END DO statement, if one is specified.

Before each execution of the DO range, the logical expression is evaluated. If it is true, the statements in the body of the loop are executed. If it is false, the DO construct terminates and control transfers to the statement following the loop.
If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive.

If no label appears in a DO WHILE statement, the DO WHILE loop must be terminated with an END DO statement.

You can transfer control out of a DO WHILE loop but not into a loop from elsewhere in the program.

**Example**

The following example shows a DO WHILE statement:

```plaintext
CHARACTER*132 LINE
...
I = 1
DO WHILE (LINE(I:I) .EQ. ' ')
   I = I + 1
END DO
```

The following examples show required and optional END DO statements:

<table>
<thead>
<tr>
<th>Required</th>
<th>Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO WHILE (I .GT. J)</td>
<td>DO 10 WHILE (I .GT. J)</td>
</tr>
<tr>
<td>ARRAY(I,J) = 1.0</td>
<td>ARRAY(I,J) = 1.0</td>
</tr>
<tr>
<td>I = I - 1</td>
<td>I = I - 1</td>
</tr>
<tr>
<td>END DO</td>
<td>10 END DO</td>
</tr>
</tbody>
</table>

The following shows another example:

```plaintext
CHARACTER(1) input
input = ' '  
DO WHILE ((input .NE. 'n') .AND. (input .NE. 'y'))
   WRITE (*, '(A)') 'Enter y or n: '
   READ (*, '(A)') input
END DO
```

Execution Control Overview

**DOT_PRODUCT**

**Transformational Intrinsic Function (Generic):**
Performs dot-product multiplication of numeric or logical vectors (rank-one arrays).

**Syntax**

result = DOT_PRODUCT (vector_a, vector_b)

vector_a (Input) Must be a rank-one array of numeric (integer, real, or complex) or logical type.

vector_b (Input) Must be a rank-one array of numeric type if vector_a is of numeric type, or of logical type if vector_a is of logical type. It must be the same size as vector_a.

**Results**

The result is a scalar whose type depends on the types of vector_a and vector_b.

If vector_a is of type integer or real, the result value is SUM ( vector_a* vector_b ).
If \( \text{vector}_a \) is of type complex, the result value is \( \text{SUM} \left( \text{CONJG} \left( \text{vector}_a \right) \times \text{vector}_b \right) \).

If \( \text{vector}_a \) is of type logical, the result has the value \( \text{ANY} \left( \text{vector}_a \land \text{vector}_b \right) \).

If either rank-one array has size zero, the result is zero if the array is of numeric type, and false if the array is of logical type.

**Example**

\[
\text{DOT\_PRODUCT} \left( (1, 2, 3) /, (3, 4, 5) / \right) \text{ has the value } 26, \text{ calculated as follows:}
\]

\[
(1 \times 3) + (2 \times 4) + (3 \times 5) = 26
\]

\[
\text{DOT\_PRODUCT} \left( (1.0, 2.0), (2.0, 3.0) /, (1.0, 1.0), (1.0, 4.0) / \right) \text{ has the value } (17.0, 4.0).
\]

\[
\text{DOT\_PRODUCT} \left( (.\text{TRUE}., .\text{FALSE}. /), (.\text{FALSE}., .\text{TRUE}. /) \right) \text{ has the value false.}
\]

The following shows another example:

\[
\text{I} = \text{DOT\_PRODUCT}\{ (1,2,3), (4,5,6) \} \text{ ! returns}
\]

\[
! \text{ the value } 32
\]

**See Also**

PRODUCT
MATMUL
TRANSPOSE

**DOUBLE COMPLEX**

*Statement:* Specifies the DOUBLE COMPLEX data type.

**Syntax**

\[
\text{DOUBLE COMPLEX}
\]

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(KIND=8) or DOUBLE COMPLEX constants. (For more information, see REAL and DOUBLE PRECISION.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* T\text{\_floating} format.

**Example**

\[
\text{DOUBLE COMPLEX} \text{ vector, arrays(7,29)}
\]

\[
\text{DOUBLE COMPLEX} \text{ pi, pi2 /3.141592654, 6.283185308/}
\]

**Valid COMPLEX(8) or DOUBLE COMPLEX constants**

\[
(547.3\text{E}_0, 1.44 \_8)
\]

\[
(1.7039\text{E}0, -1.7039\text{D}0)
\]

\[
(+12739\text{D}3, 0.\text{D}0)
\]

**Invalid COMPLEX(8) or DOUBLE COMPLEX constants**

\[
(1.23\text{D}0,)
\]

Second constant missing.
Hollerith constants not allowed.

Neither constant is DOUBLE PRECISION; this is a valid single-precision real constant.

See Also
General Rules for Complex Constants
DOUBLE PRECISION
Complex Data Types
DOUBLE PRECISION
REAL Statement

DOUBLE PRECISION

Statement: Specifies the DOUBLE PRECISION data type.

Syntax
DOUBLE PRECISION

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE* T_floating format is used.

For more information, see General Rules for Real Constants.

Example
DOUBLE PRECISION varnam
DOUBLE PRECISION,PRIVATE :: zz

Valid REAL(8) or DOUBLE PRECISION constants

123456789D+5
123456789E+5_8
+2.7843D00
-.522D-12
2E200_8
2.3_8
3.4E7_8

Invalid REAL(8) or DOUBLE PRECISION constants

-.25D0_2 2 is not a valid kind type for reals.
+2.7182812846182 No D exponent designator is present; this is a valid single-precision constant.
123456789.D400 Too large for any double-precision format.
123456789.D-400 Too small for any double-precision format.
DPROD

*Elemental Intrinsic Function (Specific): Produces a higher precision product. This is a specific function that has no generic function associated with it.*

**Syntax**

```fortran
result = DPROD (x, y)
```

- `x` *(Input)* Must be of type REAL(4) or REAL(8).
- `y` *(Input)* Must have the same type and kind parameters as `x`.

**Results**

If `x` and `y` are of type REAL(4), the result type is double-precision real (REAL(8) or REAL*8). If `x` and `y` are of type REAL(8), the result type is REAL(16). The result value is equal to `x` * `y`.

The setting of compiler options specifying real size can affect this function.

**Example**

- DPROD (2.0, -4.0) has the value -8.00D0.
- DPROD (5.0D0, 3.0D0) has the value 15.00Q0.

The following shows another example:

```fortran
REAL(4) e
REAL(8) d

e = 123456.7
d = 123456.7D0

! DPROD (e,e) returns 15241557546.4944
! DPROD (d,d) returns 15241556774.8899992813874268904328
```

DRAND, DRANDM

*Portability Functions: Return double-precision random numbers in the range 0.0 to 1.0, not including the end points.*

**Module**

```fortran
USE IFPORT
```

**Syntax**

```fortran
result = DRAND (iflag)
result = DRANDM (iflag)
```

- `iflag` *(Input)* INTEGER(4). Controls the way the random number is selected.

**Results**

The result type is REAL(8). DRAND and DRANDM return random numbers in the range 0.0 to 1.0, not including the end points.
<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, then restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.

The intrinsic functions RANDOM_NUMBER and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

**Example**

```fortran
USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
CALL print_rand
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,':',num
  END SUBROUTINE
END
```

**See Also**

RANDOM_NUMBER
RANDOM_SEED

**DRANSET**

*Portability Subroutine:* Sets the seed for the random number generator.

**Module**

USE IFPORT

**Syntax**

```fortran
CALL DRANSET (seed)
```

*seed* (Input) REAL(8). The reset value for the seed.

**See Also**

RANGET
**DREAL**

*Elemental Intrinsic Function (Specific):* Converts the real part of a double complex argument to double-precision type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{DREAL} (a)
\]

*a*  
(Input) Must be of type double complex (COMPLEX(8) or COMPLEX*16).

**Results**

The result type is double precision real (REAL(8) or REAL*8).

**Example**

DREAL ((2.0d0, 3.0d0)) has the value 2.0d0.

**See Also**

REAL Function

**DSHIFTL**

*Elemental Intrinsic Function (Specific):* Selects the left 64 bits after shifting a 128-bit integer value to the left. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{DSHIFTL} (\text{ileft}, \text{iright}, \text{ishift})
\]

*ileft*  
(Input) INTEGER(8).

*iright*  
(Input) INTEGER(8).

*ishift*  
(Input) INTEGER(8). Must be nonnegative and less than or equal to 64. This is the shift count.

**Results**

The result type is INTEGER(8). The result value is the 64-bit value starting at bit \(128 - \text{ishift}\) of the 128-bit concatenation of the values of *ileft* and *iright*.

**Example**

Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /  
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /  
PRINT *, DSHIFTL (ILEFT, IRIGHT, 16_8) ! prints 1306643199093243919
```

**DSHIFTR**

*Elemental Intrinsic Function (Specific):* Selects the left 64 bits after shifting a 128-bit integer value to the right. This function cannot be passed as an actual argument.
Syntax
result = DSHIFTR (ileft, iright, ishift)

ileft (Input) INTEGER(8).
iright (Input) INTEGER(8).
isshift (Input) INTEGER(8). Must be nonnegative and less than or equal to 64. This is the shift count.

Results
The result type is INTEGER(8). The result value is the 64-bit value starting at bit 64 + ishift of the 128-bit concatenation of the values of ileft and iright.

Example
Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /
PRINT *, DSHIFTR (ILEFT, IRIGHT, 16_8)  ! prints 1306606910610341887
```

DTIME
**Portability Function:** Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.

Module
USE IFPORT

Syntax
result = DTIME (tarray)

tarray (Output) REAL(4). A rank one array with two elements:

- `tarray(1)` - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
- `tarray(2)` - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

Results
The result type is REAL(4). The result is the total CPU time, which is the sum of `tarray(1)` and `tarray(2)`. If an error occurs, -1 is returned.

Example
```
USE IFPORT
REAL(4) I, TA(2)
I = DTIME(TA)
WRITE(*,*) 'Program has been running for', I, 'seconds.'
WRITE(*,*) ' This includes', TA(1), 'seconds of user time and', &
& 'TA(2), 'seconds of system time.'
```

DATE_AND_TIME
CPU_TIME
ELEMENTAL

Keyword: Asserts that a user-defined procedure is defined on scalar arguments that may be called with array arguments. An elemental procedure may be a pure procedure or an impure procedure.

Description
To specify an elemental procedure, use this keyword in a FUNCTION or SUBROUTINE statement.

An explicit interface must be visible to the caller of an ELEMENTAL procedure.

An elemental procedure can be passed an array, which is acted upon one element at a time.

For functions, the result must be scalar; it cannot have the POINTER or ALLOCATABLE attribute.

Dummy arguments have the following restrictions:

- They must be scalar.
- They cannot have the POINTER or ALLOCATABLE attribute.
- They (or their subobjects) cannot appear in a specification expression except as an argument to one of the intrinsic functions BIT_SIZE, LEN, KIND, or the numeric inquiry functions.
- They cannot be *.
- They cannot be dummy procedures.

If the actual arguments are all scalar, the result is scalar. If the actual arguments are array valued, the values of the elements (if any) of the result are the same as if the function or subroutine had been applied separately, in any order, to corresponding elements of each array actual argument.

Elemental procedures are pure procedures and all rules that apply to pure procedures also apply to elemental procedures, unless you specify that the elemental procedure is IMPURE. In that case, the rules for pure procedures do not apply.

Example
Consider the following:

```
MIN (A, 0, B) ! A and B are arrays of shape (S, T)
```

In this case, the elemental reference to the MIN intrinsic function is an array expression whose elements have the following values:

```
MIN (A(I,J), 0, B(I,J)), I = 1, 2, ..., S, J = 1, 2, ..., T
```

FUNCTION
SUBROUTINE
Procedures that Require Explicit Interfaces
Optional Arguments

ELLIPSE, ELLIPSE_W (W*S)

Graphics Functions: Draw a circle or an ellipse using the current graphics color.

Module
USE IFQWIN
Syntax

result = ELLIPSE (control, x1, y1, x2, y2)
result = ELLIPSE_W (control, wx1, wy1, wx2, wy2)

control  (Input) INTEGER(2). Fill flag. Can be one of the following symbolic constants:
  • $GFILLINTERIOR - Fills the figure using the current color and fill mask.
  • $GBORDER - Does not fill the figure.

x1, y1   (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2   (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the ellipse is clipped or partially out of bounds, the ellipse is considered successfully drawn, and the return is 1. If the ellipse is drawn completely out of bounds, the return is 0.

The border is drawn in the current color and line style.

When you use ELLIPSE, the center of the ellipse is the center of the bounding rectangle defined by the viewport-coordinate points (x1, y1) and (x2, y2). When you use ELLIPSE_W, the center of the ellipse is the center of the bounding rectangle defined by the window-coordinate points (wx1, wy1) and (wx2, wy2). If the bounding-rectangle arguments define a point or a vertical or horizontal line, no figure is drawn.

The control option given by $GFILLINTERIOR is equivalent to a subsequent call to the FLOODFILLRGB function using the center of the ellipse as the start point and the current color (set by SETCOLORRGB) as the boundary color.

NOTE
The ELLIPSE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Ellipse routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Ellipse.

Example

The following program draws the shape shown below.

! compile as QuickWin or Standard Graphics application
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80;  y1 = 50
x2 = 240; y2 = 150
dummy = ELLIPSE( $GFILLINTERIOR, x1, y1, x2, y2 )
END

ELSE Statement
Statement: Marks an optional branch in an IF Construct.

See Also
See IF Construct.

ELSE Directive
Statement: Marks an optional branch in an IF Directive Construct.

See Also
See IF Directive Construct.

ELSEIF Directive
Statement: Marks an optional branch in an IF Directive Construct.

See Also
See IF Directive Construct.

ELSE IF
Statement: Marks an optional branch in an IF Construct.

See Also
See IF Construct.

ELSE WHERE
Statement: Marks the beginning of an ELSE WHERE block within a WHERE construct.

Syntax
[name:]WHERE (mask-expr1)
WHERE (mask-expr2) [name]  
  [where-body-stmt]...
[ELSE WHERE(mask-expr2) [name]  
  [where-body-stmt]...
[ELSE WHERE[name]  
  [where-body-stmt]...
END WHERE [name]

name  
  Is the name of the WHERE construct.

mask-expr1, mask-expr2  
  Are logical array expressions (called mask expressions).

where-body-stmt  
  Is one of the following:
  • An assignment statement of the form: array variable = array expression.
  
  The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
  • A WHERE statement or construct

Description

Every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with "NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

Example

WHERE (pressure <= 1.0)  
  pressure = pressure + inc_pressure  
  temp = temp - 5.0  
ELSEWHERE  
  raining = .TRUE.  
END WHERE

The variables temp, pressure, and raining are all arrays.

See Also

WHERE

ENCODE

Statement: Translates data from internal (binary) form to character form. It is comparable to using internal files in formatted sequential WRITE statements.

Syntax

ENCODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]

c  
  Is a scalar integer expression. It is the number of characters to be translated to internal form.

f  
  Is a format identifier. An error occurs if more than one record is specified.

b  
  Is a scalar or array reference. If b is an array reference, its elements are processed in the order of subscript progression.
The number of characters that the ENCODE statement can translate depends on the data type of \( b \). For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

Example

Consider the following:

```plaintext
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
   ENCODE(12,100,B) K(3), K(2), K(1)
```

The DECODE statement stores the 12 characters into array K:

\[
\begin{align*}
K(1) &= 1234 \\
K(2) &= 5678 \\
K(3) &= 9012
\end{align*}
\]

The ENCODE statement translates the values K(3), K(2), and K(1) to character form and stores the characters in the character variable B.:  

\[
B = '901256781234'
\]

READ Statement
WRITE Statement
DECODE

END Statement: Marks the end of a program unit. It takes one of the following forms:

Syntax

```
END [PROGRAM [program-name]]
END [FUNCTION [function-name]]
END [SUBROUTINE [subroutine-name]]
```
In main programs, function subprograms, and subroutine subprograms, END statements are executable and can be branch target statements. If control reaches the END statement in these program units, the following occurs:

- In a main program, execution of the program terminates.
- In a function or subroutine subprogram, a RETURN statement is implicitly executed.

The END statement cannot be continued in a program unit, and no other statement in the program unit can have an initial line that appears to be the program unit END statement.

The END statements in a module or block data program unit are nonexecutable.

Example

C An END statement must be the last statement in a program unit:
C
PROGRAM MyProg
 WRITE (*, '("Hello, world!")')
 END
C
C An example of a named subroutine
C
SUBROUTINE EXT1 (X,Y,Z)
   Real, Dimension (100,100) :: X, Y, Z
 END SUBROUTINE EXT1

Program Units and Procedures Overview
Branch Statements Overview

END DO
Statement: Marks the end of a DO or DO WHILE loop.

Syntax
END DO

Description
There must be a matching END DO statement for every DO or DO WHILE statement that does not contain a label reference.

An END DO statement can terminate only one DO or DO WHILE statement. If you name the DO or DO WHILE statement, the END DO statement can specify the same name.

Example
The following examples both produce the same output:

DO ivar = 1, 10
   PRINT ivar
END DO
ivar = 0
do2: DO WHILE (ivar .LT. 10)
   ivar = ivar + 1
   PRINT ivar
END DO do2
See Also
DO Statement
DO WHILE
CONTINUE

ENDIF Directive

Statement: Marks the end of an IF Directive Construct.

See Also
See IF Directive Construct.

END IF

Statement: Marks the end of an IF Construct.

See Also
See IF Construct.

ENDFILE

Statement: For sequential files, writes an end-of-file record to the file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

Syntax
It can have either of the following forms:

ENDFILE ([UNIT=} io-unit] [, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])
ENDFILE io-unit

io-unit
  (Input) Is an external unit specifier.

label
  Is the label of the branch target statement that receives control if an error occurs.

msg-var
  (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var
  (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description
If the unit specified in the ENDFILE statement is not open, the default file is opened for unformatted output.

An end-of-file record can be written only to files with sequential organization that are accessed as formatted-sequential or unformatted-segmented sequential files. An ENDFILE performed on a direct access file always truncates the file.

End-of-file records should not be written in files that are read by programs written in a language other than Fortran.

NOTE
If you use compiler option vms and an ENDFILE is performed on a sequential unit, an actual one byte record containing a CTRL+Z is written to the file. If this option is not specified, an internal ENDFILE flag is set and the file is truncated. The option does not affect ENDFILE on relative files; such files are truncated.
If a parameter of the ENDFILE statement is an expression that calls a function, that function must not cause an I/O statement or the EOF intrinsic function to be executed, because unpredictable results can occur.

**Example**

The following statement writes an end-of-file record to I/O unit 2:

```
ENDFILE 2
```

Suppose the following statement is specified:

```
ENDFILE (UNIT=9, IOSTAT=IOS, ERR=10)
```

An end-of-file record is written to the file connected to unit 9. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable `IOS`.

The following shows another example:

```
WRITE (6, *) x
ENDFILE 6
REWIND 6
READ (6, *) y
```

**See Also**

REWIND
Data Transfer I/O Statements Overview
Branch Specifiers (END=, EOR=, ERR=)

**END FORALL**

**Statement:** Marks the end of a FORALL construct.

**See Also**
See FORALL.

**END INTERFACE**

**Statement:** Marks the end of an INTERFACE block.

**See Also**
See INTERFACE.

**END TYPE**

**Statement:** Specifies the end of a derived type TYPE statement.

**See Also**
See TYPE Statement (Derived Types).

**END WHERE**

**Statement:** Marks the end of a WHERE construct.

**Example**

```
WHERE (pressure <= 1.0)
   pressure = pressure + inc_pressure
   temp = temp - 5.0
ELSEWHERE
   raining = .TRUE.
END WHERE
```

Note that the variables `temp`, `pressure`, and `raining` are all arrays.
See Also
See WHERE.

ENTRY

**Statement:** Provides one or more entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram.

**Syntax**

ENTRY name[ ( [d-arg[,d-arg]]... ) ] [RESULT (r-name)]

- **name** Is the name of an entry point. If RESULT is specified, this entry name must not appear in any specification statement in the scoping unit of the function subprogram.
- **d-arg** (Optional) Is a dummy argument. The dummy argument can be an alternate return indicator (*) if the ENTRY statement is within a subroutine subprogram.
- **r-name** (Optional) Is the name of a function result. This name must not be the same as the name of the entry point, or the name of any other function or function result. This parameter can only be specified for function subprograms.

**Description**

ENTRY statements can only appear in external procedures or module procedures.

An ENTRY statement must not appear in a CASE, DO, IF, FORALL, or WHERE construct, or a nonblock DO loop.

When the ENTRY statement appears in a subroutine subprogram, it is referenced by a CALL statement. When the ENTRY statement appears in a function subprogram, it is referenced by a function reference.

An entry name within a function subprogram can appear in a type declaration statement.

Within the subprogram containing the ENTRY statement, the entry name must not appear as a dummy argument in the FUNCTION or SUBROUTINE statement, and it must not appear in an EXTERNAL or INTRINSIC statement. For example, neither of the following are valid:

1. SUBROUTINE SUB(E)
   
   ENTRY E
   
   ...

2. SUBROUTINE SUB
   
   EXTERNAL E
   
   ENTRY E
   
   ...

The procedure defined by an ENTRY statement can reference itself if the function or subroutine was defined as RECURSIVE.

Dummy arguments can be used in ENTRY statements even if they differ in order, number, type and kind parameters, and name from the dummy arguments used in the FUNCTION, SUBROUTINE, and other ENTRY statements in the same subprogram. However, each reference to a function, subroutine, or entry must use an actual argument list that agrees in order, number, and type with the dummy argument list in the corresponding FUNCTION, SUBROUTINE, or ENTRY statement.
Dummy arguments can be referred to only in executable statements that follow the first SUBROUTINE, FUNCTION, or ENTRY statement in which the dummy argument is specified. If a dummy argument is not currently associated with an actual argument, the dummy argument is undefined and cannot be referenced. Arguments do not retain their association from one reference of a subprogram to another.

Example

C  This fragment writes a message indicating whether num is positive or negative
C  IF (num .GE. 0) THEN
   CALL Sign
ELSE
   CALL Negative
END IF
END SUBROUTINE Sign
   WRITE (*, *) 'It''s positive.'
RETURN
ENTRY Negative
   WRITE (*, *) 'It''s negative.'
RETURN
END SUBROUTINE

See Also

Entry Points in Function Subprograms

EOF

Inquiry Intrinsic Function (Generic): Checks whether a file is at or beyond the end-of-file record.

Syntax
result = EOF (unit)

unit  (Input) Must be of type integer. It represents a unit specifier corresponding to an open file. It cannot be zero unless you have reconnected unit zero to a unit other than the screen or keyboard.

Results
The result type is default logical. The value of the result is .TRUE. if the file connected to unit is at or beyond the end-of-file record; otherwise, .FALSE..

Example

!  Creates a file of random numbers, reads them back
REAL x, total
INTEGER count
OPEN (1, FILE = 'TEST.DAT')
DO I = 1, 20
   CALL RANDOM_NUMBER(x)
   WRITE (1, '(F6.3)') x * 100.0
END DO
CLOSE(1)
OPEN (1, FILE = 'TEST.DAT')
DO WHILE (.NOT. EOF(1))
   count = count + 1
   READ (1, *) value
total = total + value
END DO
100 IF (count.GT.0) THEN
    WRITE (*,*) 'Average is: ', total / count
ELSE
    WRITE (*,*) 'Input file is empty'
END IF
STOP
END

See Also
ENDFILE

EOSHIFT

Transformational Intrinsic Function (Generic):
Performs an end-off shift on a rank-one array, or
performs end-off shifts on all the complete rank-one
sections along a given dimension of an array of rank
two or greater. Elements are shifted off at one end of
a section and copies of a boundary value are filled in
at the other end. Different sections can have different
boundary values and can be shifted by different
amounts and in different directions.

Syntax
result = EOSHIFT (array, shift [,boundary][,dim])

array
  (Input) Must be an array (of any data type).

shift
  (Input) Must be a scalar integer or an array with a rank that is one less
  than array, and shape (d1, d2, ..., dim+1, ..., dn), where (d1, d2, ...,
dn) is the shape of array.

boundary
  (Input; optional) Must have the same type and kind parameters as array. It
  must be a scalar or an array with a rank that is one less than array, and
  shape (d1, d2, ..., dim+1, ..., dn). The boundary specifies a value to
  replace spaces left by the shifting procedure.
  If boundary is not specified, it is assumed to have the following default
  values (depending on the data type of array):

<table>
<thead>
<tr>
<th>array Type</th>
<th>boundary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>0</td>
</tr>
<tr>
<td>Real</td>
<td>0.0</td>
</tr>
<tr>
<td>Complex</td>
<td>(0.0, 0.0)</td>
</tr>
<tr>
<td>Logical</td>
<td>false</td>
</tr>
<tr>
<td>Character(len)</td>
<td>len blanks</td>
</tr>
</tbody>
</table>

dim
  (Input; optional) Must be a scalar integer with a value in the range 1 to n,
  where n is the rank of array. If dim is omitted, it is assumed to be 1.
Results

The result is an array with the same type and kind parameters, and shape as array.

If array has rank one, the same shift is applied to each element. If an element is shifted off one end of the array, the boundary value is placed at the other end the array.

If array has rank greater than one, each section \((s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)\) of the result is shifted as follows:

- By the value of shift, if shift is scalar
- According to the corresponding value in \(shift(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)\), if shift is an array

If an element is shifted off one end of a section, the boundary value is placed at the other end of the section.

The value of shift determines the amount and direction of the end-off shift. A positive shift value causes a shift to the left (in rows) or up (in columns). A negative shift value causes a shift to the right (in rows) or down (in columns).

Example

V is the integer array \((1, 2, 3, 4, 5, 6)\).

EOSHIFT (V, SHIFT=2) shifts the elements in V to the left by 2 positions, producing the value \((3, 4, 5, 6, 0, 0)\). 1 and 2 are shifted off the beginning and two elements with the default BOUNDARY value are placed at the end.

EOSHIFT (V, SHIFT= -3, BOUNDARY= 99) shifts the elements in V to the right by 3 positions, producing the value \((99, 99, 99, 1, 2, 3)\). 4, 5, and 6 are shifted off the end and three elements with BOUNDARY value 99 are placed at the beginning.

M is the CHARACTER(LEN=1) array

\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

EOSHIFT (M, SHIFT = 1, BOUNDARY = '*', DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
5 & 6 & * \\
8 & 9 & * \\
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. This causes the first element in each row to be shifted off the beginning, and the BOUNDARY value to be placed at the end.

EOSHIFT (M, SHIFT = -1, DIM = 1) produces the result

\[
\begin{bmatrix}
^ & ^ & ^ \\
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. This causes the last element in each column to be shifted off the end and the BOUNDARY value (the default character boundary value <space>, represented by "^") to be placed at the beginning.

EOSHIFT (M, SHIFT = (/1, -1, 0/), BOUNDARY = (/ '*', '?', '/' /), DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
? & 4 & 5 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position, causing the first element to be shifted off the beginning and the BOUNDARY value * to be placed at the end. Each element in row 2 is shifted to the right by 1 position, causing the last element to be shifted off the end and the BOUNDARY value ? to be placed at the beginning. No element in row 3 is shifted at all, so the specified BOUNDARY value is not used.
The following shows another example:

```fortran
INTEGER shift(3)
CHARACTER(1) array(3, 3), AR1(3, 3)
array = RESHAPE (('/A', 'D', 'G', 'B', 'E', 'H', &
   'C', 'F', 'I'/), (/3,3/))
! array is A B C
!             D E F
!             G H I
shift = (-1, 1, 0/)
AR1 = EOSHIFT (array, shift, BOUNDARY = (/**','?','#'/), DIM= 2)
! returns         * A B
!             E F ?
!             G H I
```

ISHFT
ISHFTC
TRANSPOSE

**Epsilon**

*Inquiry Intrinsic Function (Generic)*: Returns a positive model number that is almost negligible compared to unity in the model representing real numbers.

**Syntax**

result = EPSILON (x)

x (Input) Must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of the same type and kind parameters as x. The result has the value \( b^{1-p} \). Parameters \( b \) and \( p \) are defined in Model for Real Data.

EPSILON makes it easy to select a \( \delta \) for algorithms (such as root locators) that search until the calculation is within \( \delta \) of an estimate. If \( \delta \) is too small (smaller than the decimal resolution of the data type), the algorithm might never halt. By scaling the value returned by EPSILON to the estimate, you obtain a \( \delta \) that ensures search termination.

**Example**

If \( x \) is of type REAL(4), EPSILON (X) has the value \( 2^{-23} \).

TINY

**Data Representation Models**

**EQUIVALENCE**

*Statement*: Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area.

**Syntax**

EQUIVALENCE (equiv-list) [,(equiv-list)]...
equiv-list Is a list of two or more variable names, array elements, or substrings, separated by commas (also called an equivalence set). If an object of derived type is specified, it must be a sequence type. Objects cannot have the TARGET attribute.

Each expression in a subscript or a substring reference must be an integer initialization expression. A substring must not have a length of zero.

Description

The following objects cannot be specified in EQUIVALENCE statements:

- A dummy argument
- An allocatable variable
- An automatic object
- A pointer
- An object of nonsequence derived type
- A derived-type object that has an allocatable or pointer component at any level
- A component of a derived-type object
- A function, entry, or result name
- A named constant
- A structure component
- A subobject of any of the above objects
- A coarray
- An object with either the DLLIMPORT or DLLEXPORT attribute
- A variable with the BIND attribute
- A variable in a common block that has the BIND attribute

The EQUIVALENCE statement causes all of the entities in one parenthesized list to be allocated storage beginning at the same storage location.

If an equivalence object has the PROTECTED attribute, all of the objects in the equivalence set must have the PROTECTED attribute.

Association of objects depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Type of Associated Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric ^1 or numeric sequence</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence</td>
<td>Can be of either of these types ^2</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

^1 Default integer, default real, double precision real, default complex, double complex, or default logical.

^2 The lengths do not have to be equal.

So, objects can be associated if they are of different numeric type. For example, the following is valid:

```
INTEGER A(20)
REAL Y(20)
EQUIVALENCE (A, Y)
```

Objects of default character do not need to have the same length. The following example associates character variable D with the last 4 (of the 6) characters of character array F:

```
CHARACTER (LEN=4) D
CHARACTER (LEN=3) F (2)
EQUIVALENCE (D, F (1) (3:))
```
Entities having different data types can be associated because multiple components of one data type can share storage with a single component of a higher-ranked data type. For example, if you make an integer variable equivalent to a complex variable, the integer variable shares storage with the real part of the complex variable.

The same storage unit cannot occur more than once in a storage sequence, and consecutive storage units cannot be specified in a way that would make them nonconsecutive.

Intel® Fortran lets you associate character and noncharacter entities, for example:

```fortran
CHARACTER*1 char1(10)
REAL reala, realb
EQUIVALENCE (reala, char1(1))
EQUIVALENCE (realb, char1(2))
```

EQUIVALENCE statements require only the first subscript of a multidimensional array (unless the STRICT compiler directive is in effect). For example, the array declaration `var(3,3), var(4)` could appear in an EQUIVALENCE statement. The reference is to the fourth element of the array (`var(1,2)`), not to the beginning of the fourth row or column.

If you use the STRICT directive, the following rules apply to the kinds of variables and arrays that you can associate:

- If an EQUIVALENCE object is default integer, default real, double-precision real, default complex, default logical, or a sequenced derived type of all numeric or logical components, all objects in the EQUIVALENCE statement must be one of these types, though it is not necessary that they be the same type.
- If an EQUIVALENCE object is default character or a sequenced derived type of all character components, all objects in the EQUIVALENCE statement must be one of these types. The lengths do not need to be the same.
- If an EQUIVALENCE object is a sequenced derived type that is not purely numeric or purely character, all objects in the EQUIVALENCE statement must be the same derived type.
- If an EQUIVALENCE object is an intrinsic type other than the default (for example, INTEGER(1)), all objects in the EQUIVALENCE statement must be the same type and kind.

**Example**

The following EQUIVALENCE statement is invalid because it specifies the same storage unit for `X(1)` and `X(2)`:

```fortran
REAL, DIMENSION(2) :: X
REAL :: Y
EQUIVALENCE (X(1), Y), (X(2), Y)
```

The following EQUIVALENCE statement is invalid because `A(1)` and `A(2)` will not be consecutive:

```fortran
REAL A(2)
DOUBLE PRECISION D(2)
EQUIVALENCE (A(1), D(1)), (A(2), D(2))
```

In the following example, the EQUIVALENCE statement causes the four elements of the integer array `IARR` to share the same storage as that of the double-precision variable `DVAR`:

```fortran
DOUBLE PRECISION DVAR
INTEGER(KIND=2) IARR(4)
EQUIVALENCE (DVAR, IARR(1))
```

In the following example, the EQUIVALENCE statement causes the first character of the character variables `KEY` and `STAR` to share the same storage location. The character variable `STAR` is equivalent to the substring `KEY(1:10)`.

```fortran
CHARACTER KEY*16, STAR*10
EQUIVALENCE (KEY, STAR)
```
The following shows another example:

```plaintext
CHARACTER name, first, middle, last
DIMENSION name(60), first(20), middle(20), last(20)
EQUIVALENCE (name(1), first(1)), (name(21), middle(1))
EQUIVALENCE (name(41), last(1))
```

Consider the following:

```plaintext
CHARACTER (LEN = 4) :: a, b
CHARACTER (LEN = 3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))
```

This causes the following alignment:

```
1  2  3  4  5  6  7
a(1:1) a(2:2) a(3:3) a(4:4) b(1:1) b(2:2) b(3:3) b(4:4)
c(1)(1:1) c(1)(2:2) c(1)(3:3) c(2)(1:1) c(2)(2:2) c(2)(3:3)
```

Note that the fourth element of `a`, the first element of `b`, and the first element of `c(2)` share the same storage unit.

**ERF**

*Elemental Intrinsic Function (Generic):* Returns the error function of an argument.

**Syntax**

```plaintext
result = ERF (x)
```

`x` (Input) Must be of type real.

**Results**

The result type and kind is the same as `x`. The result is in the range -1 to 1.

ERF returns the error function of `x` defined as follows:

```
\frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-t^2} dt
```

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERF</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERF</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERF</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ERF (1.0) has the value 0.842700794.

**See Also**
- ERFC
**ERFC**

*Elemental Intrinsic Function (Generic): Returns the complementary error function of an argument.*

**Syntax**

```fortran
result = ERFC (x)
```

- **x**: (Input) Must be of type real.

**Results**

The result type and kind is the same as `x`. The result is in the range 0 to 2.

`ERFC` returns `1 - ERF(x)` and is defined as follows:

\[
\frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt
\]

`ERFC` is provided because of the extreme loss of relative accuracy if `ERF(x)` is called for large `x` and the result is subtracted from 1.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERFC</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERFC</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERFC</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

`ERFC (1.0)` has the value 0.1572992057.

**See Also**

ERF

**ERFC_SCALED**

*Elemental Intrinsic Function (Generic): Returns the scaled complementary error function of an argument.*

**Syntax**

```fortran
result = ERFC_SCALED (x)
```

- **x**: (Input) Must be of type real.

**Results**

The result type and kind are the same as `x`. The result has a value equal to a processor-dependent approximation to the exponentially-scaled complementary error function of

\[
\exp \left( x^2 \right) \frac{2}{\sqrt{x}} \int_x^\infty \exp \left( -t^2 \right) dt
\]
NOTE

The complementary error function is asymptotic to \( \exp\left(-X^2\right)/\left(X \sqrt{\pi}\right) \). As such, it underflows for \( X > \infty \) when using IEEE single precision arithmetic. The exponentially-scaled complementary error function is asymptotic to \( 1/\left(X \sqrt{\pi}\right) \). As such, it does not underflow until \( X > \text{HUGE}(X)/\sqrt{\pi} \).

Example

ERFC_SCALED (20.0) has the approximate value 0.02817434874.

ERFC

ERRSNS

Intrinsic Subroutine (Generic): Returns information about the most recently detected I/O system error condition. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL ERRSNS ([io_err] [, sys_err] [, stat] [, unit] [, cond])

io_err (Output; Optional) Is an integer variable or array element that stores the most recent Run-Time Library error number that occurred during program execution. For a listing of error numbers, see Compiler Reference: Error Handling.

A zero indicates no error has occurred since the last call to ERRSNS or since the start of program execution.

sys_err (Output; Optional) Is an integer variable or array element that stores the most recent system error number associated with io_err. This code is one of the following:

- On Windows* systems, it is the value returned by GETLASTERROR() at the time of the error.
- On Linux* and OS X* systems, it is an errno value. (See errno(2).)

stat (Output; Optional) Is an integer variable or array element that stores a status value that occurred during program execution. This value is always set to zero.

unit (Output; Optional) Is an integer variable or array element that stores the logical unit number, if the last error was an I/O error.

cond (Output; Optional) Is an integer variable or array element that stores the actual processor value. This value is always set to zero.

If you specify INTEGER(2) arguments, only the low-order 16 bits of information are returned or adjacent data can be overwritten. Because of this, it is best to use INTEGER(4) arguments.

The saved error information is set to zero after each call to ERRSNS.
Example
Any of the arguments can be omitted. For example, the following is valid:

CALL ERRSNS (SYS_ERR=I1, STAT=I2, UNIT=I4)

ESTABLISHQQ
Portability Function: Lets you specify a routine to handle errors detected by the Run-Time Library (RTL). It lets you take appropriate steps in addition to the RTL's error-handling behavior, or it lets you replace that behavior.

Module
USE IFESTABLISH

Syntax
result = ESTABLISHQQ (handler_routine, context, prev_handler, prev_context)

handler_routine (Input) Is of type "procedure(establishqq_handler)", which is defined in module IFESTABLISH. This is the routine that will handle errors detected by the RTL.

context (Input) INTEGER(INT_PTR_KIND()). This is the way you pass information to the handler routine for use when it is called. It can be data or a pointer to a block of data.

prev_handler (Optional; output) Is of type "procedure(establishqq_handler), pointer, intent(out), optional", which is defined in module IFESTABLISH. This is the previous handler routine, if any.

prev_context (Optional; output) INTEGER(INT_PTR_KIND()). This is the context specified for the previous handler routine, if any; otherwise, zero.

Results
The result type for ESTABLISHQQ is LOGICAL(4). It indicates whether the handler was successfully established. .TRUE. means it was established successfully; .FALSE. means it was not.

The handler routine is called when an error occurs. The result for the handler is set by your code in the handler. .TRUE. means that the error has been handled and the application should not issue an error message. .FALSE. means that the application should issue an error message and continue as if there had never been a handler.

After you specify ESTABLISHQQ and an error occurs, the following input arguments are set up by the RTL when it calls the handler routine:

error_code
This is the error code number from IOSTAT.

continuable
This specifies whether a condition is continuable. The value is .TRUE. if the application can continue from the error. In this case, the handler can return .TRUE. or .FALSE. to determine what should happen.

If you want to terminate the application, the handler should specify the STOP statement.
39
message_string

This is the error message as contructed by the RTL.
For example:
"forrtl: severe (408): fort: (2): Subscript #1 of the
array ..."

context

This is the context you specified for
ESTABLISHQQ.

If you want to handle errors using a C/C++ handler, use the ISO_C_BINDINGS module features to call the
C/C++ routine.

Example
! Compile with "-fpe0 -check bounds".

ISO_C_BINDING Module

ETIME

Portability Function: On single processor systems, returns the elapsed CPU time, in seconds, of the process that calls it. On multi-core or multi-processor systems, returns the elapsed wall-clock time, in seconds.

Module
USE IFPORT

Syntax
result = ETIME (array)

array
  (Output) REAL(4). Must be a rank one array with two elements:
  
  - array(1) - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. On single processors, ETIME returns the elapsed CPU time, in seconds, of the process that calls it. On multiple processors, ETIME returns the elapsed wall-clock time, in seconds.
  
  - array(2) - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive) on single processors; on multiple processors, this value is zero.

Results
The result type is REAL(4). The result is the total CPU time, which is the sum of array(1) and array(2).

Example
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
write(*) 'Program has used', I, 'seconds of CPU time.'
write(*) ' This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'

DATE_AND_TIME

EXECUTE_COMMAND_LINE

Intrinsic Subroutine: Executes a command line.
Syntax

CALL EXECUTE_COMMAND_LINE (command [, wait, exitstat, cmdstat, cmdmsg])

command (Input) Must be a scalar of type default character. It is the command line to be executed. The interpretation is processor dependent.

wait (Input; optional) Must be a scalar of type logical. If wait is present with the value FALSE and the processor supports asynchronous execution of the command, the command is executed asynchronously; otherwise it is executed synchronously.

exitstat (Inout; optional) Must be a scalar of type integer. If the command is executed synchronously, exitstat is assigned the value of the processor-dependent exit status of the executed command. Otherwise, the value of exitstat is unchanged.

cmdstat (Output; optional) Must be a scalar of type integer. It is assigned one of the following values:

- -1 if the processor does not support command line execution
- A processor-dependent positive value if an error condition occurs
- -2 if no error condition occurs but wait is present with the value FALSE and the processor does not support asynchronous execution.
- 0 otherwise

cmdmsg (Inout; optional) Must be a scalar of type default character. If an error condition occurs, cmdmsg is assigned a processor-dependent explanatory message. Otherwise, cmdmsg is unchanged.

Description

When command is executed synchronously, EXECUTE_COMMAND_LINE returns after the command line has completed execution. Otherwise, EXECUTE_COMMAND_LINE returns without waiting.

If a condition occurs that would assign a nonzero value to cmdstat but cmdstat is not present, execution is terminated.

NOTE

If the application has a standard console window, command output will appear in that window. On Windows* OS, if the application does not have a console window, including QuickWin applications, command output will not be shown.

Example

INTEGER :: CSTAT, ESTAT
CHARACTER(100) :: CMSG
CALL EXECUTE_COMMAND_LINE ("dir > dir.txt", EXITSTAT=ESTAT, &
   CMDSTAT=CSTAT, CMDSMGS=CMSG)
IF (CSTAT > 0) THEN
   PRINT *, "Command execution failed with error ", TRIM(CMSG)
ELSE IF (CSTAT < 0) THEN
   PRINT *, "Command execution not supported"
ELSE
   PRINT *, "Command completed with status ", ESTAT
END IF
END
In the above example, EXECUTE_COMMAND_LINE is called to execute a "dir" command with output redirected to a file. Since the WAIT argument was omitted, the call waits for the command to complete and the command's exit status is returned in ESTAT. If the command cannot be executed, the error message returned in CMSG is displayed, but note that this is not based on the success or failure of the command itself.

**EXIT Statement**

**Statement:** Terminates execution of a DO loop or a BLOCK construct.

**Syntax**

```fortran
EXIT [name]
```

*name* (Optional) Is the name of the DO loop or BLOCK construct.

**Description**

The EXIT statement causes execution of a DO loop or a named BLOCK construct to be terminated. If *name* is specified, the EXIT statement must be within the range of that named construct. Otherwise, the EXIT statement must be within a DO loop and it exits the innermost DO within which it appears.

If a DO loop is terminated, any inner DO loops are also terminated and the DO control variables retain their last value. If a non-DO construct is terminated, any DO loops inside that construct are also terminated.

An EXIT statement must not appear within a CRITICAL or DO CONCURRENT construct if it belongs to that construct or an outer construct.

**Example**

The following example shows an EXIT statement:

```fortran
LOOP_A : DO I = 1, 15
    N = N + 1
    IF (N > I) EXIT LOOP_A
END DO LOOP_A
```

The following shows another example:

```fortran
INTEGER numpoints, point
REAL datarray(1000), sum
sum = 0.0
DO point = 1, 1000
    sum = sum + datarray(point)
    IF (datarray(point+1) .EQ. 0.0) EXIT
END DO
```

The following shows another example:

```fortran
DO I=1,N
    MyBlock:  BLOCK
        REAL :: T
        T = A(I) + B(I)
        IF (T == 0.0) EXIT MyBlock
        C(I) = T + SQRT(T)
    END BLOCK
END DO
```

**See Also**

DO Statement
DO WHILE
EXIT Subroutine

_Intrinsic Subroutine (Generic):_ Terminates program execution, closes all files, and returns control to the operating system. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL EXIT [( [status] )]
```

*status* (Output; optional) Is an integer argument you can use to specify the image exit-status value.

The exit-status value may not be accessible after program termination in some application environments.

**Example**

```fortran
INTEGER(4) exvalue
! all is well, exit with 1
   exvalue = 1
   CALL EXIT(exvalue)
! all is not well, exit with diagnostic -4
   exvalue = -4
   CALL EXIT(exvalue)
! give no diagnostic, just exit
   CALL EXIT ( )
```

**See Also**

END
ABORT

**EXP**

_Ellemental Intrinsic Function (Generic):_ Computes an exponential value.

**Syntax**

```fortran
result = EXP (x)
```

*x* (Input) Must be of type real or complex.

**Results**

The result type and kind is the same as *x*. The value of the result is $e^x$. If *x* is of type complex, its imaginary part is regarded as a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>

1The setting of compiler options specifying real size can affect CEXP.
Specific Name | Argument Type | Result Type
---|---|---
\(^2\)This function can also be specified as ZEXP.

**Example**

EXP (2.0) has the value 7.389056.

EXP (1.3) has the value 3.669297.

The following shows another example:

```fortran
! Given initial size and growth rate,
! calculates the size of a colony at a given time.
REAL sizei, sizef, time, rate
sizei = 10000.0
time = 40.5
rate = 0.0875
sizef = sizei * EXP (rate * time)
WRITE (*, 100) sizef
100 FORMAT (' The final size is ', E12.6)
END
```

**See Also**

LOG

**EXPONENT**

*Elemental Intrinsic Function (Generic):* Returns the exponent part of the argument when represented as a model number.

**Syntax**

```fortran
result = EXPONENT (x)
```

\(x\) (Input) must be of type real.

**Results**

The result type is default integer. If \(x\) is not equal to zero, the result value is the exponent part of \(x\). The exponent must be within default integer range; otherwise, the result is undefined.

If \(x\) is zero, the exponent of \(x\) is zero. For more information on the exponent part (\(e\)) in the real model, see [Model for Real Data](#).

**Example**

EXPONENT (2.0) has the value 2.

If 4.1 is a REAL(4) value, EXPONENT (4.1) has the value 3.

The following shows another example:

```fortran
REAL(4) r1, r2
REAL(8) r3, r4
r1 = 1.0
r2 = 123456.7
r3 = 1.0d0
r4 = 123456789123456.7
write(*,*) EXPONENT(r1) ! prints 1
write(*,*) EXPONENT(r2) ! prints 17
write(*,*) EXPONENT(r3) ! prints 1
write(*,*) EXPONENT(r4) ! prints 47
END
```

EXTENDS_TYPE_OF

Inquiry Intrinsic Function (Generic): Inquires whether the dynamic type of an object is an extension type of the dynamic type of another object.

Syntax

\[
\text{result} = \text{EXTENDS\_TYPE\_OF} (a, \text{mold})
\]

\(a\) (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

\(\text{mold}\) (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

Results

The result type is default logical scalar.

The following determines the result value:

- If \(\text{mold}\) is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .TRUE..
- If \(a\) is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .FALSE..
- If the dynamic type of \(a\) or \(\text{mold}\) is extensible, the result is true only if the dynamic type of \(a\) is an extension type of the dynamic type of \(\text{mold}\).

Otherwise, the result is processor dependent.

EXTERNAL

Statement and Attribute: Allows an external procedure, a dummy procedure, a procedure pointer, or a block data subprogram to be used as an actual argument. (To specify intrinsic procedures as actual arguments, use the INTRINSIC attribute.)

Syntax

The EXTERNAL attribute can be specified in a type declaration statement or an EXTERNAL statement, and takes one of the following forms:

Type Declaration Statement:

\[
\text{type}, [\text{att-ils}], \text{EXTERNAL} [, \text{att-ils}] :: \text{ex-pro[, ex-pro]}...
\]

Statement:

\[
\text{EXTERNAL} \ [::] \text{ex-pro[, ex-pro]}...
\]

\(\text{type}\) Is a data type specifier.
**att-ls**
Is an optional list of attribute specifiers.

**ex-pro**
Is the name of an external (user-supplied) procedure, a dummy procedure, a procedure pointer, or block data subprogram.

**Description**
In a type declaration statement, only functions can be declared EXTERNAL. However, you can use the EXTERNAL statement to declare subroutines and block data program units, as well as functions, to be external.

The name declared EXTERNAL is assumed to be the name of an external procedure, even if the name is the same as that of an intrinsic procedure. For example, if SIN is declared with the EXTERNAL attribute, all subsequent references to SIN are to a user-supplied function named SIN, not to the intrinsic function of the same name.

You can include the name of a block data program unit in the EXTERNAL statement to force a search of the object module libraries for the block data program unit at link time. However, the name of the block data program unit must not be used in a type declaration statement.

If you want to describe a routine with greater detail, use the INTERFACE statement. This statement automatically declares a routine as EXTERNAL, and provides information on result types and argument types.

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

**Example**
The following example shows type declaration statements specifying the EXTERNAL attribute:

```fortran
PROGRAM TEST
...
INTEGER, EXTERNAL :: BETA
LOGICAL, EXTERNAL :: COS
...
CALL SUB(BETA)       ! External function BETA is an actual argument
```

You can use a name specified in an EXTERNAL statement as an actual argument to a subprogram, and the subprogram can then use the corresponding dummy argument in a function reference or a CALL statement; for example:

```fortran
EXTERNAL FACET
CALL BAR(FACET)
SUBROUTINE BAR(F)
EXTERNAL F
CALL F(2)
```

Used as an argument, a complete function reference represents a value, not a subprogram; for example, `FUNC(B)` represents a value in the following statement:

```fortran
CALL SUBR(A, FUNC(B), C)
```

The following shows another example:

```fortran
EXTERNAL MyFunc, MySub
C MyFunc and MySub are arguments to Calc
   CALL Calc (MyFunc, MySub)
C Example of a user-defined function replacing an intrinsic
C EXTERNAL SIN
   x = SIN (a, 4.2, 37)
```

INTRINSIC
Program Units and Procedures Overview
**FDATE**

*Portability Function and Subroutine: Returns the current date and time as an ASCII string.*

**Module**

USE IFPORT

**Syntax**

**Function Syntax**

result = FDATE()

**Subroutine Syntax:**

CALL FDATE ( [string] )

*string* (Output; optional) Character*(*). It is returned as a 24-character string in the form:

```
Mon Jan 31 04:37:23 2001
```

Any value in *string* before the call is destroyed.

**Results**

The result of the function FDATE and the value of *string* returned by the subroutine FDATE(*string*) are identical. Newline and NULL are not included in the string.

When you use FDATE as a function, declare it as:

```
CHARACTER*24 FDATE
```

**Example**

USE IFPORT
CHARACTER*24 today
!
CALL FDATE(today)
write (*,*), 'Today is ', today
!
write (*,*), 'Today is ', fdate()

**See Also**

DATE_AND_TIME

**FGGETC**

*Portability Function: Reads the next available character from a file specified by a Fortran unit number.*

**Module**

USE IFPORT

**Syntax**

result = FGGETC (lunit, char)
lunit  (Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.

char  (Output) CHARACTER*1. Next available character in the file. If lunit is connected to a console device, then no characters are returned until the Enter key is pressed.

Results
The result type is INTEGER(4). The result is zero if the read is successful, or -1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:
EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).

If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read Portability Routines.

Example
USE IFPORT
CHARACTER inchar
INTEGER istatus
istatus = FGETC(5,inchar)
PRINT *, inchar
END

GETCHARQQ
READ Statement

FIND
Statement: Positions a direct access file at a particular record and sets the associated variable of the file to that record number. It is comparable to a direct access READ statement with no I/O list, and it can open an existing file. No data transfer takes place.

Syntax
FIND ([UNIT=] io-unit, REC= r[, ERR= label] [, IOSTAT= i-var])
FIND (io-unit 'r [, ERR=label] [, IOSTAT=i-var])

io-unit  Is a logical unit number. It must refer to a relative organization file (see Unit Specifier).

r  Is the direct access record number. It cannot be less than one or greater than the number of records defined for the file (see Record Specifier).

label  Is the label of the executable statement that receives control if an error occurs.

i-var  Is a scalar integer variable that is defined as a positive integer if an error occurs, and as zero if no error occurs (see I/O Status Specifier).

Example
In the following example, the FIND statement positions logical unit 1 at the first record in the file. The file's associated variable is set to one:

FIND(1, REC=1)
In the following example, the FIND statement positions the file at the record identified by the content of INDX. The file's associated variable is set to the value of INDX:

```
FIND(4, REC=INDX)
```

**See Also**
- Record Specifier (REC=)
- Record Specifier (REC=)

**FINDFILEQQ**

*Portability Function:* Searches for a specified file in the directories listed in the path contained in the environment variable.

**Module**

```
USE IFPORT
```

**Syntax**

```
result = FINDFILEQQ (filename, varname, pathbuf)
```

**filename**

*(Input)* Character*(*). Name of the file to be found.

**varname**

*(Input)* Character*(*). Name of an environment variable containing the path to be searched.

**pathbuf**

*(Output)* Character*(*). Buffer to receive the full path of the file found.

**Results**

The result type is INTEGER(4). The result is the length of the string containing the full path of the found file returned in *pathbuf*, or 0 if no file is found.

**Example**

```
USE IFPORT
CHARACTER(256) pathname
INTEGER(4) pathlen
pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)
WRITE (*,*) pathname
END
```

**See Also**

- FULLPATHQQ
- GETFILEINFOQQ
- SPLITPATHQQ

**FIRSTPRIVATE**

*Parallel Directive Clause:* Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.

**Syntax**

```
FIRSTPRIVATE (list)
```
list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different threads are initialized to the value the variable had upon entering the parallel region.

To avoid race conditions, which are caused by unintended sharing of data, concurrent updates of the original variable must be synchronized with the read of the original variable that occurs as a result of the FIRSTPRIVATE clause.

If the original variable has the POINTER attribute, the new variable receives the same association status of the original variable as if by pointer assignment.

If the original variable does not have the POINTER attribute, initialization of the new variable occurs as if by intrinsic assignment, unless the original variable has the allocation status of "not currently allocated". In this case, the new variable also has the status of "not currently unallocated".

The following are restrictions for the FIRSTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a FIRSTPRIVATE clause.
- A variable that is private within a parallel region must not appear in a FIRSTPRIVATE clause in a worksharing construct if any of the worksharing regions arising from the worksharing construct ever bind to any of the parallel regions arising from the parallel construct.
- A variable that appears in a REDUCTION clause of a PARALLEL construct must not appear in a FIRSTPRIVATE clause in a worksharing or task construct if any of the worksharing or task regions arising from the worksharing or task construct ever bind to any of the parallel regions arising from the parallel construct.
- A variable that appears in a REDUCTION clause in a WORKSHARE construct must not appear in a FIRSTPRIVATE clause in a task construct encountered during execution of any of the worksharing regions arising from the worksharing construct.
- Assumed-size arrays must not appear in a PRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

NOTE
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

Example
Consider the following:

A = 3
B = 4
!$OMP PARALLEL PRIVATE(A) FIRSTPRIVATE(B)

In this case, variable A has an undefined value at the beginning of the parallel region. However, variable B has the value 4, which was specified in the serial region preceding the parallel region.

PRIVATE Clause
LASTPRIVATE
**FIXEDFORMLINESIZE**

*General Compiler Directive:* Sets the line length for fixed-form Fortran source code.

**Syntax**

```
!DIR$ FIXEDFORMLINESIZE:{72 | 80 | 132}
```

You can set FIXEDFORMLINESIZE to 72 (the default), 80, or 132 characters. The FIXEDFORMLINESIZE setting remains in effect until the end of the file, or until it is reset.

The FIXEDFORMLINESIZE directive sets the source-code line length in include files, but not in USE modules, which are compiled separately. If an include file resets the line length, the change does not affect the host file.

This directive has no effect on free-form source code.

**Example**

```
!DIR$ NOFREEFORM
!DIR$ FIXEDFORMLINESIZE:132
   WRITE (*,*) 'Sentence that goes beyond the 72nd column without continuation.'
```

---

**FLOAT**

*Elemental Intrinsic Function (Generic):* Converts an integer to REAL(4).

**See Also**
REAL Function

---

**FLOODFILL, FLOODFILL_W (W*S)**

*Graphics Functions:* Fill an area using the current color index and fill mask.

**Module**
USE IFQWIN

**Syntax**

```
result = FLOODFILL (x, y, bcolor)
result = FLOODFILL_W (wx, wy, bcolor)
```

- **x, y** (Input) INTEGER(2). Viewport coordinates for fill starting point.
- **bcolor** (Input) INTEGER(2). Color index of the boundary color.
- **wx, wy** (Input) REAL(8). Window coordinates for fill starting point.
Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color bcolor, or if the starting point lies outside the clipping region).

FLOODFILL begins filling at the viewport-coordinate point (x,y). FLOODFILL_W begins filling at the window-coordinate point (wx,wy). The fill color used by FLOODFILL and FLOODFILL_W is set by SETCOLOR. You can obtain the current fill color index by calling GETCOLOR. These functions allow access only to the colors in the palette (256 or less). To access all available colors on a VGA (262,144 colors) or a true color system, use the RGB functions FLOODFILLRGB and FLOODFILLRGB_W.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current graphics color index set by SETCOLOR. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color bcolor.

NOTE

The FLOODFILL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the FloodFill routine by including the IFWIN module, you need to specify the routine name as MSFWIN$FloodFill.

Example

USE IFQWIN
INTEGER(2) status, bcolor, red, blue
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
red = 4
blue = 1
status = SETCOLOR(red)
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLOR() status = SETCOLOR (blue)
xinterior = 160; yinterior = 100
status = FLOODFILL (xinterior, yinterior, bcolor)
END

SETCLIPRGN (W*S)
SETCOLOR (W*S)
SETFILLMASK (W*S)

FLOODFILLRGB, FLOODFILLRGB_W (W*S)

Graphics Functions: Fill an area using the current Red-Green-Blue (RGB) color and fill mask.

Module

USE IFQWIN
Syntax

\[
\text{result} = \text{FLOODFILLRGB} (x, y, \text{color}) \\
\text{result} = \text{FLOODFILLRGB}_W (wx, wy, \text{color})
\]

- **x, y** (Input) INTEGER(2). Viewport coordinates for fill starting point.
- **color** (Input) INTEGER(4). RGB value of the boundary color.
- **wx, wy** (Input) REAL(8). Window coordinates for fill starting point.

Results

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color \text{color}, or if the starting point lies outside the clipping region).

FLOODFILLRGB begins filling at the viewport-coordinate point (x, y). FLOODFILLRGB_W begins filling at the window-coordinate point (wx, wy). The fill color used by FLOODFILLRGB and FLOODFILLRGB_W is set by SETCOLORRGB. You can obtain the current fill color by calling GETCOLORRGB.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current color set by SETCOLORRGB. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color \text{color}.

Example

```fortran
! Build as a QuickWin or Standard Graphics App.
USE IPQWIN
INTEGER(2) status
INTEGER(4) result, bcolor
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
result = SETCOLORRGB(Z'008080') ! red
status = RECTANGLE($GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLORRGB( )
result = SETCOLORRGB (Z'FF0000') ! blue
xinterior = 160; yinterior = 100
result = FLOODFILLRGB (xinterior, yinterior, bcolor)
END
```

FLOOR

*Elemental Intrinsic Function (Generic):* Returns the greatest integer less than or equal to its argument.
Syntax

\[
\text{result} = \text{FLOOR} \left( a[\text{kind}] \right)
\]

\(\text{a} \quad \) (Input) Must be of type real.

\(\text{kind} \quad \) (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the greatest integer less than or equal to \(\text{a}\).

The setting of compiler options specifying integer size can affect this function.

Example

FLOOR (4.8) has the value 4.

FLOOR (-5.6) has the value -6.

The following shows another example:

\[
\begin{align*}
\text{I} &= \text{FLOOR}(3.1) \quad \text{! returns 3} \\
\text{I} &= \text{FLOOR}(-3.1) \quad \text{! returns -4}
\end{align*}
\]

See Also

CEILING

FLUSH Directive

OpenMP* Fortran Compiler Directive: Identifies synchronization points at which the threads in a team must provide a consistent view of memory.

Syntax

\[
\text{!$OMP FLUSH } [(\text{list})]
\]

\(\text{list} \quad \) Is the name of one or more variables to be flushed. Names must be separated by commas.

The binding thread set for a FLUSH construct is the encountering thread.

The FLUSH directive must appear at the precise point in the code at which the synchronization is required. To avoid flushing all variables, specify a \(\text{list}\).

Thread-visible variables are written back to memory at the point at which this directive appears. Modifications to thread-visible variables are visible to all threads after this point. Subsequent reads of thread-visible variables fetch the latest copy of the data.

Thread-visible variables include the following data items:

- Globally visible variables (common blocks and modules)
- Local variables that do not have the SAVE attribute but have had their address taken and saved or have had their address passed to another subprogram
- Local variables that do not have the SAVE attribute that are declared shared in a parallel region within the subprogram
- Dummy arguments
- All pointer dereferences

The FLUSH directive is implied for the following directives (unless the NOWAIT keyword is used):
- ATOMIC and END ATOMIC
- BARRIER
- CRITICAL and END CRITICAL
- END DO
- END PARALLEL
- END SECTIONS
- END SINGLE
- END WORKSHARE
- ORDERED and END ORDERED
- PARALLEL and END PARALLEL
- PARALLEL DO and END PARALLEL DO
- PARALLEL SECTIONS and END PARALLEL SECTIONS
- TARGET
- TARGET DATA
- TARGET ENTER DATA on entry
- TARGET EXIT DATA on exit
- TARGET UPDATE on entry if TO is present and on exit if FROM is present

**Example**

The following example uses the FLUSH directive for point-to-point synchronization between pairs of threads:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(ISYNC)
   IAM = OMP_GET_THREAD_NUM()
   ISYNC(IAM) = 0
!$OMP BARRIER
   CALL WORK()
   C I AM DONE WITH MY WORK, SYNCHRONIZE WITH MY NEIGHBOR
   ISYNC(IAM) = 1
!$OMP FLUSH(ISYNC)
   C WAIT TILL NEIGHBOR IS DONE
   DO WHILE (ISYNC(NEIGH) .EQ. 0)
     !$OMP FLUSH(ISYNC)
     END DO
!$OMP END PARALLEL
```

**See Also**

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

**FLUSH Statement**

**Statement:** Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. It takes one of the following forms:

**Syntax**

```
FLUSH([UNIT=]io-unit [, ERR=label] [, IOMSG=msg-var] [IOSTAT=i-var])
```

**FLUSH io-unit**

- `io-unit` (Input) Is an external unit specifier.

- `label` (Input) Is the label of the branch target statement that receives control if an error occurs.
msg-var  (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var  (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

The FLUSH statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

This statement has no effect on file position.

**FLUSH Subroutine**

*Portability Subroutine:* Flushes the contents of an external unit buffer into its associated file.

**Module**

USE IFPORT

**Syntax**

CALL FLUSH (lunit)

**lunit**  (Input) INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.

**NOTE**

The flush is performed in a non-blocking mode. In this mode, the command may return before the physical write is completed. If you want to use a blocking mode of FLUSH use COMMITQQ.

**See Also**

COMMITQQ

**FMA and NOFMA**

*General Compiler Directives:* FMA tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions. NOFMA disables the generation of FMA instructions.

**Syntax**

!DIR$ FMA

!DIR$ NOFMA

These directives affect the current program unit but they also apply to subsequent program units in the source file, unless and until a program unit containing another FMA or NOFMA directive is encountered.

Once a NOFMA directive has been specified, it is in effect from that point forward. The setting impacts later routines in the source file. For example, consider that the following are in the same source file:

```fortran
real function fms_mul2( a, b, c, d)
  implicit none
  real :: a, b, c, d
  ! the default !dir$ fma leads to fma generation:
  ! this is transformed into FMS(a,b,FMA(c,d,0))
!dir$ nofma
```

![Image](https://via.placeholder.com/150)
The NOFMA directive specified in `fms_mul2` will also impact the routine `fms_mul`. You must explicitly specify the FMA directive to override the effect of the NOFMA directive.

**FOCUSQQ (W*S)**

*QuickWin Function:* Sets focus to the window with the specified unit number.

**Module**

USE IFQWIN

**Syntax**

```
result = FOCUSQQ (iunit)
```

*iunit* (Input) INTEGER(4). Unit number of the window to which the focus is set. Unit numbers 0, 5, and 6 refer to the default startup window.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Units 0, 5, and 6 refer to the default window only if the program does not specifically open them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

Unlike SETACTIVEQQ, FOCUSQQ brings the specified unit to the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```fortran
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

SETACTIVEQQ (W*S)
INQFOCUSQQ (W*S)
FOR__SET_FTN_ALLOC

Run-Time Function: Lets you specify your own routine to dynamically allocate common blocks. This function is especially useful when you are sharing libraries.

Syntax

\[
\text{result} = \text{FOR__SET_FTN_ALLOC}(\text{alloc\_routine})
\]

\text{alloc\_routine}  
(Input) Character. Is the name of a user-defined allocation routine. The routine takes the same arguments as the routine prototype \_FTN_ALLOC, which is defined in module IFCORE. For more information on \_FTN_ALLOC and its arguments, see Allocating Common Blocks.

Results

The result has the same type as the type of the argument. The return value is a pointer to the previous allocation routine you specified for allocation of COMMONs, or to a null pointer if you did not specify a previous allocation routine.

The caller of FOR__SET_FTN_ALLOC must include a USE IFCOMMONALLOC statement. The allocation routine should include ISO_C_BINDING so it can correctly declare the arguments.

This function takes precedence over \_FTN_ALLOC.

Example

The following shows an example of a user-defined routine that can be used with FOR__SET_FTN_ALLOC.

Note that you must compile the program using option \([Q] \text{dyncom}\) to name the commons you want to be dynamically allocated.

```fortran
! User's allocation routine
!
subroutine my_Fortran_alloc_routine (mem, size, name)
  use, intrinsic :: ISO_C_BINDING
  implicit none
  type(C_PTR), intent(OUT) :: mem
  integer(C_INT), intent(INOUT) :: size
  character, dimension(*), intent(IN) :: name
  ! Users would put their allocation code here. This example text
  ! does not contain code to allocate memory.
end subroutine my_Fortran_alloc_routine

! This routine uses module IFCOMMONALLOC to swap allocation
! routines for dynamic COMMONs.
!
subroutine swap_alloc_routines( for_old )
  use ifcommonalloc
  use, intrinsic :: ISO_C_BINDING
  implicit none
  logical for_old
  ! The routine to use, defined above.
  !
  procedure(alloc_rtn) :: my_Fortran_alloc_routine
```

1378
! Where to save the old one.
! type(C_FUNPTR) :: saved_alloc_routine

! Do the swap
!
print *, "my_Fortran_alloc_routine"
if (for_old) then
    saved_alloc_routine = set_ftn_alloc( C_FUNLOC(my_Fortran_alloc_routine) )
else
    saved_alloc_routine = set_ftn_alloc( saved_alloc_routine )
end if
end subroutine swap_alloc_routines

FOR_DESCRIPTOR_ASSIGN (W*S)

Run-Time Subroutine: Creates an array descriptor in memory.

Module

USE IFCORE

Syntax

CALL FOR_DESCRIPTOR_ASSIGN (dp, base, size, reserved, rank, dims_info)

dp

(Input) A Fortran pointer to an array; the array can be of any data type.
base
(Input) INTEGER(4) or INTEGER(8). The base address of the data being described by dp.

Note that a Fortran pointer describes both the location and type of the data item.

size
(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).

reserved
(Input) INTEGER(4). A logical bitwise OR combination of the following constants, which are defined in IFCORE.F90:

- FOR_DESCRIPTOR_ARRAY_DEFINED - Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.
- FOR_DESCRIPTOR_ARRAY_NODEALLOC - Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

```fortran
integer, pointer :: p(:)
integer, target :: t
p => t   ! t cannot be deallocated
allocate(p(10)) ! t can be deallocated
```

If the bit is set, the array cannot be deallocated.
- FOR_DESCRIPTOR_ARRAY_CONTIGUOUS - Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

rank
(Input) INTEGER(4). The rank of the array pointed to.

dims_info
(Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```fortran
TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND  !Lower bound for the dimension
  INTEGER(4) UPPERBOUND  !Upper bound for the dimension
  INTEGER(4) STRIDE      !Stride for the dimension
END TYPE FOR_DIMS_INFO
```

The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

Example

```fortran
use IFCORE
common/c_array/ array
real(8) array(5,5)
external  init_array
external  c_print_array
real(8),pointer :: p_array(:,:)
type(FOR_DIMS_INFO) dims_info(2)
call init_array()

do i=1,5
  do j=1,5
    print *,i,j, array(i,j)
  end do
end do
```
end do
end do

dims_info(1)%LOWERBOUND = 11
 dims_info(1)%UPPERBOUND = 15
 dims_info(1)%STRIDE = 1

dims_info(2)%LOWERBOUND = -5
 dims_info(2)%UPPERBOUND = -1
 dims_info(2)%STRIDE = 1

call FOR_DESCRIPTOR_ASSIGN(p_array, &
 LOC(array), &
 SIZEOF(array(1,1)), &
 FOR_DESCRIPTOR_ARRAY_DEFINED .or. &
 FOR_DESCRIPTOR_ARRAY_NODEALLOC .or. &
 FOR_DESCRIPTOR_ARRAY_CONTIGUOUS, &
 2, &
 dims_info )

p_array = p_array + 1
 call c_print_array()
end

The following shows the C program containing init_array and c_print_array:

#include <stdio.h>
#if !defined(_WIN32) && !defined(_WIN64)
define C_ARRAY c_array_
define INIT_ARRAY init_array_
define C_PRINT_ARRAY c_print_array_
#endif
double C_ARRAY[5][5];
void INIT_ARRAY(void);
void C_PRINT_ARRAY(void);
void INIT_ARRAY(void) {
    int i,j;
    for(i=0;i<5;i++)
        for(j=0;j<5;j++)
            C_ARRAY[i][j] = j + 10*i;
}
void C_PRINT_ARRAY(void) {
    int i,j;
    for(i=0;i<5;i++){
        for(j=0;j<5;j++)
            printf("%f ", C_ARRAY[i][j]);
        printf("\n");
    }
}

POINTER - Fortran

FOR_GET_FPE

Run-Time Function: Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.
Module
USE IFCORE
Syntax
result = FOR_GET_FPE()

Results
The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFPORT module file.
This function is not available on Intel® 64 architecture, targeting Intel® MIC Architecture.
To set floating-point exception flags after program initialization, use FOR_SET_FPE.

Example
USE IFCORE
INTEGER*4 FPE_FLAGS
FPE_FLAGS = FOR_GET_FPE()

See Also
FOR_SET_FPE

FOR_IFCORE_VERSION
Portability Function: Returns the version of the Fortran run-time library (ifcore).

Module
USE IFPORT
Syntax
result = FOR_IFCORE_VERSION (string)

string (Output) Character*(*)]. The version information for the Fortran run-time library (ifcore).

Results
The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.
If string is not long enough to contain the version information, the result is truncated on the right. If string is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

Example
Consider the following:
program what_ifcore
  use ifport
  integer :: res
  character*56 :: str
  res = for_ifcore_version( str )
  print ("(3A)"), "", str, ""
end program what_ifcore
FOR_IFPORT_VERSION

Portability Function: Returns the version of the Fortran portability library (ifport).

Module

USE IFPORT

Syntax

result = FOR_IFPORT_VERSION (string)

string (Output) Character*(*) . The version information for the Fortran portability library (ifport).

Results

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If string is not long enough to contain the version information, the result is truncated on the right. If string is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

Example

Consider the following:

program what_ifport
  use ifport
  integer :: res
  character*56 :: str

  res = for_ifport_version( str )
  print ("(3A)"), ",", str, ""
end program what_ifport

The above example will produce a result similar to the following, depending on spacing and the actual version information:

'Intel Fortran portability library V16.0-001 May 27 2014 '  

for_rtl_finish_

Run-Time Function: Cleans up the Fortran run-time environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.

Syntax

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

result = for_rtl_finish_ ( )

Results

The result is an I/O status value. For information on these status values, see Error Handling: Using the IOSTAT Value and Fortran Exit Codes.

To initialize the Fortran run-time environment, use function for_rtl_init_. 
**Example**

Consider the following C code:

```c
int io_status;
int for_rtl_finish_();
io_status = for_rtl_finish_();
```

**See Also**

for_rtl_init_

**for_rtl_init_**

**Run-Time Subroutine:** Initializes the Fortran run-time environment and causes Fortran procedures and subroutines to behave the same as when called from a Fortran main program. On Linux* OS and OS X*, it also establishes handlers and floating-point exception handling.

**Syntax**

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

CALL for_rtl_init_ (argcount, actarg)

_argcount_ Is a command-line parameter describing the argument count.

_actarg_ Is a command-line parameter describing the actual arguments.

To clean up the Fortran run-time environment, use function for_rtl_finish_.

**Example**

Consider the following C code:

```c
int argc;
char **argv;
void for_rtl_init_ (int *, char **);
for_rtl_init_ (&argc, argv);
```

**See Also**

for_rtl_finish_

**FOR_SET_FPE**

**Run-Time Function:** Sets the floating-point exception flags. This routine can be called from a C or Fortran program.

**Module**

USE IFCORE

**Syntax**

result = FOR_SET_FPE (a)

_a_ Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

**Results**

The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file.
This function is not available on Intel® 64 architecture, targeting Intel® MIC Architecture.

To get the current settings of the floating-point exception flags, use FOR_GET_FPE.

**Example**

```fortran
USE IFCORE
INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS
OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)

The following example program is compiled without any fpe options. However, it uses calls to for_set_fpe to enable the same flags as when compiling with option fpe:0. The new flags can be verified by compiling the program with option -fpe:0.

```
toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_TRAP_DIV0 :", toggle

if ( IAND(fpe_flags, FPE_M_TRAP_INV) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_TRAP_INV :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_UND) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_UND :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_OVF) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_OVF :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_DIV0) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_DIV0 :", toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_INV) .ne. 0 ) then ! ABRUPT_INV
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_INV :", toggle, "  (ftz related)"
end subroutine PRINT_FPE_FLAGS

The following shows the output from the above program:

>ifort set_fpe_sample01.f90
>set_fpe_sample01.exe

The original FPE FLAGS were:
FPE FLAGS = 0X00000000 B'00000000000000000000000000000000
  FPE_TRAP_UND :OFF
  FPE_TRAP_OVF :OFF
  FPE_TRAP_DIV0 :OFF
  FPE_TRAP_INV :OFF
  FPE_ABRUPT_UND :OFF
The new FPE FLAGS are:
FPE FLAGS = 0X0011000F B'00000000000100010000000000001111
FPE_TRAP_UND :ON
FPE_TRAP_OVF :ON
FPE_TRAP_DIV0 :ON
FPE_TRAP_INV :ON
FPE_ABRUPT_UND :ON
FPE_ABRUPT_OVF :OFF
FPE_ABRUPT_DIV0 :ON
FPE_ABRUPT_INV :OFF
FPE_ABRUPT_DMZ :ON (ftz related)

The following example builds a library that has to have a particular setting of the fpe flags internally, and has to work with user programs built with any combination of the fpe flags.

!-- file USE.F90 starts here

ifort -c -fpic -no-ftz -fpe3 use.f90
ifort -c -fpic -ftz flush.f90
ifort -c -fpic main.f90
ifort -o main.exe main.o use.o flush.o

**FOR_SET_REENTRANCY**

*Run-Time Function:* Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits. *This routine can be called from a C or Fortran program.*

**Module**

USE IFCORE

**Syntax**

result = FOR_SET_REENTRANCY (mode)

**mode**

Must be of type INTEGER(4) and contain one of the following options:

<table>
<thead>
<tr>
<th>FOR_K_REENTRANCY</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>NONE</em></td>
<td>Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will not be reentered due to asynchronous system traps (ASTs) or threads within the application.</td>
</tr>
<tr>
<td><em>ASYNCH</em></td>
<td>Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.</td>
</tr>
</tbody>
</table>
FOR_K_REENTRANCY
_THREADED
Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.

FOR_K_REENTRANCY
_INFO
Tells the Fortran RTL to return the current reentrancy mode.

Results
The result type is INTEGER(4). The return value represents the previous setting of the Fortran Run-Time Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in which case the return value represents the current setting.

You must be using an RTL that supports the level of reentrancy you desire. For example, FOR_SET_REENTRANCY ignores a request for thread protection (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe RTL.

Example

```fortran
PROGRAM SETREENT
USE IFCORE
INTEGER*4  MODE
CHARACTER*10 REENT_TXT(3) /'NONE    ','ASYNCH  ','THREADED'/:  
PRINT*, 'Setting Reentrancy mode to ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
PRINT*, 'Previous Reentrancy mode was ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
PRINT*, 'Current Reentrancy mode is ', REENT_TXT(MODE+1)
END
```

FORALL

**Statement and Construct:** The FORALL statement and construct is an element-by-element generalization of the masked array assignment in the WHERE statement and construct. It allows more general array shapes to be assigned, especially in construct form.

**Syntax**

**Statement:**

```
FORALL (triplet-spec[, triplet-spec] ...[, mask-expr]) assign-stmt
```

**Construct:**

```
[name:] FORALL (triplet-spec[, triplet-spec] ...[, mask-expr])
  forall-body-stmt
  [forall-body-stmt]...
END FORALL [name]
```

**triplet-spec**

Is a triplet specification with the following form:

```
subscript-name= subscript-1: subscript-2[: stride]
```

The **subscript-name** is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The **subscripts** and **stride** cannot contain a reference to any subscript-name in triplet-spec.
The stride cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

desc

Is a logical array expression (called the mask expression). If it is omitted, the value .TRUE. is assumed. The mask expression can reference the subscript name in triplet-spec.

triplet-spec

Is a triplet specification with the following form:

```
subscript-name= subscript-1: subscript-2[: stride]
```

The subscript-name is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The subscripts and stride cannot contain a reference to any subscript-name in triplet-spec.

The stride cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

Description

If a construct name is specified in the FORALL statement, the same name must appear in the corresponding END FORALL statement.

A FORALL statement is executed by first evaluating all bounds and stride expressions in the triplet specifications, giving a set of values for each subscript name. The FORALL assignment statement is executed for all combinations of subscript name values for which the mask expression is true.

The FORALL assignment statement is executed as if all expressions (on both sides of the assignment) are completely evaluated before any part of the left side is changed. Valid values are assigned to corresponding elements of the array being assigned to. No element of an array can be assigned a value more than once.

A FORALL construct is executed as if it were multiple FORALL statements, with the same triplet specifications and mask expressions. Each statement in the FORALL body is executed completely before execution begins on the next FORALL body statement.

Any procedure referenced in the mask expression or FORALL assignment statement must be pure.

Pure functions can be used in the mask expression or called directly in a FORALL statement. Pure subroutines cannot be called directly in a FORALL statement, but can be called from other pure procedures.

Example

The following example, which is not expressible using array syntax, sets diagonal elements of an array to 1:

```fortran
REAL, DIMENSION(N, N) :: A
FORALL (I=1:N) A(I, I) = 1
```

Consider the following:

```fortran
FORALL(I = 1:N, J = 1:N, A(I, J) .NE. 0.0) B(I, J) = 1.0 / A(I, J)
```

This statement takes the reciprocal of each nonzero element of array A(1:N, 1:N) and assigns it to the corresponding element of array B. Elements of A that are zero do not have their reciprocal taken, and no assignments are made to corresponding elements of B.

Every array assignment statement and WHERE statement can be written as a FORALL statement, but some FORALL statements cannot be written using just array syntax. For example, the preceding FORALL statement is equivalent to the following:

```fortran
WHERE(A /= 0.0) B = 1.0 / A
```
However, the following FORALL example cannot be written using just array syntax:

```fortran
FORALL(I = 1:N, J = 1:N) H(I, J) = 1.0/REAL(I + J - 1)
```

This statement sets array element $H(I, J)$ to the value $1.0/REAL(I + J - 1)$ for values of $I$ and $J$ between 1 and $N$.

Consider the following:

```fortran
TYPE MONARCH
  INTEGER, POINTER :: P
END TYPE MONARCH

TYPE(MONARCH), DIMENSION(8) :: PATTERN
INTEGER, DIMENSION(8), TARGET :: OBJECT

FORALL(J=1:8) PATTERN(J)%P => OBJECT(1+IEOR(J-1,2))
```

This FORALL statement causes elements 1 through 8 of array PATTERN to point to elements 3, 4, 1, 2, 7, 8, 5, and 6, respectively, of OBJECT. IEOR can be referenced here because it is pure.

The following example shows a FORALL construct:

```fortran
FORALL(I = 3:N + 1, J = 3:N + 1)
  C(I, J) = C(I, J + 2) + C(I, J - 2) + C(I + 2, J) + C(I - 2, J)
  D(I, J) = C(I, J)
END FORALL
```

The assignment to array D uses the values of C computed in the first statement in the construct, not the values before the construct began execution.

**See Also**

WHERE

**FORMAT**

**Statement:** Specifies the form of data being transferred and the data conversion (editing) required to achieve that form.

**Syntax**

```fortran
FORMAT (format-list)
```

*format-list* is a list of one or more of the following edit descriptors, separated by commas or slashes (/):

- **Data edit descriptors:** I, B, O, Z, F, E, EN, ES, D, G, L, and A.
- **Control edit descriptors:** T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.
- **String edit descriptors:** H, 'c', and "c", where c is a character constant.

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

2 These delimiters can also be quotation marks (").
**FP_CLASS**

*Elemental Intrinsic Function (Generic):* Returns the class of an IEEE* real (S_floating, T_floating, or X_floating) argument. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{FP_CLASS} (x)
\]

\(x\) (Input) Must be of type real.

**Results**

The result type is INTEGER(4). The return value is one of the following:

<table>
<thead>
<tr>
<th>Class of Argument</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signaling NaN</td>
<td>FOR_K_FP_SNAN</td>
</tr>
<tr>
<td>Quiet NaN</td>
<td>FOR_K_FP_QNAN</td>
</tr>
<tr>
<td>Positive Infinity</td>
<td>FOR_K_FP_POS_INF</td>
</tr>
<tr>
<td>Negative Infinity</td>
<td>FOR_K_FP_NEG_INF</td>
</tr>
<tr>
<td>Positive Normalized Number</td>
<td>FOR_K_FP_POS_NORM</td>
</tr>
<tr>
<td>Negative Normalized Number</td>
<td>FOR_K_FP_NEG_NORM</td>
</tr>
<tr>
<td>Positive Denormalized Number</td>
<td>FOR_K_FP_POS_DENORM</td>
</tr>
<tr>
<td>Negative Denormalized Number</td>
<td>FOR_K_FP_NEG_DENORM</td>
</tr>
<tr>
<td>Positive Zero</td>
<td>FOR_K_FP_POS_ZERO</td>
</tr>
<tr>
<td>Negative Zero</td>
<td>FOR_K_FP_NEG_ZERO</td>
</tr>
</tbody>
</table>

The preceding return values are defined in file for_fpclass.for.

**Example**

FP_CLASS (4.0_8) has the value 4 (FOR_K_FP_POS_NORM).

**FPUTC**

*Portability Function:* Writes a character to the file specified by a Fortran external unit, bypassing normal Fortran input/output.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{FPUTC} (\text{lunit}, \text{char})
\]

\(\text{lunit}\) (Input) INTEGER(4). Unit number of a file.

\(\text{char}\) (Output) Character*(*) Variable whose value is to be written to the file corresponding to \(\text{lunit}\).
**Results**

The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

EINVAL - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with `lunit`, be sure to read Input and Output Routines in Overview of Portability Routines.

**Example**

```fortran
use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit, file = 'fputc.dat')
do i = 1,26
   char1 = char(123-i)
   i4 = fputc(1,char1) ! make valid writes
   if (i4.ne.0) iflag = 1
enddo
rewind (1)
read (1,'(a)') string
print *, string
```

**See Also**

I/O Formatting Overview

**FRACTION**

**Elemental Intrinsic Function (Generic):** Returns the fractional part of the model representation of the argument value.

**Syntax**

```
result = FRACTION(x)
```

- `x` (Input) Must be of type real.

**Results**

The result type and kind is the same as `x`. The result has the value `x * b^e`. Parameters `b` and `e` are defined in Model for Real Data. If `x` has the value zero, the result has the value zero.

**Example**

If 3.0 is a REAL(4) value, `FRACTION(3.0)` has the value 0.75.

The following shows another example:

```fortran
REAL result
result = FRACTION(3.0) ! returns 0.75
result = FRACTION(1024.0) ! returns 0.5
```

**See Also**

DIGITS
RADIX
EXPONENT
Data Representation Models
**FREE**

*Intrinsic Subroutine (Specific):* Frees a block of memory that is currently allocated. **Intrinsic subroutines cannot be passed as actual arguments.**

**Syntax**

```
CALL FREE (addr)
```

`addr` (Input) Must be of type `INTEGER(4)` on IA-32 architecture; `INTEGER(8)` on Intel® 64 architecture. This value is the starting address of the memory block to be freed, previously allocated by `MALLOC`.

If the freed address was not previously allocated by `MALLOC`, or if an address is freed more than once, results are unpredictable.

**Example**

```
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
```

**FREEFORM and NOFREEFORM**

*General Compiler Directives:* `FREEFORM` specifies that source code is in free-form format. `NOFREEFORM` specifies that source code is in fixed-form format.

**Syntax**

```
!DIR$ FREEFORM
!DIR$ NOFREEFORM
```

When the `FREEFORM` or `NOFREEFORM` directives are used, they remain in effect for the remainder of the program unit, or until the opposite directive is used. When in effect, they apply to include files, but do not affect `USE` modules, which are compiled separately.

Equivalent Compiler Options

**FSEEK**

*Portability Function:* Repositions a file specified by a Fortran external unit.

**Module**

```
USE IFPORT
```

**Syntax**

```
result = FSEEK (lunit, offset, from)
```
lunit 
(Input) INTEGER(4). External unit number of a file.

offset 
(Input) INTEGER(4) or INTEGER(8). Offset in bytes, relative to from, that is to be the new location of the file marker.

from 
(Input) INTEGER(4). A position in the file. It must be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Variable</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SEEK_SET</td>
<td>Positions the file relative to the beginning of the file.</td>
</tr>
<tr>
<td>1</td>
<td>SEEK_CUR</td>
<td>Positions the file relative to the current position.</td>
</tr>
<tr>
<td>2</td>
<td>SEEK_END</td>
<td>Positions the file relative to the end of the file.</td>
</tr>
</tbody>
</table>

Results
The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:
EINVAL: The specified unit is invalid (either not already open, or an invalid unit number), or the from parameter is invalid.
The file specified in lunit must be open.

Example
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1,file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1,offset,ipos)
if (.NOT. stat) then
   istat=fgetc(1,ichar)
   print *, 'data is ',ichar
end if

FSTAT
Portability Function: Returns detailed information about a file specified by a external unit number.

Module
USE IFPORT

Syntax
result = FSTAT (lunit, statb)
lunit 
(Input) INTEGER(4). External unit number of the file to examine.
(Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of `statb` contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(3)</td>
<td>Access mode of the file</td>
<td>See the table in Results</td>
</tr>
<tr>
<td>statb(4)</td>
<td>Number of hard links to the file</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(5)</td>
<td>User ID of owner</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(6)</td>
<td>Group ID of owner</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(7)</td>
<td>Raw device the file resides on</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td></td>
</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed(^1)</td>
<td>W*S: Only available on non-FAT file systems; undefined on FAT systems</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified(^1)</td>
<td></td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change(^1)</td>
<td>W*S: Same as stat(10)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
</tbody>
</table>
The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINVAL (lunit is not a valid unit number, or is not open).

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Constant</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>

</tbody>
</table>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

**Example**

USE IFPORT
integer(4) statarray(12), istat
OPEN (unit=1,file='datfile.dat')
ISTAT = FSTAT (1, statarray)
if (.NOT. istat) then
    print *, statarray
end if

**See Also**

INQUIRE
STAT

**FTELL, FTELLI8**

*Portability Functions:* Return the current position of a file.

**Module**

USE IFPORT

**Syntax**

result = FTELL (lunit)
result = FTELLI8 (lunit)

lunit (Input) INTEGER(4). External unit number of a file.

**Results**

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

EINVAL: lunit is not a valid unit number, or is not open.

**FULLPATHQQ**

*Portability Function:* Returns the full path for a specified file or directory.
39
Module
USE IFPORT

Syntax
result = FULLPATHQQ (name,pathbuf)
(Input) Character*(*). Item for which you want the full path. Can be the
name of a file in the current directory, a relative directory or file name, or a
network uniform naming convention (UNC) path.

name

pathbuf

(Output) Character*(*). Buffer to receive full path of the item specified in

name.

Results
The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails. This
function does not verify that the resulting path and file name are valid nor that they exist.
The length of the full path depends upon how deeply the directories are nested on the drive you are using. If
the full path is longer than the character buffer provided to return it ( pathbuf), FULLPATHQQ returns only
that portion of the path that fits into the buffer.
Check the length of the path before using the string returned in pathbuf. If the longest full path you are likely
to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the
largest possible path buffer with the following statements:

USE IFPORT
CHARACTER($MAXPATH) pathbuf
$MAXPATH is a symbolic constant defined in IFPORT.F90 as 260.

Example
USE IFPORT
USE IFCORE
CHARACTER($MAXPATH) buf
CHARACTER(3)
drive
CHARACTER(256)
dir
CHARACTER(256)
name
CHARACTER(256)
ext
CHARACTER(256)
file
INTEGER(4)
len
DO WHILE (.TRUE.)
WRITE (*,*)
WRITE (*,'(A, \)') ' Enter filename (Hit &
RETURN to exit): '
len = GETSTRQQ(file)
IF (len .EQ. 0) EXIT
len = FULLPATHQQ(file, buf)
IF (len .GT. 0) THEN
WRITE (*,*) buf(:len)
ELSE
WRITE (*,*) 'Can''t get full path'
EXIT
END IF
!
!

Split path
WRITE (*,*)
len = SPLITPATHQQ(buf, drive, dir, name, ext)
IF (len .NE. 0) THEN

1403


WRITE (*, 900) ' Drive: ', drive
WRITE (*, 900) ' Directory: ', dir(1:len)
WRITE (*, 900) ' Name: ', name
WRITE (*, 900) ' Extension: ', ext
ELSE
WRITE (*, *) 'Can''t split path'
END IF
END DO
900 FORMAT (A, A)
END

SPLITPATHQQ

FUNCTION
Statement: The initial statement of a function subprogram. A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression.

Syntax

[prefix [prefix]] FUNCTION name ([([d-arg-list])]) [suffix]

   [specification-part]
   [execution-part]

[CONTAINS
   [internal-subprogram-part]]
END [FUNCTION [name]]

prefix

(Optional) Is any of the following:

- A data type specifier
- ELEMENTAL
  Acts on one array element at a time. This is a restricted form of pure procedure.
- IMPURE
  Asserts that the procedure has side effects.
- MODULE
  Indicates a separate module procedure. See separate module procedures.
- PURE
  Asserts that the procedure has no side effects.
- RECURSIVE
  Permits direct recursion to occur. If a function is directly recursive and array valued, RESULT must also be specified.

At most one of each of the above can be specified. You cannot specify both ELEMENTAL and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if lang-binding is specified in suffix.

name

Is the name of the function. If RESULT is specified, the function name must not appear in any specification statement in the scoping unit of the function subprogram.
The function name can be followed by the length of the data type. The
length is specified by an asterisk (*) followed by any unsigned, nonzero
integer that is a valid length for the function's type. For example, REAL
FUNCTION LGFUNC*8 (Y, Z) specifies the function result as REAL(8) (or
REAL*8).

This optional length specification is not permitted if the length has already
been specified following the keyword CHARACTER.

**d-arg-list**

(Optional) Is a list of one or more dummy arguments.

If there are no dummy arguments and no RESULT variable, the parentheses
can be omitted. For example, the following is valid:

```plaintext
FUNCTION F
```

**suffix**

(Optional) Takes one of the following forms:

```
[RESULT (r-name)] lang-binding
lang-binding [RESULT (r-name)]
```

- **r-name** (Optional) Is the name of the function result. This
  name must not be the same as the function name.

- **lang-binding** Takes the following form:
  ```
  BIND (C [, NAME=ext-name])
  ```

- **ext-name** Is a character scalar initialization
  expression that can be used to
  construct the external name.

**specification-part**

Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE
statement is specified, it has no effect.

**execution-part**

Is one or more executable constructs or statements, except for ENTRY or
RETURN statements.

**internal-subprogram-part**

Is one or more internal subprograms (defining internal procedures). The
internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

The type and kind parameters (if any) of the function's result can be defined in the FUNCTION statement or
in a type declaration statement within the function subprogram, but not both. If no type is specified, the type
is determined by implicit typing rules in effect for the function subprogram.

Execution begins with the first executable construct or statement following the FUNCTION statement. Control
returns to the calling program unit once the END statement (or a RETURN statement) is executed.

If you specify CHARACTER(LEN=*) as the type of the function, the function assumes the length declared for
it in the program unit that invokes it. This type of the resulting character function can have different lengths
when it is invoked by different program units.
If the length is specified as an integer constant, the value must agree with the length of the function specified in the program unit that invokes the function. If no length is specified, a length of 1 is assumed.

If the function is array-valued or a pointer, the declarations within the function must state these attributes for the function result name. The specification of the function result attributes, dummy argument attributes, and the information in the procedure heading collectively define the interface of the function.

The value of the result variable is returned by the function when it completes execution. Certain rules apply depending on whether the result is a pointer, as follows:

- If the result is a pointer, its allocation status must be determined before the function completes execution. The function must associate a target with the pointer, or cause the pointer to be explicitly disassociated from a target.
  
  The shape of the value returned by the function is determined by the shape of the result variable when the function completes execution.

- If the result is not a pointer, its value must be defined before the function completes execution. If the result is an array, all the elements must be defined. If the result is a derived-type structure, all the components must be defined.

A function subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A function can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

Example

The following example uses the Newton-Raphson iteration method \( F(X) = \cosh(X) + \cos(X) - A = 0 \) to get the root of the function:

```fortran
FUNCTION ROOT(A)
    X  = 1.0
    DO
        EX = EXP(X)
        EMINX = 1./EX
        ROOT  = X - ((EX+EMINX)*.5+COS(X)-A)/((EX-EMINX)*.5-SIN(X))
        IF (ABS((X-ROOT)/ROOT) .LT. 1E-6) RETURN
        X  = ROOT
    END DO
END
```

In the preceding example, the following formula is calculated repeatedly until the difference between \( X_i \) and \( X_{i+1} \) is less than 1.0E-6:

\[
X_{i+1} = X_i - \frac{\cos(X_i) + \cos(X_i) - A}{\sinh(X_i) - \sin(X_i)}
\]

The following example shows an assumed-length character function:

```fortran
CHARACTER*(*) FUNCTION REDO(CARG)
    CHARACTER*1 CARG
    DO I=1,LEN(REDO)
        REDO(I:I) = CARG
    END DO
RETURN
END FUNCTION
```

This function returns the value of its argument, repeated to fill the length of the function.
Within any given program unit, all references to an assumed-length character function must have the same length. In the following example, the REDO function has a length of 1000:

```
CHARACTER*1000 REDO, MANYAS, MANYZS
MANYAS = REDO('A')
MANYZS = REDO('Z')
```

Another program unit within the executable program can specify a different length. For example, the following REDO function has a length of 2:

```
CHARACTER HOLD*6, REDO*2
HOLD = REDO('A')//REDO('B')//REDO('C')
```

The following example shows a dynamic array-valued function:

```
FUNCTION SUB (N)
    REAL, DIMENSION(N) :: SUB
    ...
END FUNCTION
```

The following shows another example:

```
INTEGER Divby2
10 PRINT *, 'Enter a number'
    READ *, i
    Print *, Divby2(i)
    GOTO 10
END
C
C     This is the function definition
C
INTEGER FUNCTION Divby2 (num)
    Divby2=num / 2
END FUNCTION
```

The following example shows an allocatable function with allocatable arguments:

```
MODULE AP
CONTAINS

FUNCTION ADD_VEC(P1,P2)
    ! Function to add two allocatable arrays of possibly differing lengths.
    ! The arrays may be thought of as polynomials (coefficients)
    REAL, ALLOCATABLE :: ADD_VEC(:), P1(:), P2(:)

    ! This function returns an allocatable array whose length is set to
    ! the length of the larger input array.
    ALLOCATE(ADD_VEC(MAX(SIZE(P1), SIZE(P2))))
    M = MIN(SIZE(P1), SIZE(P2))
    ! Add up to the shorter input array size
    ADD_VEC(:M) = P1(:M) + P2(:M)
    ! Use the larger input array elements afterwards (from P1 or P2)
    IF(SIZE(P1) > M) THEN
        ADD_VEC(M+1:) = P1(M+1:)
    ELSE IF(SIZE(P2) > M) THEN
        ADD_VEC(M+1:) = P2(M+1:)
    ENDIF
    END FUNCTION
END MODULE

PROGRAM TEST
USE AP
REAL, ALLOCATABLE :: P(:), Q(:), R(:), S(:)
ALLOCATE(P(3))
ALLOCATE(Q(2))
ALLOCATE(R(3))
ALLOCATE(S(3))

! Notice that P and Q differ in length
P = (/4,2,1/)  ! P = X**2 + 2X + 4
Q = (/1,1/)    ! Q = X - 1
PRINT *, 'Result should be:  3.000000       3.000000       1.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(P, Q) ! X**2 + 3X + 3

P = (/1,1,1/)  ! P = X**2 + X + 1
R = (/2,2,2/)  ! R = 2X**2 + 2X + 2
S = (/3,3,3/)  ! S = 3X**2 + 3X + 3
PRINT *, 'Result should be:  6.000000       6.000000       6.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(ADD_VEC(P,R), S)
END

G

GAMMA

Elemental Intrinsic Function (Generic): Returns the gamma value of its argument.

Syntax
result = GAMMA (x)

x      (Input) Must be of type real. It must not be zero or a negative number.

Results
The result type and kind are the same as x.
The result has a value equal to a processor-dependent approximation to the gamma function of x,

\[ \Gamma(X) = \begin{cases} \int_0^\infty t^{X-1} \exp(-t) \, dt & X > 0 \\ \int_0^\infty t^{X-1} \exp(-t) - \sum_{k=0}^{\infty} \left( \frac{(-t)^k}{k!} \right) \, dt & -n-1 < X < -n, \, n \text{ an integer} \geq 0 \end{cases} \]

Example
GAMMA (1.0) has the approximate value 1.000.
**GERROR**

**Run-Time Subroutine:** Returns a message for the last error detected by a Fortran run-time routine.

**Module**

USE IFCORE

**Syntax**

CALL GERROR (string)

string (Output) Character*(*) Message corresponding to the last detected error.

The last detected error does not necessarily correspond to the most recent function call. The compiler resets string only when another error occurs.

**Example**

USE IFCORE
character*40 errtext
character char1

IERRNO

**GETACTIVEQQ (W*S)**

**QuickWin Function:** Returns the unit number of the currently active child window.

**Module**

USE IFQWIN

**Syntax**

result = GETACTIVEQQ()

**Results**

The result type is INTEGER(4). The result is the unit number of the currently active window. If no child window is active, it returns the parameter QWIN$NOACTIVEWINDOW (defined in IFQWIN.F90).

**See Also**

SETACTIVEQQ (W*S)
GETHWNDQQ (W*S)

**GETARCINFO (W*S)**

**Graphics Function:** Determines the endpoints (in viewport coordinates) of the most recently drawn arc or pie.
Module
USE IFQWIN

Syntax
result = GETARCINFO (lpstart, lpend, lppaint)

lpstart  (Output) Derived type xycoord. Viewport coordinates of the starting point of the arc.
lpend   (Output) Derived type xycoord. Viewport coordinates of the end point of the arc.
lppaint (Output) Derived type xycoord. Viewport coordinates of the point at which the fill begins.

Results
The result type is INTEGER(2). The result is nonzero if successful. The result is zero if neither the ARC nor the PIE function has been successfully called since the last time CLEARSCREEN or SETWINDOWCONFIG was successfully called, or since a new viewport was selected.

GETARCINFO updates the lpstart and lpend xycoord derived types to contain the endpoints (in viewport coordinates) of the arc drawn by the most recent call to the ARC or PIE functions. The xycoord derived type, defined in IFQWIN.F90, is:

```fortran
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

The returned value in lppaint specifies a point from which a pie can be filled. You can use this to fill a pie in a color different from the border color. After a call to GETARCINFO, change colors using SETCOLORRGB. Use the new color, along with the coordinates in lppaint, as arguments for the FLOODFILLRGB function.

Example
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
TYPE (xycoord) xystart, xyend, xyfillpt
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 80
x4 = 90; y4 = 180
status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
status = GETARCINFO(xystart, xyend, xyfillpt)
END

See Also
ARC, ARC_W (W*S)
FLOODFILLRGB, FLOODFILLRGB_W (W*S)
GETCOLORRGB (W*S)
GRSTATUS (W*S)
PIE, PIE_W (W*S)
SETCOLORRGB (W*S)
**GETARG**

**Intrinsic Subroutine:** Returns the specified command-line argument (where the command itself is argument number zero). Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL GETARG (n, buffer[, status])
```

- **n** (Input) Must be a scalar of type integer. This value is the position of the command-line argument to retrieve. The command itself is argument number 0.

- **buffer** (Output) Must be a scalar of type default character. Its value is the returned command-line argument.

- **status** (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status.

  If there were no errors, **status** returns the number of characters in the retrieved command-line argument before truncation or blank-padding. (That is, **status** is the original number of characters in the command-line argument.) Errors return a value of -1. Errors include specifying an argument position less than 0 or greater than the value returned by IARGC.

GETARG returns the \( n \)th command-line argument. If \( n \) is zero, the name of the executing program file is returned.

GETARG returns command-line arguments as they were entered. There is no case conversion.

If the command-line argument is shorter than **buffer**, GETARG pads **buffer** on the right with blanks. If the argument is longer than **buffer**, GETARG truncates the argument on the right. If there is an error, GETARG fills **buffer** with blanks.

**Example**

Assume a command-line invocation of `PROG1 -g -c -a`, and that **buffer** is at least five characters long. The following calls to GETARG return the corresponding arguments in **buffer** and **status**:

<table>
<thead>
<tr>
<th>Statement</th>
<th>String returned in <strong>buffer</strong></th>
<th>Length returned in <strong>status</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL GETARG (0, buffer, status)</td>
<td>PROG1</td>
<td>5</td>
</tr>
<tr>
<td>CALL GETARG (1, buffer)</td>
<td>-g</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (2, buffer, status)</td>
<td>-c</td>
<td>2</td>
</tr>
<tr>
<td>CALL GETARG (3, buffer)</td>
<td>-a</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (4, buffer, status)</td>
<td>all blanks</td>
<td>-1</td>
</tr>
</tbody>
</table>

COMMAND_ARGUMENT_COUNT
GET_COMMAND
GET_COMMAND_ARGUMENT
GETBKCOLOR (W*S)

*Graphics Function:* Returns the current background color index for both text and graphics output.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETBKCOLOR}( )
\]

**Results**

The result type is INTEGER(4). The result is the current background color index.

GETBKCOLOR returns the current background color index for both text and graphics, as set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.

**NOTE**

The GETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetBkColor.

**Example**

USE IFQWIN
INTEGER(4) bcindex
bcindex = GETBKCOLOR()

**See Also**

GETBKCOLORRGB (W*S)
SETBKCOLOR (W*S)
GETCOLOR (W*S)
GETTEXTCOLOR (W*S)
REMAPALLPALETTERGB, REMAPPALETTERGB (W*S)

GETBKCOLORRGB (W*S)

*Graphics Function:* Returns the current background Red-Green-Blue (RGB) color value for both text and graphics.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETBKCOLORRGB}( )
\]
Results

The result type is INTEGER(4). The result is the RGB value of the current background color for both text and graphics.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
   Bit  31 (MSB)  24  23  16  15  8  7  0
   RGB  0 0 0 0 0 0 0 0 B B B B B B G G G G G G R R R R R R R R
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB and returned with GETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB and returned with GETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETBKCOLOR, SETCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

```fortran
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) back, fore, oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETCOLORRGB(Z'FF') ! red
! reverse the screen
back = GETBKCOLORRGB()
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)
oldcolor = SETCOLORRGB(back)
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

GETC

Portability Function: Reads the next available character from external unit 5, which is normally connected to the console.
Module
USE IFPORT

Syntax
result = GETC (char)

(char) Character*( ). First character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

Results
The result type is INTEGER(4). The result is zero if successful, or -1 if an end-of-file was detected.

Example
use IFPORT
character ans, errtxt*40
print *, 'Enter a character: '
ISTAT = GETC (ans)
if (istat) then
  call gerror(errtxt)
end if

See Also
GETCHARQQ
GETSTRQQ

GETCHARQQ

Run-Time Function: Returns the next keystroke.

Module
USE IFCORE

Syntax
result = GETCHARQQ( )

Results
The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character. If the key pressed is a function or direction key, a hex Z'00' or Z'E0' is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.

If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn't there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQQ in your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application. The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQQ.
Example

! Program to demonstrate GETCHARQQ
USE IFQCORE
CHARACTER(1) key / 'A' /
PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)
WRITE (*,*) ' Type a key: (or q to quit)'
! Read keys until ESC or q is pressed
DO WHILE (ICHAR (key) .NE. ESC)
  key = GETCHARQQ()
  ! Some extended keys have no ASCII representation
  IF(ICHAR(key) .EQ. NOREP) THEN
    key = GETCHARQQ()
    WRITE (*, 900) 'Not ASCII. Char = NA'
    WRITE (*,*)
  ELSE
    WRITE (*,900) 'ASCII. Char = '
    WRITE (*,901) key
    END IF
  IF (key .EQ. 'q' ) THEN
    EXIT
  END IF
END DO
900 FORMAT (1X, A, )
901 FORMAT (A)
END

GETCOLOR (W*S)

Graphics Function: Returns the current graphics color index.

Module
USE IFQWIN

Syntax
result = GETCOLOR( )

Results
The result type is INTEGER(2). The result is the current color index, if successful; otherwise, -1.
GETCOLOR returns the current color index used for graphics over the background color as set with SETCOLOR. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.
Example

! Program to demonstrate GETCOLOR
PROGRAM COLORS
USE IFQWIN
INTEGER(2) loop, loop1, status, color
LOGICAL(4) winstat
REAL rnd1, rnd2, xnum, ynum
type (windowconfig) wc
status = SETCOLOR(INT2(0))
! Color random pixels with 15 different colors
DO loop1 = 1, 15
    color = INT2(MOD(GETCOLOR() +1, 16))
    status = SETCOLOR (color) ! Set to next color
    DO loop = 1, 75
        ! Set color of random spot, normalized to be on screen
        CALL RANDOM(rnd1)
        CALL RANDOM(rnd2)
        winstat = GETWINDOWCONFIG(wc)
        xnum = wc%numxpixels
        ynum = wc%numypixels
        status = &
            SETPIXEL(INT2(rnd1*xnum+1),INT2(rnd2*ynum))
        status = &
            SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum+1))
        status = &
            SETPIXEL(INT2(rnd1*xnum-1),INT2(rnd2*ynum))
        status = &
            SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum-1))
    END DO
END DO
END

GETCOLORRGB (W*S)

*Graphics Function:* Returns the current graphics color Red-Green-Blue (RGB) value (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB).

Module

USE IFQWIN

Syntax

result = GETCOLORRGB( )

Results

The result type is INTEGER(4). The result is the RGB value of the current graphics color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:
Larger numbers correspond to stronger color intensity with binary 111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETCOLORRGB returns the RGB color value of graphics over the background color (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB), set with SETCOLORRGB. GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB.

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

! Build as a QuickWin or Standard Graphics App.
USE IPQWIN
INTEGER(2) numfonts
INTEGER(4) fore, oldcolor
numfonts = INITIALIZEFONTS ( )
oldcolor = SETCOLORRGB(Z'FF')  ! set graphics color to red
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore) ! set background to graphics color
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB (Z'FF0000')  ! set graphics color to blue
CALL OUTGTEXT("hello, world")
END

**GET_COMMAND**

_Intrinsic Subroutine:_ Returns the entire command that was used to invoke the program.

**Syntax**

CALL GET_COMMAND ([command, length, status])

command (Output; optional) Must be a scalar of type default character. If specified, its value is the entire command that was used to invoke the program. If the command cannot be determined, its value is all blanks.
length (Output; optional) Must be a scalar of type integer. If specified, its value is the significant length of the command that was used to invoke the program. This length includes trailing blanks, but it does not include any truncation or padding used in the command. If the command length cannot be determined, its value is zero.

status (Output; optional) Must be a scalar of type integer. If specified, its value is -1 if the command argument is present and has a length less than the significant length of the command. If the command cannot be retrieved, its value is positive; otherwise, it is assigned the value zero.

Example
See the example in COMMAND_ARGUMENT_COUNT.

See Also

COMMAND_ARGUMENT_COUNT
GET_COMMAND_ARGUMENT

GET_COMMAND_ARGUMENT
Intrinsic Subroutine: Returns a command line argument of the command that invoked the program. Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL GET_COMMAND_ARGUMENT (number[, value, length, status])

number (Input) Must be a scalar of type integer. It must be non-negative and less than or equal to the value returned by the COMMAND_ARGUMENT_COUNT function. Its value is the position of the command-line argument to retrieve. The command itself is argument number zero.

value (Output; optional) Must be a scalar of type default character. If specified, its value is the returned command-line argument or all blanks if the value is unknown.

length (Output; optional) Must be a scalar of type integer. If specified, its value is the length of the returned command-line argument or zero if the length of the argument is unknown. This length includes significant trailing blanks. It does not include any truncation or padding that occurs when the argument is assigned to the value argument.

status (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. It is assigned the value -1 if the value argument is present and has a length less than the significant length of the command argument specified by number. It is assigned a processor-dependent positive value if the argument retrieval fails. Otherwise, it is assigned the value zero.

GET_COMMAND_ARGUMENT returns command-line arguments as they were entered. There is no case conversion.
Example
See the example in COMMAND_ARGUMENT_COUNT.

GETCONTROLFPQQ
Portability Subroutine: Returns the floating-point processor control word.

Module
USE IFPORT

Syntax
CALL GETCONTROLFPQQ (controlword)

controlword (Output) INTEGER(2). Floating-point processor control word.

The floating-point control word is a bit flag that controls various modes of
the floating-point coprocessor.

The control word can be any of the following constants (defined in
IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>

</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be disabled by setting the control bits to 1 with SETCONTROLFPQQ.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues.

You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings.

**Example**

```fortran
USE IFPORT
INTEGER(2) control
CALL GETCONTROLFPQQ (control)
  ! if not rounding down
  IF (IAND(control, FPCW$DOWN) .NE. FPCW$DOWN) THEN
    control = IAND(control, NOT(FPCW$MCW_RC)) ! clear all
      ! rounding
    control = IOR(control, FPCW$DOWN)         ! set to
      ! round down
  CALL SETCONTROLFPQQ(control)
END IF
END
```

**See Also**

- GETSTATUSFPQQ (W*S)
- SIGNALQQ
- CLEARSTATUSFPQQ

**GETCURRENTPOSITION, GETCURRENTPOSITION_W (W*S)**

*Graphics Subroutines:* Return the coordinates of the current graphics position.

**Module**

USE IFQWIN

**Syntax**

CALL GETCURRENTPOSITION (s)
CALL GETCURRENTPOSITION_W (s)

s (Output) Derived type xycoord. Viewport coordinates of current graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord   ! x-coordinate
  INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

LINETO, MOVETO, and OUTGTEXT all change the current graphics position. It is in the center of the screen when a window is created.

Graphics output starts at the current graphics position returned by GETCURRENTPOSITION or GETCURRENTPOSITION_W. This position is not related to normal text output (from OUTTEXT or WRITE, for example), which begins at the current text position (see SETTEXTPOSITION). It does, however, affect graphics text output from OUTGTEXT.

Example

```
! Program to demonstrate GETCURRENTPOSITION
USE IFQWIN
TYPE (xycoord) position
INTEGER(2) result
result = LINETO(INT2(300), INT2(200))
CALL GETCURRENTPOSITION( position )
IF (position%xcoord .GT. 50) THEN
  CALL MOVETO(INT2(50), position%ycoord, position)
  WRITE(*,*) "Text unaffected by graphics position"
END IF
result = LINETO(INT2(300), INT2(200))
END
```

See Also

LINETO, LINETO_W (W*S)

GETCWD

*Portability Function: Returns the path of the current working directory.*

Module

USE IFPORT

Syntax

```
result = GETCWD (dirname)
```

dirname (Output) Character (*(*). Name of the current working directory path, including drive letter.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.
Example

USE IFPORT
  character*30 dirname
!  variable dirname must be long enough to hold entire string
integer(4) istat
  ISTAT = GETCWD (dirname)
  IF (ISTAT == 0) write *, 'Current directory is ',dirname

See Also
GETDRIVEDIRQQ

GETDAT

Portability Subroutine: Returns the date.

Module
USE IFPORT

Syntax

CALL GETDAT (iyr, imon, iday)

iyr  (Output) INTEGER(4) or INTEGER(2). Year (xxxxAD).
imon (Output) INTEGER(4) or INTEGER(2). Month (1-12).
iday (Output) INTEGER(4) or INTEGER(2). Day of the month (1-31).

This subroutine is thread-safe.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4). If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example

! Program to demonstrate GETDAT and GETTIM
USE IFPORT
INTEGER(4) tmpday, tmpmonth, tmpyear
INTEGER(4) tmphour, tmpminute, tmpsecond, tmphund
CHARACTER(1) mer
  CALL GETDAT(tmpyear, tmpmonth, tmpday)
  CALL GETTIM(tmphour, tmpminute, tmpsecond, tmphund)
  IF (tmphour .GT. 12) THEN
    mer = 'p'
    tmphour = tmphour - 12
  ELSE
    mer = 'a'
  END IF
  WRITE (*, 900) tmpmonth, tmpday, tmpyear
  900  FORMAT(I2, '/', I2.2, '/', I4.4)
  WRITE (*, 901) tmphour, tmpminute, tmpsecond, tmphund, mer
  901  FORMAT(I2, ':', I2.2, ':', I2.2, ':', I2.2, ' ',&
                   A, 'm')
END

SETTIM
DATE Portability Routine
GETDRIVEDIRQQ

Portability Function: Returns the path of the current working directory on a specified drive.

Module
USE IFPORT

Syntax
result = GETDRIVEDIRQQ (drivedir)

drivedir (Input; output) Character*(*) On input, the drive whose current working directory path is to be returned. On output, the string containing the current directory on that drive in the form d:\dir.

Results
The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory on the specified drive. Zero is returned if the path is longer than the size of the character buffer drivedir.

You specify the drive from which to return the current working directory by putting the drive letter into drivedir before calling GETDRIVEDIRQQ. To make sure you get information about the current drive, put the symbolic constant FILE$CURDRIVE (defined in IFPORT.F90) into drivedir.

Because drives are identified by a single alphabetic character, GETDRIVEDIRQQ examines only the first letter of drivedir. For instance, if drivedir contains the path c:\fps90\bin, GETDRIVEDIRQQ (drivedir) returns the current working directory on drive C and disregards the rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive specified in drivedir. If the full path is longer than the length of drivedir, GETDRIVEDIRQQ returns only the portion of the path that fits into drivedir. If you are likely to encounter a long path, allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* and OS X* systems, the function gets a path only when symbolic constant FILE$CURDRIVE has been applied to drivedir.

Example

! Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
! Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length.GT.0) THEN
  WRITE ('*','(A)') 'Current directory is: ' dir
ELSE
  WRITE ('*','(A)') 'Failed to get current directory'
END IF
END

SPLITPATHQQ

**GETDRIVESIZEQQ**

*Portability Function:* Returns the total size of the specified drive and space available on it.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{GETDRIVESIZEQQ}(\text{drive, total, avail})
\]

- **drive** (Input) Character*(*) String containing the letter of the drive to get information about.
- **total** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Total number of bytes on the drive.
- **avail** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Number of bytes of available space on the drive.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The data types and dimension (if any) specified for the total and avail arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of drive. The drive letter can be uppercase or lowercase. You can use the constant FILE$CURDRIVE (defined in IFPORT.F90) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

**Example**

```fortran
! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A, A)') 'Drives available: ', drives
!
! Cycle through them for free space and write to console
DO i = 1, 26
  adrive = drives(i:i)
  status = .FALSE.
  WRITE (*,'(A, A, A, \)') 'Drive ', CHAR(i + 64), ':'
```

---

1424

**Intel® Fortran Compiler 16.0 User and Reference Guide**
IF (adrive .NE. ' ') THEN
  status = GETDRIVESIZEQQ(adrive, total, avail)
END IF
IF (status) THEN
  WRITE (*,*) avail, ' of ', total, ' bytes free.'
ELSE
  WRITE (*,*) 'Not available'
END IF
END DO
END

GETDRIVESQQ

**Portability Function:** Reports which drives are available to the system.

**Module**
USE IFPORT

**Syntax**
result = GETDRIVESQQ( )

**Results**
The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.

The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A CD' is returned.

On Linux* and OS X* systems, the function returns a string filled with spaces.

**Example**
See the example for GETDRIVESIZEQQ.

GETENV

**Portability Subroutine:** Returns the value of an environment variable.

**Module**
USE IFPORT

**Syntax**
CALL GETENV (ename, evalue)
**ename**

(Input) Character*(*)*. Environment variable to search for.

**evalue**

(Output) Character*(*)*. Value found for ename. Blank if ename is not found.

**Example**

use IFPORT
character*40 libname
CALL GETENV ("LIB",libname)
TYPE *, "The LIB variable points to ",libname

**See Also**

GETENVQQ

GET_ENVIRONMENT_VARIABLE

**Intrinsic Subroutine**: Gets the value of an environment variable.

**Syntax**

CALL GET_ENVIRONMENT_VARIABLE (name [,value,length,status,trim_name])

**name**

(Input) Must be a scalar of type default character. It is the name of the environment variable.

**value**

(Output; optional) Must be a scalar of type default character. If specified, it is assigned the value of the environment variable specified by name. If the environment variable does not exist, value is assigned all blanks.

**length**

(Output; optional) Must be a scalar of type integer. If specified, its value is the length of the environment variable, if it exists; otherwise, length is set to 0.

**status**

(Output; optional) Must be a scalar of type integer. If specified, it is assigned a value of 0 if the environment variable exists and either has no value or its value is successfully assigned to value.

It is assigned a value of -1 if the value argument is present and has a length less than the significant length of the environment variable value. It is assigned a value of 1 if the environment variable does not exist. For other error conditions, it is assigned a processor-dependent value greater than 2.

**trim_name**

(Input; optional) Must be a scalar of type logical. If the value is FALSE, then trailing blanks in name are considered significant. Otherwise, they are not considered part of the environment variable's name.

**Example**

The following program asks for the name of an environment variable. If the environment variable exists in the program's environment, it prints out its value:

```fortran
program print_env_var
character name*20, val*40
integer len, status
write (*,*) 'enter the name of the environment variable'
read (*,*) name
call get_environment_variable (name, val, len, status, .true.)
if (status .ge. 2) then
    write (*,*) 'get_environment_variable failed: status = ', status
```
stop
end if
if (status .eq. 1) then
    write (*,*) 'env var does not exist'
    stop
end if
if (status .eq. -1) then
    write (*,*) 'env var length = ', len, ' truncated to 40'
    len = 40
end if
if (len .eq. 0) then
    write (*,*) 'env var exists but has no value'
    stop
end if
write (*,*) 'env var value = ', val (1:len)
end

When the above program is invoked, the following line is displayed:

enter the name of the environment variable

The following shows an example of what could be displayed if you enter "HOME".

- On a Linux* or OS X* system:
  env var value = /home/our_space/usr4
- On a Windows* system:
  env var value = C:/

The following shows an example of what could be displayed if you enter "PATH".

- On a Linux or OS X system:
  env var length = 307 truncated to 40
  env var value = /site/our_space/usr4/progs/build_area
- On a Windows system:
  env var length = 829 truncated to 40
  env var value = C:\OUR_SPACE\BUILD_AREA\build_objects\path

GETENVQQ

**Portability Function:** Returns the value of an environment variable.

**Module**

USE IFPORT

**Syntax**

```
result = GETENVQQ (varname, value)
```

- **varname** (Input) Character*(*). Name of environment variable.
- **value** (Output) Character*(*). Value of the specified environment variable, in uppercase.

**Results**

The result type is INTEGER(4). The result is the length of the string returned in value. Zero is returned if the given variable is not defined.

GETENVQQ searches the list of environment variables for an entry corresponding to varname. Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.
Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQVQ uses the C runtime routine getenv and SETENVQVQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system’s environment.

Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQVQ.

GETENVQVQ and SETENVQVQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

Example

! Program to demonstrate GETENVQVQ and SETENVQVQ
USE IFPORT
USE IFCORE
INTEGER(4) lenv, lval
CHARACTER(80) env, val, enval
WRITE (*,900) ' Enter environment variable name to create, &
    modify, or delete: '
lenv = GETSTRQVQ(env)
IF (lenv .EQ. 0) STOP
WRITE (*,900) ' Value of variable (ENTER to delete): '
lval = GETSTRQVQ(val)
IF (lval .EQ. 0) val = ' '
enval = env(1:lenv) // '=' // val(1:lval)
IF (SETENVQVQ(enval)) THEN
  lval = GETENVQVQ(env(1:lenv), val)
  IF (lval .EQ. 0) THEN
    WRITE (*,')' 'Can''t get environment variable'
  ELSE IF (lval .GT. LEN(val)) THEN
    WRITE (*',') 'Buffer too small'
  ELSE
    WRITE (*',') 'Length: ', lval
  END IF
ELSE
  WRITE (*',') 'Can''t set environment variable'
END IF
900  FORMAT (A, 
END

SETENVQVQ
GETLASTERRORQVQ
GETEXCEPTIONPTRQVQ (W*S)

Run-Time Function: Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQVQ or direct calls to the C rtl signal( ) routine.

Module
USE IFCORE
Syntax

```fortran
result = GETEXCEPTIONPTRSQQ()
```

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the `eptr` argument to routine `TRACEBACKQQ` to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling `GETEXCEPTIONPTRSQQ` is only valid within a user-defined handler that was established with `SIGNALQQ` or a direct call to the C rtl `signal( )` function.

For a full description of exceptions and error handling, see Compiler Reference: Error Handling.

Example

```fortran
PROGRAM SIGTEST
USE IFCORE
...
R3 = 0.0E0
STS = SIGNALQQ(MY_HANDLER)
! Cause a divide by zero exception
R1 = 3.0E0/R3
...
END
INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM)
USE IFCORE
...
EPTRS = GETEXCEPTIONPTRSQQ()
...
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)
...
MY_HANDLER = 1
END
```

- `CLEARSTATUSFPQQ`
- `SETCONTROLFPQQ`
- `GETCONTROLFPQQ`
- `SIGNALQQ`
- `GETEXITQQ (W*S)`

QuickWin Function: Returns the setting for a QuickWin application's exit behavior.

Module

```fortran
USE IFQWIN
```

Syntax

```fortran
result = GETEXITQQ()
```

Results

The result type is INTEGER(4). The result is exit mode with one of the following constants (defined in `IFQWIN.F90`):
• **QWIN$EXITPROMPT** - Displays a message box that reads "Program exited with exit status \( n \). Exit Window?", where \( n \) is the exit status from the program.

  If you choose Yes, the application closes the window and terminates. If you choose No, the dialog box disappears and you can manipulate the window as usual. You must then close the window manually.

• **QWIN$EXITNOPERSIST** - Terminates the application without displaying a message box.

• **QWIN$EXITPERSIST** - Leaves the application open without displaying a message box.

The default for both QuickWin and Console Graphics applications is QWIN$EXITPROMPT.

### Example

```fortran
! Program to demonstrate GETEXITQQ
USE IFQWIN
INTEGER i
i = GETEXITQQ()
SELECT CASE (i)
CASE (QWIN$EXITPROMPT)
  WRITE(*, *) "Prompt on exit."
CASE (QWIN$EXITNOPERSIST)
  WRITE(*, *) "Exit and close."
CASE (QWIN$EXITPERSIST)
  WRITE(*, *) "Exit and leave open."
END SELECT
END
```

### See Also

SETEXITQQ

### GETFILEINFOQQ

**Portability Function:** Returns information about the specified file. File names can contain wildcards (* and ?).

### Module

USE IFPORT

### Syntax

```
result = GETFILEINFOQQ (files, buffer, handle)
```

**files**

(Input) Character*(*). Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).

**buffer**

(Output) Derived type FILE$INFO or derived type FILE$INFOI8. Information about a file that matches the search criteria in files. The derived type FILE$INFO is defined in IFPORT.F90 as follows:

```
TYPE FILE$INFO
  INTEGER(4) CREATION ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS ! LAST ACCESS (-1 on FAT)
  INTEGER(4) LENGTH ! LENGTH OF FILE
  INTEGER(4) PERMIT ! FILE ACCESS MODE
  CHARACTER(255) NAME ! FILE NAME
END TYPE FILE$INFO
```
The derived type file$INFO is defined in ifport.f90 as follows:

```fortran
TYPE FILE$INFO
  INTEGER(4) CREATION       ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE      ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS     ! LAST ACCESS (-1 on FAT)
  INTEGER(8) LENGTH         ! LENGTH OF FILE
  INTEGER(4) PERMIT         ! FILE ACCESS MODE
  CHARACTER(255) NAME       ! FILE NAME
END TYPE FILE$INFO
```

Handle

(Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Control mechanism. One of the following constants, defined in IFPORT.F90:

- FILE$FIRST - First matching file found.
- FILE$LAST - Previous file was the last valid file.
- FILE$ERROR - No matching file found.

Results

The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.

The derived-type element variables FILE$INFO%CREATION, FILE$INFO%LASTWRITE, and FILE$INFO%LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively.

To break the time and date into component parts, call UNPACKTIMEQQ. FILE$INFO%LENGTH contains the length of the file in bytes. FILE$INFO%PERMIT contains a set of bit flags describing access information about the file as follows:

<table>
<thead>
<tr>
<th>Bit flag</th>
<th>Access information for the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE$ARCHIVE</td>
<td>Marked as having been copied to a backup device.</td>
</tr>
<tr>
<td>FILE$DIR</td>
<td>A subdirectory of the current directory. Each MS-DOS* directory contains two special files, &quot;.&quot; and &quot;...&quot;. These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory's parent directory.</td>
</tr>
<tr>
<td>FILE$HIDDEN</td>
<td>Hidden. It does not appear in the directory list you request from the command line, the Microsoft* visual development environment browser, or File Manager.</td>
</tr>
<tr>
<td>FILE$READONLY</td>
<td>Write-protected. You can read the file, but you cannot make changes to it.</td>
</tr>
<tr>
<td>FILE$SYSTEM</td>
<td>Used by the operating system.</td>
</tr>
</tbody>
</table>
Bit flag | Access information for the file
---|---
FILE$VOLUME | A logical volume, or partition, on a physical disk drive. This type of file appears only in the root directory of a physical device.

You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILE$INFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILE$INFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERROR to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

**Example**

```fortran
USE IFPORT
USE IFCORE
   CALL SHOWPERMISSION( )
END

! SUBROUTINE to demonstrate GETFILEINFO
SUBROUTINE SHOWPERMISSION( )
USE IFPORT
   CHARACTER(80) files
   INTEGER(KIND=INT_PTR_KIND( )) handle
   INTEGER(4) length
   CHARACTER(5) permit
   TYPE (FILE$INFO) info
   WRITE (*, 900) ' Enter wildcard of files to view: '
   900 FORMAT (A, ")
   length = GETSTRQ(files)
   handle = FILE$FIRST
   DO WHILE (.TRUE.)
      length = GETFILEINFOQ(files, info, handle)
      IF ((handle .EQ. FILE$LAST) .OR. &
         (handle .EQ. FILE$ERROR)) THEN
         SELECT CASE (GETLASTERRORQ( ))
            CASE (ERR$NOMEM)
               WRITE (*,*) 'Out of memory'
            CASE (ERR$NOENT)
               EXIT
            CASE DEFAULT
               WRITE (*,*) 'Invalid file or path name'
         END SELECT
      END IF
      permit = ' ']
      IF ((info%permit .AND. FILE$HIDDEN) .NE. 0) &
         permit(1:1) = 'H'
      IF ((info%permit .AND. FILE$SYSTEM) .NE. 0) &
         permit(2:2) = 'S'
      IF ((info%permit .AND. FILE$READONLY) .NE. 0) &
         permit(3:3) = 'R'
      IF ((info%permit .AND. FILE$ARCHIVE) .NE. 0) &
         permit(4:4) = 'A'
   END DO
```

---

1432
IF ((info%permit .AND. FILE$DIR) .NE. 0) & permit(5:5) = 'D'
WRITE (*, 9000) info%name, info%length, permit
9000 FORMAT (1X, A5, I9, ' ',A6)
END DO
END SUBROUTINE

GETFILLMASK (W*S)

Graphics Subroutine: Returns the current pattern used to fill shapes.

Module
USE IFQWIN

Syntax
CALL GETFILLMASK (mask)

mask (Output) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in mask, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of mask becomes the top 8 bits of the pattern, and the eighth element (byte) of mask becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of 0 are unchanged. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

Example
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1) style(8). array(8)
INTEGER(2) i
style = 0
style(1) = Z'F'
style(3) = Z'F'
style(5) = Z'F'
style(7) = Z'F'
CALL SETFILLMASK (style)
...
CALL GETFILLMASK (array)
WRITE (*, *) 'Fill mask in bits: '
DO i = 1, 8
  WRITE (*, '(B8)') array(i)
END DO
END

PIE, PIE_W (W*S)
POLYGON, POLYGON_W (W*S)
RECTANGLE, RECTANGLE_W (W*S)
SETFILLMASK (W*S)

GETFONTINFO (W*S)

*Graphics Function:* Returns the current font characteristics.

**Module**
USE IFQWIN

**Syntax**
result = GETFONTINFO (font)

*font (Output)* Derived type FONTINFO. Set of characteristics of the current font. The FONTINFO derived type is defined in IFQWIN.F90 as follows:

<table>
<thead>
<tr>
<th>INTEGER(4) type</th>
<th>! 1 = truetype, 0 = bit map</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(4) ascent</td>
<td>! Pixel distance from top to baseline</td>
</tr>
<tr>
<td>INTEGER(4) pixwidth</td>
<td>! Character width in pixels, 0=proportional</td>
</tr>
<tr>
<td>INTEGER(4) pixheight</td>
<td>! Character height in pixels</td>
</tr>
<tr>
<td>INTEGER(4) avgwidth</td>
<td>! Average character width in pixels</td>
</tr>
<tr>
<td>CHARACTER(81) filename</td>
<td>! File name including path</td>
</tr>
<tr>
<td>CHARACTER(32) facename</td>
<td>! Font name</td>
</tr>
<tr>
<td>LOGICAL(1) italic</td>
<td>! .TRUE. if current font formatted italic</td>
</tr>
<tr>
<td>LOGICAL(1) emphasized</td>
<td>! .TRUE. if current font formatted bold</td>
</tr>
<tr>
<td>LOGICAL(1) underline</td>
<td>! .TRUE. if current font formatted underlined</td>
</tr>
</tbody>
</table>

**Results**
The result type is INTEGER(2). The result is zero if successful; otherwise, -1.

You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETFONTINFO.

**Example**

! Build as QuickWin or Standard Graphics
USE IFQWIN

  TYPE (FONTINFO) info
  INTEGER(2) numfonts, return, line_spacing
  numfonts = INITIALIZEFONTS ( )
  return = GETFONTINFO(info)
  line_spacing = info%pixheight + 2

END

**See Also**

INITIALIZEFONTS (W*S)
SETFONT (W*S)

GETGID

**Portability Function:** Returns the group ID of the user of a process.

**Module**
USE IFPORT

**Syntax**

```
result = GETGID()
```

**Results**

The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  - Note that on Windows systems, domain accounts and local accounts can overlap.
- On Linux* and OS X* systems, this function returns the group identity for the current process.

**Example**

```
USE IFPORT
ISTAT = GETGID()
```

GETGTEXTEXTENT (W*S)

**Graphics Function:** Returns the width in pixels that would be required to print a given string of text (including any trailing blanks) with OUTGTEXT using the current font.

**Module**
USE IFQWIN

**Syntax**

```
result = GETGTEXTEXTENT (text)
```

- `text` (Input) Character*. Text to be analyzed.

**Results**

The result type is INTEGER(2). The result is the width of `text` in pixels if successful; otherwise, -1 (for example, if fonts have not been initialized with INITIALIZEFONTS).

This function is useful for determining the size of text that uses proportionally spaced fonts. You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETGTEXTEXTENT.

**Example**

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status, pwidth
CHARACTER(80) text
status = INITIALIZEFONTS()
```
See Also
GETFONTINFO (W*S)
OUTGTEXT (W*S)
SETFONT (W*S)
INITIALIZEFONTS (W*S)
GETGTEXTROTATION (W*S)

GETGTEXTROTATION (W*S)

*Graphics Function:* Returns the current orientation of the font text output by OUTGTEXT.

**Module**
USE IFQWIN

**Syntax**

```
result = GETGTEXTROTATION ( )
```

**Results**

The result type is INTEGER(4). It is the current orientation of the font text output in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 tenths of degrees (90°) is straight up, 1800 tenths of degrees (180°) is upside-down and left, 2700 tenths of degrees (270°) is straight down, and so forth.

The orientation for text output with OUTGTEXT is set with SETGTEXTROTATION.

**Example**

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER ang
REAL rang
ang = GETGTEXTROTATION ( )
rang = FLOAT(ang)/10.0
WRITE(*,*) "Text tilt in degrees is: ", rang
END
```

See Also
OUTGTEXT (W*S)
SETFONT (W*S)
SETGTEXTROTATION (W*S)

GETHWNDQQ (W*S)

*QuickWin Function:* Converts a window unit number into a Windows* handle.

**Module**
USE IFQWIN

**Syntax**

```
result = GETHWNDQQ (unit)
```
unit (Input) INTEGER(4). The window unit number. If unit is set to QWIN $FRAMEWINDOW (defined in IFQWIN.F90), the handle of the frame window is returned.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a true Windows handle to the window. If unit is not open, it returns -1.

GETIMAGE, GETIMAGE_W (W*S)
Graphics Subroutines: Store the screen image defined by a specified bounding rectangle.

Module
USE IFQWIN

Syntax
CALL GETIMAGE (x1, y1, x2, y2, image)
CALL GETIMAGE_W (wx1, wy1, wx2, wy2, image)

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
image (Output) INTEGER(1). Array of single-byte integers. Stored image buffer.

GETIMAGE defines the bounding rectangle in viewport-coordinate points (x1, y1) and (x2, y2).
GETIMAGE_W defines the bounding rectangle in window-coordinate points (wx1, wy1) and (wx2, wy2).

The buffer used to store the image must be large enough to hold it. You can determine the image size by calling IMAGESIZE at run time, or by using the formula described under IMAGESIZE. After you have determined the image size, you can dimension the buffer accordingly.

Example
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1), ALLOCATABLE:: buffer (:)
INTEGER(2) status, x, y, error
INTEGER(4) imsize
x = 50
y = 30
status = ELLIPSE ($GFILLINTERIOR, INT2(x-15), 
                   INT2(y-15), INT2(x+15), INT2(y+15))
imsize = IMAGESIZE (INT2(x-16), INT2(y-16), &
         INT2( x+16), INT2(y+16))
ALLOCATE(buffer (imsize), STAT = error)
IF (error .NE. 0) THEN
   STOP 'ERROR: Insufficient memory'
END IF
CALL GETIMAGE (INT2(x-16), INT2(y-16), &
         INT2( x+16), INT2(y+16), buffer)
END

GETLASTERROR

Portability Function: Returns the last error set.

Module
USE IFPORT

Syntax
result = GETLASTERROR( )

Results
The result type is INTEGER(4). The result is the integer corresponding to the last run-time error value that was set.

For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining errno. Your application can then take appropriate action based upon the error number.

GETLASTERRORQQ

Portability Function: Returns the last error set by a run-time procedure.

Module
USE IFPORT

Syntax
result = GETLASTERRORQQ( )

Results
The result type is INTEGER(4). The result is the most recent error code generated by a run-time procedure. Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERRORQQ retrieves the most recent error message. The error constants are defined in IFPORT.F90. The following table shows some library routines and the errors each routine produces:

<table>
<thead>
<tr>
<th>Library routine</th>
<th>Errors produced</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>

GETLINESTYLE (W*S)

Graphics Function: Returns the current graphics line style.

Module
USE IFQWIN

Syntax
result = GETLINESTYLE( )

Results
The result type is INTEGER(2). The result is the current line style.

GETLINESTYLE retrieves the mask (line style) used for line drawing. The mask is a 16-bit number, where each bit represents a pixel in the line being drawn.

If a bit is 1, the corresponding pixel is colored according to the current graphics color and logical write mode; if a bit is 0, the corresponding pixel is left unchanged. The mask is repeated for the entire length of the line. The default mask is Z'FFFF' (a solid line). A dashed line can be represented by Z'FF00' (long dashes) or Z'F0F0' (short dashes).

The line style is set with SETLINESTYLE. The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

The line style retrieved by GETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE or PIE.

Example
! Build as Graphics
USE IFQWIN
INTEGER(2) lstyle
lstyle = GETLINESTYLE()
WRITE (*, 100) lstyle, lstyle
100 FORMAT (1X, 'Line mask in Hex ', Z4, ' and binary ', B16)
END

See Also
LINETO, LINETO_W (W*S)
POLYGON, POLYGON_W (W*S)
RECTANGLE, RECTANGLE_W (W*S)
SETCOLORRGB (W*S)
SETFILLMASK (W*S)
SETLINESTYLE (W*S)
SETWRITEMODE (W*S)

GETLINEWIDTHQQ (W*S)

Graphics Function: Gets the current line width or the line width set by the last call to SETLINEWIDTHQQ.

Module
USE IFQWIN

Syntax
result = GETLINEWIDTHQQ( )
Results
The result is of type INTEGER(4). It contains the current width of the line in pixels.
If there is no call to SETLINEWIDTHQQ in the program (or on that particular graphics window), it returns 1.
(The default width of a line drawn by any graphics routine is 1 pixel.)

See Also
SETLINEWIDTHQQ (W*S)

GETLOG
Portability Subroutine: Returns the user's login name.

Module
USE IFPORT

Syntax
CALL GETLOG (name)

name (Output) Character*(*). User's login name.

The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it
is truncated. The actual parameter corresponding to name should be long enough to hold the login name. If
the supplied actual parameter is too short to hold the login name, the login name is truncated.
If the login name is shorter than the actual parameter corresponding to name, the login name is padded with
blanks at the end, until it reaches the length of the actual parameter.
If the login name cannot be determined, all blanks are returned.

Example
use IFPORT
character*20 username
CALL GETLOG (username)
print *, "You logged in as ",username

GETPHYSCOORD (W*S)
Graphics Subroutine: Translates viewport coordinates to physical coordinates.

Module
USE IFQWIN

Syntax
CALL GETPHYSCOORD (x, y, s)

x, y (Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.
(Output) Derived type xycoord. Physical coordinates of the input viewport position. The xycoord derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord   ! x-coordinate
  INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.

**Example**

```fortran
! Program to demonstrate GETPHYSCOORD, GETVIEWCOORD,
! and GETWINDOWCOORD. Build as QuickWin or Standard
! Graphics
USE IFQWIN
TYPE (xycoord)  viewxy, physxy
TYPE (wxycoord) windxy
CALL SETVIEWPORT(INT2(80), INT2(50), &
                   INT2(240), INT2(150))

! Get viewport equivalent of point (100, 90)
CALL GETVIEWCOORD (INT2(100), INT2(90), viewxy)

! Get physical equivalent of viewport coordinates
CALL GETPHYSCOORD (viewxy%xcoord, viewxy%ycoord, &
                    physxy)

! Get physical equivalent of viewport coordinates
CALL GETWINDOWCOORD (viewxy%xcoord, viewxy%ycoord, &
                      windxy)

! Write viewport coordinates
WRITE (*,*) viewxy%xcoord, viewxy%ycoord
! Write physical coordinates
WRITE (*,*) physxy%xcoord, physxy%ycoord
! Write window coordinates
WRITE (*,*) windxy%wx, windxy%wy
END
```

**See Also**

GETVIEWCOORD, GETVIEWCOORD_W (W*S)
GETWINDOWCOORD (W*S)
SETCLIPRGN (W*S)
SETVIEWPORT (W*S)

**GETPID**

*Portability Function:* Returns the process ID of the current process.

**Module**

USE IFPORT

**Syntax**

```fortran
result = GETPID()
```
Results
The result type is INTEGER(4). The result is the process ID number of the current process.

Example
USE IFPORT
INTEGER(4) istat
istat = GETPID()

GETPIXEL, GETPIXEL_W (W*S)

Graphics Functions: Return the color index of the pixel at a specified location.

Module
USE IFQWIN

Syntax
result = GETPIXEL (x, y)
result = GETPIXEL_W (wx, wy)

x, y (Input) INTEGER(2). Viewport coordinates for pixel position.
wx, wy (Input) REAL(8). Window coordinates for pixel position.

Results
The result type is INTEGER(2). The result is the pixel color index if successful; otherwise, -1 (if the pixel lies outside the clipping region, for example).

Color routines without the RGB suffix, such as GETPIXEL, use color indexes, not true color values, and limit you to colors in the palette, at most 256. To access all system colors, use SETPIXELRGB to specify an explicit Red-Green-Blue value and retrieve the value with GETPIXELRGB.

NOTE
The GETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetPixel.

SETCOLOR (W*S)
GETPIXELS (W*S)
SETPIXEL, SETPIXEL_W (W*S)

GETPIXELRGB, GETPIXELRGB_W (W*S)

Graphics Functions: Return the Red-Green-Blue (RGB) color value of the pixel at a specified location.

Module
USE IFQWIN
Syntax

\[
\text{result} = \text{GETPIXELRGB} \; (x, y)
\]
\[
\text{result} = \text{GETPIXELRGB} \; (wx, wy)
\]

\(x, \; y\) 

(Input) INTEGER(2). Viewport coordinates for pixel position.

\(wx, \; wy\) 

(Input) REAL(8). Window coordinates for pixel position.

Results

The result type is INTEGER(4). The result is the pixel’s current RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETPIXELRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 0 B B B B B B G G G G G G G R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex ‘Z’FF’) the maximum for each of the three components. For example, ‘Z’0000FF’ yields full-intensity red, ‘Z’00FF00’ full-intensity green, ‘Z’FF0000’ full-intensity blue, and ‘Z’FFFFFF’ full-intensity for all three, resulting in bright white.

GETPIXELRGB returns the true color value of the pixel, set with SETPIXELRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixel’s position and the current configuration of the screen.

SETPIXELRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIEXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) pixcolor, rseed
INTEGER(2) status
REAL rnd1, rnd2
LOGICAL(4) winstat
TYPE (windowconfig) wc
CALL GETTIM (status, status, status, INT2(rseed))
CALL SEED (rseed)
CALL RANDOM (rnd1)
CALL RANDOM (rnd2)
!
! Get the color index of a random pixel, normalized to
! be in the window. Then set current color to that
! pixel color.
!
winstat = GETWINDOWCONFIG(wc)
xnum = wc%numxpixels
ynum = wc%numypixels
pixcolor = GETPIXELRGB( INT2( rnd1*xnum ), INT2( rnd2*ynum ))
status = SETCOLORRGB (pixcolor)
END
See Also
SETPIXELRGB, SETPIXELRGB_W (W*S)
GETPIXELRGB (W*S)
SETPIXELRGB (W*S)
GETPIXEL, GETPIXEL_W (W*S)

GETPIXELS (W*S)

**Graphics Subroutine:** Returns the color indexes of multiple pixels.

Module
USE IFQWIN

Syntax
CALL GETPIXELS (n,x,y,color)

n (Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other arguments.

x, y (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to get.

color (Output) INTEGER(2). Array to be filled with the color indexes of the pixels at x and y.

GETPIXELS fills in the array color with color indexes of the pixels specified by the two input arrays x and y. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If the pixel is outside the clipping region, the value placed in the color array is undefined. Calls to GETPIXELS with n less than 1 are ignored. GETPIXELS is a much faster way to acquire multiple pixel color indexes than individual calls to GETPIXEL.

The range of possible pixel color index values is determined by the current video mode and palette, at most 256 colors. To access all system colors you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function such as SETPIXELRGB and retrieve the value with GETPIXELRGB, rather than a palette index with a non-RGB color function.

See Also
GETPIXELRGB (W*S)
SETPIXELRGB (W*S)
GETPIXEL, GETPIXEL_W (W*S)
SETPIXELS (W*S)

GETPIXELRGB (W*S)

**Graphics Subroutine:** Returns the Red-Green-Blue (RGB) color values of multiple pixels.

Module
USE IFQWIN

Syntax
CALL GETPIXELRGB (n,x,y,color)
GETPIXELS fills in the array *color* with the RGB color values of the pixels specified by the two input arrays *x* and *y*. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the values you retrieve with GETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
+----------------+----------------+----------------+
<table>
<thead>
<tr>
<th>Bit</th>
<th>Bit</th>
<th>Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>24</td>
<td>16</td>
</tr>
<tr>
<td>MSB</td>
<td>(MSB)</td>
<td>(MSB)</td>
</tr>
<tr>
<td>23</td>
<td>23</td>
<td>23</td>
</tr>
<tr>
<td>22</td>
<td>22</td>
<td>22</td>
</tr>
<tr>
<td>21</td>
<td>21</td>
<td>21</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELSRGB is a much faster way to acquire multiple pixel RGB colors than individual calls to GETPIXELRGB. GETPIXELSRGB returns an array of true color values of multiple pixels, set with SETPIXELSRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixels' positions and the current configuration of the screen.

SETPIXELSRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) color(50), result
INTEGER(2) x(50), y(50), status
TYPE (xycoord) pos
result = SETCOLORRGB(Z'FF')
CALL MOVETO(INT2(0), INT2(0), pos)
status = LINETO(INT2(100), INT2(200))
! Get 50 pixels at line 30 in viewport
DO i = 1, 50
   x(i) = i-1
   y(i) = 30
END DO
CALL GETPIXELSRGB(300, x, y, color)
! Move down 30 pixels and redisplay pixels
DO i = 1, 50
   y(i) = y(i) + 30
```
CALL SETPIXELSRGB (50, x, y, color)

GETPIXELS (W*S)  
SETPIXELS (W*S)  

GETPOS, GETPOSI8

Module
USE IFPORT

Syntax
result = GETPOS (lunit)
result = GETPOSI8 (lunit)

lunit (Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and the file must be connected.

Results
The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the offset, in bytes, from the beginning of the file. If an error occurs, the result value is -1 and the following error code is returned in errno:
EINVAL: lunit is not a valid unit number, or is not open.
These functions are equivalent to FTELL, FTELLI8.

GETSTATUSFPQQ (W*S)

Portability Subroutine: Returns the floating-point processor status word.

Module
USE IFPORT

Syntax
CALL GETSTATUSFPQQ (status)

status (Output) INTEGER(2). Floating-point processor status word.

The floating-point status word shows whether various floating-point exception conditions have occurred. The compiler initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>Z'003F'</td>
<td>Status Mask (set all flags to 1)</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Hex value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>Z'0001'</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>Z'0002'</td>
<td>A denormal (very small number) occurred</td>
</tr>
<tr>
<td>FPSW$ZERODIVIDE</td>
<td>Z'0004'</td>
<td>A divide by zero occurred</td>
</tr>
<tr>
<td>FPSW$OVERFLOW</td>
<td>Z'0008'</td>
<td>An overflow occurred</td>
</tr>
<tr>
<td>FPSW$UNDERFLOW</td>
<td>Z'0010'</td>
<td>An underflow occurred</td>
</tr>
<tr>
<td>FPSW$INEXACT</td>
<td>Z'0020'</td>
<td>Inexact precision occurred</td>
</tr>
</tbody>
</table>

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause runtime errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

Example

```fortran
! Program to demonstrate GETSTATUSFPQQ
USE IFPORT
INTEGER(2) status
CALL GETSTATUSFPQQ(status)
! check for divide by zero
IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
    WRITE (*,*) 'Divide by zero occurred. Look &
    for NaN or signed infinity in resultant data.'
END IF
END
```

GETCONTROLFPQQ
SIGNALQQ
CLEARSTATUSFPQQ

GETSTRQQ

*Run-Time Function:* Reads a character string from the keyboard using buffered input.

Module

USE IFCORE

Syntax

result = GETSTRQQ (buffer)
buffer (Output) Character*(*). Character string returned from keyboard, padded on the right with blanks.

Results
The result type is INTEGER(4). The result is the number of characters placed in buffer.
The function does not complete until you press Return or Enter.

Example

```fortran
! Program to demonstrate GETSTRQQ
USE IFCORE
USE IFPORT
INTEGER(4) length, result
CHARACTER(80) prog, args
WRITE (*, '(A, ', I4, ')') 'Enter program to run: ', prog
length = GETSTRQQ (prog)
WRITE (*, '(A, ', I4, ')') 'Enter arguments: ', args
length = GETSTRQQ (args)
result = RUNQQ (prog, args)
IF (result .EQ. -1) THEN
  WRITE (*, *) 'Couldn''t run program'
ELSE
  WRITE (*, '(A, ', Z4, ')') 'Return code : ', result, 'h'
END IF
END
```

See Also
READ Statement
GETCHARQQ
PEEKCHARQQ
GETTEXTCOLOR (W*S)

**Graphics Function:** Returns the current text color index.

Module
USE IFQWIN

Syntax

```fortran
result = GETTEXTCOLOR( )
```

Results
The result type is INTEGER(2). It is the current text color index.

GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.
The default text color index is 15, which is associated with white unless the user remaps the palette.
NOTE
The GETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetTextColor.

See Also
OUTTEXT (W*S)
REMAPALLPALETTERGB, REMAPPALETTERGB (W*S)
SETCOLOR (W*S)
SETTEXTCOLOR (W*S)

GETTEXTCOLORRGB (W*S)

Graphics Function: Returns the Red-Green-Blue (RGB) value of the current text color (used with OUTTEXT, WRITE and PRINT).

Module
USE IFQWIN

Syntax
result = GETTEXTCOLORRGB( )

Results
The result type is INTEGER(4). It is the RGB value of the current text color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB. The RGB color value used for graphics is set and returned with SETCOLORRGB and GETCOLORRGB. SETCOLORRGB controls the color used by the graphics function OUTGTEXT, while SETTEXTCOLORRGB controls the color used by all other text output functions. The RGB background color value for both text and graphics is set and returned with SETBKCOLORRGB and GETBKCOLORRGB.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETCOLORRGB) sets the color to a color value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) oldtextc, oldbackc, temp
TYPE (rccoord) curpos
!

! Save color settings
oldtextc = GETTEXTCOLORRGB()
oldbackc = GETBKCOLORRGB()
CALL CLEARSCREEN( $GCLEARSCREEN )
!

! Reset colors
temp = SETTEXTCOLORRGB(Z'00FFFF')  ! full red + full green
     ! = full yellow text
temp = SETBKCOLORRGB(Z'FF0000')    ! blue background
CALL SETTEXTPOSITION( INT2(4), INT2(15), curpos)
CALL OUTTEXT( 'Hello, world')
!

! Restore colors
temp = SETTEXTCOLORRGB(oldtextc)
temp = SETBKCOLORRGB(oldbackc)
END

See Also
SETTEXTCOLORRGB (W*S)
GETBKCOLORRGB (W*S)
GETCOLORRGB (W*S)
GETTEXTCOLOR (W*S)

GETTEXTPOSITION (W*S)

Graphics Subroutine: Returns the current text position.

Module
USE IFQWIN

Syntax
CALL GETTEXTPOSITION (s)

s

(Output) Derived type rccoord. Current text position. The derived type
rccoord is defined in IFQWIN.F90 as follows:

TYPE rccoord
  INTEGER(2) row  ! Row coordinate
  INTEGER(2) col  ! Column coordinate
END TYPE rccoord

The text position given by coordinates (1, 1) is defined as the upper-left corner of the text window. Text output from the OUTTEXT function (and WRITE and PRINT statements) begins at the current text position. Font text is not affected by the current text position. Graphics output, including OUTGTEXT output, begins at the current graphics output position, which is a separate position returned by GETCURRENTPOSITION.

Example
!

! Build as QuickWin or Standard Graphics
USE IFQWIN
  TYPE (rccoord) textpos
CALL GETTEXTPOSITION (textpos)
END

See Also
GETTEXTPOSITION (W*S)
GETCURRENTPOSITION, GETCURRENTPOSITION_W (W*S)
OUTTEXT (W*S)
WRITE Statement
SETTEXTWINDOW (W*S)

GETTEXTWINDOW (W*S)

*Graphics Subroutine: Finds the boundaries of the current text window.*

**Module**

USE IFQWIN

**Syntax**

CALL GETTEXTWINDOW (r1, c1, r2, c2)

- **r1, c1** (Output) INTEGER(2). Row and column coordinates for upper-left corner of the text window.
- **r2, c2** (Output) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

Output from OUTTEXT and WRITE is limited to the text window. By default, this is the entire window, unless the text window is redefined by SETTEXTWINDOW.

The window defined by SETTEXTWINDOW has no effect on output from OUTGTEXT.

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) top, left, bottom, right
DO i = 1, 10
   WRITE(*,*) "Hello, world"
END DO
! Save text window position
CALL GETTEXTWINDOW (top, left, bottom, right)
! Scroll text window down seven lines
CALL SCROLLTEXTWINDOW (INT2(-7))
! Restore text window
CALL SETTEXTWINDOW (top, left, bottom, right)
WRITE(*,*) "At beginning again"
END
```

**See Also**

GETTEXTPOSITION (W*S)
OUTTEXT (W*S)
WRITE Statement
SCROLLTEXTWINDOW (W*S)
SETTEXTPOSITION (W*S)
SETTEXTWINDOW (W*S)
WRAPON (W*S)

GETTIM

*Portability Subroutine: Returns the time.*

**Module**

USE IFPORT

**Syntax**

CALL GETTIM (ihr, imin, isec, i100th)

Output) INTEGER(4) or INTEGER(2). Hour (0-23).

(Output) INTEGER(4) or INTEGER(2). Minute (0-59).

(Output) INTEGER(4) or INTEGER(2). Second (0-59).

(Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example

See the example in GETDAT.

SECONDS Portability Routine
TIME Portability Routine
TIMEF
GETTIMEOFDAY

Portability Subroutine: Returns seconds and microseconds since 00:00 Jan 1, 1970.

Module

USE IFPORT

Syntax

CALL GETTIMEOFDAY (ret, err)

ret

(Output) INTEGER(4). One-dimensional array with 2 elements used to contain numeric time data. The elements of ret are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ret(1)</td>
<td>Seconds</td>
</tr>
<tr>
<td>ret(2)</td>
<td>Microseconds</td>
</tr>
</tbody>
</table>

err

(Output) INTEGER(4).

If an error occurs, err contains a value equal to -1 and array ret contains zeros.
On Windows* systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

GETUID

*Portability Function: Returns the user ID of the calling process.*

**Module**

USE IFPORT

**Syntax**

```
result = GETUID()
```

**Results**

The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  
  Note that on Windows systems, domain accounts and local accounts can overlap.

- On Linux* and OS X* systems, this function returns the user identity for the current process.

**Example**

```
USE IFPORT
integer(4) istat
istat = GETUID()
```

GETUNITQQ (W*S)

*QuickWin Function: Returns the unit number corresponding to the specified Windows* handle.*

**Module**

USE IFQWIN

**Syntax**

```
result = GETUNITQQ(whandle)
```

**whandle**  
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The Windows handle to the window; this is a unique ID.

**Results**

The result type is INTEGER(4). The result is the unit number corresponding to the specified Windows handle. If *whandle* does not exist, it returns -1.

This routine is the inverse of GETHWNDQQ.

**See Also**

GETHWNDQQ (W*S)

GETVIEWCOORD, GETVIEWCOORD_W (W*S)

*Graphics Subroutines: Translate physical coordinates or window coordinates to viewport coordinates.*
Module
USE IFQWIN

Syntax
CALL GETVIEWCOORD (x, y, s)
CALL GETVIEWCOORD_W (wx, wy, s)

x, y  (Input) INTEGER(2). Physical coordinates to be converted to viewport coordinates.
wx, wy (Input) REAL(8). Window coordinates to be converted to viewport coordinates.
s  (Output) Derived type xycoord. Viewport coordinates. The xycoord derived type is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord   ! x-coordinate
  INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Physical coordinates refer to the whole screen. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.

Example
See the example program in GETPHYSCOORD.

See Also
GETPHYSCOORD (W*S)
GETWINDOWCOORD (W*S)
GETWINDOWCONFIG (W*S)

QuickWin Function: Returns the properties of the current window.

Module
USE IFQWIN

Syntax
result = GETWINDOWCONFIG (wc)

wc  (Output) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```
TYPE windowconfig
  INTEGER(2) numxpixels             ! Number of pixels on x-axis
  INTEGER(2) numypixels             ! Number of pixels on y-axis
  INTEGER(2) numtextcols            ! Number of text columns available
  INTEGER(2) numtextrows            ! Number of text rows available
  INTEGER(2) numcolors              ! Number of color indexes
  INTEGER(4) fontsize           ! Size of default font. Set to QWIN$EXTENDFONT when specifying
                                ! extended attributes, in which
END TYPE windowconfig
```
Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE. (for example, if there is no active child window).

GETWINDOWCONFIG returns information about the active child window. If you have not set the window properties with SETWINDOWCONFIG, GETWINDOWCONFIG returns default window values.

A typical set of values would be 1024 x pixels, 768 y pixels, 128 text columns, 48 text rows, and a font size of 8x16 pixels. The resolution of the display and the assumed font size of 8x16 pixels generates the number of text rows and text columns. The resolution (in this case, 1024 x pixels by 768 y pixels) is the size of the virtual window. To get the size of the physical window visible on the screen, use GETWSIZEQQ. In this case, GETWSIZEQQ returned the following values: (0,0) for the x and y position of the physical window, 25 for the height or number of rows, and 71 for the width or number of columns.

The number of colors returned depends on the video drive. The window title defaults to “Graphic1” for the default window. All of these values can be changed with SETWINDOWCONFIG.

Note that the bitsperpixel field in the windowconfig derived type is an output field only, while the other fields return output values to GETWINDOWCONFIG and accept input values from SETWINDOWCONFIG.

Example

!Build as QuickWin or Standard Graphics App.
USE IQQWIN
LOGICAL(4) status
TYPE (windowconfig) wc
status = GETWINDOWCONFIG(wc)
IF(wc%numtextrows .LT. 10) THEN
    wc%numtextrows = 10
    status = SETWINDOWCONFIG(wc)
    IF(.NOT. status ) THEN ! if setwindowconfig error
        status = SETWINDOWCONFIG(wc) ! reset
        ! setwindowconfig with corrected values
        status = GETWINDOWCONFIG(wc)
    IF(wc%numtextrows .NE. 10) THEN
        WRITE(*,*) 'Error: Cannot increase text rows to 10'
    END IF
END IF
Graphics Subroutine: Converts viewport coordinates to window coordinates.

Module
USE IFQWIN

Syntax
CALL GETWINDOWCOORD (x, y, s)

x, y (Input) INTEGER(2). Viewport coordinates to be converted to window coordinates.

s (Output) Derived type wxycoord. Window coordinates. The wxycoord derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE wxycoord
  REAL(8) wx ! x-coordinate
  REAL(8) wy ! y-coordinate
END TYPE wxycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.

Example
See the example program in GETPHYSCOORD.

GETPHYSCOORD (W*S)
GETVIEWCOORD, GETVIEWCOORD_W (W*S)
MOVETO, MOVETO_W (W*S)
SETVIEWPORT (W*S)
SETWINDOW (W*S)

Graphics Function: Returns the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions.

Module
USE IFQWIN
Syntax
result = GETWRITEMODE( )

Results
The result type is INTEGER(2). The result is the current write mode. Possible return values are:

- $GPSET - Causes lines to be drawn in the current graphics color. (default)
- $GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- $GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- $GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- $GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

The default value is $GPSET. These constants are defined in IFQWIN.F90.

The write mode is set with SETWRITEMODE.

Example
! Build as QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) mode
mode = GETWRITEMODE()
END

SETCOLORRGB (W*S)
SETFILLMASK (W*S)
GRSTATUS (W*S)

GETWSIZEQQ (W*S)
QuickWin Function: Returns the size and position of a window.

Module
USE IFQWIN

Syntax
result = GETWSIZEQQ (unit, ireq, winfo)

unit (Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5 and 6 refer to the default startup window only if you have not explicitly opened them with the OPEN statement. To access information about the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW, defined in IFQWIN.F90.
**ireq**

(Input) INTEGER(4). Specifies what information is obtained. The following symbolic constants, defined in `IFQWIN.F90`, are available:

- QWIN$SIZE$MAX - Gets information about the maximum window size.
- QWIN$SIZE$CURR - Gets information about the current window size.

**winfo**

(Output) Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in `IFQWIN.F90` as follows:

```
TYPE QWINFO
  INTEGER(2) TYPE  ! request type (controls
                !   SETWSIZEQQ)
  INTEGER(2) X     ! x coordinate for upper left
  INTEGER(2) Y     ! y coordinate for upper left
  INTEGER(2) H     ! window height
  INTEGER(2) W     ! window width
END TYPE QWINFO
```

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width returned for a frame window reflects the size in pixels of the client area excluding any borders, menus, and status bar at the bottom of the frame window. You should adjust the values used in SETWSIZEQQ to take this into account.

The client area is the area actually available to place child windows.

GETWINDOWCONFIG (W*S)

SETWSIZEQQ (W*S)

**GMTIME**

*Portability Subroutine:* Returns the Greenwich mean time in an array of time elements.

**Module**

USE IFPORT

**Syntax**

CALL GMTIME (stime,tarray)

**stime**

(Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.

**tarray**

(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of tarray are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tarray(1)</td>
<td>Seconds (0-61, where 60-61 can be returned for leap seconds)</td>
</tr>
</tbody>
</table>
Element                Value

tarray(2)        Minutes (0-59)
tarray(3)        Hours (0-23)
tarray(4)        Day of month (1-31)
tarray(5)        Month (0-11)
tarray(6)        Number of years since 1900

tarray(7)        Day of week (0-6, where 0 is Sunday)
tarray(8)        Day of year (0-365)
tarray(9)        Daylight saving flag (0 if standard time, 1 if daylight saving time)

**CAUTION**
This subroutine may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Example**

```
use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
!   00:00:00 GMT January 1, 1970
stime = time()
CALL GMTIME (stime, timearray)
print *, timearray
end
```

**See Also**
DATE_AND_TIME

**GOTO - Assigned**

*Statement:* Transfers control to the statement whose label was most recently assigned to a variable. This feature has been deleted in the Fortran Standard.
*Intel® Fortran fully supports features deleted in the Fortran Standard.*

**Syntax**

```
GOTO var[[ ,] (label-list)]
```

- **var**        Is a scalar integer variable.
- **label-list** Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the assigned GO TO statement. The same label can appear more than once in this list.

The variable must have a statement label value assigned to it by an ASSIGN statement (not an arithmetic assignment statement) before the GO TO statement is executed.

If a list of labels appears, the statement label assigned to the variable must be one of the labels in the list.

Both the assigned GO TO statement and its associated ASSIGN statement must be in the same scoping unit.
### Example

The following example is equivalent to `GO TO 200`:

```fortran
ASSIGN 200 TO IGO
GO TO IGO
```

The following example is equivalent to `GO TO 450`:

```fortran
ASSIGN 450 TO IBEG
GO TO IBEG, (300,450,1000,25)
```

The following example shows an invalid use of an assigned variable:

```fortran
ASSIGN 10 TO I
J = I
GO TO J
```

In this case, variable J is not the variable assigned to, so it cannot be used in the assigned GO TO statement.

The following shows another example:

```fortran
ASSIGN 10 TO n
GOTO n
10  CONTINUE
```

The following example uses an assigned GOTO statement to check the value of `view`:

```fortran
C   Show user appropriate view of data depending on
C   security clearance.
GOTO view (100, 200, 400)
```

- GOTO - Computed
- GOTO - Unconditional
- Execution Control Overview

#### GOTO - Computed

**Statement:** Transfers control to one of a set of labeled branch target statements based on the value of an expression. It is an obsolescent feature in Fortran 95.

**Syntax**

```fortran
GOTO (label-list) [ , ] expr
```

- **label-list**
  
  Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the computed GO TO statement. (Also called the *transfer list.*) The same label can appear more than once in this list.

- **expr**
  
  Is a scalar numeric expression in the range 1 to `n`, where `n` is the number of statement labels in `label-list`. If necessary, it is converted to integer data type.

When the computed GO TO statement is executed, the expression is evaluated first. The value of the expression represents the ordinal position of a label in the associated list of labels. Control is transferred to the statement identified by the label. For example, if the list contains (30,20,30,40) and the value of the expression is 2, control is transferred to the statement identified with label 20.

If the value of the expression is less than 1 or greater than the number of labels in the list, control is transferred to the next executable statement or construct following the computed GO TO statement.
Example
The following example shows valid computed GO TO statements:

```
GO TO (12,24,36), INDEX
GO TO (320,330,340,350,360), SITU(J,K) + 1
```

The following shows another example:

```
next = 1
C
C The following statement transfers control to statement 10:
C
  GOTO (10, 20) next
  ...
  10 CONTINUE
  ...
  20 CONTINUE
```

See Also
Obsolescent Language Features in the Fortran Standard
GOTO - Unconditional
Execution Control Overview

GOTO - Unconditional

**Statement:** Transfers control to the same branch target statement every time it executes.

**Syntax**

```
GO TO label
```

*label*  
Is the label of a valid branch target statement in the same scoping unit as the GO TO statement.

The unconditional GO TO statement transfers control to the branch target statement identified by the specified label.

Example
The following are examples of GO TO statements:

```
GO TO 7734
GO TO 99999
```

The following shows another example:

```
integer(2) in
10  print *, 'enter a number from one to ten: '
   read *, in
   select case (in)
   case (1:10)
     exit
   case default
     print *, 'wrong entry, try again'
     goto 10
   end select
```

GOTO - Computed
Execution Control Overview
GRSTATUS (W*S)

**Graphics Function:** Returns the status of the most recently used graphics routine.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = GRSTATUS()
```

**Results**

The result type is INTEGER(2). The result is the status of the most recently used graphics function.

Use GRSTATUS immediately following a call to a graphics routine to determine if errors or warnings were generated. Return values less than 0 are errors, and values greater than 0 are warnings.

The following symbolic constants are defined in the *IFQWIN.F90* module file for use with GRSTATUS:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GRFILEWRITEERROR</td>
<td>Error writing bitmap file</td>
</tr>
<tr>
<td>$GRFILEOPENERROR</td>
<td>Error opening bitmap file</td>
</tr>
<tr>
<td>$GRIMAGEREADERERROR</td>
<td>Error reading image</td>
</tr>
<tr>
<td>$GRBITMAPDISPLAYERROR</td>
<td>Error displaying bitmap</td>
</tr>
<tr>
<td>$GRBITMAPTOOLARGE</td>
<td>Bitmap too large</td>
</tr>
<tr>
<td>$GRIMPROPERBITMAPFORMAT</td>
<td>Improper format for bitmap file</td>
</tr>
<tr>
<td>$GRFILEREADERROR</td>
<td>Error reading file</td>
</tr>
<tr>
<td>$GRNOBITMAPFILE</td>
<td>No bitmap file</td>
</tr>
<tr>
<td>$GRINVALIDIMAGEBUFFER</td>
<td>Image buffer data inconsistent</td>
</tr>
<tr>
<td>$GRINSUFFICIENTMEMORY</td>
<td>Not enough memory to allocate buffer or to complete a fill operation</td>
</tr>
<tr>
<td>$GRINVALIDPARAMETER</td>
<td>One or more parameters invalid</td>
</tr>
<tr>
<td>$GRRMODENOTSUPPORTED</td>
<td>Requested video mode not supported</td>
</tr>
<tr>
<td>$GRERROR</td>
<td>Graphics error</td>
</tr>
<tr>
<td>$GROK</td>
<td>Success</td>
</tr>
<tr>
<td>$GRNOOUTPUT</td>
<td>No action taken</td>
</tr>
<tr>
<td>$GRCLIPPED</td>
<td>Output was clipped to viewport</td>
</tr>
<tr>
<td>$GRPARAMETERALTERED</td>
<td>One or more input parameters was altered to be within range, or pairs of parameters were interchanged to be in the proper order</td>
</tr>
</tbody>
</table>
After a graphics call, compare the return value of GRSTATUS to $GROK. to determine if an error has occurred. For example:

```fortran
IF ( GRSTATUS .LT. $GROK ) THEN
    ! Code to handle graphics error goes here
ENDIF
```

The following routines cannot give errors, and they all set GRSTATUS to $GROK:

- `DISPLAYCURSOR`
- `GETCOLORRGB`
- `GETTEXTCOLOR`
- `GETTEXTWINDOW`
- `GETBKCOLORRGB`
- `GETTEXTCOLORRGB`
- `WRAPON`
- `GETCOLOR`
- `GETTEXTPOSITION`

The following table lists some other routines with the error or warning messages they produce for GRSTATUS:

<table>
<thead>
<tr>
<th>Function</th>
<th>Possible GRSTATUS error codes</th>
<th>Possible GRSTATUS warning codes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC, ARC_W</td>
<td>$GRINVALIDPARAMETER</td>
<td></td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>$GRINVALIDPARAMETER</td>
<td></td>
</tr>
<tr>
<td>ELLIPSE, ELLIPSE_W</td>
<td>$GRINVALIDPARAMETER, $GRINSUFFICIENTMEMORY</td>
<td>$GRNOOUTPUT</td>
</tr>
<tr>
<td>FLOODFILLRGB</td>
<td>$GRINVALIDPARAMETER, $GRINSUFFICIENTMEMORY</td>
<td>$GRNOOUTPUT</td>
</tr>
<tr>

HOSTNAM

**Portability Function:** Returns the current host computer name. This function can also be specified as `HOSTNM`.

**Module**

USE IFPORT

**Syntax**

```fortran
result = HOSTNAM (name)
```

**name** (Output) Character*(*) Type. Name of the current host. Should be at least as long as `MAX_HOSTNAM_LENGTH + 1`. `MAX_HOSTNAM_LENGTH` is defined in the IFPORT module.

**Results**

The result type is INTEGER(4). The result is zero if successful. If `name` is not long enough to contain all of the host name, the function truncates the host name and returns -1.

**Example**

```fortran
use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
```

HUGE

**Inquiry Intrinsic Function (Generic):** Returns the largest number in the model representing the same type and kind parameters as the argument.

**Syntax**

```fortran
result = HUGE (x)
```

**x** (Input) Must be of type integer or real; it can be scalar or array valued.

**Results**

The result is a scalar of the same type and kind parameters as `x`. If `x` is of type integer, the result has the value `r q - 1`. If `x` is of type real, the result has the value `(1 - b ^ -p)b e_max`.

Integer parameters `r` and `q` are defined in Model for Integer Data; real parameters `b`, `p`, and `e_max` are defined in Model for Real Data.
Example
If X is of type REAL(4), HUGE (X) has the value \((1 - 2^{-24}) \times 2^{128}\).

TINY
Data Representation Models

HYPOT
Elemental Intrinsic Function (Generic): Returns the value of the Euclidean distance of the arguments.

Syntax
\[
\text{result} = \text{HYPOT} (x, y)
\]

\(x\) (Input) Must be of type real.

\(y\) (Input) Must be of type real. It must be the same type and kind as \(x\).

Results
The result type and kind are the same as \(x\).

The result has a value equal to a processor-dependent approximation to the Euclidean distance, \(\sqrt{x^2 + y^2}\), without undue overflow or underflow.

Example
HYPOT (3.0, 4.0) has the approximate value 5.0.

IACHAR
Elemental Intrinsic Function (Generic): Returns the position of a character in the ASCII character set, even if the processor's default character set is different. In Intel® Fortran, IACHAR is equivalent to the ICHAR function.

Syntax
\[
\text{result} = \text{IACHAR} (c [, kind])
\]

\(c\) (Input) Must be of type character of length 1.

\(kind\) (Input; optional) Must be a scalar integer initialization expression.

Results
The result type is integer. If \(kind\) is present, the kind parameter of the result is that specified by \(kind\); otherwise, the kind parameter of the result is that of default integer. If \(c\) is in the ASCII collating sequence, the result is the position of \(c\) in that sequence and satisfies the inequality \((0 \leq \text{IACHAR}(c) \leq 127)\).

The results must be consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE(C, D) is true, IACHAR(C) \(\leq\) IACHAR(D) is also true.

Example
IACHAR ('Y') has the value 89.
IACHAR ('%') has the value 37.

LLT

IALL
Transformational Intrinsic Function (Generic):
Reduces an array with a bitwise AND operation.

Syntax
result = IALL (array, dim [, mask])
result = IALL (array[, mask])

array
(Input) Must be an array of type integer.
dim
(Input) Must be a scalar integer with a value in the range 1 <= dim <= n,
where n is the rank of array. The corresponding actual argument must not
be an optional dummy argument.
mask
(Input; optional) Must be of type logical and conformable with array.

Results
The result has the same type and kind parameters as array. It is scalar if dim does not appear or if array has
rank one; otherwise, the result is an array of rank n - 1 and shape [d1, d2, ..., d_dim-1, d_dim+1, ..., d_n] where
[d1, d2, ..., d_n] is the shape of array.

If array has size zero the result value is equal to NOT (INT (0, KIND (array))). Otherwise, the result of IALL
(array) has a value equal to the bitwise AND of all the elements of array.

The result of IALL (array, MASK=mask) has a value equal to IALL (PACK (array, mask)).

The result of IALL (array, DIM=dim [, MASK=mask]) has a value equal to that of IALL (array [, 
MASK=mask]) if array has rank one. Otherwise, the value of element (s1, s2, ..., s_dim-1, s_dim+1, ..., s_n) of the
result is equal to IALL (array (s1, s2, ..., s_dim-1, :, s_dim+1, ..., s_n) [, MASK = mask (s1, s2, ..., s_dim-1 , :, s_dim +1 , ..., s_n)])

Example
IALL ([14, 13, 11]) has the value 8. IALL ([14, 13, 11], MASK=[.true., .false., .true]) has the value 10.

IANY
IPARITY

IAND
Elemental Intrinsic Function (Generic): Performs
a logical AND on corresponding bits. This function can
also be specified as AND.

Syntax
result = IAND (i,j)
i  (Input) Must be of type integer or of type logical (which is treated as an integer).

j  (Input) Must be of type integer or logical with the same kind parameter as i. If the kinds of i and j do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result.

Results

The result type and kind is the same as i. The result value is derived by combining i and j bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>IAND (i, j)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIAND</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>

</tr>
<tr>
<td>JIAND</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIAND</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

Example

IAND (2, 3) has the value 2.

IAND (4, 6) has the value 4.

The following shows another example:

```fortran
INTEGER(1) i, m
INTEGER result
INTEGER(2) result2
i = 1
m = 3
result = IAND(i, m) ! returns an integer of default type
           ! (INTEGER(4) unless reset by user) whose
           ! value = 1
result2 = IAND(i, m) ! returns an INTEGER(2) with value = 1
```

IANY

Transformational Intrinsic Function (Generic):
Reduces an array with a bitwise OR operation.

Syntax

\[
\text{result} = \text{IANY}(\text{array}, \text{dim} [, \text{mask}]) \\
\text{result} = \text{IANY}(\text{array}[, \text{mask}])
\]

array  
(Input) Must be an array of type integer.

dim  
(Input) Must be a scalar integer with a value in the range \(1 \leq \text{dim} \leq n\), where \(n\) is the rank of \(\text{array}\). The corresponding actual argument must not be an optional dummy argument.

mask  
(Input; optional) Must be of type logical and conformable with \(\text{array}\).

Results

The result has the same type and kind parameters as \(\text{array}\). It is scalar if \(\text{dim}\) does not appear; otherwise, the result is an array of rank \(n - 1\) and shape \([d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n]\) where \([d_1, d_2, \ldots, d_n]\) is the shape of \(\text{array}\).

The result of IANY \((\text{array})\) is the bitwise OR of all the elements of \(\text{array}\). If \(\text{array}\) has size zero, the result value is equal to zero.

The result of IANY \((\text{array}, \text{MASK}=\text{mask})\) has a value equal to IANY \((\text{PACK}(\text{array}, \text{mask}))\).

The result of IANY \((\text{array}, \text{DIM}=\text{dim} [, \text{MASK}=\text{mask}])\) has a value equal to that of IANY \((\text{array} [, \text{MASK}=\text{mask}])\) if \(\text{array}\) has rank one. Otherwise, the value of element \((s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of the result is equal to IANY \((\text{array} (s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n) [, \text{MASK}=\text{mask} (s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)])\).

Example

IANY \(([14, 13, 8])\) has the value 15. IANY \(([14, 13, 8], \text{MASK}=\{.true., .false., .true}\}) has the value 14.

IALL
IPARITY

IARGC

Inquiry Intrinsic Function (Specific): Returns the index of the last command-line argument. It cannot be passed as an actual argument. This function can also be specified as IARG or NUMARG.

Syntax

\[
\text{result} = \text{IARGC}()
\]

Results

The result type is INTEGER(4). The result is the index of the last command-line argument, which is also the number of arguments on the command line. The command is not included in the count. For example, IARGC returns 3 for the command-line invocation of PROG1 -g -c -a.

IARGC returns a value that is 1 less than that returned by NARGS.
For a command-line invocation of PROG1 -g -c -a, the program above prints:

total command line arguments are 3

IBCHNG

Elemental Intrinsic Function (Generic): Reverses the value of a specified bit in an integer.

Syntax
result = IBCHNG (i, pos)

i
(Input) Must be of type integer or of type logical (which is treated as an integer). This argument contains the bit to be reversed.

pos
(Input) Must be of type integer. This argument is the position of the bit to be changed.

The rightmost (least significant) bit of \( i \) is in position 0.

Results
The result type and kind is the same as \( i \). The result is equal to \( i \) with the bit in position \( pos \) reversed.

For more information, see Bit Functions.

Example

```
INTEGER J, K
J = IBCHNG(10, 2)     ! returns 14 = 1110
K = IBCHNG(10, 1)     ! returns 8 = 1000
```

**IBITS**

*Elemental Intrinsic Function (Generic):* Extracts a sequence of bits (a bit field).

**Syntax**

\[
\text{result} = \text{IBITS}(i, pos, len)
\]

- **i**  
  (Input) Must be of type integer.

- **pos**  
  (Input) Must be of type integer. It must not be negative and \(pos + len\) must be less than or equal to \(\text{BIT\_SIZE}(i)\). The rightmost (least significant) bit of \(i\) is in position 0.

- **len**  
  (Input) Must be of type integer. It must not be negative.

**Results**

The result type and kind is the same as \(i\). The result has the value of the sequence of \(len\) bits in \(i\), beginning at \(pos\), right-adjusted and with all other bits zero.

For more information, see *Bit Functions*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**ICHAR**

**Elemental Intrinsic Function (Generic):** Returns the position of a character in the processor’s character set.

**Syntax**

```fortran
result = ICHAR (c [, kind])
```
(Input) Must be of type character of length 1.

kind

(Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer.

The result value is the position of c in the processor's character set. c is in the range zero to n - 1, where n is the number of characters in the character set.

For any characters C and D (capable of representation in the processor), C .LE. D is true only if ICHAR(C) .LE. ICHAR(D) is true, and C .EQ. D is true only if ICHAR(C) .EQ. ICHAR(D) is true.

<table>
<thead>

CHAR
Character and Key Code Charts for Windows*

**IDATE Intrinsic Procedure**

**Intrinsic Subroutine (Generic):** Returns three integer values representing the current month, day, and year. IDATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL IDATE (i, j, k)

i (Output) Must be of type integer. It is the current month.

j (Output) Must be of type integer with the same kind type parameter as i. It is the current day.

k (Output) Must be of type integer with the same kind type parameter as i. It is the current year.

The current month is returned in i; the current day in j. The last two digits of the current year are returned in k.
CAUTION
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
If the current date is September 16, 1999, the values of the integer variables upon return are: I = 9, J = 16, and K = 99.

See Also
DATE Intrinsic Procedure
DATE_AND_TIME
GETDAT
IDATE Portability Routine

IDATE Portability Routine
Portability Subroutine: Returns the month, day, and year of the current system. IDATE can be used as a portability subroutine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module
USE IFPORT

Syntax
CALL IDATE (i, j, k)
-or-
CALL IDATE (iarray)

i (Output) INTEGER(4). Is the current system month.

j (Output) INTEGER(4). Is the current system day.

k (Output) INTEGER(4). Is the current system year as an offset from 1900.

iarray (Output) INTEGER(4). Is a three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is greater than or equal to 1969 and is returned as 2 digits.

CAUTION
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
use IFPORT
    integer(4) imonth, iday, iyear, datarray(3)
! If the date is July 11, 1999:
    CALL IDATE(IMONTH, IDAY, IYEAR)
! sets IMONTH to 7, IDAY to 11 and IYEAR to 99.
    CALL IDATE (DATARRAY)
! datarray is (/11,7,99/)
**See Also**
DATE Portability Routine
DATE_AND_TIME
GETDAT
IDATE Intrinsic Procedure

**IDATE4**

*Portability Subroutine:* Returns the month, day, and year of the current system.

**Module**
USE IFPORT

**Syntax**

CALL IDATE4 (i,j,k)
-or-
CALL IDATE4 (iarray)

- **i** (Output) INTEGER(4). The current system month.
- **j** (Output) INTEGER(4). The current system day.
- **k** (Output) INTEGER(4). The current system year as an offset from 1900.
- **iarray** (Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

**IDENT**

*General Compiler Directive:* Specifies a string that identifies an object module. The compiler places the string in the identification field of an object module when it generates the module for each source program unit.

**Syntax**

!DIR$ IDENT string

- **string** Is a character constant containing printable characters. The number of characters is limited by the length of the source line.

Only the first IDENT directive is effective; the compiler ignores any additional IDENT directives in a program unit or module.

**See Also**
General Compiler Directives
Syntax Rules for Compiler Directives

**IDFLOAT**

*Portability Function:* Converts an INTEGER(4) argument to double-precision real type.
Module
USE IFPORT

Syntax
result = IDFLOAT (i)

i (Input) Must be of type INTEGER(4).

Results
The result type is double-precision real (REAL(8) or REAL*8).

See Also
DFLOAT

IEEE_CLASS
Elemental Module Intrinsic Function (Generic):
Returns the IEEE class.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_CLASS (x)

x (Input) Must be of type REAL.

Results
The result is of type TYPE(IEEE_CLASS_TYPE). The result value is one of the following:

- IEEE_SIGNALING_NAN
- IEEE_QUIET_NAN
- IEEE_POSITIVE_INF
- IEEE_NEGATIVE_INF
- IEEE_POSITIVE_NORMAL
- IEEE_NEGATIVE_NORMAL
- IEEE_POSITIVE_ZERO
- IEEE_NEGATIVE_ZERO

IEEE_CLASS does not return IEEE_OTHER_VALUE in Intel® Fortran.

Example
IEEE_CLASS(1.0) has the value IEEE_POSITIVE_NORMAL.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_COPY_SIGN
Elemental Module Intrinsic Function (Generic):
Returns an argument with a copied sign. This is equivalent to the IEEE copysign function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC
**Syntax**

result = IEEE_COPY_SIGN (x, y)

\[
x \quad \text{(Input) Must be of type REAL.}
\]

\[
y \quad \text{(Input) Must be of type REAL.}
\]

**Results**

The result type and kind is the same as \(x\). The result has the value \(x\) with the sign of \(y\). This is true even for IEEE special values, such as NaN or infinity.

The flags information is returned as a set of 1-bit flags.

**Example**

The value of IEEE_COPY_SIGN (X,3.0) is ABS (X), even when X is NaN.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_FLAGS**

*Portability Function:* Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of IEEE Standard 754-1985 arithmetic in a Fortran program.

**Module**

USE IFPORT

**Syntax**

result = IEEE_FLAGS (action, mode, in, out)

\[
\text{action} \quad \text{(Input) Character*(*). One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.}
\]

\[
\text{mode} \quad \text{(Input) Character*(*). One of the following literal values: 'direction', 'precision', or 'exception'.}
\]

\[
\text{in} \quad \text{(Input) Character*(*). One of the following literal values: 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive', 'extended', 'double', 'single', or ' ', which represents an unused (null) value.}
\]

\[
\text{out} \quad \text{(Output) Must be at least CHARACTER*9. One of the literal values listed for in.}
\]

The descriptions for the values allowed for \(in\) and \(out\) can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nearest'</td>
<td>Rounding direction flags</td>
</tr>

<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears all flags. Sets rounding to 'nearest', sets precision to 'double' (W<em>S) or 'extended' (L</em>X, M*X), and sets all exception flags to 0. Returns 0 if successful.</td>
</tr>
</tbody>
</table>

**Results**

IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.

The flags information is returned as a set of 1-bit flags.

**Example**

The following example gets the highest priority exception that has a flag raised. It passes the input argument in as a null string:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)
```

The following example sets the rounding direction to the default ('nearest'):

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out, in
iflag = ieee_flags('clear', 'direction', '', '' )
```

The following example clears all exceptions:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear', 'exception', 'all', '' )
```
The following example restores default direction and precision settings, and sets all exception flags to 0:

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '')
```

The following example detects an underflow exception:

```
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'
```

---

**IEEE_GET_FLAG**

*Elemental Module Intrinsic Subroutine (Generic): Returns whether an exception flag is signaling.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

```
CALL IEEE_GET_FLAG (flag, flag_value)
```

*flag* *(Input)* Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

*flag_value* *(Output)* Must be of type default logical. If the exception in 'flag' is signaling, the result is true; otherwise, false.

**Example**

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL ON
...
CALL IEEE_GET_FLAG(IEEE_INVALID, ON)
```

If flag IEEE_INVALID is signaling, the value of ON is true; if it is quiet, the value of ON is false.

IEEE Intrinsic Modules Quick Reference Tables

---

**IEEE_GET_HALTING_MODE**

*Elemental Module Intrinsic Subroutine (Generic): Stores the halting mode for an exception.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

```
CALL IEEE_GET_HALTING_MODE (flag, halting)
```

**flag**

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

- IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

**halting**

(Output) Must be of type default logical. If the exception in "flag" causes halting, the result is true; otherwise, false.

**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting
```

**See Also**

- IEEE_EXCEPTIONS Intrinsic Module

**IEEE_GET_ROUNDING_MODE**

**Intrinsic Module Subroutine (Generic):** Stores the current IEEE rounding mode. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
CALL IEEE_GET_ROUNDING_MODE (round_value)
```

**round_value**

(Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It returns one of the following IEEE floating-point rounding values:

- IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, or IEEE_UP; otherwise, IEEE_OTHER.

The result can only be used if IEEE_SET_ROUNDING_MODE is invoked.

**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE(IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE(ROUND)  ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE(IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE(VALUE)  ! Restores the previous rounding mode
```

**IEEE_ARITHMETIC Intrinsic Module**

IEEE Intrinsic Modules Quick Reference Tables
**IEEE_GET_STATUS**

*Intrinsic Module Subroutine (Generic):* Stores the current state of the floating-point environment. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_GET_STATUS (status_value)

**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS    ! Can also use IEEE_ARITHMETIC
TYPE(IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS(STATUS)   ! Stores the floating-point status
CALL IEEE_SET_FLAG(IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS(STATUS)   ! Restores the floating-point status
```

**See Also**

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

---

**IEEE_GET_UNDERFLOW_MODE**

*Intrinsic Module Subroutine (Generic):* Stores the current underflow mode. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

CALL IEEE_GET_UNDERFLOW_MODE (gradual)

**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL GRAD
...
CALL IEEE_GET_UNDERFLOW_MODE(GRAD)
IF (GRAD) THEN ! underflows are gradual
  ...
```

The result is true if the current underflow mode is gradual (IEEE denormals are allowed) and false if the current underflow mode is abrupt (underflowed results are set to zero).
ELSE ! underflows are abrupt
...
END IF

IEEE_HANDLER

Portability Function: Establishes a handler for IEEE exceptions.

Module
USE IFPORT

Syntax
result = IEEE_HANDLER (action, exception, handler)

action  (Input) Character*(*). One of the following literal IEEE actions: 'GET', 'SET', or 'CLEAR'. For more details on these actions, see IEEE_FLAGS.

exception (Input) Character*(*). One of the following literal IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all' (which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division'). The flags 'all' or 'common' should only be used for actions SET or CLEAR.

handler (Input) The address of an external signal-handling routine.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appear in the following table (defined in the IFPORT module):

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>Invalid operation</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>Divide-by-zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>Numeric overflow</td>
</tr>
<tr>
<td>FPE$UNDERFLOW</td>
<td>Numeric underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>Inexact result (precision)</td>
</tr>
</tbody>
</table>

'GET' actions return the location of the current handler routine for exception cast to an INTEGER.

Example
The following example creates a handler routine and sets it to trap divide-by-zero:

```fortran
PROGRAM TEST_IEEE
  REAL :: X, Y, Z
  CALL FPE_SETUP
```
X = 0.
Y = 1.
Z = Y / X
END PROGRAM

SUBROUTINE FPE_SETUP
USE IFPORT
IMPLICIT NONE
INTERFACE
  SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
    INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
  END SUBROUTINE
END INTERFACE
INTEGER IR
IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE FPE_SETUP

SUBROUTINE FPE_HANDLER(SIG, CODE)
USE IFPORT
IMPLICIT NONE
INTEGER SIG, CODE
IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *,'Occurred divide by zero.'
CALL ABORT
END SUBROUTINE FPE_HANDLER

IEEE_FLAGS

IEEE_IS_FINITE
Elemental Module Intrinsic Function (Generic):
Returns whether an IEEE value is finite.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_IS_FINITE (x)

x (Input) Must be of type REAL.

Results
The result type is default logical. The result has the value true if the value of x is finite; otherwise, false.

An IEEE value is finite if IEEE_CLASS(x) has one of the following values:

IEEE_POSITIVE_NORMAL  IEEE_NEGATIVE_DENORMAL
IEEE_NEGATIVE_NORMAL   IEEE_POSITIVE_ZERO
IEEE_POSITIVE_DENORMAL IEEE_NEGATIVE_ZERO

Example

IEEE_IS_FINITE (-2.0) has the value true.

IEEE Intrinsic Modules Quick Reference Tables
**IEEE_IS_NAN**

*Elemental Module Intrinsic Function (Generic):*
*Returns whether an IEEE value is Not-a-Number (NaN).*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_IS_NAN (x)

*x* (Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if the value of *x* is NaN; otherwise, false.

**Example**

IEEE_IS_NAN (SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_IS_NEGATIVE**

*Elemental Module Intrinsic Function (Generic):*
*Returns whether an IEEE value is negative.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_IS_NEGATIVE (x)

*x* (Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if the value of *x* is negative; otherwise, false.

An IEEE value is negative if IEEE_CLASS(x) has one of the following values:

- IEEE_NEGATIVE_NORMAL
- IEEE_NEGATIVE_ZERO
- IEEE_NEGATIVE_DENORMAL
- IEEE_NEGATIVE_INF

**Example**

IEEE_IS_NEGATIVE (2.0) has the value false.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
IEEE_IS_NORMAL

*Elemental Module Intrinsic Function (Generic):* Returns whether an IEEE value is normal.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_IS_NORMAL (x)

x (Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if the value of x is normal; otherwise, false.

An IEEE value is normal if IEEE_CLASS(x) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_POSITIVE_NORMAL</th>
<th>IEEE_POSITIVE_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

**Example**

IEEE_IS_NORMAL (SQRT(-2.0)) has the value false if IEEE_SUPPORT_SQRT (-2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

IEEE_LOGB

*Elemental Module Intrinsic Function (Generic):* Returns a floating-point value equal to the unbiased exponent of the argument. This is equivalent to the IEEE logb function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_LOGB (x)

x (Input) Must be of type REAL.

**Results**

The result type and kind is the same as x. The result has the value of the unbiased exponent of x if the value of x is not zero, infinity, or NaN. The value of the result is equal to EXPONENT(x) - 1.

If x is equal to 0, the result is -infinity if IEEE_SUPPORT_INF(x) is true; otherwise, -HUGE(x). In either case, the IEEE_DIVIDE_BY_ZERO exception is signaled.

**Example**

IEEE_LOGB (3.4) has the value 1.0; IEEE_LOGB (4.0) has the value 2.0.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_NEXT_AFTER

Elemental Module Intrinsic Function (Generic):
Returns the next representable value after X toward Y. This is equivalent to the IEEE nextafter function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_NEXT_AFTER (x, y)

x (Input) Must be of type REAL.
y (Input) Must be of type REAL.

Results
The result type and kind is the same as x. If x is equal to y, the result is x; no exception is signaled. If x is not equal to y, the result has the value of the next representable neighbor of x toward y. The neighbors of zero (of either sign) are both nonzero.

The following exceptions are signaled under certain cases:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Signalled</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_OVERFLOW</td>
<td>When X is finite but IEEE_NEXT_AFTER(X,Y) is infinite</td>
</tr>
<tr>
<td>IEEE_UNDERFLOW</td>
<td>When IEEE_NEXT_AFTER(X,Y) is denormalized</td>
</tr>
<tr>
<td>IEEE_INEXACT</td>
<td>In both the above cases</td>
</tr>
</tbody>
</table>

Example
The value of IEEE_NEXT_AFTER (2.0, 3.0) is 2.0 + EPSILON (X).

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REM

Elemental Module Intrinsic Function (Generic):
Returns the result value from a remainder operation. This is equivalent to the IEEE rem function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_REM (x, y)

x (Input) Must be of type REAL.
y (Input) Must be of type REAL.
**Results**
The result type is real with the kind type parameter of whichever argument has greater precision.

Regardless of the rounding mode, the result value is \( x - yN \), where \( N \) is the integer nearest to the value \( x / y \). If \(|N - x / y| = 1/2\), \( N \) is even. If the result value is zero, the sign is the same as \( x \).

**Example**
The value of IEEE_REM (5.0,4.0) is 1.0; the value of IEEE_REM (2.0,1.0) is 0.0; the value of IEEE_REM (3.0,2.0) is -1.0.

**See Also**
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_RINT**
*Elemental Module Intrinsic Function (Generic):*
Returns an integer value rounded according to the current rounding mode.

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
```fortran
result = IEEE_RINT (x)
```

\( x \) (Input) Must be of type REAL.

**Results**
The result type and kind is the same as \( x \). The value of the result is \( x \) rounded to an integer according to the current rounding mode. If the result value is zero, the sign is the same as \( x \).

**Example**
If the current rounding mode is IEEE_UP, the value of IEEE_RINT (2.2) is 3.0.

If the current rounding mode is IEEE_NEAREST, the value of IEEE_RINT (2.2) is 2.0.

**See Also**
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SCALB**
*Elemental Module Intrinsic Function (Generic):*
Returns the exponent of a radix-independent floating-point number. This is equivalent to the IEEE scalb function.

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
```fortran
result = IEEE_SCALB (x,i)
```

\( x \) (Input) Must be of type REAL.
Results
The result type and kind is the same as x. The result is x multiplied by 2**i, if the value can be represented as a normal number.

If x (2**i) is too small and there is a loss of accuracy, the exception IEEE_UNDERFLOW is signaled. The result value is the nearest number that can be represented with the same sign as x.

If x is finite and x (2**i) is too large, an IEEE_OVERFLOW exception occurs. If IEEE_SUPPORT_INF (x) is true, the result value is infinity with the same sign as x; otherwise, the result value is SIGN (HUGE(x), x).

If x is infinite, the result is the same as x; no exception is signaled.

Example
The value of IEEE_SCALB (2.0,3) is 16.0.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SELECTED_REAL_KIND
Transformational Module Intrinsic Function (Generic): Returns the the value of the kind parameter of an IEEE REAL data type.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SELECTED_REAL_KIND ( [p] [,r] )

p (Input; optional) Must be scalar and of type INTEGER.

r (Input; optional) Must be scalar and of type INTEGER.

At least one argument must be specified.

Results
The result is a scalar of type default integer. The result has a value equal to a value of the kind parameter of an IEEE real data type with decimal precision, as returned by the function PRECISION, of at least p digits and a decimal exponent range, as returned by the function RANGE, of at least r.

If no such kind type parameter is available on the processor, the result is as follows:

- -1 if the precision is not available
- -2 if the exponent range is not available
- -3 if neither the precision nor the exponent range is available
- -4 if one but not both of the precision and the exponent range is available.

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision.

Example
IEEE_SELECTED_REAL_KIND (6, 70) = 8.
**IEEE_SET_FLAG**

*Elemental Module Intrinsic Function (Generic):*

Assigns a value to an exception flag. This is a pure subroutine.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_FLAG (flag, flag_value)

flag

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
- IEEE_DIVIDE_BY_ZERO
- IEEE_INVALID
- IEEE_OVERFLOW
- IEEE_UNDERFLOW

flag_value

(Output) Must be of type default logical. If it has the value true, the exception in 'flag' is set to signal; otherwise, the exception is set to be quiet.

**Example**

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS  ! Can also use module IEEE_ARITHMETIC
...
CALL IEEE_SET_FLAG (IEEE_INVALID, .TRUE.) ! Sets the IEEE_INVALID flag to signal

**See Also**

IEEE_EXCEPTIONS Intrinsic Module

---

**IEEE_SET_HALTING_MODE**

*Elemental Module Intrinsic Function (Generic):*

Controls halting or continuation after an exception. This is a pure subroutine.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_HALTING_MODE (flag, halting)

flag

(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
- IEEE_DIVIDE_BY_ZERO
- IEEE_INVALID
- IEEE_OVERFLOW
- IEEE_UNDERFLOW

halting

(Output) Must be of type default logical. If it has the value true, the exception in 'flag' is set to signal; otherwise, the exception is set to be quiet.
halting (Input) Must be scalar and of type default logical. If the value is true, the exception specified in FLAG will cause halting; otherwise, execution will continue after this exception.

Example
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting
```

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SET_ROUNDING_MODE**

**Intrinsic Module Subroutine (Generic):** Sets the IEEE rounding mode. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
CALL IEEE_SET_ROUNDING_MODE (round_value)
```

round_value (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It specifies one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, IEEE_UP, or IEEE_OTHER.

Example
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE (IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE (ROUND)  ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE (IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE (VALUE)  ! Restores the previous rounding mode
```

**IEEE_SET_STATUS**

**Intrinsic Module Subroutine (Generic):** Restores the state of the floating-point environment. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

```fortran
CALL IEEE_SET_STATUS (status_value)
```
Status_value

(Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). Its value must be set in a previous invocation of IEEE_GET_STATUS.

Example

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS (STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG (IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS (STATUS) ! Restores the floating-point status
```

IEEE_SET_UNDERFLOW_MODE

*Intrinsic Module Subroutine (Generic):* Sets the current underflow mode. This is an impure subroutine.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```fortran
CALL IEEE_SET_UNDERFLOW_MODE (gradual)
```

`gradual`  
(Input) Must be scalar and of type default logical. If it is true, the current underflow mode is set to gradual underflow (denormals may be produced on underflow). If it is false, the current underflow mode is set to abrupt (underflowed results are set to zero).

Example

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL :: SG
...
CALL IEEE_GET_UNDERFLOW_MODE (SG) ! Stores underflow mode
CALL IEEE_SET_UNDERFLOW_MODE (.FALSE.) ! Resets underflow mode
...                                    ! Abrupt underflows happens here
CALL IEEE_SET_UNDERFLOW_MODE (SG) ! Restores previous undeflow mode
```

IEEE_SUPPORT_DATATYPE

*Inquiry Module Intrinsic Function (Generic):* Returns whether the processor supports IEEE arithmetic.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```fortran
result = IEEE_SUPPORT_DATATYPE ([x])
```

`x`  
(Input; optional) Must be scalar and of type REAL.
Results

The result is a scalar of type default logical. If \( x \) is omitted, the result has the value true if the processor supports IEEE arithmetic for all real values; otherwise, false.

If \( x \) is specified, the result has the value true if the processor supports IEEE arithmetic for real variables of the same kind type parameter as \( x \); otherwise, false.

If real values are implemented according to the IEEE standard except that underflowed values flush to zero (abrupt) instead of being denormal.

Example

IEEE_SUPPORT_DATATYPE (3.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_DENORMAL

Inquiry Module Intrinsic Function (Generic): Returns whether the processor supports IEEE denormalized numbers.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

\[
\text{result} = \text{IEEE\_Support\_Denormal}\ ([x])
\]

\( x \)  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If \( x \) is omitted, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for all real values; otherwise, false.

If \( x \) is specified, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for real variables of the same kind type parameter as \( x \); otherwise, false.

Example

IEEE_SUPPORT_DENORMAL () has the value true if IEEE denormalized numbers are supported for all real types.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_DIVIDE

Inquiry Module Intrinsic Function (Generic): Returns whether the processor supports IEEE divide.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC
**Syntax**

```plaintext
result = IEEE_SUPPORT_DIVIDE ([x])
```

- `x` (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for real variables of the same kind type parameter as `x`; otherwise, false.

**Example**

`IEEE_SUPPORT_DIVIDE ( )` has the value true if IEEE divide is supported for all real types.

**See Also**

### IEEE_SUPPORT_FLAG

**Inquiry Module Intrinsic Function (Generic):**

Returns whether the processor supports IEEE exceptions.

**Module**

```plaintext
USE, INTRINSIC :: IEEE_EXCEPTIONS
```

**Syntax**

```plaintext
result = IEEE_SUPPORT_FLAG (flag [, x])
```

- `flag` (Input) Must be a scalar of type TYPE (IEEE_FLAG_TYPE). Its value is one of the following IEEE flags:
  - IEEE_DIVIDE_BY_ZERO
  - IEEE_INEXACT
  - IEEE_INVALID
  - IEEE_OVERFLOW
  - IEEE_UNDERFLOW.

- `x` (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor supports detection of the exception specified by "flag" for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor supports detection of the exception specified by "flag" for real variables of the same kind type parameter as `x`; otherwise, false.

**Example**

`IEEE_SUPPORT_FLAG (IEEE_UNDERFLOW)` has the value true if the IEEE_UNDERFLOW exception is supported for all real types.

**See Also**

IEEE_SUPPORT_HALTING

Inquiry Module Intrinsic Function (Generic):

Returns whether the processor supports IEEE halting.

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

result = IEEE_SUPPORT_HALTING(flag)

flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

Results

The result is a scalar of type default logical. The result has the value true if the processor supports the ability to control halting after the exception specified by "flag"; otherwise, false.

Example

IEEE_SUPPORT_HALTING (IEEE_UNDERFLOW) has the value true if halting is supported after an IEEE_UNDERFLOW exception

IEEE_SUPPORT_INF

Inquiry Module Intrinsic Function (Generic):

Returns whether the processor supports IEEE infinities.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_INF ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports IEEE infinities (positive and negative) for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports IEEE infinities for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_INF( ) has the value true if IEEE infinities are supported for all real types.

IEEE_SUPPORT_IO

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE base conversion rounding during formatted I/O.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_IO ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports base conversion rounding during formatted input and output for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports base conversion rounding during formatted input and output for real variables of the same kind type parameter as x; otherwise, false.
The base conversion rounding applies to modes IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.

Example
IEEE_SUPPORT_IO () has the value true if base conversion rounding is supported for all real types during formatted I/O.

IEEE_SUPPORT_NAN

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE Not-a-Number feature.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_NAN ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports NaNs for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports NaNs for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_NAN () has the value true if IEEE NaNs are supported for all real types.

**IEEE_SUPPORT_ROUNDING**

*Inquiry Module Intrinsic Function (Generic):*  
Returns whether the processor supports IEEE rounding mode.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```
result = IEEE_SUPPORT_ROUNDING (round_value [, x])
```

- `round_value`  
  (Input) Must be of type TYPE(IEEE_ROUND_TYPE). It specifies one of the following rounding modes:  
  IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.

- `x`  
  (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor supports the rounding mode specified by `round_value` for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor supports the rounding mode specified by `round_value` for real variables of the same kind type parameter as `x`; otherwise, false.

**Example**

IEEE_SUPPORT_ROUNDING (IEEE_DOWN) has the value true if rounding mode IEEE_DOWN is supported for all real types.

**See Also**

**IEEE_SUPPORT_SQRT**

*Inquiry Module Intrinsic Function (Generic):*  
Returns whether the processor supports IEEE SQRT (square root).

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```
result = IEEE_SUPPORT_SQRT ([x])
```

- `x`  
  (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If `x` is omitted, the result has the value true if the processor implements SQRT in accord with the IEEE standard for all real values; otherwise, false.

If `x` is specified, the result has the value true if the processor implements SQRT in accord with the IEEE standard for real variables of the same kind type parameter as `x`; otherwise, false.
Example

IEEE_SUPPORT_SQRT ( ) has the value true if IEEE SQRT is supported for all real types.

IEEE_SUPPORT_STANDARD

**Inquiry Module Intrinsic Function (Generic):**
Returns whether the processor supports IEEE features defined in the standard.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_STANDARD ([x])

x 
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. The result has the value true if the results of all the following functions are true (x can be omitted):

- IEEE_SUPPORT_DATATYPE([x])
- IEEE_SUPPORT_DENORMAL([x])
- IEEE_SUPPORT_DIVIDE([x])
- IEEE_SUPPORT_FLAG(flag [, x])¹
- IEEE_SUPPORT_HALTING(flag)¹
- IEEE_SUPPORT_INF([x])
- IEEE_SUPPORT_NAN([x])
- IEEE_SUPPORT_ROUNDING(round_value [, x])²
- IEEE_SUPPORT_SQRT([x])

¹ "flag" must be a valid value
² "round_value" must be a valid value

Otherwise, the result has the value, false.

Example

IEEE_SUPPORT_STANDARD ( ) has the value false if both IEEE and non-IEEE real kinds are supported.

IEEE_SUPPORT_UNDERFLOW_CONTROL
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports the ability to control the underflow mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_UNDERFLOW_CONTROL ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports controlling the underflow mode for all real values; otherwise, false. If x is specified, the result has the value true if the processor supports controlling the underflow mode for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_UNDERFLOW_CONTROL () has the value true if controlling the underflow mode is supported for all real types.

See Also
IEEE_ARITHMETIC Intrinsic Module

IEEE_UNORDERED
Elemental Module Intrinsic Function (Generic):
Returns whether one or more of the arguments is Not-a-Number (NaN). This is equivalent to the IEEE unordered function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_UNORDERED (x,y)

x (Input) Must be of type REAL.
y (Input) Must be of type REAL.

Results
The result type is default logical. The result has the value true if x or y is a NaN, or both are NaNs; otherwise, false.

Example
IEEE_UNORDERED (0.0, SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
**IEEE_VALUE**

*Elemental Module Intrinsic Function (Generic):*

*Creates an IEEE value.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_VALUE (x, class)
```

- `x` *(Input)* Must be of type REAL.
- `class` *(Input)* Must be of type TYPE (IEEE_CLASS_TYPE). Its value is one of the following:

<table>
<thead>
<tr>
<th><code>IEEE_SIGNALING_NAN</code></th>
<th><code>IEEE_NEGATIVE_NORMAL</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IEEE_QUIET_NAN</code></td>
<td><code>IEEE_POSITIVE_DENORMAL</code></td>
</tr>
<tr>
<td><code>IEEE_POSITIVE_INF</code></td>
<td><code>IEEE_NEGATIVE_DENORMAL</code></td>
</tr>
<tr>
<td><code>IEEE_NEGATIVE_INF</code></td>
<td><code>IEEE_POSITIVE_ZERO</code></td>
</tr>
<tr>
<td><code>IEEE_POSITIVE_NORMAL</code></td>
<td><code>IEEE_NEGATIVE_ZERO</code></td>
</tr>
</tbody>
</table>

**Results**

The result type and kind is the same as `x`. The result value is an IEEE value as specified by "class".

When `IEEE_VALUE` returns a signaling NaN, it is processor dependent whether or not invalid is signaled and processor dependent whether or not the signaling NaN is converted to a quiet NaN.

**Example**

`IEEE_VALUE (1.0,IEEE_POSITIVE_INF)` has the value `+infinity`.

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

**IEOR**

*Elemental Intrinsic Function (Generic):* *Performs an exclusive OR on corresponding bits. This function can also be specified as XOR or IXOR.*

**Syntax**

```fortran
result = IEOR (i, j)
```

- `i` *(Input)* Must be of type integer or of type logical (which is treated as an integer).
- `j` *(Input)* Must be of type integer with the same kind parameter as `i`. If the kinds of `i` and `j` do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result.
**Results**

The result type and kind is the same as \( i \). The result value is derived by combining \( i \) and \( j \) bit-by-bit according to the following truth table:

\[
\begin{array}{ccc}
  i & j & \text{IEOR}(i, j) \\
  1 & 1 & 0 \\
  1 & 0 & 1 \\
  0 & 1 & 1 \\
  0 & 0 & 0 \\
\end{array}
\]

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIEOR(^1)</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIEOR(^2)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIEOR(^3)</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIEOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or BIXOR
\(^2\)Or HIEOR, HIXOR, or IIXOR
\(^3\)Or JIXOR

**Example**

\( \text{IEOR}(12, 7) \) has the value 11; binary 1100 exclusive OR with binary 0111 is binary 1011.

The following shows another example:

```fortran
INTEGER I
I = IEOR(240, 90)  ! returns 170
               ! IEOR (B'11110000', B'1011010') == B'10101010'
```

The following shows an example using alternate option XOR:

```fortran
INTEGER i, j, k
i = 3             ! B'011'
j = 5             ! B'101'
k = XOR(i, j)     ! returns 6 = B'110'
```

IAND
IOR
NOT
IALL
IANY
IPARITY
IERRNO

**IERRNO**

*Portability Function:* Returns the number of the last detected error from any routines in the IFPORT module that return error codes.

**Module**

USE IFPORT
Syntax

result = IERRNO( )

Results

The result type is INTEGER(4). The result value is the last error code from any portability routines that return error codes. These error codes are analogous to errno on a Linux* or OS X* system. The module IFPORT.F90 provides parameter definitions for the following errno names (typically found in errno.h on Linux systems):

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>1</td>
<td>Insufficient permission for operation</td>
</tr>
<tr>
<td>ENOENT</td>
<td>2</td>
<td>No such file or directory</td>
</tr>
<tr>
<td>ESRCH</td>
<td>3</td>
<td>No such process</td>
</tr>
<tr>
<td>EIO</td>
<td>5</td>
<td>I/O error</td>
</tr>
<tr>
<td>E2BIG</td>
<td>7</td>
<td>Argument list too long</td>
</tr>
<tr>
<td>ENOEXEC</td>
<td>8</td>
<td>File is not executable</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>12</td>
<td>Not enough resources</td>
</tr>
<tr>
<td>EACCES</td>
<td>13</td>
<td>Permission denied</td>
</tr>
<tr>
<td>EXDEV</td>
<td>18</td>
<td>Cross-device link</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>20</td>
<td>Not a directory</td>
</tr>
<tr>
<td>EINVAL</td>
<td>22</td>
<td>Invalid argument</td>
</tr>
</tbody>
</table>

The value returned by IERRNO is updated only when an error occurs. For example, if an error occurs on a GETLOG call and then two CHMOD calls succeed, a subsequent call to IERRNO returns the error for the GETLOG call.

Examine IERRNO immediately after returning from a portability routine. IERRNO is set on a per thread basis.

Example

USE IFPORT
CHARACTER*20 username
INTEGER(4) ierrval
ierrval=0 !initialize return value
CALL GETLOG(username)
IF (IERRNO( ) == ierrval) then
  print *, 'User name is ',username
  exit
ELSE
  ierrval = ierrno()
  print *, 'Error is ',ierrval
END IF

IF - Arithmetic

**Statement:** Conditionally transfers control to one of three statements, based on the value of an arithmetic expression. It is an obsolescent language feature in Standard Fortran.
Syntax

IF (expr) label1, label2, label3

**expr**  
Is a scalar numeric expression of type integer or real (enclosed in parentheses).

**label1, label2, label3**  
Are the labels of valid branch target statements that are in the same scoping unit as the arithmetic IF statement.

Description

All three labels are required, but they do not need to refer to three different statements. The same label can appear more than once in the same arithmetic IF statement.

During execution, the expression is evaluated first. Depending on the value of the expression, control is then transferred as follows:

<table>
<thead>
<tr>
<th>If the Value of <strong>expr</strong> is:</th>
<th>Control Transfers To:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 0</td>
<td>Statement <strong>label1</strong></td>
</tr>
<tr>
<td>Equal to 0</td>
<td>Statement <strong>label2</strong></td>
</tr>
<tr>
<td>Greater than 0</td>
<td>Statement <strong>label3</strong></td>
</tr>
</tbody>
</table>

Example

The following example transfers control to statement 50 if the real variable THETA is less than or equal to the real variable CHI. Control passes to statement 100 only if THETA is greater than CHI.

```
IF (THETA - CHI) 50, 50, 100
```

The following example transfers control to statement 40 if the value of the integer variable NUMBER is even. It transfers control to statement 20 if the value is odd.

```
IF (NUMBER / 2 * 2 - NUMBER) 20, 40, 20
```

The following statement transfers control to statement 10 for n < 10, to statement 20 for n = 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 20, 30
```

The following statement transfers control to statement 10 if n <= 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 10, 30
```

SELECT CASE and END SELECT  
Execution Control Overview  
Obsolescent Language Features in the Fortran Standard

IF - Logical

**Statement:** Conditionally executes one statement based on the value of a logical expression. (This statement was called a logical IF statement in FORTRAN 77.)

Syntax

IF (expr) stmt

**expr**  
Is a scalar logical expression enclosed in parentheses.
**stmt**

Is any complete, unlabeled, executable Fortran statement, except for the following:

- A CASE, DO, IF, FORALL, or WHERE construct
- Another IF statement
- The END statement for a program, function, or subroutine

When an IF statement is executed, the logical expression is evaluated first. If the value is true, the statement is executed. If the value is false, the statement is not executed and control transfers to the next statement in the program.

**Example**

The following examples show valid IF statements:

IF (J.GT.4 .OR. J.LT.1) GO TO 250

IF (REF(J,K) .NE. HOLD) REF(J,K) = REF(J,K) * (-1.5D0)

IF (ENDRUN) CALL EXIT

The following shows another example:

```fortran
USE IFPORT
INTEGER(4) istat, errget
character(inchar)
real x
istat = getc(inchar)
IF (istat) errget = -1
...
! IF (x .GT. 2.3) call new_subr(x)
...```

**See Also**

IF Construct
Execution Control Overview

**IF Clause**

**Parallel Directive Clause:** Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.

**Syntax**

```fortran
IF (expression)
```

**Expression**

Must be a scalar logical expression that evaluates to .TRUE. or .FALSE..

At most one IF clause can appear in the directive.

**Description**

The following are additional rules that apply to specific OpenMP Fortran directives:

- For the CANCEL OpenMP* Fortran directive, if expression evaluates to false, the construct does not request cancellation.
- For the PARALLEL OpenMP Fortran directive:
  - The enclosed code section is executed in parallel only if expression evaluates to .TRUE.. Otherwise, the parallel region is serialized. If this clause is not used, the region is executed as if an IF(.TRUE.) clause were specified.
- This clause is evaluated by the master thread before any data scope attributes take effect.
- For the TARGET OpenMP Fortran directive, if expression evaluates to .FALSE., the target region is not executed by the device. It is executed by the encountering task.
- For the TARGET DATA OpenMP Fortran directive, if expression evaluates to .FALSE., the new device data environment is not created.
- For the TARGET UPDATE OpenMP Fortran directive, if expression evaluates to .FALSE., the TARGET UPDATE directive is ignored.
- For the TASK OpenMP Fortran directive:
  - The enclosed code section is to be executed in parallel only if expression evaluates to .TRUE.. If this clause is not used, the region is executed as if an IF(.TRUE.) clause was specified.
  - If expression evaluates to .FALSE., the encountering thread must suspend the current task region and begin execution of the generated task immediately. The suspended task region will not be resumed until the generated task is completed.
  - This clause is evaluated by the master thread before any data scope attributes take effect.

**IF Construct**

**Statement:** Conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. (This construct was called a block IF statement in FORTRAN 77.)

**Syntax**

```
[name:] IF (expr) THEN
    block
  [ELSE IF (expr) THEN [name]
    block]
  [ELSE [name]
    block]
END IF [name]
```

- name (Optional) Is the name of the IF construct.
- expr Is a scalar logical expression enclosed in parentheses.
- block Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified at the beginning of an IF THEN statement, the same name must appear in the corresponding END IF statement. If a construct name is specified on an ELSE IF or ELSE statement, the same name must appear in the corresponding IF THEN and END IF statements.

The same construct name must not be used for different named constructs in the same scoping unit.

Depending on the evaluation of the logical expression, one block or no block is executed. The logical expressions are evaluated in the order in which they appear, until a true value is found or an ELSE or END IF statement is encountered.

Once a true value is found or an ELSE statement is encountered, the block immediately following it is executed and the construct execution terminates.

If none of the logical expressions evaluate to true and no ELSE statement appears in the construct, no block in the construct is executed and the construct execution terminates.
NOTE
No additional statement can be placed after the IF THEN statement in a block IF construct. For example, the following statement is invalid in the block IF construct:

IF (e) THEN I = J

This statement is translated as the following logical IF statement:

IF (e) THEN I = J

You cannot use branching statements to transfer control to an ELSE IF statement or ELSE statement. However, you can branch to an END IF statement from within the IF construct.

The following figure shows the flow of control in IF constructs:
You can include an IF construct in the statement block of another IF construct, if the nested IF construct is completely contained within a statement block. It cannot overlap statement blocks.

**Example**

The following example shows the simplest form of an IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN block</td>
<td>IF (ABS(ADJU) .GE. 1.0E-6) THEN</td>
</tr>
<tr>
<td>END IF</td>
<td>TOTERR = TOTERR + ABS(ADJU)</td>
</tr>
<tr>
<td></td>
<td>QUEST = ADJU/FNDVAL</td>
</tr>
<tr>
<td></td>
<td>END IF</td>
</tr>
</tbody>
</table>
This construct conditionally executes the block of statements between the IF THEN and the END IF statements.

The following shows another example:

! Simple block IF:
  IF (i .LT. 10) THEN
    ! the next two statements are only executed if i < 10
    j = i
    slice = TAN (angle)
  END IF

The following example shows a named IF construct:

BLOCK_A: IF (D > 0.0) THEN        ! Initial statement for named construct
  RADIANS = ACOS(D)               ! These two statements
  DEGREES = ACOSD(D)              ! form a block
END IF BLOCK_A                    ! Terminal statement for named construct

The following example shows an IF construct containing an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (NAME .LT. 'N') THEN block1 IFront = IFRONT + 1 FRLET(IFRONT) = NAME(1:2) ELSE END IF</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE block2 IBACK = IBACK + 1 END IF</td>
</tr>
</tbody>
</table>

Block1 consists of all the statements between the IF THEN and ELSE statements. Block2 consists of all the statements between the ELSE and the END IF statements.

If the value of the character variable NAME is less than 'N', block1 is executed. If the value of NAME is greater than or equal to 'N', block2 is executed.

The following example shows an IF construct containing an ELSE IF THEN statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN block1 D = B F = A - B ELSE IF (expr) THEN ELSE IF (A .GT. B/2.) THEN block2 D = B/2. F = A - B/2. END IF END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B, but A is greater than B/2, block2 is executed. If A is not greater than B and A is not greater than B/2, neither block1 nor block2 is executed. Control transfers directly to the next executable statement after the END IF statement.

The following shows another example:

! Block IF with ELSE IF statements:

IF (j .GT. 1000) THEN
  ! Statements here are executed only if J > 1000
ELSE IF (j .GT. 100) THEN
  ! Statements here are executed only if J > 100 and j <= 1000
ELSE IF (j .GT. 10) THEN
  ! Statements here are executed only if J > 10 and j <= 100
ELSE
  ! Statements here are executed only if j <= 10
END IF
The following example shows an IF construct containing several ELSE IF THEN statements and an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td></td>
<td>F = A - B</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. C) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = C</td>
</tr>
<tr>
<td></td>
<td>F = A - C</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. Z) THEN</td>
</tr>
<tr>
<td>block3</td>
<td>D = Z</td>
</tr>
<tr>
<td></td>
<td>F = A - Z</td>
</tr>
<tr>
<td>ELSE</td>
<td>block4</td>
</tr>
<tr>
<td></td>
<td>D = 0.0</td>
</tr>
<tr>
<td></td>
<td>F = A</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B but is greater than C, block2 is executed. If A is not greater than B or C but is greater than Z, block3 is executed. If A is not greater than B, C, or Z, block4 is executed.

The following example shows a nested IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .LT. 100) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>INRAN = INRAN + 1</td>
</tr>
<tr>
<td>IF (expr2) THEN</td>
<td>IF (ABS(A-AVG) .LE. 5.) THEN</td>
</tr>
<tr>
<td>block1a</td>
<td>INAVG = INAVG + 1</td>
</tr>
<tr>
<td>ELSE</td>
<td>block1b</td>
</tr>
<tr>
<td></td>
<td>OUTAVG = OUTAVG + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
<tr>
<td>ELSE</td>
<td>block2</td>
</tr>
<tr>
<td></td>
<td>OUTRAN = OUTRAN + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is less than 100, the code immediately following the IF is executed. This code contains a nested IF construct. If the absolute value of A minus AVG is less than or equal to 5, block1a is executed. If the absolute value of A minus AVG is greater than 5, block1b is executed.

If A is greater than or equal to 100, block2 is executed, and the nested IF construct (in block1) is not executed.

The following shows another example:

```fortran
! Nesting of constructs and use of an ELSE statement following
! a block IF without intervening ELSE IF statements:
IF (i .LT. 100) THEN
  ! Statements here executed only if i < 100
  IF (j .LT. 10) THEN
    ! Statements here executed only if i < 100 and j < 10
  END IF
  ! Statements here executed only if i < 100
ELSE
  ! Statements here executed only if i >= 100
  IF (j .LT. 10) THEN
    ! Statements here executed only if i >= 100 and j < 10
  END IF
  ! Statements here executed only if i >= 100
END IF

IF Directive Construct

**General Compiler Directive:** A conditional compilation construct that begins with an IF or IF DEFINED directive. IF tests whether a logical expression is .TRUE. or .FALSE.. IF DEFINED tests whether a symbol has been defined.

**Syntax**

```
!DIR$ IF (expr) -or- !DIR$ IF DEFINED (name)

block
```

- `expr` Is a logical expression that evaluates to .TRUE. or .FALSE..
- `name` Is the name of a symbol to be tested for definition.
- `block` Are executable statements that are compiled (or not) depending on the value of logical expressions in the IF directive construct.

The IF and IF DEFINED directive constructs end with an ENDIF directive and can contain one or more ELSEIF directives and at most one ELSE directive. If the logical condition within a directive evaluates to .TRUE. at compilation, and all preceding conditions in the IF construct evaluate to .FALSE., then the statements contained in the directive block are compiled.

A `name` can be defined with a DEFINE directive, and can optionally be assigned an integer value. If the symbol has been defined, with or without being assigned a value, IF DEFINED (name) evaluates to .TRUE.; otherwise, it evaluates to .FALSE..

If the logical condition in the IF or IF DEFINED directive is .TRUE., statements within the IF or IF DEFINED block are compiled. If the condition is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If the logical expression in an ELSEIF directive is .TRUE., statements within the ELSEIF block are compiled. If the expression is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If control reaches an ELSE directive because all previous logical conditions in the IF construct evaluated to .FALSE., the statements in an ELSE block are compiled unconditionally.

You can use any Fortran logical or relational operator or symbol in the logical expression of the directive, including: .LT., <, .GT., >, .EQ., ==, .LE., <=, .GE., >=, .NE., /=, .EQV., .NEQV., .NOT., .AND., .OR., and .XOR.. The logical expression can be as complex as you like, but the whole directive must fit on one line.

**Example**

```
! When the following code is compiled and run,
! the output is:
! Or this compiled if all preceding conditions .FALSE.
!
!DIR$ DEFINE flag=3
!DIR$ IF (flag .LT. 2)
    WRITE (*,*) "This is compiled if flag less than 2."
!DIR$ ELSEIF (flag >= 8)
```

39
WRITE (*,*) "Or this compiled if flag greater than 
or equal to 8."

!DIR$ ELSE
WRITE (*,*) "Or this compiled if all preceding 
conditions .FALSE."
!DIR$ ENDIF
END

DEFINE and UNDEFINE
IF Construct
General Compiler Directives
Syntax Rules for Compiler Directives

IF DEFINED Directive
Statement: Marks the start of an IF Directive Construct.

See Also
See IF Directive Construct.

IFIX
Elemental Intrinsic Function (Generic): Converts a single-precision real argument to an integer by truncating.

See Also
See INT.

IFLOATI, IFLOATJ
Portability Functions: Convert an integer to single-precision real type.

Module
USE IFPORT

Syntax
result = IFLOATI (i)
result = IFLOATJ (j)

i (Input) Must be of type INTEGER(2).

j (Input) Must be of type INTEGER(4).

Results
The result type is single-precision real (REAL(4) or REAL*4).

See Also
DFLOAT

ILEN
Inquiry Intrinsic Function (Generic): Returns the length (in bits) of the two's complement representation of an integer.
Syntax
result = ILEN (i)

i  Must be of type integer.

Results
The result type and kind is the same as i. The result value is (LOG2( i+ 1 )) if i is not negative; otherwise, the result value is (LOG2( -i )).

Example
ILEN (4) has the value 3.
ILEN (-4) has the value 2.

**IMAGE_INDEX**
*Inquiry Intrinsic Function (Generic): Converts cosubscripts to an image index.*

Syntax
result = IMAGE_INDEX (coarray, sub)

coarray  (Input) Must be a coarray; it can be of any type.

sub  (Input) Must be a rank-one integer array of size equal to the corank of coarray.

Results
The result is default integer scalar. The result is the index of the corresponding image if the value of sub is a valid sequence of cosubscripts for coarray. Otherwise, the result is zero.

Example
If coarray D is declared as D [0:*] and coarray C is declared as C(5,10) [10, 0:9, 0:*], IMAGE_INDEX (D, [0]) has the value 1 and IMAGE_INDEX (C, [3, 1, 2]) has the value 213 (on any image).

**IMAGESIZE, IMAGESIZE_W (W*S)**
*Graphics Functions: Return the number of bytes needed to store the image inside the specified bounding rectangle. IMAGESIZE is useful for determining how much memory is needed for a call to GETIMAGE.*

Module
USE IFQWIN

Syntax
result = IMAGESIZE (x1,y1,x2,y2)
result = IMAGESIZE_W (wx1,wy1,wx2,wy2)

x1, y1  (Input) INTEGER(2). Viewport coordinates for upper-left corner of image.
x2, y2  (Input) INTEGER(2). Viewport coordinates for lower-right corner of image.
wx1, wy1  (Input) REAL(8). Window coordinates for upper-left corner of image.
wx2, wy2  (Input) REAL(8). Window coordinates for lower-right corner of image.

Results
The result type is INTEGER(4). The result is the storage size of an image in bytes.
IMAGESIZE defines the bounding rectangle in viewport-coordinate points (x1, y1) and (x2, y2).
IMAGESIZE_W defines the bounding rectangle in window-coordinate points (wx1, wy1) and (wx2, wy2).
IMAGESIZE_W defines the bounding rectangle in terms of window-coordinate points (wx1, wy1) and (wx2, wy2).

Example
See the example in GETIMAGE.

See Also
GETIMAGE, GETIMAGE_W (W*S)
GRSTATUS (W*S)
PUTIMAGE, PUTIMAGE_W (W*S)

IMPLICIT
Statement: Overrides the default implicit typing rules for names. (The default data type is INTEGER for names beginning with the letters I through N, and REAL for names beginning with any other letter.)

Syntax
The IMPLICIT statement takes one of the following forms:

IMPLICIT type(a[,a]...)[,type(a[,a]...)]...
IMPLICIT NONE

description
Is a data type specifier (CHARACTER*(*) is not allowed).

a
Is a single letter, a dollar sign ($), or a range of letters in alphabetical order. The form for a range of letters is a1-a2, where the second letter follows the first alphabetically (for example, A-C).

The dollar sign can be used at the end of a range of letters, since IMPLICIT interprets the dollar sign to alphabetically follow the letter Z. For example, a range of X-$ would apply to identifiers beginning with the letters X, Y, Z, or $.

In Intel® Fortran, the parentheses around the list of letters are optional.

Description
The IMPLICIT statement assigns the specified data type (and kind parameter) to all names that have no explicit data type and begin with the specified letter or range of letters. It has no effect on the default types of intrinsic procedures.

When the data type is CHARACTER*len, len is the length for character type. The len is an unsigned integer constant or an integer specification expression enclosed in parentheses. The range for len is 1 to 2**31-1 on IA-32 architecture; 1 to 2**63-1 on Intel® 64 architecture.

Names beginning with a dollar sign ($) are implicitly INTEGER.

The IMPLICIT NONE statement disables all implicit typing defaults. When IMPLICIT NONE is used, all names in a program unit must be explicitly declared. An IMPLICIT NONE statement must precede any PARAMETER statements, and there must be no other IMPLICIT statements in the scoping unit.
NOTE
To receive diagnostic messages when variables are used but not declared, you can specify compiler option warn declarations instead of using IMPLICIT NONE.

The following IMPLICIT statement represents the default typing as specified by the Fortran Standard for names when they are not explicitly typed:

```
IMPLICIT INTEGER (I-N), REAL (A-H, O-Z)
```

**Example**
The following are examples of the IMPLICIT statement:

```
IMPLICIT DOUBLE PRECISION (D) IMPLICIT COMPLEX (S,Y), LOGICAL(1) (L,A-C)
IMPLICIT CHARACTER*32 (T-V)
IMPLICIT CHARACTER*2 (W)
IMPLICIT TYPE(COLORS) (E-F), INTEGER (G-H)
```

The following shows another example:

```
SUBROUTINE FF (J)
   IMPLICIT INTEGER (a-b), CHARACTER*(J+1) (n), TYPE(fried) (c-d)
   TYPE fried
   INTEGER e, f
   REAL g, h
END TYPE
age = 10 ! integer
name = 'Paul' ! character
c%c = 1 ! type fried, integer component
```

**See Also**
Data Types, Constants, and Variables Overview
warn

**IMPORT**
Statement: Makes host entities accessible in the interface body of an interface block. It takes the following form:

```
IMPORT [[::] import-name-list]
```

*import-name-list* (Input) Is the name of one or more entities in the host scoping unit.

An IMPORT statement can appear only in an interface body. Each of the named entities must be explicitly declared before the interface body containing the IMPORT statement.

If *import-name-list* is not specified, all of the accessible named entities in the host scoping unit are imported.

The default is that all accessible symbols are imported. This statement can optionally name only those symbols you choose.

The names of imported entities must not appear in any context that causes the host entity to be inaccessible.

**Example**
The following example shows how the IMPORT statement can be applied.

```
module mymod
   type mytype
      integer comp
   end type mytype
interface
```
**IMPURE**

**Keyword:** Asserts that a user-defined procedure has side effects.

**Description**

This kind of procedure is specified by using the prefix IMPURE in a FUNCTION or SUBROUTINE statement. By default all user-defined procedures are impure, that is, they are allowed to have side effects, except for elemental procedures.

An IMPURE elemental procedure has the restrictions that apply to elemental procedures, but it does not have any of the restrictions of PURE elemental procedures.

An impure elemental procedure can have side effects and it can contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement or an ERROR STOP statement
- An image control statement

An impure elemental procedure cannot be referenced in a context that requires a procedure to be pure; for example:

- It cannot be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It cannot be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, or finalization.
- It cannot be passed as an actual argument to a pure procedure.

**Example**

```fortran
module my_rand_mod

contains

impure elemental subroutine my_rand (r)

! my_rand updates module variable my_rand_seed (an array)  
! and returns the next value of a “pseudo” random sequence in 
! output dummy argument r

   real, intent(out) :: r

   ! code goes here

end subroutine my_rand

end module my_rand_mod
```

**See Also**

FUNCTION

SUBROUTINE
INCHARQQ (W'S)

QuickWin Function: Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering.

Module

USE IFQWIN

Syntax

result = INCHARQQ()

Results

The result type is INTEGER(2). The result is the ASCII key code.

The keystroke is read from the child window that currently has the focus. You must call INCHARQQ before the keystroke is made (INCHARQQ does not read the keyboard buffer). This function does not echo its input. For function keys, INCHARQQ returns 0xE0 as the upper 8 bits, and the ASCII code as the lower 8 bits. For direction keys, INCHARQQ returns 0xF0 as the upper 8 bits, and the ASCII code as the lower 8 bits. To allow direction keys to be read, you must use the PASSDIRKEYSQQ function. The escape characters (the upper 8 bits) are different from those of GETCHARQQ. Note that console applications do not need, and cannot use PASSDIRKEYSQQ.

Example

use IFQWIN
integer*4 res
integer*2 exchar
character*1 ch, ch1

Print *,"Type X to exit, S to scroll, D to pass Direction keys"

123 continue
exchar = incharqq()
! check for escapes
! 0xE0 0x?? is a function key
! 0xF0 0x?? is a direction key
ch = char(rshift(exchar,8) .and. Z'00FF')
ch1= char(exchar .and. Z'00FF')

if (ichar(ch) .eq. 224) then
  print *,"function key = ",ichar(ch), " ",ichar(ch1)," ",ch1
  goto 123
endif

if (ichar(ch) .eq. 240) then
  print *,"direction key = ",ichar(ch), " ",ichar(ch1)," ",ch1
  goto 123
endif

print *,"other key  = ",ichar(ch)," ",ichar(ch1)," ",ch1

if(ch1 .eq. 'S') then
  res = passdirkeysqq(.false.)
  print *, "Entering Scroll mode"
endif
if(ch1 .eq. 'D') then
    res = passdirkeysqq(.true.)
    print *, "Entering Direction keys mode"
endif

if(ch1 .ne. 'X') go to 123
end

See Also
GETCHARQQ
READ Statement
MBINCHARQQ (W*S)
GETC
PASSDIRKEYSQQ (W*S)

INCLUDE

Statement: Directs the compiler to stop reading statements from the current file and read statements in an included file or text module.

Syntax
The INCLUDE line takes the following form:

INCLUDE 'filename[/NO]LIST'

filename
   Is a character string specifying the name of the file to be included; it must not be a named constant.
   The form of the file name must be acceptable to the operating system, as described in your system documentation.

[NO]LIST
   Specifies whether the incorporated code is to appear in the compilation source listing. In the listing, a number precedes each incorporated statement. The number indicates the "include" nesting depth of the code. The default is /NOLIST. /LIST and /NOLIST must be spelled completely.
   You can only use /[NO]LIST if you specify compiler option vms (which sets OpenVMS defaults).

Description
An INCLUDE line can appear anywhere within a scoping unit. The line can span more than one source line, but no other statement can appear on the same line. The source line cannot be labeled.

An included file or text module cannot begin with a continuation line, and each Fortran statement must be completely contained within a single file.

An included file or text module can contain any source text, but it cannot begin or end with an incomplete Fortran statement.

The included statements, when combined with the other statements in the compilation, must satisfy the statement-ordering restrictions shown in Statements.

Included files or text modules can contain additional INCLUDE lines, but they must not be recursive. INCLUDE lines can be nested until system resources are exhausted.

When the included file or text module completes execution, compilation resumes with the statement following the INCLUDE line.

You can use modules instead of include files to achieve encapsulation of related data types and procedures. For example, one module can contain derived type definitions as well as special operators and procedures that apply to those types. For information on how to use modules, see Program Units and Procedures.
Example
In the following example, a file named COMMON.FOR (in the current working directory) is included and read as input.

Including Text from a File

<table>
<thead>
<tr>
<th>Main Program File</th>
<th>COMMON.FOR File</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM</td>
<td>INTEGER, PARAMETER :: M=100</td>
</tr>
<tr>
<td>INCLUDE 'COMMON.FOR'</td>
<td>REAL, DIMENSION (M) :: X, Y</td>
</tr>
<tr>
<td>REAL, DIMENSION (M) :: Z</td>
<td>COMMON X, Y</td>
</tr>
<tr>
<td>CALL CUBE</td>
<td>COMMON X, Y</td>
</tr>
<tr>
<td>DO I = 1, M</td>
<td>Z(I) = X(I) + SQRT(Y(I))</td>
</tr>
<tr>
<td>END DO</td>
<td>...</td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE CUBE</td>
<td></td>
</tr>
<tr>
<td>INCLUDE 'COMMON.FOR'</td>
<td></td>
</tr>
<tr>
<td>DO I = 1, M</td>
<td>X(I) = Y(I)**3</td>
</tr>
<tr>
<td>END DO</td>
<td>RETURN</td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
</tbody>
</table>

The file COMMON.FOR defines a named constant M, and defines arrays X and Y as part of blank common.

The following example program declares its common data in an include file. The contents of the file INCLUDE.INC are inserted in the source code in place of every INCLUDE 'INCLUDE.INC' line. This guarantees that all references to common storage variables are consistent.

| INTEGER i |
| REAL x |
| INCLUDE 'INCLUDE.INC' |

DO i = 1, 5
   READ (*, '(F10.5)') x
   CALL Push (x)
END DO

See Also
MODULE
USE
INDEX

**Elemental Intrinsic Function (Generic):** Returns the starting position of a substring within a string.

**Syntax**

result = INDEX (string, substring [, back] [, kind])

*string* (Input) Must be of type character.

*substring* (Input) Must be of type character.

*back* (Input; optional) Must be of type logical.
**kind**

(Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *back* does not appear (or appears with the value false), the value returned is the minimum value of I such that \( {\text{string}}(I : I + \text{LEN}(\text{substring}) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN}({\text{string}}) < \text{LEN}(\text{substring}) \), zero is returned. If \( \text{LEN}(\text{substring}) = 0 \), 1 is returned.

If *back* appears with the value true, the value returned is the maximum value of I such that \( {\text{string}}(I : I + \text{LEN}(\text{substring}) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN}({\text{string}}) < \text{LEN}(\text{substring}) \), zero is returned. If \( \text{LEN}(\text{substring}) = 0 \), \( \text{LEN}({\text{string}}) + 1 \) is returned.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
</tbody>
</table>

1 The setting of compiler options specifying integer size can affect this function.

**Example**

INDEX ('FORTRAN', 'O', BACK = .TRUE.) has the value 2.
INDEX ('XXXX', ' ', BACK = .TRUE.) has the value 5.
The following shows another example:

```
I = INDEX('banana','an', BACK = .TRUE.) ! returns 4
I = INDEX('banana', 'an') ! returns 2
```

**See Also**

SCAN

**INITIALIZEFONTS (W*S)**

*Graphics Function:* Initializes Windows* fonts.

**Module**

USE IFQWIN

**Syntax**

```
result = INITIALIZEFONTS( )
```

**Results**

The result type is INTEGER(2). The result is the number of fonts initialized.

All fonts on Windows systems become available after a call to INITIALIZEFONTS. Fonts must be initialized with INITIALIZEFONTS before any other font-related library function (such as GETFONTINFO, GETGTEXTEXTENT, SETFONT, OUTGTEXT) can be used.

The font functions affect the output of OUTGTEXT only. They do not affect other Fortran I/O functions (such as WRITE) or graphics output functions (such as OUTTEXT).
For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

Example

! build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
numfonts = INITIALIZEFONTS()
WRITE (*,*) numfonts
END

See Also
SETFONT (W*S)
OUTGTEXT (W*S)

INITIALSETTINGS (W*S)
QuickWin Function: Initializes QuickWin.

Module
USE IFQWIN

Syntax
result = INITIALSETTINGS( )

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can change the initial appearance of an application’s default frame window and menus by defining an INITIALSETTINGS function. Do not use INITIALSETTINGS to open or size child windows.

If no user-defined INITIALSETTINGS function is supplied, QuickWin calls a predefined INITIALSETTINGS routine to control the default frame window and menu appearance. You do not need to call INITIALSETTINGS if you define it, since it will be called automatically during initialization.

APPENDMENUQQ (W*S)
INSERTMENUQQ (W*S)
DELETEMENUQQ (W*S)
SETWSIZEQQ (W*S)

INLINE, FORCEINLINE, and NOINLINE
General Compiler Directives: Tell the compiler to perform the specified inlining on routines within statements or DO loops.

Syntax
!DIR$ INLINE [RECURSIVE]
!DIR$ FORCEINLINE [RECURSIVE]
!DIR$ NOINLINE

The INLINE directive specifies that the routines can be inlined.

The FORCEINLINE directive specifies that a routine should be inlined whenever the compiler can do so. This condition can also be specified by using compiler option [Q]inline-forceinline.

The NOINLINE directive specifies that a routine should not be inlined.
These directives apply only to the immediately following statement or DO construct. All statements within the immediately following DO construct are affected.

If keyword RECURSIVE is specified, the specified inlining is performed when the routine calls itself directly or indirectly.

The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

**CAUTION**
When you use directive FORCEINLINE, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**Example**
Consider the following:

```
!DIR$ INLINE
A = F(B) + G(C)  ! inline the call to function F and inline the call to function G

!DIR$ INLINE
DO I = 1, N
    CALL F1 ( G1(A), G2(A)) ! inline the call to F1 and the function executions of G1 and G2
!DIR$ NOINLINE
    DO J = 1, M
            M(J) = F (M(J)) ! do not inline this call to F (M is a data array)
    END DO
    M(I) = F2 (X)           ! F2 gets inlined from the directive before DO I
!DIR$ FORCEINLINE RECURSIVE
    CALL F3 () ! F3 must be inlined and it calls itself recursively so inline those calls too
END DO
```

**See Also**

Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements
inline-forceinline, Qinline-forceinline compiler option

**INMAX**

*Portability Function:* Returns the maximum positive value for an integer.

**Module**
USE IFPORT

**Syntax**

```fortran
result = INMAX (i)
```

*i* (Input) INTEGER(4).

**Results**
The result type is INTEGER(4). The result is the maximum 4-byte signed integer value for the argument.
**INQFOCUSQQ (W*S)**

*QuickWin Function:* Determines which window has the focus.

**Module**

USE IFQWIN

**Syntax**

result = INQFOCUSQQ (unit)

- **result** (Output) INTEGER(4). Unit number of the window that has the I/O focus.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero. The function fails if the window with the focus is associated with a closed unit.

Unit numbers 0, 5, and 6 refer to the default window only if the program has not specifically opened them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

The window with focus is always in the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```fortran
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**See Also**

FOCUSQQ (W*S)

**INQUIRE**

*Statement:* Returns information on the status of specified properties of a file, logical unit, or directory. It takes one of the following forms:

**Syntax**

Inquiring by File:

```fortran
```

Inquiring by Unit:

```fortran
```

Inquiring by Directory:

```fortran
INQUIRE (DIRECTORY=dir, EXIST=ex [, DIRSPEC=dirspec] [, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, SIZE=sz] [, IOSTAT=i-var])
```

Inquiring by Output List:

```fortran
INQUIRE (IOLENGTH=len) out-item-list
```
name  Is a scalar default character expression specifying the name of the file for inquiry. For more information, see FILE Specifier and STATUS Specifier.

label  Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

id-var  Is a scalar integer expression identifying a data transfer operation that was returned using the ID= specifier in a previous asynchronous READ or WRITE statement. For more information, see ID Specifier.

msg-var  Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

sz  Is a scalar integer variable that is assigned the size of the file in file storage units. For more information, see Size Specifier.

i-var  Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. For more information, see I/O Status Specifier.

def  Is a scalar default character expression specifying a default file pathname string. (For more information, see the DEFAULTFILE specifier.)

slist  Is one or more of the following inquiry specifiers (each specifier can appear only once):

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Specifier</th>
<th>Specifier</th>
<th>Specifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>DELIM</td>
<td>NEXTREC</td>
<td>RECL</td>
</tr>
<tr>

<tr>
<td>CONVERT</td>
<td>NAME</td>
<td>READ</td>
<td>WRITE</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NAMED</td>
<td>READWRITE</td>
<td></td>
</tr>
</tbody>
</table>

io-unit  Is an external unit specifier.

The unit does not have to exist, nor does it need to be connected to a file. If the unit is connected to a file, the inquiry encompasses both the connection and the file.

dir  Is a scalar default character expression specifying the name of the directory for inquiry. If you are inquiring by directory, it must be present.
Is a scalar default logical variable that is assigned the value .TRUE. if *dir* names a directory that exists; otherwise, *ex* is assigned the value .FALSE.. If you are inquiring by directory, it must be present. For more information, see the EXIST Specifier.

**dirspec**

Is a scalar default character variable that is assigned the value of the full directory specification of *dir* if *ex* is assigned the value .TRUE.. This specifier can only be used when inquiring by directory.

**len**

(Output) Is a scalar integer variable that is assigned a value corresponding to the length of an unformatted, direct-access record resulting from the use of the *out-item-list* in a WRITE statement.

The value is suitable to use as a RECL specifier value in an OPEN statement that connects a file for unformatted, direct access.

The unit of the value is 4-byte longwords, by default. However, if you specify compiler option assume byterecl, the unit is bytes.

**out-item-list**

(Output) Is a list of one or more output items (see I/O Lists).

### Description

The control specifiers ([UNIT=] *io-unit*, ERR= *label*, and IOSTAT= *i-var*) and inquiry specifiers can appear anywhere within the parentheses following INQUIRE. However, if the UNIT keyword is omitted, the *io-unit* must appear first in the list.

An INQUIRE statement can be executed before, during, or after a file is connected to a unit. The specifier values returned are those that are current when the INQUIRE statement executes.

To get file characteristics, specify the INQUIRE statement after opening the file.

### Example

The following are examples of INQUIRE statements:

```
INQUIRE (FILE='FILE_B', EXIST=EXT)
INQUIRE (4, FORM=FM, IOSTAT=IOS, ERR=20)
INQUIRE (IOLENGTH=LEN) A, B
```

In the last statement, you can use the length returned in LEN as the value for the RECL specifier in an OPEN statement that connects a file for unformatted direct access. If you have already specified a value for RECL, you can check LEN to verify that A and B are less than or equal to the record length you specified.

The following shows another example:

```
! This program prompts for the name of a data file.
! The INQUIRE statement then determines whether
! the file exists. If it does not, the program
! prompts for another file name.

CHARACTER*12 fname
LOGICAL exists

! Get the name of a file:
100 WRITE (*, '(1X, A)') 'Enter the file name: '
    READ (*, '(A)') fname

! INQUIRE about file's existence:
INQUIRE (FILE = fname, EXIST = exists)

IF (.NOT. exists) THEN
```

**INSERTMENUQQ (W*S)**

*QuickWin Function: Inserts a menu item into a QuickWin menu and registers its callback routine.*

**Module**
USE IFQWIN

**Syntax**

```fortran
result = INSERTMENUQQ (menuID, itemID, flag, text, routine)
```

- `menuID` (Input) INTEGER(4). Identifies the menu in which the item is inserted, starting with 1 as the leftmost menu.
- `itemID` (Input) INTEGER(4). Identifies the position in the menu where the item is inserted, starting with 0 as the top menu item.
- `flag` (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results section below). The following constants are available:
  - `$MENUGRAYED` - Disables and grays out the menu item.
  - `$MENUDISABLED` - Disables but does not gray out the menu item.
  - `$MENUENABLED` - Enables the menu item.
  - `$MENUSEPARATOR` - Draws a separator bar.
  - `$MENUCHECKED` - Puts a check by the menu item.
  - `$MENUUNCHECKED` - Removes the check by the menu item.
- `text` (Input) Character*. Menu item name. Must be a null-terminated C string, for example, words of text'C.
- `routine` (Input) EXERNAL. Callback subroutine that is called if the menu item is selected. You can assign the following predefined routines to menus:
  - `WINPRINT` - Prints the program.
  - `WINSAVE` - Saves the program.
  - `WINEXIT` - Terminates the program.
  - `WINSELECTTEXT` - Selects text from the current window.
• WINSELECTGRAPHICS - Selects graphics from the current window.
• WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZETOFIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.

Menus and menu items must be defined in order from left to right and top to bottom. For example,
INSERTMENUQQ fails if you try to insert menu item 7 when 5 and 6 are not defined yet. For a top-level menu item, the callback routine is ignored if there are subitems under it.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to INSERTMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY(ALT+R in the example) as an alternative to selecting the item with the mouse.

Example

USE IFQWIN
LOGICAL(4) :: status
CHARACTER (80) :: text_input

! insert new item into Menu 5 (Window)
status= INSERTMENUQQ(5, 5, $MENUCHECKED, 'New Item:Status 5_5'C, WINSTATUS)
! insert new menu in position 2
status= INSERTMENUQQ(2, 0, $MENUENABLED, 'New Menu:2_0'C, NUL)
! insert new menu in position 3, and mark it disabled & grayed
status= INSERTMENUQQ(3, 0, IOR($MENUGRAYED,$MENUDISABLED), 'New Disabled Menu:3_0'C, NUL)
! insert new item under the new menu 2 in position 1
status= INSERTMENUQQ(2, 1, $MENUENABLED, 'New Item:Print'C, WINPRINT)
! insert separator bar under the new menu 2 in position 2
status= INSERTMENUQQ(2, 2, $MENUSEPARATOR, 'New Separator'C, NUL)
! insert new item under the new menu 2 in position 3
status = INSERTMENUQQ(2, 3, IOR($MENUCHECKED, $MENUENABLED), 'New Item: Select Text', & WINSELECTTEXT)

! insert new item under the new menu 2 in position 5

status = INSERTMENUQQ(2, 4, $MENUENABLED, 'New Item: Copy Selected Text', WINCOPY)

! insert new item under the new menu 2 in position 6

status = INSERTMENUQQ(2, 5, $MENUENABLED, 'New Item: Paste Selected Text', WINPASTE)

write(*,'("Enter (or cut and paste) a text value: ")', advance='no')
read (*, "(A)") text_input
write(*,'("You just entered: ", A1, A, A1) "", trim(text_input), "")"'

END

INT

Elemental Intrinsic Function (Generic): Converts a value to integer type.

Syntax
result = INT (a[,kind])

a
    (Input) Must be of type integer, real, or complex.

kind
    (Input; optional) Must be a scalar integer initialization expression.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of a, as follows:

- If a is of type integer, INT(a) = a.
- If a is of type real and |a| < 1, INT(a) has the value zero.
  
  If a is of type real and |a| >=1, INT(a) is the integer whose magnitude is the largest integer that does not exceed the magnitude of a and whose sign is the same as the sign of a.
- If a is of type complex, INT(a) is the value obtained by applying the preceding rules (for a real argument) to the real part of a.

### Specific Name 1 | Argument Type | Result Type
--- | --- | ---
INT4\(^{10}\) | INTEGER(1), INTEGER(2), INTEGER(4),
INTEGER(8), REAL(4), REAL(8), REAL(16),
COMPLEX(4), COMPLEX(8), COMPLEX(16) | INTEGER(4)
INT8\(^{10}\) | INTEGER(1), INTEGER(2), INTEGER(4),
INTEGER(8), REAL(4), REAL(8), REAL(16),
COMPLEX(4), COMPLEX(8), COMPLEX(16) | INTEGER(8)

\(^{1}\)These specific functions cannot be passed as actual arguments.

\(^{2}\)This function can also be specified as HFIX.

\(^{3}\)The setting of compiler options specifying integer size or real size can affect IFIX.

\(^{4}\)For compatibility with older versions of Fortran, IFIX is treated as a generic function.

\(^{5}\)Or JINT.

\(^{6}\)The setting of compiler options specifying integer size can affect INT, IDINT, and IQINT.

\(^{7}\)Or JIFIX.

\(^{8}\)Or JIDINT. For compatibility with older versions of Fortran, IDINT can also be specified as a generic function.

\(^{9}\)Or JIQINT. For compatibility with older versions of Fortran, IQINT can also be specified as a generic function.

\(^{10}\)For compatibility, these functions can also be specified as generic functions.

If the argument is a boz-constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

INT (-4.2) has the value -4.

INT (7.8) has the value 7.

**INTC**

*Portability Function:* Converts an INTEGER(4) argument to INTEGER(2) type.
Module
USE IFPORT

Syntax
result = INTC (i)

i  
   (Input) INTEGER(4). A value or expression.

Results
The result type is INTEGER(2). The result is the value of i with type INTEGER(2). Overflow is ignored.

INT_PTR_KIND

Inquiry Intrinsic Function (Specific): Returns the INTEGER KIND that will hold an address. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = INT_PTR_KIND( )

Results
The result type is default integer. The result is a scalar with the value equal to the value of the kind parameter of the integer data type that can represent an address on the targeted platform.

The result value is 4 on IA-32 architecture; 8 on Intel® 64 architecture.

Example
REAL A(100)
POINTER (P, A)
INTEGER (KIND=INT_PTR_KIND()) SAVE_P
P = MALLOC (400)
SAVE_P = P

INTEGER Statement

Statement: Specifies the INTEGER data type.

Syntax
INTEGER
INTEGER([KIND=]  n)
INTEGER* n

n  Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind which holds the constant.

The default kind can also be changed by using the INTEGER directive or compiler options specifying integer size.
Example

! Entity-oriented declarations:
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER (2) :: k=4
INTEGER (2), PARAMETER :: limit=12

! Attribute-oriented declarations:
INTEGER days, hours
INTEGER (2):: k=4, limit
DIMENSION days(:), hours(:)
POINTER days, hours
PARAMETER (limit=12)

See Also
INTEGRER Directive
Integer Data Types
Integer Constants

INTEGRER Directive
General Compiler Directive: Specifies the default integer kind.

Syntax
!DIR$ INTEGER:{ 2 | 4 | 8 }

The INTEGER directive specifies a size of 2 (KIND=2), 4 (KIND=4), or 8 (KIND=8) bytes for default integer numbers.

When the INTEGER directive is in effect, all default integer variables are of the kind specified. Only numbers specified or implied as INTEGER without KIND are affected.

The INTEGER directive can only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module or a block data program unit. INTEGER cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

The default logical kind is the same as the default integer kind. So, when you change the default integer kind you also change the default logical kind.

Example

INTEGER i           ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i) ! still a 4-byte integer
  ! not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
 !DIR$ INTEGER:2
 INTEGER j           ! a 2-byte integer
 WRITE(*,*) KIND(j)
END SUBROUTINE

INTEGERTORGB (W*S)

QuickWin Subroutine: Converts an RGB color value into its red, green, and blue components.

Module
USE IFQWIN

Syntax
CALL INTEGERTORGB (rgb, red, green, blue)

rgb (Input) INTEGER(4). RGB color value whose red, green, and blue components are to be returned.

red (Output) INTEGER(4). Intensity of the red component of the RGB color value.

green (Output) INTEGER(4). Intensity of the green component of the RGB color value.

blue (Output) INTEGER(4). Intensity of the blue component of the RGB color value.

INTEGERTORGB separates the four-byte RGB color value into the three components as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>

Example
! build as a QuickWin App.
USE IFQWIN
INTEGER(4) r, g, b
CALL INTEGERTORGB(2456, r, g, b)
write(*,*) r, g, b
END

INTENT

Statement and Attribute: Specifies the intended use of one or more dummy arguments.

Syntax
The INTENT attribute can be specified in a type declaration statement or an INTENT statement, and takes one of the following forms:
Type Declaration Statement:

type, [att-ls,] INTENT (intent-spec) [, att-ls] :: d-arg[, d-arg]...

Statement:

INTENT (intent-spec) [:] d-arg[, d-arg] ...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

intent-spec Is one of the following specifiers:

IN Specifies that the dummy argument will be used only to provide data to the procedure. The dummy argument must not be redefined (or become undefined) during execution of the procedure. Any associated actual argument must be definable.

OUT Specifies that the dummy argument will be used to pass data from the procedure back to the calling program. The dummy argument is undefined on entry, although it may have subcomponents that are initialized by default. An undefined argument must be defined before it is referenced in the procedure.

INOUT Specifies that the dummy argument can both provide data to the procedure and return data to the calling program. Any associated actual argument must be definable.

d-arg Is the name of a dummy argument or dummy pointer. It cannot be a dummy procedure.

Description

The INTENT statement can only appear in the specification part of a subprogram or interface body.

If no INTENT attribute is specified for a dummy argument, its use is subject to the limitations of the associated actual argument.

If a function specifies a defined operator, the dummy arguments must have intent IN.

If a subroutine specifies defined assignment, the first argument must have intent OUT or INOUT, and the second argument must have intent IN.

An entity with the INTENT (OUT) attribute must not be an allocatable coarray or have a subobject that is an allocatable coarray.

A non-pointer dummy argument with intent IN (or a subobject of such a dummy argument) must not appear as any of the following:

- A DO variable
- The variable of an assignment statement
- The pointer-object of a pointer assignment statement
- An object or STAT variable in an ALLOCATE or DEALLOCATE statement
- An input item in a READ statement
- A variable name in a NAMELIST statement if the namelist group name appears in a NML specifier in a READ statement
• An internal file unit in a WRITE statement
• A definable variable in an INQUIRE statement
• An IOSTAT or SIZE specifier in an I/O statement
• An actual argument in a reference to a procedure with an explicit interface if the associated dummy argument has intent OUT or INOUT

INTENT on a pointer dummy argument refers to the pointer association status of the pointer and has no effect on the value of the target of the pointer.

A pointer dummy argument with intent IN (or a subobject of such a pointer argument) must not appear as any of the following:

• A pointer-object in a NULLIFY statement
• A pointer-object in a pointer assignment statement
• An object in an ALLOCATE or DEALLOCATE statement
• An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

If an actual argument is an array section with a vector subscript, it cannot be associated with a dummy array that is defined or redefined (has intent OUT or INOUT).

On entry to a routine, given an INTENT(OUT) dummy argument:

• If it is a pointer, it should be deallocated.
• If it is an allocatable, all of its allocatable subcomponents should be deallocated, and then it should also be deallocated.
• If it is a non-pointer, non-allocatable, all its allocatable subcomponents should be deallocated, and then default initialization should be applied, as specified by the program.

Example

The following example shows type declaration statements specifying the INTENT attribute:

```fortran
SUBROUTINE TEST(I, J)
  INTEGER, INTENT(IN) :: I
  INTEGER, INTENT(OUT), DIMENSION(I) :: J
END SUBROUTINE TEST
```

The following are examples of the INTENT statement:

```fortran
SUBROUTINE TEST(A, B, X)
  INTENT(INOUT) :: A, B
...
SUBROUTINE CHANGE(FROM, TO)
  USE EMPLOYEE_MODULE
  TYPE(EMPLOYEE) FROM, TO
  INTENT(IN) FROM
  INTENT(OUT) TO
...```

The following shows another example:

```fortran
SUBROUTINE AVERAGE(value, data1, cube_ave)
  TYPE DATA
    INTEGER count
    REAL avg
  END TYPE
  TYPE(DATA) data1
  REAL tmp
  ! value cannot be changed, while cube_ave must be defined
  ! before it can be used. Data1 is defined when the procedure is
  ! invoked, and becomes redefined in the subroutine.
  INTENT(IN)::value; INTENT(OUT)::cube_ave
  INTENT(INOUT)::data1
  ! count number of times AVERAGE has been called on the data set
```
! being passed.
tmp = data1%count*data1%avg + value
data1%count = data1%count + 1
data1%avg = tmp/data1%count
cube_ave = data1%avg**3
END SUBROUTINE

Argument Association in Procedures
Type Declarations
Type Declarations

INTERFACE
Statement: Defines an explicit interface for an external or dummy procedure. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.

Syntax
INTERFACE [generic-spec]
  [interface-body]...
  [[MODULE]PROCEDURE name-list]...
END INTERFACE [generic-spec]

generic-spec (Optional) Is one of the following:

- A generic name
  For information on generic names, see Defining Generic Names for Procedures.
- OPERATOR ( op)
  Defines a generic operator ( op). It can be a defined unary, defined binary, or extended intrinsic operator. For information on defined operators, see Defining Generic Operators.
- ASSIGNMENT (=)
  Defines generic assignment. For information on defined assignment, see Defining Generic Assignment.

interface-body
Is one or more function or subroutine subprograms or a procedure pointer. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

The subprogram must not contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

The subprogram can contain a USE statement. It can also contain the prefix MODULE before FUNCTION or SUBROUTINE to indicate a separate module procedure.

name-list
Is the name of one or more procedures or module procedures that are accessible in the host. The MODULE keyword is only allowed if the interface block specifies a generic-spec and has a host that is a module (or accesses a module by use association).
The characteristics of module procedures are not given in interface blocks, but are assumed from the module subprogram definitions.

If the prefix MODULE appears in interface-body, you can only specify one name.

**Description**

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

A *generic-spec* can only appear in the END INTERFACE statement if one appears in the INTERFACE statement; they must be identical.

The characteristics specified for the external or dummy procedure must be consistent with those specified in the procedure's definition.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

Internal, module, and intrinsic procedures are all considered to have explicit interfaces. External procedures have implicit interfaces by default; when you specify an interface block for them, their interface becomes explicit. A procedure must not have more than one explicit interface in a given scoping unit. This means that you cannot include internal, module, or intrinsic procedures in an interface block, unless you want to define a generic name for them.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

A interface block containing *generic-spec* specifies a generic interface for the following procedures:

- The procedures within the interface block
  - Any generic name, defined operator, or equals symbol that appears is a generic identifier for all the procedures in the interface block. For the rules on how any two procedures with the same generic identifier must differ, see *Unambiguous Generic Procedure References*.
  - The module procedures listed in the MODULE PROCEDURE statement
    - The module procedures must be accessible by a USE statement.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

The following rules apply to interface blocks containing pure procedures:

- The interface specification of a pure procedure must declare the INTENT of all dummy arguments except pointer and procedure arguments.
- A procedure that is declared pure in its definition can also be declared pure in an interface block. However, if it is not declared pure in its definition, it must not be declared pure in an interface block.

**Example**

The following example shows a simple procedure interface block with no generic specification:

```fortran
SUBROUTINE SUB_B (B, FB)
  REAL B
  ...
  INTERFACE
    FUNCTION FB (GN)
      REAL FB, GN
    END FUNCTION
  END INTERFACE
END SUBROUTINE
```
The following shows another example:

```
!An interface to an external subroutine SUB1 with header:
!SUBROUTINE SUB1(I1,I2,R1,R2)
!INTEGER I1,I2
!REAL R1,R2
INTERFACE
  SUBROUTINE SUB1(int1,int2,real1,real2)
    INTEGER int1,int2
    REAL real1,real2
  END SUBROUTINE SUB1
END INTERFACE
INTEGER int
...```

PROCEDURE
FUNCTION
MODULE
SUBMODULE
MODULE PROCEDURE
SUBROUTINE
PURE
Procedure Interfaces
Use and Host Association Overview
Unambiguous Generic Procedure References

**INTERFACE TO**

**Statement:** Identifies a subprogram and its actual arguments before it is referenced or called.

**Syntax**

```
INTERFACE TO subprogram-stmt
  [formal-declarations]
END

subprogram-stmt Is a function or subroutine declaration statement.
formal-declarations (Optional) Are type declaration statements (including optional attributes) for the arguments.
```

The INTERFACE TO block defines an explicit interface, but it contains specifications for only the procedure declared in the INTERFACE TO statement. The explicit interface is defined only in the program unit that contains the INTERFACE TO statement.

The recommended method for defining explicit interfaces is to use an INTERFACE block.

**Example**

Consider that a C function that has the following prototype:

```c
extern void Foo (int i);
```
The following INTERFACE TO block declares the Fortran call to this function:

```fortran
INTERFACE TO SUBROUTINE Foo [C.ALIAS: '_Foo'] (I)
   INTEGER*4 I
END
```

See Also

INTERFACE

INTRANSCIC

**Statement and Attribute:** Allows the specific name of an intrinsic procedure to be used as an actual argument.

**Syntax**

The INTRINSIC attribute can be specified in a type declaration statement or an INTRINSIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls,] INTRINSIC [, att-ls] :: in-pro[, in-pro]...
```

**Statement:**

```
INTRINSIC [::] in-pro[, in-pro] ...
```

- *type* is a data type specifier.
- *att-ls* is an optional list of attribute specifiers.
- *in-pro* is the name of an intrinsic procedure.

**Description**

In a type declaration statement, only *functions* can be declared INTRINSIC. However, you can use the INTRINSIC statement to declare subroutines, as well as functions, to be intrinsic.

The name declared INTRINSIC is assumed to be the name of an intrinsic procedure. If a generic intrinsic function name is given the INTRINSIC attribute, the name retains its generic properties.

Some specific intrinsic function names cannot be used as actual arguments. For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures Overview.

**Example**

The following example shows a type declaration statement specifying the INTRINSIC attribute:

```fortran
PROGRAM EXAMPLE
...
REAL(8), INTRINSIC :: DACOS
...
CALL TEST(X, DACOS)    ! Intrinsic function DACOS is an actual argument
```

The following example shows an INTRINSIC statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL CTN</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td>INTRINSIC SIN, COS</td>
<td>Y = F(X)</td>
</tr>
<tr>
<td>...</td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
</tbody>
</table>
Note that when TRIG is called with a second argument of SIN or COS, the function reference F(X) references the Standard Fortran library functions SIN and COS; but when TRIG is called with a second argument of CTN, F(X) references the user function CTN.

The following shows another example:

```fortran
INTRINSIC SIN, COS
REAL X, Y, R
! SIN and COS are arguments to Calc2:
R = Calc2 (SIN, COS)
```

Type Declarations

**INUM**

*Elemental Intrinsic Function (Specific):* Converts a character string to an INTEGER(2) value. This function cannot be passed as an actual argument.

**Syntax**

```fortran
result = INUM (i)
```

*i*  
(Input) Must be of type character.

**Results**

The result type is INTEGER(2). The result value is the INTEGER(2) value represented by the character string *i*.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

**Example**

INUM ("451") has the value 451 of type INTEGER(2).

**IOR**

*Elemental Intrinsic Function (Generic):* Performs an inclusive OR on corresponding bits. This function can also be specified as OR.

**Syntax**

```fortran
result = IOR (i,j)
```
\( i \)  
(Input) Must be of type integer or of type logical (which is treated as an integer).

\( j \)  
(Input) Must be of type integer with the same kind parameter as \( i \). If the kinds of \( i \) and \( j \) do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result.

**Results**

The result type and kind is the same as \( i \). The result value is derived by combining \( i \) and \( j \) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>( i )</th>
<th>( j )</th>
<th>( IOR \ (i, j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIOR</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIOR(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIOR</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or HIOR.

**Example**

IOR (1, 4) has the value 5.

IOR (1, 2) has the value 3.

The following shows another example:

```fortran
INTEGER result
result = IOR(240, 90) ! returns 250
```

IAND  
IEOR  
NOT  
IALL  
IANY  
IPARITY

**IPARITY**

*Transformational Intrinsic Function (Generic):*

*Returns the result of a bitwise exclusive OR operation.*

**Syntax**

\[
\text{result} = \text{IPARITY} \ (\text{array}, \ dim [, \ mask]) \]

\[
\text{result} = \text{IPARITY} \ (\text{array}[, \ mask])
\]
array (Input) Must be an array of type integer.
dim (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array. The corresponding actual argument must not be an optional dummy argument.
mask (Input; optional) Must be of type logical and conformable with array.

Results
The result has the same type and kind parameters as array. It is scalar if dim does not appear; otherwise, the result has rank n - 1 and shape \([d_1, d_2, \ldots, d_{dim-1}, d_{dim+1}, \ldots, d_n]\) where \([d_1, d_2, \ldots, d_n]\) is the shape of array.

The result of IPARITY (array) has a value equal to the bitwise exclusive OR of all the elements of array. If array has size zero, the result value is equal to zero.

The result of IPARITY (array, MASK=mask) has a value equal to IPARITY (PACK (array, mask)).

The result of IPARITY (array, DIM=dim [, MASK=mask]) has a value equal to that of IPARITY (array [, MASK=mask]) if array has rank one. Otherwise, the value of element \((s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)\) of the result is equal to IPARITY (array \((s_1, s_2, \ldots, s_{dim-1} :, s_{dim+1}, \ldots, s_n)\) [, MASK = mask \((s_1, s_2, \ldots, s_{dim-1}, :, s_{dim+1}, \ldots, s_n)\)]).

Example
IPARITY ([14, 13, 8]) has the value 11. IPARITY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 6.

IANY
IALL

IPXFARGC

**POSIX Function:** Returns the index of the last command-line argument.

Module
USE IFPOSIX

Syntax
result = IPXFARGC()

Results
The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.

See Also
PXGETARG

IPXFCONST

**POSIX Function:** Returns the value associated with a constant defined in the C POSIX standard.

Module
USE IFPOSIX
Syntax
result = IPXCONST (constname)

constname (Input) Character. The name of a C POSIX standard constant.

Results
The result type is INTEGER(4). If constname corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is -1.

See Also
PXGETARG
PXCONST

IPXLENTSTRIM
POSIX Function: Returns the index of the last non-blank character in an input string.

Module
USE IFPOSIX

Syntax
result = IPXLENTSTRIM (string)

string (Input) Character. A character string.

Results
The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument string, or zero if all characters in string are blank characters.

IPXFWEXITSTATUS (L*X, M*X)
POSIX Function: Returns the exit code of a child process.

Module
USE IFPOSIX

Syntax
result = IPXFWEXITSTATUS (istat)

istat (Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results
The result type is INTEGER(4). The result is the low-order eight bits of the output argument of PXFWAIT or PXFWAITPID.

The IPXFWEXITSTATUS function should only be used if PXFWIFEXITED returns TRUE.

Example
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET, IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xabcd"
   call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid", IPID
   print *," Now I am waiting for the end of the child process"
   call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program

See Also
PXFWAIT (L*X, M*X)
PXFWAITPID (L*X, M*X)
PXFWIFEXITED (L*X, M*X)

IPXFWSTOPSIG (L*X, M*X)

POSIX Function: Returns the number of the signal that caused a child process to stop.

Module
USE IFPOSIX

Syntax
result = IPXFWSTOPSIG (istat)

istat (Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results
The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop.
The IPXFWSTOPSIG function should only be used if PXFWIFSTOPPED returns TRUE.

See Also
PXFWAIT (L*X, M*X)
PXFWAITPID (L*X, M*X)
PXFWIFSTOPPED (L*X, M*X)

IPXFWTERMSIG (L*X, M*X)

POSIX Function: Returns the number of the signal that caused a child process to terminate.
Module
USE IFPOSIX

Syntax
result = IPXFWTERMSIG (istat)

istat  (Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results
The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.

The IPXFWTERMSIG function should only be used if PXFWIFSIGNALED returns TRUE.

See Also
PXFWAIT (L*X, M*X)
PXFWAITPID (L*X, M*X)
PXFWIFSIGNALED (L*X, M*X)

IRAND, IRANDM
Portability Functions: Return random numbers in the range 0 through (2**31)-1, or 0 through (2**15)-1 if called without an argument.

Module
USE IFPORT

Syntax
result = IRAND ([iflag])
result = IRANDM ([iflag])

iflag  (Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If iflag is omitted, it is assumed to be 0, and the return range is 0 through (2**15)-1 (inclusive).

Results
The result type is INTEGER(4). If iflag is 1, the generator is restarted and the first random value is returned. If iflag is 0, the next random number in the sequence is returned. If iflag is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

Example
USE IFPORT
INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND (flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do

RANDOM_SEED
SRAND

**IRANGET**

*Portability Subroutine:* Returns the current seed.

**Module**
USE IFPORT

**Syntax**
CALL IRANGET (seed)

*seed* (Output) INTEGER(4). The current seed value.

See Also
IRANSET

**IRANSET**

*Portability Subroutine:* Sets the seed for the random number generator.

**Module**
USE IFPORT

**Syntax**
CALL IRANSET (seed)

*seed* (Input) INTEGER(4). The reset value for the seed.

See Also
IRANGET

**IS_CONTIGUOUS**

*Inquiry Intrinsic Function (Generic):* Tests the contiguity of an array.

**Syntax**
result = IS_CONTIGUOUS (array)

*array* (Input) Is an array; it can be of any data type. If it is a pointer, it must be associated.

**Results**
The result is default logical scalar. The result has the value .TRUE. if array is contiguous; otherwise, .FALSE..

**Example**
After the pointer assignment MY_P => TARGET (2:20:4), IS_CONTIGUOUS (MY_P) has the value .FALSE..

**IS_IOSTAT_END**

*Elemental Intrinsic Function (Generic): Tests for an end-of-file condition.*

**Syntax**

```fortran
result = IS_IOSTAT_END(i)
```

*i* (Input) Must be of type integer.

**Results**

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-file condition.

**Example**

```fortran
INTEGER IO_STATUS
...
READ (20, IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_END (IO_STATUS)) THEN
    ! process end of file
ENDIF
...  ! process data read
```

**IS_IOSTAT_EOR**

*Elemental Intrinsic Function (Generic): Tests for an end-of-record condition.*

**Syntax**

```fortran
result = IS_IOSTAT_EOR(i)
```

*i* (Input) Must be of type integer.

**Results**

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-record condition.

**Example**

```fortran
INTEGER IO_STATUS
...
READ (30, ADVANCE='YES', IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_EOR (IO_STATUS)) THEN
    ! process end of record
ENDIF
...  ! process data read
```

**ISATTY**

*Portability Function: Checks whether a logical unit number is a terminal.*

**Module**

```fortran
USE IFPORT
```
**Syntax**

\[ \text{result} = \text{ISATTY} \ (lunit) \]

\[ lunit \] (Input) INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..

If \( lunit \) is out of range or is not connected, zero is returned.

**ISHA**

*Elemental Intrinsic Function (Generic):*  
Arithmetically shifts an integer left or right by a specified number of bits.

**Syntax**

\[ \text{result} = \text{ISHA} \ (i, \text{shift}) \]

\[ i \] (Input) Must be of type integer. This argument is the value to be shifted.

\[ \text{shift} \] (Input) Must be of type integer. This argument is the direction and distance of shift.

Positive shifts are left (toward the most significant bit); negative shifts are right (toward the least significant bit).

**Results**

The result type and kind is the same as \( i \). The result is equal to \( i \) shifted arithmetically by \( \text{shift} \) bits.

If \( \text{shift} \) is positive, the shift is to the left; if \( \text{shift} \) is negative, the shift is to the right. If \( \text{shift} \) is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. If the shift is to the left, zeros are shifted in on the right. If the shift is to the right, copies of the sign bit (0 for non-negative \( i \); 1 for negative \( i \)) are shifted in on the left.

The kind of integer is important in arithmetic shifting because sign varies among integer representations (see the following example). If you want to shift a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

**Example**

```fortran
INTEGER(1) i, res1  
INTEGER(2) j, res2  
i = -128        ! equal to 10000000  
j = -32768      ! equal to 10000000 00000000  
res1 = ISHA (i, -4)  ! returns 11111000 = -8  
res2 = ISHA (j, -4)  ! returns 11111000 10100000 = -2048
```

**See Also**

ISHC  
ISHL  
ISHFT  
ISHFTC
ISHC

Elemental Intrinsic Function (Generic): Rotates an integer left or right by specified number of bits. Bits shifted out one end are shifted in the other end. No bits are lost.

Syntax

result = ISHC (i, shift)

i

(Input) Must be of type integer. This argument is the value to be rotated.

shift

(Input) Must be of type integer. This argument is the direction and distance of rotation.

Positive rotations are left (toward the most significant bit); negative rotations are right (toward the least significant bit).

Results

The result type and kind is the same as i. The result is equal to i circularly rotated by shift bits.

If shift is positive, i is rotated left shift bits. If shift is negative, i is rotated right shift bits. Bits shifted out one end are shifted in the other. No bits are lost.

The kind of integer is important in circular shifting. With an INTEGER(4) argument, all 32 bits are shifted. If you want to rotate a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

Example

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHC (i, -3)   ! returns 01000001 = 65
res2 = ISHC (j, -3)   ! returns 01000000 00000001 = ! 16385
```

ISHA
ISHL
ISHFT
ISHFTC

ISHFT

Elemental Intrinsic Function (Generic): Performs a logical shift.

Syntax

result = ISHFT (i, shift)

i

(Input) Must be of type integer.

shift

(Input) Must be of type integer. The absolute value for shift must be less than or equal to BIT_SIZE (i).
Results

The result type and kind is the same as \( i \). The result has the value obtained by shifting the bits of \( i \) by \( \text{shift} \) positions. If \( \text{shift} \) is positive, the shift is to the left; if \( \text{shift} \) is negative, the shift is to the right. If \( \text{shift} \) is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. Zeros are shifted in from the opposite end.

ISHFT with a positive \( \text{shift} \) can also be specified as LSHIFT (or LSHFT). ISHFT with a negative \( \text{shift} \) can also be specified as RSHIFT (or RSHFT) with \( | \text{shift} | \).

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>

BIT_SIZE
ISHFTC
ISHA
ISHC

ISHFTC

**Elemental Intrinsic Function (Generic):** Performs a circular shift of the rightmost bits.

**Syntax**

```fortran
result = ISHFTC (i, shift[, size])
```

\( i \) \( \text{(Input)} \) Must be of type integer.
**shift**

(Input) Must be of type integer. The absolute value of *shift* must be less than or equal to *size*.

**size**

(Input; optional) Must be of type integer. The value of *size* must be positive and must not exceed BIT_SIZE(*i*). If *size* is omitted, it is assumed to have the value of BIT_SIZE(*i*).

**Results**

The result type and kind is the same as *i*. The result value is obtained by circular shifting the *size* rightmost bits of *i* by *shift* positions. If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.

No bits are lost. Bits in *i* beyond the value specified by *size* are unaffected.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

¹Or HSHIFT.

**Example**

ISHFTC (4, 2, 4) has the value 1.

ISHFTC (3, 1, 3) has the value 6.

The following shows another example:

```plaintext
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHFTC (i, 2, 3)  ! rotates the 3 rightmost
! bits by 2 (left) and
! returns 00001001 = 9
res1 = ISHFTC (i, -2, 3) ! rotates the 3 rightmost
! bits by -2 (right) and
! returns 00001100 = 12
res2 = ISHFTC (j, 2, 3)  ! rotates the 3 rightmost
! bits by 2 and returns
! 00000000 00001001 = 9
```

**See Also**

BIT_SIZE

ISHFT

MVBITS

ISHL

**Elemental Intrinsic Function (Generic):** Logically shifts an integer left or right by the specified bits. Zeros are shifted in from the opposite end.
Syntax

\[ \text{result} = \text{ISHL}(i, \text{shift}) \]

- \(i\) (Input) Must be of type integer. This argument is the value to be shifted.
- \(\text{shift}\) (Input) Must be of type integer. This argument is the direction and distance of shift.

If positive, \(i\) is shifted left (toward the most significant bit). If negative, \(i\) is shifted right (toward the least significant bit).

Results

The result type and kind is the same as \(i\). The result is equal to \(i\) logically shifted by \(\text{shift}\) bits. Zeros are shifted in from the opposite end.

Unlike circular or arithmetic shifts, which can shift ones into the number being shifted, logical shifts shift in zeros only, regardless of the direction or size of the shift. The integer kind, however, still determines the end that bits are shifted out of, which can make a difference in the result (see the following example).

Example

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHL(i, 5)  ! returns 01000000 = 64
res2 = ISHL(j, 5)  ! returns 00000001 01000000 = 320
```

**ISNAN**

**Elemental Intrinsic Function (Generic):** Tests whether IEEE* real (S_floating, T_floating, and X_floating) numbers are Not-a-Number (NaN) values.

Syntax

\[ \text{result} = \text{ISNAN}(x) \]

- \(x\) (Input) Must be of type real.

Results

The result type is default logical. The result is .TRUE. if \(x\) is an IEEE NaN; otherwise, the result is .FALSE..

Example

```fortran
LOGICAL A
DOUBLE PRECISION B
...
A = ISNAN(B)
```

A is assigned the value .TRUE. if \(B\) is an IEEE NaN; otherwise, the value assigned is .FALSE..
ITIME

**Portability Subroutine:** Returns the time in numeric form.

**Module**

USE IFPORT

**Syntax**

CALL ITIME (array)

*array* (Output) INTEGER(4). A rank one array with three elements used to store numeric time data:

- *array(1)* - the hour
- *array(2)* - the minute
- *array(3)* - the second

**Example**

```
USE IFPORT
INTEGER(4) time_array(3)
CALL ITIME (time_array)
write(*,10) time_array
10 format (1X,I2,':',I2,':',I2)
END
```

**See Also**

DATE_AND_TIME

**IVDEP**

**General Compiler Directive:** Assists the compiler's dependence analysis of iterative DO loops.

**Syntax**

```
!DIR$ IVDEP [:: option]
```

*option* Is LOOP or BACK. This argument is only available on processors using IA-32 architecture.

The IVDEP directive is an assertion to the compiler's optimizer about the order of memory references inside a DO loop.

IVDEP:LOOP implies no loop-carried dependencies. IVDEP:BACK implies no backward dependencies.

When no *option* is specified, the following occurs:

- The compiler begins dependence analysis by assuming all dependences occur in the same forward direction as their appearance in the normal scalar execution order. This contrasts with normal compiler behavior, which is for the dependence analysis to make no initial assumptions about the direction of a dependence.

!DIR$ IVDEP with no option can also be spelled !DIR$ INIT_DEP_FWD (INITialize DEPendences ForWarD).

The IVDEP directive is applied to a DO loop in which the user knows that dependences are in lexical order. For example, if two memory references in the loop touch the same memory location and one of them modifies the memory location, then the first reference to touch the location has to be the one that appears earlier lexically in the program source code. This assumes that the right-hand side of an assignment statement is "earlier" than the left-hand side.
The IVDEP directive informs the compiler that the program would behave correctly if the statements were executed in certain orders other than the sequential execution order, such as executing the first statement or block to completion for all iterations, then the next statement or block for all iterations, and so forth. The optimizer can use this information, along with whatever else it can prove about the dependences, to choose other execution orders.

**Example**

In the following example, the IVDEP directive provides more information about the dependences within the loop, which may enable loop transformations to occur:

```fortran
!DIR$ IVDEP
DO I=1, N
   A(INDARR(I)) = A(INDARR(I)) + B(I)
END DO
```

In this case, the scalar execution order follows:

1. Retrieve INDARR(I).
2. Use the result from step 1 to retrieve A(INDARR(I)).
4. Add the results from steps 2 and 3.
5. Store the results from step 4 into the location indicated by A(INDARR(I)) from step 1.

IVDEP directs the compiler to initially assume that when steps 1 and 5 access a common memory location, step 1 always accesses the location first because step 1 occurs earlier in the execution sequence. This approach lets the compiler reorder instructions, as long as it chooses an instruction schedule that maintains the relative order of the array references.

---

**J to L**

**J to L**

**JABS**

*Portability Function: Returns an absolute value.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = JABS (i)
```

*i* (Input) INTEGER(4). A value.

**Results**

The result type is INTEGER(4). The value of the result is |i|.
**JDATE**

**Portability Function:** Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.

**Module**

USE IFPORT

**Syntax**

```fortran
result = JDATE()
```

**Results**

The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.

The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.

---

**CAUTION**

The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Example**

```fortran
! Sets julian to today's julian date
USE IFPORT
CHARACTER*8 julian
julian = JDATE()
```

**See Also**

DATE_AND_TIME

---

**JDATE4**

**Portability Function:** Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.

**Module**

USE IFPORT

**Syntax**

```fortran
result = JDATE4()
```

**Results**

The result type is character with length 10. The result is the Julian date, in the form YYYYDDD, followed by three spaces.

The Julian date is a seven-digit number whose first four digits are the year, and whose final three represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 1999032.

**See Also**

DATE_AND_TIME

---
**JNUM**

**Elemental Intrinsic Function (Specific):** Converts a character string to an INTEGER(4) value. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{JNUM} \ (\text{i})
\]

\text{i} \quad \text{(Input) Must be of type character.}

**Results**

The result type is INTEGER(4). The result value is the integer value represented by the character string \text{i}. If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

**Example**

JNUM (“46616”) has the value 46616 of type INTEGER(4).

---

**KILL**

**Portability Function:** Sends a signal to the process given by ID.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{KILL} \ (\text{pid}, \text{signum})
\]

\text{pid} \quad \text{(Input) INTEGER(4). ID of a process to be signaled.}

\text{signum} \quad \text{(Input) INTEGER(4). A signal value. For the definition of signal values, see the \text{SIGNAL} function.}

**Results**

The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error code. Possible error codes are:

- EINVAL: The \text{signum} is not a valid signal number, or PID is not the same as getpid( ) and \text{signum} does not equal SIGKILL.
- ESRCH: The given PID could not be found.
- EPERM: The current process does not have permission to send a signal to the process given by PID.

On Windows* systems, arbitrary signals can be sent only to the calling process (where \text{pid} = \text{getpid( )}). Other processes can send only the SIGKILL signal ( \text{signum} = 9), and only if the calling process has permission.

**Example**

USE IFPORT

integer(4) id_number, sig_val, istat
id_number = getpid( )
ISTAT = KILL (id_number, sig_val)

**See Also**

SIGNAL
**KIND**

*Inquiry Intrinsic Function (Generic):* Returns the kind parameter of the argument.

**Syntax**

```
result = KIND (x)
```

*x*  
(Input) Can be of any intrinsic type.

**Results**

The result is a scalar of type default integer. The result has a value equal to the kind type parameter value of *x*.

**Example**

KIND (0.0) has the kind value of default real type.

KIND (12) has the kind value of default integer type.

The following shows another example:

```fortran
INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)  ! still a 4-byte integer
! not affected by setting in subroutine
END
SUBROUTINE INTEGER2( )
  !DIR$INTEGER:2
  INTEGER j ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```

**KNUM**

*Elemental Intrinsic Function (Specific):* Converts a character string to an INTEGER(8) value.

**Syntax**

```
result = KNUM (i)
```

*i*  
(Input) Must be of type character.
Results

The result type is INTEGER(8). The result value is the integer value represented by the character string $i$.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example

KNUM ("46616") has the value 46616 of type INTEGER(8).

LASTPRIVATE

Parallel Directive Clause: Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.

Syntax

LASTPRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel region is exited, each variable has the value provided by the sequentially last section or loop iteration.

If the original variable has the POINTER attribute, its update occurs as if by pointer assignment.

If the original variable does not have the POINTER attribute, its update occurs as if by intrinsic assignment.

When the LASTPRIVATE clause appears in a DO directive, the thread that executes the sequentially last iteration updates the version of the object it had before the construct. When the LASTPRIVATE clause appears in a SECTIONS directive, the thread that executes the lexically last SECTION updates the version of the object it had before the construct.

Subobjects that are not assigned a value by the last iteration of the DO or the lexically last SECTION of the SECTIONS directive are undefined after the construct.

The original variable becomes defined at the end of the construct if there is an implicit barrier at that point. To avoid race conditions, concurrent reads or updates of the original variable must be synchronized with the update of the original variable that occurs as a result of the LASTPRIVATE clause.

If the LASTPRIVATE clause is used in a construct for which NOWAIT is specified, accesses to the original variable may create a data race. To avoid this, synchronization must be inserted to ensure that the sequentially last iteration or lexically last section construct has stored and flushed that variable.

The following are restrictions for the LASTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that is private within a parallel region, or that appears in the REDUCTION clause of a PARALLEL construct, must not appear in a LASTPRIVATE clause on a worksharing construct if any of the corresponding worksharing regions ever binds to any of the corresponding parallel regions.
- A variable that appears in a LASTPRIVATE clause must be definable.
- An original variable with the ALLOCATABLE attribute must be in the allocated state at entry to the construct containing the LASTPRIVATE clause. The variable in the sequentially last iteration or lexically last section must be in the allocated state upon exit from that iteration or section with the same bounds as the corresponding original variable.
• Assumed-size arrays must not appear in a PRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

NOTE
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

Example
Consider the following:

```!
$OMP DO PRIVATE(I) LASTPRIVATE(B)
DO I = 1, 1000
  B = I
ENDDO
$OMP END DO
```

In this case, after the construct is exited, variable B has the value 1000.

Consider the following:

```!
$OMP SECTIONS LASTPRIVATE(B)
$OMP SECTION
  B = 2
$OMP SECTION
  B = 4
$OMP SECTION
  D = 6
$OMP END SECTIONS
```

In this case the thread that executes the lexically last SECTION updates the original variable B to have a value of 4. However, variable D was not specified in the LASTPRIVATE clause, so it has an undefined value after the construct is exited.

See Also
PRIVATE Clause
FIRSTPRIVATE

LBOUND

Inquiry Intrinsic Function (Generic): Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.

Syntax

```
result = LBOUND (array [, dim] [, kind])
```

- **array**  
  (Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer.

- **dim**  
  (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank array.

- **kind**  
  (Input; optional) Must be a scalar integer initialization expression.
Results

The result type is integer. If \texttt{kind} is present, the kind parameter of the result is that specified by \texttt{kind}; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \texttt{dim} is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of \texttt{array}. Each element in the result corresponds to a dimension of \texttt{array}.

If \texttt{array} is an array section or an array expression that is not a whole array or array structure component, each element of the result has the value 1.

If \texttt{array} is a whole array or array structure component, \texttt{LBOUND (array, dim)} has a value equal to the lower bound for subscript \texttt{dim} of \texttt{array} (if \texttt{dim} is nonzero or \texttt{array} is an assumed-size array of rank \texttt{dim}). Otherwise, the corresponding element of the result has the value 1.

If \texttt{LBOUND} is invoked for an assumed-rank object that is associated with a scalar and \texttt{dim} is absent, the result is a zero-sized array. \texttt{LBOUND} cannot be invoked for an assumed-rank object that is associated with a scalar if \texttt{dim} is present because the rank of a scalar is zero and \texttt{dim} must be \texttt{>= 1}.

The setting of compiler options specifying integer size can affect this function.

Example

Consider the following:

\begin{verbatim}
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
\end{verbatim}

\texttt{LBOUND(ARRAY_A)} is \texttt{(1, 5)}. \texttt{LBOUND(ARRAY_A, DIM=2)} is 5.

\texttt{LBOUND(ARRAY_B)} is \texttt{(2, -3)}. \texttt{LBOUND(ARRAY_B (5:8,:))} is \texttt{(1,1)} because the arguments are array sections.

The following shows another example:

\begin{verbatim}
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = LBOUND (ar1)      ! returns [2, 4, -1]
res2 = LBOUND (ar1, DIM= 3)  ! returns -1
res3 = LBOUND (vec1)    ! returns [1]
END
\end{verbatim}

See Also

UBOUND

\textbf{LCOBOUND}

\textit{Inquiry Intrinsic Function (Generic):} Returns the lower cobounds of a coarray.

Syntax

\begin{verbatim}
result = LCOBOUND (coarray [,dim [, kind]])
\end{verbatim}

\textit{coarray} \hspace{1cm} (Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.

\textit{dim} \hspace{1cm} (Input; optional) Must be an integer scalar with a value in the range \texttt{1 <=} \texttt{dim} \texttt{<=} \texttt{n}, where \texttt{n} is the corank of \texttt{coarray}. The corresponding actual argument must not be an optional dummy argument.

\textit{kind} \hspace{1cm} (Input; optional) Must be a scalar integer constant expression.
Results

The result type is integer. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default integer type. The result is scalar if dim is present; otherwise, the result is an array of rank one and size n, where n is the corank of coarray.

The result depends on whether dim is specified:

- If dim is specified, LCOBOUND (COARRAY, DIM) has a value equal to the lower cobound for cosubscript dim of coarray.
- If dim is not specified, LCOBOUND (COARRAY) has a value whose ith element is equal to LCOBOUND (COARRAY, i), for i = 1, 2, . . . , n, where n is the corank of coarray.

Example

If B is allocated by the statement ALLOCATE (B [2:3, 8:*]), then LCOBOUND (B) is [2, 8] and LCOBOUND (B, DIM=2) is 8.

LCWRQQ

Portability Subroutine: Sets the value of the floating-point processor control word.

Module

USE IFPORT

Syntax

CALL LCWRQQ (controlword)

controlword (Input) INTEGER(2). Floating-point processor control word.

LCWRQQ performs the same function as the run-time subroutine SETCONTROLFPQQ and is provided for compatibility.

Example

USE IFPORT

INTEGER(2) control
CALL SCWRQQ(control) ! get control word
! Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC)  ! Clear
! control word with inverse
! of rounding control mask
control = control .OR. FPCW$UP  ! Set control word
! to round up
CALL LCWRQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END

See Also

SETCONTROLFPQQ

LEADZ

Elemental Intrinsic Function (Specific): Returns the number of leading zero bits in an integer.

Syntax

result = LEADZ (i)
**i**

(Input) Must be of type integer or logical.

**Results**

The result type is default integer. The result value is the number of leading zeros in the binary representation of the integer \(i\).

The model for the interpretation of an integer value as a sequence of bits is shown in **Model for Bit Data**.

**Example**

Consider the following:

```fortran
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
  TYPE *, LEADZ(TWO**J)  ! Prints 64 down to 23 (leading zeros)
ENDDO
END
```

**LEN**

*Inquiry Intrinsic Function (Generic): Returns the length of a character expression.*

**Syntax**

\[
\text{result} = \text{LEN} \left( \text{string} [, \text{kind}] \right)
\]

**string**

(Input) Must be of type character; it can be scalar or array valued. (It can be an array of strings.)

**kind**

(Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is a scalar of type integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters in \(\text{string}\) (if it is scalar) or in an element of \(\text{string}\) (if it is array valued).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEN (^1)</td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following example:

```fortran
CHARACTER (15) C (50)
CHARACTER (25) D
```

LEN (C) has the value 15, and LEN (D) has the value 25.
The following shows another example:

```fortran
CHARACTER(11) STR(100)
INTEGER I
I = LEN (STR)  ! returns 11
I = LEN('A phrase with 5 trailing blanks.^^^^^')
     ! returns 37
```

See Also
LEN_TRIM

Declarations for Character Types
Character Data Type

LEN_TRIM

**Elemental Intrinsic Function (Generic):** Returns the length of the character argument without counting trailing blank characters.

**Syntax**

```fortran
result = LEN_TRIM (string [, kind])
```

- `string` (Input) Must be of type character.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is a scalar of type integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the kind, the result is undefined.

The result has a value equal to the number of characters remaining after any trailing blanks in `string` are removed. If the argument contains only blank characters, the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

LEN_TRIM (' C D ') has the value 4.
LEN_TRIM (' ') has the value 0.

The following shows another example:

```fortran
INTEGER LEN1
LEN1 = LEN_TRIM (' GOOD DAY ') ! returns 9
LEN1 = LEN_TRIM (' ')          ! returns 0
```

See Also
LEN
LNBLNK

LGE

**Elemental Intrinsic Function (Generic):** Determines if a string is lexically greater than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LGE is equivalent to the (.GE.) operator.

**Syntax**

```fortran
result = LGE (string_a,string_b)
```
string_a  (Input) Must be of type character.
string_b  (Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if string_a follows string_b in the ASCII collating sequence; otherwise, the result is false.

Specific Name  Argument Type  Result Type
LGE 1,2  CHARACTER  LOGICAL(4)

1 This specific function cannot be passed as an actual argument.
2 The setting of compiler options specifying integer size can affect this function.

Example

LGE ( 'ONE', 'SIX' ) has the value false.
LGE ( 'TWO', 'THREE' ) has the value true.
The following shows another example:

LOGICAL L
L = LGE('ABC','ABD')       ! returns .FALSE.
L = LGE ('AB', 'AAAAAAB') ! returns .TRUE.

Character and Key Code Charts for Windows*

LGT

Elemental Intrinsic Function (Generic):
Determines whether a string is lexically greater than another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LGT is equivalent to the > (.GT.) operator.

Syntax

result = LGT (string_a,string_b)

string_a  (Input) Must be of type character.
string_b  (Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if string_a follows string_b in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>

**LINEAR Clause**

**Parallel Directive Clause:** Specifies that all variables in a list are private to a SIMD lane and that they have a linear relationship within the iteration space of a loop.

**Syntax**

It takes one of the following forms:

**In Construct Directive !$OMP SIMD:**

LINEAR (var-list[: linear-step])

**In Declarative Directive !$OMP DECLARE SIMD:**

LINEAR (linear-list[: linear-step])

**var-list**

Is a comma-separated list of one or more integer variables. Each list item must comply with PRIVATE clause semantics.

For each iteration of a scalar loop, the value of each var is incremented by linear-step. For each iteration of a vector loop, the value of each var is incremented by linear-step times the vector length for the loop.

**linear-step**

Is a compile-time positive, integer, scalar constant expression. If linear-step is not specified, it is assumed to be 1.

**linear-list**

Takes one of the following forms:

- **list**
- **modifier (list)**

**list**

Is a comma-separated list of one or more dummy arguments of the procedure that will be invoked concurrently on each SIMD lane. Each list item must comply with PRIVATE clause semantics.
If \textit{modifier} is not specified or it is VAL or UVAL, each \textit{list} item must be a scalar of type integer. If \textit{modifier} is REF, each \textit{list} item must be a scalar of intrinsic type.

\textit{modifier} is one of the following:

- **REF**
  
  Specifies that the storage location of each \textit{list} item on each lane corresponds to an array at the storage location upon entry to the function indexed by the logical number of the lane times \textit{linear-step}.

  The referenced values passed into the routine (which forms a vector for calculations) are located sequentially, like in an array, with the distance between elements equal to step.

  This modifier can be used only for dummy arguments passed by reference.

- **VAL**
  
  Specifies that the value of each \textit{list} item on each lane corresponds to the value of the \textit{list} item upon entry to the function plus the logical number of the lane times \textit{linear-step}.

  On each iteration of the loop from which the routine is called, the value of the parameter can be calculated as (value\_on\_previous\_iteration + step).

- **UVAL**
  
  Similar to VAL but each invocation uses the same storage location for each SIMD lane. This storage location is updated with the final value of the logically last lane. It differs from VAL as follows:

  - For VAL, a vector of addresses (references) is passed to the vector variant of the routine.
  - For UVAL, only one address (reference) is passed, which may improve performance.

  This modifier can be used only for dummy arguments passed by reference.

If \textit{modifier} is not specified or it is VAL or UVAL, the value of each \textit{list} item on each lane corresponds to the value of the \textit{list} item upon entry to the function plus the logical number of the lane times \textit{linear-step}.

You can only use \textit{REF} or \textit{VAL} if the \textit{list} item is a dummy argument without the Fortran Standard VALUE attribute.

If more than one \textit{linear-step} is specified for a \textit{var}, a compile-time error occurs. Multiple LINEAR clauses can be used to specify different values for \textit{linear-step}. The \textit{linear-step} expression must be invariant (must not be changed) during the execution of the associated construct. Multiple LINEAR clauses are merged as a union.

The value corresponding to the sequentially last iteration of the associated loops is assigned to the original \textit{list} item.

A \textit{list} item in a LINEAR clause cannot appear in any other data scope attribute clause, in another LINEAR clause, or more than once in \textit{list}. For a list of data scope attribute clauses, see the first table in \textit{Clauses Used in Multiple OpenMP* Fortran Directives}.

In the sequentially last iteration, any \textit{list} item with the ALLOCATABLE attribute must have an allocation status of allocated upon exit from that iteration.
If a list item is a dummy argument without the Fortran Standard VALUE attribute and the REF modifier is not specified, then a read of the list item must be executed before any writes to the list item.

The following cannot appear in a LINEAR clause:

- Variables that have the POINTER attribute
- Cray* pointers

The LINEAR (REF) clause is very important because Fortran passes dummy arguments by reference. By default, the compiler places consecutive addresses in a vector register, which leads to an inefficient gather of the addresses.

In the following example, LINEAR (REF (X)) tells the compiler that the 4 addresses for the dummy argument X are consecutive, so the code only needs to dereference X once and then copy consecutive values to a vector register.

**Example**

Consider the following:

The following are the loop examples referenced above.

VALUE statement and attribute
SIMD Directive (OpenMP* API)
DECLARE SIMD

**LINETO, LINETO_W (W'S)**

**Graphics Function:** Draws a line from the current graphics position up to and including the end point.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = LINETO (x, y)
result = LINETO_W (wx, wy)
```

- `x, y` (Input) INTEGER(2). Viewport coordinates of end point.
- `wx, wy` (Input) REAL(8). Window coordinates of end point.

**Results**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0.

The line is drawn using the current graphics color, logical write mode, and line style. The graphics color is set with `SETCOLORRGB`, the write mode with `SETWRITEMODE`, and the line style with `SETLINESTYLE`.

If no error occurs, LINETO sets the current graphics position to the viewport point `(x, y)`, and LINETO_W sets the current graphics position to the window point `(wx, wy)`.

If you use `FLOODFILLRGB` to fill in a closed figure drawn with LINETO, the figure must be drawn with a solid line style. Line style is solid by default and can be changed with `SETLINESTYLE`.

**NOTE**

The LINETO routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the LineTo routine by including the IFWIN module, you need to specify the routine name as MSFWIN$LineTo.
Example

This program draws the figure shown below.

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) xy
CALL MOVETO(INT2(80), INT2(50), xy)
status = LINETO(INT2(240), INT2(150))
status = LINETO(INT2(240), INT2(50))
END
```

<tr>
<td>cnt</td>
<td>(Input) INTEGER(4). Length of each coordinate array; all should be the same size.</td>
</tr>
</tbody>
</table>

Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.
The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

Example

! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3), fy(3), tx(3), ty(3), result
integer(4) cnt, i
! load the points
do i = 1, 3
! from here
fx(i) = 20 * i
fy(i) = 10
! to there
tx(i) = 20 * i
ty(i) = 60
end do
! draw the lines all at once
! 3 white vertical lines in upper left corner
result = LINETOAR(loc(fx), loc(fy), loc(tx), loc(ty), 3)
end

See Also

LINETOAREX (W*S)
LOC
SETCOLORRGB (W*S)
SETLINESTYLE (W*S)
SETWRITEMODE (W*S)

LINETOAREX (W*S)

**Graphics Function:** Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. Each line is drawn with the specified graphics color and line style.

Module
USE IFQWIN

Syntax

result = LINETOAREX (loc(fx), loc(fy), loc(tx), loc(ty), loc(C), loc(S), cnt)

- \( fx \) (Input) INTEGER(2). From x viewport coordinate array.
- \( fy \) (Input) INTEGER(2). From y viewport coordinate array.
- \( tx \) (Input) INTEGER(2). To x viewport coordinate array.
- \( ty \) (Input) INTEGER(2). To y viewport coordinate array.
- \( C \) (Input) INTEGER(4). Color array.
- \( S \) (Input) INTEGER(4). Style array.
- \( cnt \) (Input) INTEGER(4). Length of each coordinate array; also the length of the color array and style array. All of the arrays should be the same size.
Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the specified graphics colors and line styles, and with the current write mode. The current write mode is set with SETWRITEMODE.

If the color has the Z'80000000' bit set, the color is an RGB color; otherwise, the color is a palette color.

The styles are as follows from wingdi.h:

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOLID</td>
<td>0</td>
</tr>
<tr>
<td>DASH</td>
<td>1     /* ------ */</td>
</tr>
<tr>
<td>DOT</td>
<td>2     /* ....... */</td>
</tr>
<tr>
<td>DASHDOT</td>
<td>3     /* <em>.</em>.<em>.</em> */</td>
</tr>
<tr>
<td>DASHDOTDOT</td>
<td>4     /* <em>..</em>.._ */</td>
</tr>
<tr>
<td>NULL</td>
<td>5</td>
</tr>
</tbody>
</table>

Example

! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3),fy(3),tx(3),ty(3),result
integer(4) C(3),S(3),cnt,i,color

color = #000000FF

! load the points
do i = 1,3
  S(i) = 0 ! all lines solid
  C(i) = IOR(Z'80000000',color)
  color = color*256 ! pick another of RGB
  if(IAND(color,Z'00FFFFFF').eq.0) color = Z'000000FF'
  !from here
  fx(i) =20*i
  fy(i) =10
  !to there
  tx(i) =20*i
  ty(i) =60
end do
! draw the lines all at once
! 3 vertical lines in upper left corner, Red, Green, and Blue
result = LINETOAREX(loc(fx),loc(fy),loc(tx),loc(ty),loc(C),loc(S),3)
end

LLE

*Elemental Intrinsic Function (Generic):*
Determines whether a string is lexically less than or equal to another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LLE is equivalent to the (.LE.) operator.
**Syntax**

```
result = LLE (string_a, string_b)
```

`string_a`  
(Input) Must be of type character.

`string_b`  
(Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if `string_a` precedes `string_b` in the ASCII collating sequence; otherwise, the result is false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLE 1,2</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

1This specific function cannot be passed as an actual argument.

2The setting of compiler options specifying integer size can affect this function.

**Example**

LLE ( 'TWO', 'THREE' ) has the value false.

LLE ( 'ONE', 'FOUR' ) has the value false.

The following shows another example:

```
LOGICAL L
L = LLE ('ABC', 'ABC') ! returns .TRUE.
L = LLE ('ABC', 'AABCD') ! returns .FALSE.
```

**See Also**

LGE

Character and Key Code Charts for Windows*

**LLT**

*Elemental Intrinsic Function (Generic):*

Determines whether a string is lexically less than another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LLT is equivalent to the < (.LT.) operator.

**Syntax**

```
result = LLT (string_a, string_b)
```

`string_a`  
(Input) Must be of type character.

`string_b`  
(Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.
The result is true if string_a precedes string_b in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLT 1,2</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

1. This specific function cannot be passed as an actual argument.
2. The setting of compiler options specifying integer size can affect this function.

Example

LLT ('ONE', 'SIX') has the value true.
LLT ('ONE', 'FOUR') has the value false.

The following shows another example:

```
LOGICAL L
L = LLT ('ABC', 'ABC') ! returns .FALSE.
L = LLT ('AAXYZ', 'ABCDE') ! returns .TRUE.
```

LNBLNK

*Portability Function: Locates the position of the last nonblank character in a string.

Module
USE IFPORT

Syntax

```
result = LNBLNK (string)
```

\(\text{string} \quad \text{(Input) Character}^*(\ast)\). String to be searched. Cannot be an array.

Results

The result type is INTEGER(4). The result is the index of the last nonblank character in string.

LNBLNK is very similar to the intrinsic function LEN_TRIM, except that string cannot be an array.

Example

```
USE IFPORT
integer(4) p
p = LNBLNK(' GOOD DAY ') ! returns 9
p = LNBLNK(' ') ! returns 0
```

See Also
LEN_TRIM

LOADIMAGE, LOADIMAGE_W (W*S)

*Graphics Functions: Read an image from a Windows bitmap file and display it at a specified location.*
Module
USE IFQWIN

Syntax
result = LOADIMAGE (filename, xcoord, ycoord)
result = LOADIMAGE_W (filename, wxcoord, wycoord)

filename (Input) Character*(*). Path of the bitmap file.
xcoord, ycoord (Input) INTEGER(4). Viewport coordinates for upper-left corner of image display.
wxcoord, wycoord (Input) REAL(8). Window coordinates for upper-left corner of image display.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.
The image is displayed with the colors in the bitmap file. If the color palette in the bitmap file is different from the current system palette, the current palette is discarded and the bitmap's palette is loaded.
LOADIMAGE specifies the screen placement of the image in viewport coordinates. LOADIMAGE_W specifies the screen placement of the image in window coordinates.

See Also
SAVEIMAGE, SAVEIMAGE_W (W*S)

LOC
Inquiry Intrinsic Function (Generic): Returns the internal address of a storage item. This function cannot be passed as an actual argument.

Syntax
result = LOC (x)

x (Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.
This function performs the same function as the %LOC built-in function.

Example
The Fortran standard provides the C_LOC intrinsic module function as an alternative to the non-standard LOC. For more information, see the descriptions of C_LOC, C_FUNLOC, C_F_POINTER and C_F_PROCPOINTER.

! Example of using the LOC intrinsic
integer :: array(2) = [10,20]
integer :: t
pointer (p,t) ! Integer pointer extension
! p is pointer, t is pointee (target)
%LOC

**Built-in Function:** Computes the internal address of a storage item.

**Syntax**

```
result = %LOC (a)
```

- `result` (Output) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

**Description**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the LOC intrinsic function.

**LOCK and UNLOCK**

- **Statements:** A LOCK statement causes a lock variable to become locked by an image. An UNLOCK statement causes the lock variable to become unlocked. They take the following forms:

**Syntax**

```
LOCK (lock-var [, ACQUIRED_LOCK=log-var] [, STAT=stat-var] [, ERRMSG=err-var])
UNLOCK (lock-var [, STAT=stat-var] [, ERRMSG=err-var])
```

- `lock-var` Is a scalar variable of type LOCK_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.
- `log-var` Is a scalar logical variable.
- `stat-var` Is a scalar integer variable in which the status of the synchronization is stored.
- `err-var` Is a scalar default character variable in which explanatory text is stored if an error occurs.

ACQUIRED_LOCK=, STAT=, and ERRMSG= can appear in any order, but only once in a LOCK statement.

STAT= and ERRMSG= can appear in either order, but only once in an UNLOCK statement.

**Description**

- A lock variable is unlocked if its value is equal to that of the structure constructor LOCK_TYPE ( ). If it has any other value, it is locked.
- A lock variable is locked by an image if it was locked by execution of a LOCK statement on that image and has not been subsequently unlocked by execution of an UNLOCK statement on the same image.
When a LOCK statement is specified without an ACQUIRED_LOCK= specifier, it causes the lock variable to become locked by that image. If the lock variable is already locked by another image, that LOCK statement causes the lock variable to become defined after the other image causes the lock variable to become unlocked.

If the lock variable is unlocked, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier causes the lock variable to become locked by that image and the log-var to become defined with the value TRUE. If the lock variable is already locked by a different image, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier leaves the lock variable unchanged and causes the log-var to become defined with the value FALSE.

During the execution of the program, the value of a lock variable changes through a sequence of locked and unlocked states when LOCK and UNLOCK statements are executed. If a lock variable becomes unlocked by execution of an UNLOCK statement on image M and next becomes locked by execution of a LOCK statement on image T, the segments preceding the UNLOCK statement on image M precede the segments following the LOCK statement on image T. Execution of a LOCK statement that does not cause the lock variable to become locked does not affect segment ordering.

An error condition occurs in the following cases:

- If the lock variable in a LOCK statement is already locked by the executing image
- If the lock variable in an UNLOCK statement is not already locked by the executing image

If an error condition occurs during execution of a LOCK or UNLOCK statement, the value of the lock variable is not changed and the value of the ACQUIRED_LOCK variable, if any, is not changed.

Example

The following example shows the use of LOCK and UNLOCK statements to manage a work queue:

```
USE, INTRINSIC :: ISO_FORTRAN_ENV

TYPE(Task) :: work_queue(50)[*]          ! List of tasks on queue to perform
INTEGER :: work_queue_size[*]
TYPE(LOCK_TYPE) :: work_queue_lock[*]    ! Lock to manage the work queue

my_image = THIS_IMAGE()
DO
    ! Process the next task in the work queue
    LOCK (work_queue_lock)              ! Start of new segment A
        ! Segment A is ordered with respect to segment B
        ! executed by image my_image-1 below because of lock exclusion
        IF (work_queue_size>0) THEN
            ! Get the next job from the queue
            current_task = work_queue(work_queue_size)
            work_queue_size = work_queue_size-1
        END IF
    UNLOCK (work_queue_lock) ! Segment ends
    ...
    ! Add a new task on the neighboring queue:
    LOCK(work_queue_lock[my_image+1])      ! Starts segment B
        ! Segment B is ordered with respect to segment A
        ! executed by image my_image+1 above because of lock exclusion
        IF (work_queue_size[my_image+1]<SIZE(work_queue)) THEN
            work_queue_size[my_image+1] = work_queue_size[my_image+1]+1
            work_queue(work_queue_size[my_image+1])[my_image+1] = current_task
```

Coarrays
Using Coarrays

**LOG**

*Elemental Intrinsic Function (Generic):* Returns the natural logarithm of the argument.

**Syntax**

```fortran
result = LOG (x)
```

**x**  
(Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

**Results**

The result type and kind is the same as x. The result value is approximately equal to log_e x.

If the arguments are complex, the result is the principal value with imaginary part omega in the range -pi <= omega <= pi.

If the real part of x < 0 and the imaginary part of x is a positive real zero, the imaginary part of the result is pi.

If the real part of x < 0 and the imaginary part of x is a negative real zero, the imaginary part of the result is -pi.

<table>
<thead>
<tr>

<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

¹This function is treated like LOG.
²The setting of compiler options specifying real size can affect ALOG, LOG, and CLOG.
³This function can also be specified as ZLOG.
⁴The setting of compiler options specifying double size can affect CDLOG.

**Example**

LOG (8.0) has the value 2.079442.

LOG (25.0) has the value 3.218876.

The following shows another example:

```fortran
REAL r
r = LOG(10.0)  ! returns 2.302585
```
See Also
EXP
LOG10

LOG_GAMMA

Elemental Intrinsic Function (Generic): Returns the logarithm of the absolute value of the gamma function of the argument.

Syntax
result = LOG_GAMMA (x)

x (Input) Must be of type real. It must not be zero or a negative integer.

Results
The result type and kind are the same as x. The result has a value equal to a processor-dependent approximation to the natural logarithm of the absolute value of the gamma function of x.

Example
LOG_GAMMA (3.0) has the approximate value 0.693.

LOG10

Elemental Intrinsic Function (Generic): Returns the common logarithm of the argument.

Syntax
result = LOG10 (x)

x (Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

Results
The result type and kind is the same as x. The result value is approximately equal to log_{10}x.

Specific Name                     Argument Type    Result Type
ALOG10 1,2                        REAL(4)          REAL(4)
DLOG10 3                          REAL(8)          REAL(8)
QLOG10                             REAL(16)         REAL(16)
CLOG102                           COMPLEX(4)       COMPLEX(4)
CDLOG103                          COMPLEX(8)       COMPLEX(8)
CQLOG10                           COMPLEX(16)      COMPLEX(16)

1This function is treated like LOG10.
2The setting of compiler options specifying real size can affect ALOG10, CLOG10, and LOG10.
3The setting of compiler options specifying double size can affect DLOG10 and CDLOG10.
Example

\[
\log_{10}(8.0) \text{ has the value } 0.9030900.
\]
\[
\log_{10}(15.0) \text{ has the value } 1.176091.
\]

The following shows another example:

```fortran
REAL r
r = LOG10(10.0)  ! returns 1.0
```

See Also
LOG

LOGICAL Statement

**Statement:** Specifies the LOGICAL data type.

Syntax

```fortran
LOGICAL
LOGICAL([KIND=n])
LOGICAL*1
```

\(n\)

Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

Example

```fortran
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (2), SAVE :: doit, dont=.FALSE.
LOGICAL switch
```

! An equivalent declaration is:

```fortran
LOGICAL flag1, flag2
LOGICAL (2) doit, dont=.FALSE.
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

See Also
Logical Data Types
Logical Constants
Data Types, Constants, and Variables Overview

LOGICAL Function

**Elemental Intrinsic Function (Generic):** Converts the logical value of the argument to a logical value with different kind parameters.

Syntax

```fortran
result = LOGICAL(l[,kind])
```

\(l\)

(Input) Must be of type logical.

\(kind\)

(Input; optional) Must be a scalar integer initialization expression.
Results
The result is of type logical. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default logical. The result value is that of l.

The setting of compiler options specifying integer size can affect this function.

Example
LOGICAL (L .OR. .NOT. L) has the value true and is of type default logical regardless of the kind parameter of logical variable L.
LOGICAL (.FALSE., 2) has the value false, with the kind parameter of INTEGER(KIND=2).

See Also
CMPLX
INT
REAL Function
Logical Data Types
LONG
Portability Function: Converts an INTEGER(2) argument to INTEGER(4) type.

Module
USE IFPORT

Syntax
result = LONG (int2)

int2 (Input) INTEGER(2). Value to be converted.

Results
The result type is INTEGER(4). The result is the value of int2 with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to int2.

See Also
INT
KIND

LOOP COUNT
General Compiler Directive: Specifies the iterations (typical trip count) for a DO loop.

Syntax
!DIR$ LOOP COUNT (n1[,n2]...)
!DIR$ LOOP COUNT= n1[,n2]...
!DIR$ LOOP COUNT MAX(n1), MIN(n1), AVG(n1)
!DIR$ LOOP COUNT MAX=n1, MIN=n1, AVG=n1

n1, n2 Is a non-negative integer constant.

The value of the loop count affects heuristics used in software pipelining, vectorization, and loop-transformations.
## Argument Form

<table>
<thead>
<tr>
<th>Argument Form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n_1, n_2 )</td>
<td>Indicates that the next DO loop will iterate ( n_1, n_2 ), or some other number of times.</td>
</tr>
<tr>
<td>MAX, MIN, and AVG</td>
<td>Indicates that the next DO loop has the specified maximum, minimum, and average number ( (n_1) ) of iterations.</td>
</tr>
</tbody>
</table>

## Example

Consider the following:

```fortran
!DIR$ LOOP COUNT (10000)
do i =1,m
  b(i) = a(i) +1 ! This is likely to enable the loop to get software-pipelined
enddo
```

Note that you can specify more than one LOOP COUNT directive for a DO loop. For example, the following directives are valid:

```fortran
!DIR$ LOOP COUNT (10, 20, 30)
!DIR$ LOOP COUNT MAX=100, MIN=3, AVG=17
DO
...```

## See Also

- General Compiler Directives
- Syntax Rules for Compiler Directives
- Rules for General Directives that Affect DO Loops
- Rules for Loop Directives that Affect Array Assignment Statements

### LSHIFT

**Elemental Intrinsic Function (Generic):** Shifts the bits in an integer left by a specified number of positions. This is the same as specifying ISHFT with a positive shift.

## See Also

- See ISHFT.

### LSTAT

**Portability Function:** Returns detailed information about a file.

## Module

USE IFPORT

## Syntax

```fortran
result = LSTAT (name, statb)
```

- **name** (Input) Character*(*). Name of the file to examine.
- **statb** (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See STAT for the possible values returned in **statb**.
Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see IERRNO).

LSTAT returns detailed information about the file named in name.

On Linux* and OS X* systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function.

INQUIRE also provides information about file properties.

Example

USE IFPORT
INTEGER(4) info_array(12), istatus
character*20 file_name
print *, "Enter name of file to examine: ",file_name
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
  print *, info_array
else
  print *, 'Error ',istatus
end if

See Also

INQUIRE
GETFILEINFOQQ
STAT
FSTAT

LTIME

*Portability Subroutine:* Returns the components of the local time zone time in a nine-element array.

Module

USE IFPORT

Syntax

CALL LTIME (time, array)

(time) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

(array) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from time.

The elements of array are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>array(1)</td>
<td>Seconds (0 - 59)</td>
</tr>
<tr>
<td>array(2)</td>
<td>Minutes (0 - 59)</td>
</tr>
<tr>
<td>array(3)</td>
<td>Hours (0 - 23)</td>
</tr>
</tbody>
</table>
### Element | Value
--- | ---
array(4) | Day of month (1 - 31)
array(5) | Month (0 - 11)
array(6) | Years since 1900
array(7) | Day of week (0 - 6, where 0 is Sunday)
array(8) | Day of year (1 - 365)
array(9) | 1 if daylight saving time is in effect; otherwise, 0.

---

**CAUTION**

This subroutine is not year-2000 compliant, use DATE_AND_TIME instead.

---

### Example

```fortran
USE IFPORT
INTEGER(4) input_time, time_array(9)
! find number of seconds since 1/1/70
input_time=TIME()
! convert number of seconds to time array
CALL LTIME (input_time, time_array)
PRINT *, time_array
```

### See Also

DATE_AND_TIME

---

### M to N

---

### MAKEDIRQQ

**Portability Function:** Creates a new directory with a specified name.

#### Module

USE IFPORT

#### Syntax

```fortran
result = MAKEDIRQQ (dirname)
```

*dirname* (Input) Character*(*) - Name of directory to be created.

#### Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or backslash (\) as valid delimiters.
If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:

- **ERR$ACCES** - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- **ERR$EXIST** - The directory already exists.
- **ERR$NOENT** - The file or path specified was not found.

**Example**

```fortran
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ('mynewdir')
IF (result) THEN
   WRITE (*,*) 'New subdirectory successfully created'
ELSE
   WRITE (*,*) 'Failed to create subdirectory'
END IF
END
```

**See Also**

GETLASTERRORQQ

**MALLOC**

*Elemental Intrinsic Function (Generic):* Allocates a block of memory. This is a generic function that has no specific function associated with it. It must not be passed as an actual argument.

**Syntax**

```
result = MALLOC (size)
```

`size` *(Input)* Must be of type integer. This value is the size (in bytes) of memory to be allocated.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the starting address of the allocated memory. The memory allocated can be freed by using the FREE intrinsic function.

**Example**

```fortran
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
```

**MAP Clause**

*Clause for TARGET Directives: Maps a variable from the data environment of the current task to the data environment of the device associated with the construct. For each original list item in this clause, a
new corresponding list item is created on the device.
This clause only applies to the TARGET directives,
which are only available on Intel® MIC Architecture.

Syntax

MAP ([map-type:] list)

determines how a list item is initialized. Possible values are:

map-type

ALLOC

On entry to the device region, each new corresponding list item has an undefined initial value.

FROM

On exit from the device region, the value of the corresponding list item is assigned to each original list item.

TO

On entry to the device region, each new corresponding list item is initialized with the value of the original list item.

TOFROM

On entry to the device region, each new corresponding list item is initialized with the value of the original list item. On exit from the device region, the value of the corresponding list item is assigned to each original list item.

If a map-type is not specified, the default is TOFROM.

The map initialization and assignment are done as if by intrinsic assignment, that is, through bitwise copy.

list

is the name of one or more variables, array sections, or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /).

If a list item is an array section, it must specify contiguous storage.

A list item can appear in at most one of the TO, FROM, or TOFROM clauses.

If a list item appears in an ALLOC clause, it cannot appear on a TO or TOFROM clause.

At least one MAP clause must appear in a directive that allows the clause.

THREADPRIVATE variables cannot appear in a MAP clause.

For the TARGET ENTER DATA directive, map-type must be either TO or ALLOC.

For the TARGET EXIT DATA directive, map-type must be FROM.

If original and corresponding list items share storage, data races can result when intervening synchronization between tasks does not occur. If variables that share storage are mapped, it causes unspecified behavior.

When a corresponding list item of the original list item is in the data environment of the device associated with the construct:

- The new device data environment uses the corresponding list item from the enclosing device data environment.
- No additional storage is allocated in the new device data environment.
- Initialization and assignment are not performed, regardless of the map-type that is specified.

When a corresponding list item is not in the data environment of the device associated with the construct:
A new list item is derived from the original list item; it becomes the corresponding list item in the new device data environment.

Storage with automatic duration is allocated for the new list item. It has the same type, type parameter, and rank as the original list item. The storage and lifetime of the new list item lasts until the block in which it is created exits. The size and alignment of the new list item are determined by the type of the variable.

Initialization and assignment are performed if specified by the map-type.

Any variables within a TARGET MAP region that are not specified in a MAP clause are treated as shared variables within the region.

MAP and END MAP

**Statement:** Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration.

**Example**

```
UNION
  MAP
    CHARACTER*20 string
  END MAP
  MAP
    INTEGER*2 number(10)
  END MAP
END UNION

UNION
  MAP
    RECORD /Cartesian/ xcoord, ycoord
  END MAP
  MAP
    RECORD /Polar/ length, angle
  END MAP
END UNION
```

**See Also**

See STRUCTURE.

**MASKL**

*Elemental Intrinsic Function (Generic):* Returns a left-justified mask.

**Syntax**

```
result = MASKL (i[,kind])
```

*i*  
(Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits *s* of the model integer defined for bit manipulation contexts.

*kind*  
(Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its leftmost I bits set to 1 and the remaining bits set to 0.
The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKL (3) has the value SHIFTL (7, BIT_SIZE (0) - 3).

**See Also**

MASKR

**MASKR**

*Elemental Intrinsic Function (Generic):* Returns a right-justified mask.

**Syntax**

\[
\text{result} = \text{MASKR} \left( i, \text{kind} \right)
\]

- \(i\) (Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits \(s\) of the model integer defined for bit manipulation contexts.

- \(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its rightmost \(I\) bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKR (3) has the value 7.

**See Also**

MASKL

**MASTER**

*OpenMP* Fortran Compiler Directive: Specifies a block of code to be executed by the master thread of the team.

**Syntax**

\[
\text{
!$OMP MASTER
block
!$OMP END MASTER}
\]

- \(\text{block}\) Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for a MAS construct is the current team. A master region binds to the innermost enclosing parallel region.

When the MASTER directive is specified, the other threads in the team skip the enclosed block (section) of code and continue execution. There is no implied barrier, either on entry to or exit from the master section.
Example
The following example forces the master thread to execute the routines OUTPUT and INPUT:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
  CALL WORK(X)
!$OMP MASTER
  CALL OUTPUT(X)
  CALL INPUT(Y)
!$OMP END MASTER
  CALL WORK(Y)
!$OMP END PARALLEL
```

See Also
OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

MATMUL

**Transformational Intrinsic Function (Generic):**
Performs matrix multiplication of numeric or logical matrices.

**Syntax**

```fortran
result = MATMUL (matrix_a, matrix_b)
```

- `matrix_a` (Input) Must be an array of rank one or two. It must be of numeric (integer, real, or complex) or logical type.
- `matrix_b` (Input) Must be an array of rank one or two. It must be of numeric type if `matrix_a` is of numeric type or logical type if `matrix_a` is logical type.
  
  At least one argument must be of rank two. The size of the first (or only) dimension of `matrix_b` must equal the size of the last (or only) dimension of `matrix_a`.

**Results**
The result is an array whose type depends on the data type of the arguments, according to the rules described in Data Type of Numeric Expressions. The rank and shape of the result depends on the rank and shapes of the arguments, as follows:

- If `matrix_a` has shape (n, m) and `matrix_b` has shape (m, k), the result is a rank-two array with shape (n, k).
- If `matrix_a` has shape (m) and `matrix_b` has shape (m, k), the result is a rank-one array with shape (k).
- If `matrix_a` has shape (n, m) and `matrix_b` has shape (m), the result is a rank-one array with shape (n).

If the arguments are of numeric type, element (i, j) of the result has the value \( \text{SUM}((\text{row } i \text{ of } matrix_a) \times (\text{column } j \text{ of } matrix_b)) \). If the arguments are of logical type, element (i, j) of the result has the value \( \text{ANY}((\text{row } i \text{ of } matrix_a) \text{ .AND. } (\text{column } j \text{ of } matrix_b)) \).

**Example**
A is matrix

```
[ 2  3  4 ]
[ 3  4  5 ],
```
**B is matrix**

\[
\begin{bmatrix}
2 & 3 \\
3 & 4 \\
4 & 5
\end{bmatrix},
\]

**X is vector (1, 2), and Y is vector (1, 2, 3).**

The result of **MATMUL (A, B)** is the matrix-matrix product AB with the value

\[
\begin{bmatrix}
29 & 38 \\
38 & 50
\end{bmatrix}.
\]

The result of **MATMUL (X, A)** is the vector-matrix product XA with the value (8, 11, 14).

The result of **MATMUL (A, Y)** is the matrix-vector product AY with the value (20, 26).

The following shows another example:

```fortran
INTEGER a(2,3), b(3,2), c(2), d(3), e(2,2), f(3), g(2)
a = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
!  a is
!   1 3 5
!    2 4 6
b = RESHAPE((/1, 2, 3, 4, 5, 6/), (/3, 2/))
!  b is
!   1 4
!    2 5
!    3 6
c = (/1, 2/) ! c is [1 2]
d = (/1, 2, 3/) ! d is [1 2 3]
e = MATMUL(a, b) ! returns 22 49
    !          28 64
f = MATMUL(c,a) ! returns [5 11 17]
g = MATMUL(a,d) ! returns [22 28]
WRITE(*,*) e, f, g
END
```

**See Also**

TRANSPOSE  
PRODUCT

**MAX**

*Elemental Intrinsic Function (Generic):* Returns the maximum value of the arguments.

**Syntax**

result = MAX (a1, a2[, a3]...)

\*a1, a2, a3\*  
(Input) All must have the same type (integer, real, or character) and kind parameters.

**Results**

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MAX0, AMAX1, DMAX1, QMAX1, IMAX0, JMAX0, and KMAX0, the result type is the same as the arguments. For MAX1, IMAX1, JMAX1, and KMAX1, the result type is integer. For AMAX0, AIMAX0, AJMAX0, and AKMAX0, the result type is real. The value of the result is that of the largest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

</tbody>
</table>

1. These specific functions cannot be passed as actual arguments.
2. Or JMAX0.
3. Or AJMAX0.AMAX0 is the same as REAL (MAX).
4. In Standard Fortran, AMAX0 and MAX1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.
5. Or JMAX1. MAX1 is the same as INT(MAX).
6. The setting of compiler options specifying integer size can affect MAX1.
7. The setting of compiler options specifying real size can affect AMAX1.

**Example**

MAX (2.0, -8.0, 6.0) has the value 6.0.

MAX (14, 32, -50) has the value 32.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MAX(5, 6, 7)    ! returns 7
m2 = MAX1(5.7, 3.2, -8.3) ! returns 5
r1 = AMAX0(5, 6, 7)  ! returns 7.0
r2 = AMAX1(6.4, -12.2, 4.9) ! returns 6.4
```

**See Also**

MAXLOC
MAXVAL
MIN
MAXEXPONENT
Inquiry Intrinsic Function (Generic): Returns the maximum exponent in the model representing the same type and kind parameters as the argument.

Syntax
result = MAXEXPONENT (x)

x (Input) Must be of type real; it can be scalar or array valued.

Results
The result is a scalar of type default integer. The result has the value $e_{\text{max}}$, as defined in Model for Real Data.

Example
REAL(4) x
INTEGER i
i = MAXEXPONENT(x) ! returns 128.

See Also
MINEXPONENT

MAXLOC
Transformational Intrinsic Function (Generic): Returns the location of the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax
result = MAXLOC (array [, dim] [, mask] [, kind])

array (Input) Must be an array of type integer, real, or character.

dim (Input; optional) Must be a scalar integer with a value in the range 1 to $n$, where $n$ is the rank of array.

mask (Input; optional) Must be a logical array that is conformable with array.

kind (Input; optional) Must be a scalar integer initialization expression.

Results
The result is an array of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if dim is omitted:

- The array result has rank one and a size equal to the rank of array.
- If MAXLOC(array) is specified, the elements in the array result form the subscript of the location of the element with the maximum value in array.
  The $i$th subscript returned lies in the range 1 to $e_i$, where $e_i$ is the extent of the $i$th dimension of array.
- If MAXLOC(array, MASK= mask) is specified, the elements in the array result form the subscript of the location of the element with the maximum value corresponding to the condition specified by mask.

The following rules apply if dim is specified:
• The array result has a rank that is one less than \( array \), and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \( array \).

• If \( array \) has rank one, \( \text{MAXLOC}( array, \ dim \ [, \ mask]) \) is a scalar and has a value equal to the first element of \( \text{MAXLOC}( array [, \ M\text{ASK} = mask]) \). Otherwise, the value of element \((s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of \( \text{MAXLOC}( array, \ dim \ [, \ mask]) \) is equal to \( \text{MAXLOC}( array(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n) [, \ M\text{ASK} = mask(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)] \).

If more than one element has maximum value, the element whose subscripts are returned is the first such element, taken in array element order. If \( array \) has size zero, or every element of \( mask \) has the value .FALSE., the value of the result is controlled by compiler option assume [no]old_maxminloc, which can set the value of the result to either 1 or 0.

If \( array \) is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

Example

The value of \( \text{MAXLOC}((/3, 7, 4, 7/)) \) is (2), which is the subscript of the location of the first occurrence of the maximum value in the rank-one array.

A is the array

\[
\begin{bmatrix}
  4 & 0 & -3 & 2 \\
  3 & 1 & -2 & 6 \\
 -1 & -4 & 5 & -5
\end{bmatrix}
\]

\( \text{MAXLOC}(A, \text{MASK}=A \ .LT. 5) \) has the value (1, 1) because these are the subscripts of the location of the maximum value (4) that is less than 5.

\( \text{MAXLOC}(A, \text{DIM}=1) \) has the value (1, 2, 3, 2). 1 is the subscript of the location of the maximum value (4) in column 1; 2 is the subscript of the location of the maximum value (1) in column 2; and so forth.

\( \text{MAXLOC}(A, \text{DIM}=2) \) has the value (1, 4, 3). 1 is the subscript of the location of the maximum value in row 1; 4 is the subscript of the location of the maximum value in row 2; and so forth.

The following shows another example:

```fortran
INTEGER i, max1(1), max
INTEGER array(3, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/7, 9, -1, -2, 5, 0, 3, 6, 9/), (/3, 3/))
! array is
!             7 -2 3
! 9 5 6
! -1 0 9
i = SIZE(SHAPE(array))   ! Get number of dimensions
! in array
ALLOCATE ( AR1(i))       ! Allocate AR1 to number
! of dimensions in array
AR1 = MAXLOC (array, MASK = array .LT. 7) ! Get
! the location (subscripts) of
! largest element less than 7
! in array
!
! MASK = array .LT. 7 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is less than 7,
! and .FALSE. if it is not. This mask causes MAXLOC to
! return the index of the element in array with the
! greatest value less than 7.
!
! array is
! 7 -2 3 and MASK=array .LT. 7 is
! 1 0 1
! 9 5 6
! 1 0 0
```
! and AR1 = MAXLOC(array, MASK = array .LT. 7) returns
! (2, 3), the location of the element with value 6
maxl = MAXLOC((/1, 4, 3, 4/))  ! returns 2, the first
! occurrence of maximum
END

MAXVAL
MINLOC
MINVAL

MAXVAL

Transformational Intrinsic Function (Generic):
Returns the maximum value of all elements in an
array, a set of elements in an array, or elements in a
specified dimension of an array.

Syntax
result = MAXVAL (array[,dim] [,mask])

array       (Input) Must be an array of type integer, real, or character.
dim       (Input; optional) Must be a scalar integer expression with a value in the
          range 1 to n, where n is the rank of array.
mask       (Input; optional) Must be a logical array that is conformable with array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is omitted or array has rank one.
The following rules apply if dim is omitted:
• If MAXVAL( array ) is specified, the result has a value equal to the maximum value of all the elements in array.
• If MAXVAL( array, MASK = mask ) is specified, the result has a value equal to the maximum value of the elements in array corresponding to the condition specified by mask.
The following rules apply if dim is specified:
• An array result has a rank that is one less than array, and shape (d1, d2, ..., d_{dim-1}, d_{dim+1}, ..., dn), where (d1, d2, ..., dn) is the shape of array.
• If array has rank one, MAXVAL( array, dim[ ,mask] ) has a value equal to that of MAXVAL( array[,MASK = mask] ). Otherwise, the value of element (s1, s2, ..., s_{dim-1}, s_{dim+1}, ..., sn) of MAXVAL( array, dim[,mask] ) is equal to MAXVAL( array(s1, s2, ..., s_{dim-1}, :, s_{dim+1}, ..., sn) [,MASK = mask(s1, s2, ..., s_{dim-1}, :, s_{dim+1}, ..., sn)]).
If array has size zero or if there are no true elements in mask, the result (if dim is omitted), or each element in the result array (if dim is specified), has the value of the negative number of the largest magnitude supported by the processor for numbers of the type and kind parameters of array.
If array is of type character, the comparison is done using the ASCII collating sequence.

Example
The value of MAXVAL ((/2, 3, 4/)) is 4 because that is the maximum value in the rank-one array.
MAXVAL (B, MASK=B .LT. 0.0) finds the maximum value of the negative elements of B.
C is the array

\[
\begin{bmatrix}
2 & 3 & 4 \\
5 & 6 & 7 \\
\end{bmatrix}
\]

MAXVAL (C, DIM=1) has the value (5, 6, 7). 5 is the maximum value in column 1; 6 is the maximum value in column 2; and so forth.

MAXVAL (C, DIM=2) has the value (4, 7). 4 is the maximum value in row 1 and 7 is the maximum value in row 2.

The following shows another example:

```
INTEGER array(2,3), i(2), max
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/),(/2, 3/))
! array is   1 5 3
!            4 2 6
i = SHAPE(array)      ! i = [2 3]
ALLOCATE (AR1(i(2)))  ! dimension AR1 to the number of
! elements in dimension 2
! (a column) of array
ALLOCATE (AR2(i(1)))  ! dimension AR2 to the number of
! elements in dimension 1
! (a row) of array
max = MAXVAL(array, MASK = array .LT. 4) ! returns 3
AR1 = MAXVAL(array, DIM = 1)  ! returns [ 4 5 6 ]
AR2 = MAXVAL(array, DIM = 2)  ! returns [ 5 6 ]
END
```

MAXLOC
MINVAL
MINLOC

MBCharLen (W*S)

**NLS Function:** Returns the length, in bytes, of the first character in a multibyte-character string.

**Module**
USE IFNLS

**Syntax**

```
result = MBCharLen (string)
```

**string** (Input) Character*(*) String containing the character whose length is to be determined. Can contain multibyte characters.

**Results**

The result type is INTEGER(4). The result is the number of bytes in the first character contained in string. The function returns 0 if string has no characters (is length 0).

MBCharLen does not test for multibyte character validity.

See Also
MBCurMax (W*S)
MBLead (W*S)
MBLen (W*S)
MBLen_Trim (W*S)
MBConvertMBToUnicode (W*S)

*NLS Function: Converts a multibyte-character string from the current codepage to a Unicode string.*

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBConvertMBToUnicode (mbstr, unicodestr[, flags])
```

*mbstr* (Input) Character*(*) - Multibyte codepage string to be converted.

*unicodestr* (Output) INTEGER(2) - Array of integers that is the translation of the input string into Unicode.

*flags* (Input; optional) INTEGER(4) - If specified, modifies the string conversion. If *flags* is omitted, the value NLS$Precomposed is used. Available values (defined in IFNLS.F90) are:

- NLS$Precomposed - Use precomposed characters always. (default)
- NLS$Composite - Use composite wide characters always.
- NLS$UseGlyphChars - Use glyph characters instead of control characters.
- NLS$ErrorOnInvalidChars - Returns -1 if an invalid input character is encountered.

The flags NLS$Precomposed and NLS$Composite are mutually exclusive. You can combine NLS$UseGlyphChars with either NLS$Precomposed or NLS$Composite using an inclusive OR (IOR or OR).

**Results**

The result type is INTEGER(4). If no error occurs, the result is the number of bytes written to *unicodestr* (bytes are counted, not characters), or the number of bytes required to hold the output string if *unicodestr* has zero size. If the *unicodestr* array is bigger than needed to hold the translation, the extra elements are set to space characters. If *unicodestr* has zero size, the function returns the number of bytes required to hold the translation and nothing is written to *unicodestr*.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficientBuffer - The *unicodestr* argument is too small, but not zero size so that the needed number of bytes would be returned.
- NLS$ErrorInvalidFlags - The *flags* argument has an illegal value.
- NLS$ErrorInvalidCharacter - A character with no Unicode translation was encountered in *mbstr*. This error can occur only if the NLS$InvalidCharsError flag was used in *flags*.

**NOTE**

By default, or if *flags* is set to NLS$Precomposed, the function MBConvertMBToUnicode attempts to translate the multibyte codepage string to a precomposed Unicode string. If a precomposed form does not exist, the function attempts to translate the codepage string to a composite form.

**See Also**

MBConvertUnicodeToMB (W*S)
**MBConvertUnicodeToMB (W*S)**

**NLS Function:** Converts a Unicode string to a multibyte-character string from the current codepage.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBConvertUnicodeToMB (unicondestr, mbstr[,flags])
```

- **unicodestr**
  - (Input) INTEGER(2). Array of integers holding the Unicode string to be translated.

- **mbstr**
  - (Output) Character*(*). Translation of Unicode string into multibyte character string from the current codepage.

- **flags**
  - (Input; optional) INTEGER(4). If specified, argument to modify the string conversion. If `flags` is omitted, no extra checking of the conversion takes place. Available values (defined in `IFNLS.F90`) are:
    - NLS$CompositeCheck - Convert composite characters to precomposed.
    - NLS$SepChars - Generate separate characters.
    - NLS$DiscardDns - Discard nonspacing characters.
    - NLS$DefaultChars - Replace exceptions with default character.

The last three flags (NLS$SepChars, NLS$DiscardDns, and NLS$DefaultChars) are mutually exclusive and can be used only if NLS$CompositeCheck is set, in which case one (and only one) of them is combined with NLS$CompositeCheck using an inclusive OR (IOR or OR). These flags determine what translation to make when there is no precomposed mapping for a base character/nonspace character combination in the Unicode wide character string. The default (IOR(NLS$CompositeCheck, NLS$SepChars)) is to generate separate characters.

**Results**

The result type is INTEGER(4). If no error occurs, returns the number of bytes written to `mbstr` (bytes are counted, not characters), or the number of bytes required to hold the output string if `mbstr` has zero length. If `mbstr` is longer than the translation, it is blank-padded. If `mbstr` is zero length, the function returns the number of bytes required to hold the translation and nothing is written to `mbstr`.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficientBuffer - The `mbstr` argument is too small, but not zero length so that the needed number of bytes is returned.
- NLS$ErrorInvalidFlags - The `flags` argument has an illegal value.

**See Also**

MBConvertMBToUnicode (W*S)

**MBCurMax (W*S)**

**NLS Function:** Returns the longest possible multibyte character length, in bytes, for the current codepage.

**Module**

USE IFNLS
**Syntax**

result = MBCurMax( )

**Results**

The result type is INTEGER(4). The result is the longest possible multibyte character, in bytes, for the current codepage.

The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**See Also**

MBCharLen (W*S)

**MBINCHARQQ (W*S)**

*NLS Function:* Performs the same function as INCHARQQ except that it can read a single multibyte character at once, and it returns the number of bytes read as well as the character.

**Module**

USE IFNLS

**Syntax**

result = MBINCHARQQ (string)

string (Output) CHARACTER(MBLenMax). String containing the read characters, padded with blanks up to the length MBLenMax. The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**Results**

The result type is INTEGER(4). The result is the number of characters read.

**See Also**

INCHARQQ (W*S)

MBCurMax (W*S)

MBCharLen (W*S)

MBLead (W*S)

**MBINDEX (W*S)**

*NLS Function:* Performs the same function as INDEX except that the strings manipulated can contain multibyte characters.

**Module**

USE IFNLS

**Syntax**

result = MBINDEX (string, substring[, back])

string (Input) CHARACTER(*). String to be searched for the presence of substring. Can contain multibyte characters.
substring (Input) CHARACTER(*). Substring whose position within string is to be determined. Can contain multibyte characters.

back (Input; optional) LOGICAL(4). If specified, determines direction of the search. If back is .FALSE. or is omitted, the search starts at the beginning of string and moves toward the end. If back is .TRUE., the search starts end of string and moves toward the beginning.

Results
The result type is INTEGER(4). If back is omitted or is .FALSE., it returns the leftmost position in string that contains the start of substring. If back is .TRUE., it returns the rightmost position in string that contains the start of substring. If string does not contain substring, it returns 0. If substring occurs more than once, it returns the starting position of the first occurrence ("first" is determined by the presence and value of back).

The position returned is a byte index, not a character index because of the confounding case of multibyte characters. As an example, if a substring which is a single multi-byte character matches the second multibyte character in a string consisting of two two-byte multi-byte characters the position is 3, not 2.

See Also
INDEX
MBSCAN (W*S)
MBVERIFY (W*S)

MBJISToJMS, MBJMSToJIS (W*S)

NLS Functions: Converts Japan Industry Standard (JIS) characters to Microsoft Kanji (JMS) characters, or converts JMS characters to JIS characters.

Module
USE IFNLS

Syntax
result = MBJISToJMS (char)
result = MBJMSToJIS (char)

char (Input) CHARACTER(2). JIS or JMS character to be converted.

A JIS character is converted only if the lead and trail bytes are in the hexadecimal range 21 through 7E.

A JMS character is converted only if the lead byte is in the hexadecimal range 81 through 9F or E0 through FC, and the trail byte is in the hexadecimal range 40 through 7E or 80 through FC.

Results
The result type is character with length 2. MBJISToJMS returns a Microsoft Kanji (Shift JIS or JMS) character. MBJMSToJIS returns a Japan Industry Standard (JIS) character.

Only computers with Japanese installed as one of the available languages can use the MBJISToJMS and MBJMSToJIS conversion functions.

NLSEnumCodepages (W*S)
NLSGlobalLocale (W*S)
**MBLead (W*S)**

**NLS Function:** Determines whether a given character is the lead (first) byte of a multibyte character sequence.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBLead (char)
```

char       (Input) CHARACTER(1). Character to be tested for lead status.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if `char` is the first character of a multibyte character sequence; otherwise, .FALSE.. MBLead only works stepping forward through a whole multibyte character string. For example:

```fortran
DO i = 1, LEN(str) ! LEN returns the number of bytes, not the number of characters in str
    WRITE(*, 100) MBLead (str(i:i))
END DO
100   FORMAT (L2, 
```

MBLead is passed only one character at a time and must start on a lead byte and step through a string to establish context for the character. MBLead does not correctly identify a nonlead byte if it is passed only the second byte of a multibyte character because the status of lead byte or trail byte depends on context.

The function MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context. So, MBStrLead can be much slower than MBLead (up to \( n \) times slower, where \( n \) is the length of the string).

**See Also**

MBStrLead (W*S)
MBCharLen (W*S)

**MBLen (W*S)**

**NLS Function:** Returns the number of characters in a multibyte-character string, including trailing blanks.

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBLen (string)
```

string       (Input) CHARACTER*(*)). String whose characters are to be counted. Can contain multibyte characters.

**Results**

The result type is INTEGER(4). The result is the number of characters in `string`. MBLen recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.
See Also
MBLen_Trim (W*S)
MBStrLead (W*S)

MBLen_Trim (W*S)

**NLS Function:** Returns the number of characters in a multibyte-character string, not including trailing blanks.

Module
USE IFNLS

Syntax
result = MBLen_Trim (string)

string        (Input) Character*(*). String whose characters are to be counted. Can contain multibyte characters.

Results
The result type is INTEGER(4). The result is the number of characters in string minus any trailing blanks (blanks are bytes containing character 32 (hex 20) in the ASCII collating sequence).

MBLen_Trim recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

See Also
MBLen (W*S)
MBStrLead (W*S)

MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE (W*S)

**NLS Functions:** Perform the same functions as LGE, LGT, LLE, LLT and the logical operators .EQ. and .NE. except that the strings being compared can include multibyte characters, and optional flags can modify the comparison.

Module
USE IFNLS

Syntax
result = MBLGE (string_a,string_b, [ flags])
result = MBLGT (string_a,string_b, [ flags])
result = MBLLE (string_a,string_b, [ flags])
result = MBLLT (string_a,string_b, [ flags])
result = MBLEQ (string_a,string_b, [ flags])
result = MBLNE (string_a,string_b, [ flags])

string_a, string_b        (Input) Character*(*). Strings to be compared. Can contain multibyte characters.
flags

(Input; optional) INTEGER(4). If specified, determines which character traits to use or ignore when comparing strings. You can combine several flags using an inclusive OR (IOR or OR). There are no illegal combinations of flags, and the functions may be used without flags, in which case all flag options are turned off. The available values (defined in IFNLS.F90) are:

- NLS$MB_IgnoreCase - Ignore case.
- NLS$MB_IgnoreNonspace - Ignore nonspacing characters (this flag removes Japanese accent characters if they exist).
- NLS$MB_IgnoreSymbols - Ignore symbols.
- NLS$MB_IgnoreKanaType - Do not differentiate between Japanese Hiragana and Katakana characters (corresponding Hiragana and Katakana characters will compare as equal).
- NLS$MB_IgnoreWidth - Do not differentiate between a single-byte character and the same character as a double byte.
- NLS$MB_StringSort - Sort all symbols at the beginning, including the apostrophe and hyphen (see the Note below).

Results

The result type is LOGICAL(4). Comparisons are made using the current locale, not the current codepage. The codepage used is the default for the language/country combination of the current locale.

The results of these functions are as follows:

- MBLGE returns .TRUE. if the strings are equal or string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLGT returns .TRUE. if string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLLE returns .TRUE. if the strings are equal or string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLLT returns .TRUE. if string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLEQ returns .TRUE. if the strings are equal in the collating sequence; otherwise, .FALSE..
- MBLNE returns .TRUE. if the strings are not equal in the collating sequence; otherwise, .FALSE..

If the two strings are of different lengths, they are compared up to the length of the shortest one. If they are equal to that point, then the return value indicates that the longer string is greater.

If flags is invalid, the functions return .FALSE..

If the strings supplied contain Arabic Kashidas, the Kashidas are ignored during the comparison. Therefore, if the two strings are identical except for Kashidas within the strings, the functions return a value indicating they are "equal" in the collation sense, though not necessarily identical.

NOTE

When not using the NLS$MB_StringSort flag, the hyphen and apostrophe are special symbols and are treated differently than others. This is to ensure that words like coop and co-op stay together within a list. All symbols, except the hyphen and apostrophe, sort before any other alphanumeric character. If you specify the NLS$MB_StringSort flag, hyphen and apostrophe sort at the beginning also.

**MBNext (W*S)**

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately following the given position in a multibyte-character string.

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBNext} \left( \text{string}, \text{position} \right)
\]

- `string` *(Input) Character*(*). String to be searched for the first lead byte or single-byte character after the current position. Can contain multibyte characters.
- `position` *(Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of a trail (second) byte of a multibyte character.*

**Results**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in `string` immediately following the position given in `position`, or 0 if no following first byte is found in `string`.

**See Also**

MBPrev (W*S)

**MBPrev (W*S)**

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately preceding the given string position in a multibyte-character string.

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBPrev} \left( \text{string}, \text{position} \right)
\]

- `string` *(Input) Character*(*). String to be searched for the first lead byte or single-byte character before the current position. Can contain multibyte characters.
- `position` *(Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of the trail (second) byte of a multibyte character.*

**Results**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in `string` immediately preceding the position given in `position`, or 0 if no preceding first byte is found in `string`.

**See Also**

MBNext (W*S)
MBSCAN (W*S)

NLS Function: Performs the same function as SCAN except that the strings manipulated can contain multibyte characters.

Module
USE IFNLS

Syntax
result = MBSCAN (string, set[, back])

string (Input) Character*(*). String to be searched for the presence of any character in set.

set (Input) Character*(*). Characters to search for.

back (Input; optional) LOGICAL(4). If specified, determines direction of the search. If back is .FALSE. or is omitted, the search starts at the beginning of string and moves toward the end. If back is .TRUE., the search starts end of string and moves toward the beginning.

Results
The result type is INTEGER(4). If back is .FALSE. or is omitted, it returns the position of the leftmost character in string that is in set. If back is .TRUE., it returns the rightmost character in string that is in set. If no characters in string are in set, it returns 0.

See Also
SCAN
MBINDEX (W*S)
MBVERIFY (W*S)

MBStrLead (W*S)

NLS Function: Performs a context-sensitive test to determine whether a given character byte in a string is a multibyte-character lead byte.

Module
USE IFNLS

Syntax
result = MBStrLead (string, position)

string (Input) Character*(*). String containing the character byte to be tested for lead status.

position (Input) INTEGER(4). Position in string of the character byte in the string to be tested.

Results
The result type is LOGICAL(4). The result is .TRUE. if the character byte in position of string is a lead byte; otherwise,.FALSE.
MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context.

MBLead is passed only one character at a time and must start on a lead byte and step through a string one character at a time to establish context for the character. So, MBStrLead can be much slower than MBLead (up to \( n \) times slower, where \( n \) is the length of the string).

See Also
MBLead (W*S)

**MBVERIFY (W*S)**

**NLS Function:** Performs the same function as VERIFY except that the strings manipulated can contain multibyte characters.

Module
USE IFNLS

Syntax

\[
\text{result} = \text{MBVERIFY}(\text{string}, \text{set}[\text{, }\text{back}])
\]

\text{string} \quad \text{(Input) Character*(*). String to be searched for presence of any character not in set.}

\text{set} \quad \text{(Input) Character*(*). Set of characters tested to verify that it includes all the characters in string.}

\text{back} \quad \text{(Input; optional) LOGICAL(4). If specified, determines direction of the search. If back is .FALSE. or is omitted, the search starts at the beginning of string and moves toward the end. If back is .TRUE., the search starts end of string and moves toward the beginning.}

Results

The result type is INTEGER(4). If \( \text{back} \) is .FALSE. or is omitted, it returns the position of the leftmost character in \text{string} that is not in \text{set}. If \( \text{back} \) is .TRUE., it returns the rightmost character in \text{string} that is not in \text{set}. If all the characters in \text{string} are in \text{set}, it returns 0.

See Also
VERIFY
MBINDEX (W*S)
MBSCAN (W*S)

**MCLOCK**

**Inquiry Intrinsic Function (Specific):** Returns time accounting for a program.

Syntax

\[
\text{result} = \text{MCLOCK}(\ )
\]

Results

The result type is INTEGER(4). The result is the sum (in units of milliseconds) of the current process's user time and the user and system time of all its child processes.
**MERGE**

*Elemental Intrinsic Function (Generic):* Selects between two values or between corresponding elements in two arrays, according to the condition specified by a logical mask.

**Syntax**

\[
\text{result} = \text{MERGE}(\text{tsource}, \text{fsource}, \text{mask})
\]

- **tsource** (Input) May be of any data type.
- **fsource** (Input) Must be of the same type and type parameters as tsource.
- **mask** (Input) Must be of type logical.

**Results**

The result type and kind is the same as tsource. The value of mask determines whether the result value is taken from tsource (if mask is true) or fsource (if mask is false).

**Example**

For MERGE (1.0, 0.0, R < 0), R = -3 has the value 1.0, and R = 7 has the value 0.0.

TSOURCE is the array

\[
\begin{bmatrix}
1 & 3 & 5 \\
2 & 4 & 6
\end{bmatrix}
\]

FSOURCE is the array

\[
\begin{bmatrix}
8 & 9 & 0 \\
1 & 2 & 3
\end{bmatrix}
\]

and MASK is the array

\[
\begin{bmatrix}
\text{F} & \text{T} & \text{T} \\
\text{T} & \text{T} & \text{F}
\end{bmatrix}
\]

MERGE (TSOURCE, FSOURCE, MASK) produces the result:

\[
\begin{bmatrix}
8 & 3 & 5 \\
2 & 4 & 3
\end{bmatrix}
\]

The following shows another example:

```
INTEGER tsource(2, 3), fsource(2, 3), AR1 (2, 3)
LOGICAL mask(2, 3)
tsource = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2, 3/))
fsource = RESHAPE((/7, 0, 8, -1, 9, -2/), (/2, 3/))
mask = RESHAPE((/.TRUE., .FALSE., .FALSE., .TRUE., .TRUE., .FALSE./), (/2,3/))
! tsource is  1 2 3 , fsource is  7  8  9 , mask is  T F T
!             4 5 6               0 -1 -2            F T F
AR1 = MERGE(tsource, fsource, mask) ! returns 1 8 3
!          0 5 -2
END
```

**MERGE_BITS**

*Elemental Intrinsic Function (Generic):* Merges bits by using a mask.
Syntax
result = MERGE_BITS (i, j, mask)

\(i\)  
(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

\(j\)  
(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

\(mask\)  
(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both \(i\) and \(j\) are of type integer they must have the same kind type parameter. They cannot both be binary, octal, or hexadecimal literal constants.

If \(mask\) is of type integer, it must have the same kind type parameter as each other argument of type integer.

Results
The result type and kind are the same as \(i\) if \(i\) is of type integer; otherwise, the result type and kind is the same as \(j\).

If any argument is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to the type and kind parameter of the result. The result has the value of IOR (IAND (\(i\), \(mask\)), IAND (\(j\), NOT (\(mask\)))).

Example
MERGE_BITS (13, 18, 22) has the value 4.

MESSAGE
**General Compiler Directive:** Specifies a character string to be sent to the standard output device during the first compiler pass; this aids debugging.

Syntax
!DIR$ MESSAGE:string

string  
Is a character constant specifying a message.

Example
!DIR$ MESSAGE:'Compiling Sound Speed Equations'

See Also
General Compiler Directives
Syntax Rules for Compiler Directives

MESSAGEBOXQQ (W*S)
**QuickWin Function:** Displays a message box in a QuickWin window.

Module
USE IFQWIN

Syntax
result = MESSAGEBOXQQ (msg, caption, mtype)
msg

(INPUT) Character*(*). Null-terminated C string. Message the box displays.

caption

(INPUT) Character*(*). Null-terminated C string. Caption that appears in the title bar.

mtype

(INPUT) INTEGER(4). Symbolic constant that determines the objects (buttons and icons) and properties of the message box. You can combine several constants (defined in IFQWIN.F90) using an inclusive OR (IOR or OR). The symbolic constants and their associated objects or properties are as follows:

- MB$ABORTRETRYIGNORE - The Abort, Retry, and Ignore buttons.
- MB$DEFBUTTON1 - The first button is the default.
- MB$DEFBUTTON2 - The second button is the default.
- MB$DEFBUTTON3 - The third button is the default.
- MB$ICONASTERISK, MB$ICONINFORMATION - Lowercase i in blue circle icon.
- MB$ICONEXCLAMATION - The exclamation-mark icon.
- MB$ICONHAND, MB$ICONSTOP - The stop-sign icon.
- MB$ICONQUESTION - The question-mark icon.
- MB$OK - The OK button.
- MB$OKCANCEL - The OK and Cancel buttons.
- MB$RETRYCANCEL - The Retry and Cancel buttons.
- MB$SYSTEMMODAL - Box is system-modal: all applications are suspended until the user responds.
- MB$YESNO - The Yes and No buttons.
- MB$YESNOCANCEL - The Yes, No, and Cancel buttons.

Results

The result type is INTEGER(4). The result is zero if memory is not sufficient for displaying the message box. Otherwise, the result is one of the following values, indicating the user's response to the message box:

- MB$IDABORT - The Abort button was pressed.
- MB$IDCANCEL - The Cancel button was pressed.
- MB$IDIGNORE - The Ignore button was pressed.
- MB$IDNO - The No button was pressed.
- MB$IDOK - The OK button was pressed.
- MB$IDRETRY - The Retry button was pressed.
- MB$IDYES - The Yes button was pressed.

Example

! Build as QuickWin app
USE IFQWIN
message = MESSAGEBOXQQ('Do you want to continue?'C, &
       'Matrix'C, &
       MB$ICONQUESTION.OR.MB$YESNO.OR.MB$DEFBUTTON1)
END

See Also
ABOUTBOXQQ (W*S)
SETMESSAGEQQ (W*S)
**MIN**

**Elemental Intrinsic Function (Generic):** Returns the minimum value of the arguments.

**Syntax**

\[
\text{result} = \text{MIN} \left( a_1, a_2, \ldots \right)
\]

\[a_1, a_2, a_3\] (Input) All must have the same type (integer, real, or character) and kind parameters.

**Results**

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MIN0, AMIN1, DMIN1, QMIN1, IMIN0, JMIN0, and KMIN0, the result type is the same as the arguments. For MIN1, IMIN1, JMIN1, and KMIN1, the result type is integer. For AMIN0, AIMIN0, AJMIN0, and AKMIN0, the result type is real. The value of the result is that of the smallest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

<table>

</tbody>
</table>

\(^1\)These specific functions cannot be passed as actual arguments.

\(^2\)Or JMIN0.

\(^3\)Or AJMIN0.AMIN0 is the same as REAL (MIN).

\(^4\)In Standard Fortran, AMIN0 and MIN1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

\(^5\)Or JMIN1.MIN1 is the same as INT (MIN).

\(^6\)The setting of compiler options specifying integer size can affect MIN1.

\(^7\)The setting of compiler options specifying real size can affect AMIN1.
Example

MIN (2.0, -8.0, 6.0) has the value -8.0.
MIN (14, 32, -50) has the value -50.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MIN (5, 6, 7) ! returns 5
m2 = MIN1 (-5.7, 1.23, -3.8) ! returns -5
r1 = AMIN0 (-5, -6, -7) ! returns -7.0
r2 = AMIN1 (-5.7, 1.23, -3.8) ! returns -5.7
```

MINLOC
MINVAL
MAX

MINEXPONENT

*Inquiry Intrinsic Function (Generic):* Returns the minimum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```fortran
result = MINEXPONENT (x)
```

**x** (Input) must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. The result has the value $e_{\text{min}}$, as defined in Model for Real Data.

**Example**

If X is of type REAL(4), MINEXPONENT (X) has the value -125.

The following shows another example:

```fortran
REAL(8) r1 ! DOUBLE PRECISION REAL
INTEGER i
i = MINEXPONENT (r1) ! returns - 1021.
```

See Also

MAXEXPONENT

MINLOC

*Transformational Intrinsic Function (Generic):* Returns the location of the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

**Syntax**

```fortran
result = MINLOC (array [, dim] [, mask] [, kind])
```

**array** (Input) Must be an array of type integer, real, or character.

**dim** (Input; optional) Must be a scalar integer with a value in the range 1 to $n$, where $n$ is the rank of `array`. 
The result is an array of type integer. If \texttt{kind} is present, the kind parameter of the result is that specified by \texttt{kind}; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if \texttt{dim} is omitted:

- The array result has rank one and a size equal to the rank of \texttt{array}.
- If \texttt{MINLOC(array)} is specified, the elements in the array result form the subscript of the location of the element with the minimum value in \texttt{array}.

The \textit{i}th subscript returned lies in the range 1 to \(e_i\), where \(e_i\) is the extent of the \textit{i}th dimension of \texttt{array}.

- If \texttt{MINLOC(array, MASK= mask)} is specified, the elements in the array result form the subscript of the location of the element with the minimum value corresponding to the condition specified by \texttt{mask}.

The following rules apply if \texttt{dim} is specified:

- The array result has a rank that is one less than \texttt{array}, and shape \((d_1, d_2,\ldots d_{dim-1}, d_{dim+1},\ldots d_n)\), where \((d_1, d_2,\ldots d_n)\) is the shape of \texttt{array}.
- If \texttt{array} has rank one, \texttt{MINLOC( array, dim [, mask])} is a scalar and has a value equal to the first element of \texttt{MINLOC( array [, mask])}. Otherwise, the value of element \((s_1, s_2,\ldots s_{dim-1}, s_{dim+1},\ldots s_n)\) of \texttt{MINLOC( array, dim [, mask])} is equal to \texttt{MINLOC( array(s_1, s_2,\ldots s_{dim-1}, :, s_{dim+1},\ldots s_n) [, MASK = mask(s_1, s_2,\ldots s_{dim-1}, :, s_{dim+1},\ldots s_n)])}.

If more than one element has minimum value, the element whose subscripts are returned is the first such element, taken in array element order. If \texttt{array} has size zero, or every element of \texttt{mask} has the value .FALSE., the value of the result is controlled by compiler option assume [no]old_maxminloc, which can set the value of the result to either 1 or 0.

If \texttt{array} is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

**Example**

The value of \texttt{MINLOC ((/3, 1, 4, 1/))} is (2), which is the subscript of the location of the first occurrence of the minimum value in the rank-one array.

\begin{verbatim}
A is the array
\begin{verbatim}
[  4    0   -3    2
 [  3    1   -2    6
 [ -1   -4    5   -5
\end{verbatim}
\end{verbatim}
\texttt{MINLOC (A, MASK=A .GT. -5)} has the value (3, 2) because these are the subscripts of the location of the minimum value (-4) that is greater than -5.

\texttt{MINLOC (A, DIM=1)} has the value (3, 3, 1, 3). 3 is the subscript of the location of the minimum value (-1) in column 1; 3 is the subscript of the location of the minimum value (-4) in column 2; and so forth.

\texttt{MINLOC (A, DIM=2)} has the value (3, 3, 4). 3 is the subscript of the location of the minimum value (-3) in row 1; 3 is the subscript of the location of the minimum value (-2) in row 2; and so forth.

The following shows another example:

\begin{verbatim}
INTEGER i, minl(1)
INTEGER array(2, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/-7, 1, -2, -9, 5, 0/),(/2, 3/))
\end{verbatim}
\end{verbatim}
array is -7 -2 5
! in array
i = SIZE(SHAPE(array)) ! Get the number of dimensions in array
ALLOCATE (AR1 (i)) ! Allocate AR1 to number of dimensions in array
AR1 = MINLOC (array, MASK = array .GT. -5) ! Get the location (subscripts) of smallest element greater than -5 in array

! MASK = array .GT. -5 creates a mask array the same size and shape as array whose elements are .TRUE. if the corresponding element in array is greater than -5, and .FALSE. if it is not. This mask causes MINLOC to return the index of the element in array with the smallest value greater than -5.

! array is -7 -2 5 and MASK= array .GT. -5 is F T T
! 1 -9 0 T F T
! and AR1 = MINLOC(array, MASK = array .GT. -5) returns (1, 2), the location of the element with value -2

minl = MINLOC((-7,2,-7,5)) ! returns 1, first occurrence of minimum

END

MAXLOC
MINVAL
MAXVAL

MINVAL
Transformational Intrinsic Function (Generic):
Returns the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax
result = MINVAL (array[,dim] [,mask])

array (Input) Must be an array of type integer, real, or character.
dim (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.
mask (Input; optional) Must be a logical array that is conformable with array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is omitted or array has rank one.
The following rules apply if dim is omitted:
• If MINVAL(array) is specified, the result has a value equal to the minimum value of all the elements in array.
If `MINVAL(array, MASK=mask)` is specified, the result has a value equal to the minimum value of the elements in `array` corresponding to the condition specified by `mask`.

The following rules apply if `dim` is specified:

- An array result has a rank that is one less than `array`, and shape `(d1, d2, ..., d_dim-1, d_dim+1, ..., dn)`, where `(d1, d2, ..., dn)` is the shape of `array`.
- If `array` has rank one, `MINVAL(array, dim[, mask])` has a value equal to that of `MINVAL(array[,MASK=mask])`. Otherwise, the value of element `(s1, s2, ..., sd_dim-1, sd_dim+1, ..., sn)` of `MINVAL(array, dim[,mask])` is equal to `MINVAL(array(s1, s2, ..., sd_dim-1, :, sd_dim+1, ..., sn[,MASK=mask(s1, s2, ..., sd_dim-1, :, sd_dim+1, ..., sn)])`.

If `array` has size zero or if there are no true elements in `mask`, the result (if `dim` is omitted), or each element in the result array (if `dim` is specified), has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind parameters of `array`.

If `array` is of type character, the comparison is done using the ASCII collating sequence.

**Example**

The value of `MINVAL ((/2, 3, 4/))` is 2 because that is the minimum value in the rank-one array.

The value of `MINVAL (B, MASK=B .GT. 0.0)` finds the minimum value of the positive elements of `B`.

`C` is the array

```
  [ 2  3  4 ]
  [ 5  6  7 ].
```

`MINVAL (C, DIM=1)` has the value `(2, 3, 4)`. 2 is the minimum value in column 1; 3 is the minimum value in column 2; and so forth.

`MINVAL (C, DIM=2)` has the value `(2, 5)`. 2 is the minimum value in row 1 and 5 is the minimum value in row 2.

The following shows another example:

```fortran
INTEGER array(2, 3), i(2), minv
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
  ! array is
  !  1 5 3
  !  4 2 6
i = SHAPE(array)  ! i = [2 3]
ALLOCATE(AR1(i(2))) ! dimension AR1 to number of
  ! elements in dimension 2
  ! (a column) of array.
ALLOCATE(AR2(i(1))) ! dimension AR2 to number of
  ! elements in dimension 1
  ! (a row) of array
minv = MINVAL(array, MASK = array .GT. 4) ! returns 5
AR1 = MINVAL(array, DIM = 1)  ! returns [1 2 3]
AR2 = MINVAL(array, DIM = 2)  ! returns [1 2]
END
```

MM_PREFETCH

Intrinsic Subroutine (Generic): Prefetches data from the specified address on one memory cache line. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL MM_PREFETCH (address [, hint] [, fault] [, exclusive])

address (Input) Is the name of a scalar or array; it can be of any type or rank. It specifies the address of the data on the cache line to prefetch.

hint (Input; optional) Is an optional default integer constant with one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Prefetch Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FOR_K_PREFETCH_T0</td>
<td>Prefetches into the L1 cache (and the L2 and the L3 cache). Use this for integer data.</td>
</tr>
<tr>
<td>1</td>
<td>FOR_K_PREFETCH_T1</td>
<td>Prefetches into the L2 cache (and the L3 cache); floating-point data is used from the L2 cache, not the L1 cache. Use this for real data.</td>
</tr>
<tr>
<td>2</td>
<td>FOR_K_PREFETCH_T2</td>
<td>Prefetches into the L2 cache (and the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line frequently.</td>
</tr>
<tr>
<td>3</td>
<td>FOR_K_PREFETCH_NT</td>
<td>Prefetches into the L2 cache (but not the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line.</td>
</tr>
</tbody>
</table>

The preceding constants are defined in file fordef.for on Windows* systems and file fordef.f on Linux* and OS X* systems.

If hint is omitted, 0 is assumed.

fault (Input; optional) Is an optional default logical constant. If .TRUE. is specified, page faults are allowed to occur, if necessary; if .FALSE. is specified, page faults are not allowed to occur. If fault is omitted, .FALSE. is assumed. This argument is currently ignored.
exclusive  (Input; optional) Is an optional default logical constant. If .TRUE. is specified, you get exclusive ownership of the cache line because you intend to assign to it; if .FALSE. is specified, there is no exclusive ownership. If exclusive is omitted, .FALSE. is assumed. This argument is currently ignored.

Example

subroutine spread_lf (a, b)
PARAMETER (n = 1025)

real*8 a(n,n), b(n,n), c(n)
do j = 1,n
    do i = 1,100
        a(i, j) = b(i-1, j) + b(i+1, j)
        call mm_prefetch (a(i+20, j), 1)
        call mm_prefetch (b(i+21, j), 1)
    enddo
endo

print *, a(2, 567)
stop
end

MOD

Elemental Intrinsic Function (Generic): Returns the remainder when the first argument is divided by the second argument.

Syntax

result = MOD (a, p)

a  (Input) Must be of type integer or real.

p  (Input) Must have the same type and kind parameters as a. It must not have a value of zero.

Results

The result type and kind is the same as a. If p is not equal to zero, the value of the result is a - INT(a/p) * p. If p is equal to zero, the result is undefined.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMOD</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IMOD¹</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>MOD ²</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KMOD</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
<tr>
<td>AMOD ³</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DMOD ³,⁴</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QMOD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>
Specific Name | Argument Type | Result Type
---|---|---
1 Or HMOD.
2 Or JMOD.
3 The setting of compiler options specifying real size can affect AMOD and DMOD.
4 The setting of compiler options specifying double size can affect DMOD.

**Example**

MOD (7, 3) has the value 1.
MOD (9, -6) has the value 3.
MOD (-9, 6) has the value -3.

The following shows more examples:

<table>
<thead>
<tr>
<th>INTEGER I</th>
<th>REAL R</th>
</tr>
</thead>
<tbody>
<tr>
<td>R = MOD(9.0, 2.0) ! returns 1.0</td>
<td></td>
</tr>
<tr>
<td>I = MOD(18, 5) ! returns 3</td>
<td></td>
</tr>
<tr>
<td>I = MOD(-18, 5) ! returns -3</td>
<td></td>
</tr>
<tr>
<td>I = MOD(8, 5) ! returns 3</td>
<td></td>
</tr>
<tr>
<td>I = MOD(-8, 5) ! returns -3</td>
<td></td>
</tr>
<tr>
<td>I = MOD(8,-5) ! returns 3</td>
<td></td>
</tr>
<tr>
<td>I = MOD(-8,-5) ! returns -3</td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

MODULO

**MODIFYMENUFLAGSQQ (W*S)**

*QuickWin Function: Modifies a menu item's state.*

**Module**

USE IFQWIN

**Syntax**

result = MODIFYMENUFLAGSQQ (menuID, itemID, flag)

*menuID*  
(Input) INTEGER(4). Identifies the menu containing the item whose state is to be modified, starting with 1 as the leftmost menu.

*itemID*  
(Input) INTEGER(4). Identifies the menu item whose state is to be modified, starting with 0 as the top item.

*flags*  
(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:

- $MENUGRAYED - Disables and grays out the menu item.
- $MENUDISABLED - Disables but does not gray out the menu item.
- $MENUENABLED - Enables the menu item.
- $MENUSEPARATOR - Draws a separator bar.
- $MENUCHECKED - Puts a check by the menu item.
- $MENUUNCHECKED - Removes the check by the menu item.
Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

Example

```fortran
USE IFQWIN
LOGICAL(4)    result
CHARACTER(20) str
! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Gray out and disable the first two menu items in the
! first (FILE) menu
result = MODIFYMENUFLAGSQQ (1, 1, $MENUGRAYED)
result = MODIFYMENUFLAGSQQ (1, 2, $MENUGRAYED)
END
```

See Also
APPENDMENUQQ (W*S)
DELETEMENUQQ (W*S)
INSERTMENUQQ (W*S)
MODIFYMENUROUTINEQQ (W*S)
MODIFYMENUSTRINGQQ (W*S)

MODIFYMENUROUTINEQQ (W*S)

QuickWin Function: Changes a menu item's callback routine.

Module
USE IFQWIN

Syntax

```fortran
result = MODIFYMENUROUTINEQQ (menuIdD, itemID, routine)
```

menuID
(Input) INTEGER(4). Identifies the menu that contains the item whose callback routine is to be changed, starting with 1 as the leftmost menu.

itemID
(Input) INTEGER(4). Identifies the menu item whose callback routine is to be changed, starting with 0 as the top item.

routine
(Input) EXTERNAL. Callback subroutine called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- WINPRINT - Prints the program.
- WINSAVE - Saves the program.
- WINEXIT - Terminates the program.
- WINSELECTTEXT - Selects text from the current window.
- WINSELECTGRAPHICS - Selects graphics from the current window.
- WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZETOFIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

See Also
APPENDMENUQQ (W*S)
DELETEMENUQQ (W*S)
INSERTMENUQQ (W*S)
MODIFYMENUFLAGSQQ (W*S)
MODIFYMENUSTRINGQQ (W*S)

MODIFYMENUSTRINGQQ (W*S)
QuickWin Function: Changes a menu item's text string.

Module
USE IFQWIN

Syntax
result = MODIFYMENUSTRINGQQ (menuID, itemID, text)

menuID  (Input) INTEGER(4). Identifies the menu containing the item whose text string is to be changed, starting with 1 as the leftmost item.

itemID  (Input) INTEGER(4). Identifies the menu item whose text string is to be changed, starting with 0 as the top menu item.

text   (Input) Character*(*). Menu item name. Must be a null-terminated C string. For example, words of text ‘C.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
You can add access keys in your text strings by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, use "P&rint"C as text.

Example

```fortran
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'C
result = APPENDMENUQ (1, $MENUENABLED, str, WINSTATUS)
! Change the name of the first item in the first menu
str = '&Browse'C
result = MODIFYMENUSTRINGQ (1, 1, str)
END
```

**MODULE**

**Statement:** Marks the beginning of a module program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```
MODULE name
    [specification-part]
[CONTAINS
    [module-subprogram
        [module-subprogram]... ] ]
END[ MODULE [name]]
```

- `name` Is the name of the module.
- `specification-part` Is one or more specification statements, except for the following:
  - ENTRY
  - FORMAT
  - AUTOMATIC (or its equivalent attribute)
  - INTENT (or its equivalent attribute)
  - OPTIONAL (or its equivalent attribute)
  - Statement functions

An automatic object must not appear in a specification statement.

- `module-subprogram` Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.
A module subprogram can contain internal procedures.

**Description**

If a name follows the END statement, it must be the same as the name specified in the MODULE statement.

The module name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A module is host to any module procedures it contains, and entities in the module are accessible to the module procedures through host association.

A module must not reference itself (either directly or indirectly).

You can use the PRIVATE attribute to restrict access to procedures or variables within a module.

Although ENTRY statements, FORMAT statements, and statement functions are not allowed in the specification part of a module, they are allowed in the specification part of a module subprogram.

The following rules also apply to modules:

- The specification part of a module must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
- A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the specification part of a module includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Any executable statements in a module can only be specified in a module subprogram.

A module can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.

**Example**

The following example shows a simple module that can be used to provide global data:

```fortran
MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5)
END MODULE MOD_A

SUBROUTINE SUB_Z
  USE MOD_A               ! Makes scalar variables B and C, and array
                           !   E available to this subroutine
  ...
END SUBROUTINE SUB_Z
```

The following example shows a module procedure:

```fortran
MODULE RESULTS
  ...
CONTAINS
  FUNCTION MOD_RESULTS(X,Y)  ! A module procedure
  ...
  END FUNCTION MOD_RESULTS
END MODULE RESULTS
```

The following example shows a module containing a derived type:

```fortran
MODULE EMPLOYEE_DATA
  TYPE EMPLOYEE
    INTEGER ID
  ...
END TYPE
```

```
```
The following example shows a module containing an interface block:

```fortran
MODULE ARRAY_CALCULATOR
  INTERFACE
    FUNCTION CALC_AVERAGE(D)
      REAL :: CALC_AVERAGE
      REAL, INTENT(IN) :: D(:)
    END FUNCTION
  END INTERFACE
END MODULE ARRAY_CALCULATOR
```

The following example shows a derived-type definition that is public with components that are private:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

This design allows you to change components of a type without affecting other program units that use the module.

If a derived type is needed in more than one program unit, the definition should be placed in a module and accessed by a USE statement whenever it is needed, as follows:

```fortran
MODULE STUDENTS
  TYPE STUDENT_RECORD
    ...
  END TYPE
  CONTAINS
    SUBROUTINE COURSE_GRADE(...)
      TYPE(STUDENT_RECORD) NAME
      ...
    END SUBROUTINE
END MODULE STUDENTS
```

```fortran
PROGRAM SENIOR_CLASS
  USE STUDENTS
  TYPE(STUDENT_RECORD) ID
  ...
END PROGRAM
```

Program SENIOR_CLASS has access to type STUDENT_RECORD, because it uses module STUDENTS. Module procedure COURSE_GRADE also has access to type STUDENT_RECORD, because the derived-type definition appears in its host.

MODULE

Modules and Module Procedures

PROCEDURE
**MODULE SUBROUTINE**

*Statement:* Indicates a separate module procedure.

**Example**

```fortran
submodule (M) A
contains
  real module subroutine FOO (arg)
    type(tt), intent(in) :: arg
    arg%r = 1
  end subroutine FOO
end submodule A
```

**See Also**
Separate Module Procedures

**MODULO**

*Elemental Intrinsic Function (Generic): Returns the modulo of the arguments.*

**Syntax**

```fortran
result = MODULO (a, p)
```

*Input* Must be of type integer or real.

**p**

(Input) Must have the same type and kind parameters as *a*. It must not have a value of zero.

**Results**

The result type is the same as *a*. The result value depends on the type of *a*, as follows:

- If *a* is of type integer and *p* is not equal to zero, the value of the result is \( a - \text{FLOOR}(\text{REAL}(a) / \text{REAL}(p)) \times p \), that is, the result has a value such that \( a = q \times p + \text{result} \) where *q* is an integer. The following also applies:
  - If \( p > 0 \), then \( 0 \leq \text{result} < p \)
  - If \( p < 0 \), then \( p < \text{result} \leq 0 \)

- If *a* is of type real and *p* is not equal to zero, the value of the result is \( a - \text{FLOOR}(a / p) \times p \).

If *p* is equal to zero (regardless of the type of *a*), the result is undefined.

**Example**

MODULO (7, 3) has the value 1.

MODULO (9, -6) has the value -3.

MODULO (-9, 6) has the value 3.

The following shows more examples:

<table>
<thead>
<tr>
<th>INTEGER I</th>
<th>REAL R</th>
</tr>
</thead>
<tbody>
<tr>
<td>I= MODULO(8, 5) ! returns 3 Note: q=1</td>
<td></td>
</tr>
<tr>
<td>I= MODULO(-8, 5) ! returns 2 Note: q=-2</td>
<td></td>
</tr>
<tr>
<td>I= MODULO(8, -5) ! returns -2 Note: q=-2</td>
<td></td>
</tr>
<tr>
<td>I= MODULO(-8,-5) ! returns -3 Note: q=1</td>
<td></td>
</tr>
<tr>
<td>R= MODULO(7.285, 2.35) ! returns 0.2350001 Note: q=3</td>
<td></td>
</tr>
<tr>
<td>R= MODULO(7.285, -2.35) ! returns -2.115 Note: q=-4</td>
<td></td>
</tr>
</tbody>
</table>

MOD

MOVE_ALLOC  
**Intrinsic Subroutine (Generic):** Moves an allocation from one allocatable object to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL MOVE_ALLOC (from, to)

*from*  
(Input; output) Can be of any type, type parameters, corank, and rank; it must be allocatable.

*to*  
(Output) Must be type compatible with *from* and have the same rank and corank; it must be allocatable. *to* must be polymorphic if *from* is polymorphic. Each nondeferred type parameter of the declared type of *to* must have the same value as the corresponding type parameter of the declared type of *from*. For more information about type compatibility, see the description in **CLASS**.

If *to* is currently allocated, it is deallocated. If *from* is allocated, *to* becomes allocated with the same type, type parameters, array bounds, and values as *from*. Lastly, *from* is deallocated.

If *to* has the TARGET attribute, any pointer associated with *from* at the time of the call to MOVE_ALLOC becomes correspondingly associated with *to*. If *to* does not have the TARGET attribute, the pointer association status of any pointer associated with *from* on entry becomes undefined.

During execution of MOVE_ALLOC, the internal descriptor contents are copied from *from* to *to*, so that the storage pointed to by *to* is the storage that *from* used to point to.

Typically, MOVE_ALLOC is used to provide an efficient way to reallocate a variable to a larger size without copying the data twice.

**Example**

The following shows an example of how to increase the allocated size of X and keep the old values with only one copy of the old values. Using only assignment, a temporary variable named Y will be allocated and X assigned to Y. Then X will be deallocated and reallocated to be twice the size; then Y will be assigned to the first half of X. Finally, the temporary Y is deallocated.

```fortran
! This program uses MOVE_ALLOC to make an allocated array X bigger and  
! keep the old values of X in the variable X. Only one copy of the old values  
! of X is needed.  
integer :: I, N = 2  
real, allocatable :: X(:), Y(:)  
allocate (X(N), Y(2*N)) ! Y is twice as big as X  
X = (/ (I, I=1, N) /) ! put "old values" into X  
Y = -1 ! put different "old values" into Y  
print *, ' allocated of X is ', allocated (X)  
print *, ' allocated of Y is ', allocated (Y)  
print *, ' old X is ', X  
print *, ' old Y is ', Y  
Y (1:N) = X ! copy all of X into the first half of Y  
! this is the only copying of values required  
print *, ' new Y is ', Y  
call move_alloc (Y, X) ! X is now twice as big as it was, Y is  
! deallocated, the values were not copied from Y to X  
print *, ' allocated of X is ', allocated (X)  
```

print *, ' allocated of Y is ', allocated (Y)
print *, ' new X is ', X
end

The following shows the output for the above example:

allocated of X is  T
allocated of Y is  T
old X is    1.000000       2.000000
old Y is   -1.000000      -1.000000      -1.000000      -1.000000
new Y is    1.000000       2.000000      -1.000000      -1.000000
allocated of X is  T
allocated of Y is  F
new X is    1.000000       2.000000      -1.000000      -1.000000

MOVETO, MOVETO_W (W*S)

Graphics Subroutines: Move the current graphics position to a specified point. No drawing occurs.

Module
USE IFQWIN

Syntax
CALL MOVETO (x, y, s)
CALL MOVETO_W (wx, wy, s)

x, y
(Input) INTEGER(2). Viewport coordinates of the new graphics position.

s
(Output) Derived type xycoord. Viewport coordinates of the previous graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
   INTEGER(2) xcoord  ! x coordinate
   INTEGER(2) ycoord  ! y coordinate
END TYPE xycoord
```

wx, wy
(Input) REAL(8). Window coordinates of the new graphics position.

MOVETO sets the current graphics position to the viewport coordinate (x, y). MOVETO_W sets the current graphics position to the window coordinate (wx, wy).

MOVETO and MOVETO_W assign the coordinates of the previous position to s.

Example

! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
INTEGER(4) result
TYPE (xycoord) xy
RESULT = SETCOLORRGB(Z'FF0000')  ! blue
x = 60
! Draw a series of lines DO y = 50, 92, 3
   CALL MOVETO(x, y, xy)
   status = LINETO(INT2(x + 20), y)
END DO
END
Elemental Intrinsic Subroutine (Generic): Copies a sequence of bits (a bit field) from one location to another. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL MVBITS (from, frompos, len, to, topos)

from (Input) Integer. Can be of any integer type. It represents the location from which a bit field is transferred.

frompos (Input) Can be of any integer type; it must not be negative. It identifies the first bit position in the field transferred from from. frompos + len must be less than or equal to BIT_SIZE(from).

len (Input) Can be of any integer type; it must not be negative. It identifies the length of the field transferred from from.

to (Input; output) Can be of any integer type, but must have the same kind parameter as from. It represents the location to which a bit field is transferred. to is set by copying the sequence of bits of length len, starting at position frompos of from to position topos of to. No other bits of to are altered.

topos (Input) Can be of any integer type; it must not be negative. It identifies the starting position (within to) for the bits being transferred. topos + len must be less than or equal to BIT_SIZE(to).

For more information on bit functions, see Bit Functions.
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.
You can also use the following specific routines:

<table>
<thead>
<tr>
<th>Routine</th>
<th>Arguments</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMVBITS</td>
<td>from and to must be INTEGER(1).</td>
<td></td>
</tr>
<tr>
<td>HMVBITS</td>
<td>from and to must be INTEGER(2).</td>
<td></td>
</tr>
<tr>
<td>IMVBITS</td>
<td>from and to must be INTEGER(2).</td>
<td></td>
</tr>
<tr>
<td>JMVBITS</td>
<td>from and to must be INTEGER(4).</td>
<td></td>
</tr>
<tr>
<td>KMVBITS</td>
<td>from and to must be INTEGER(8).</td>
<td></td>
</tr>
</tbody>
</table>

Example

If TO has the initial value of 6, its value after a call to MVBITS(7, 2, 2, TO, 0) is 5.
The following shows another example:

```
INTEGER(1) :: from = 13  ! 00001101
INTEGER(1) :: to = 6     ! 00000110
CALL MVBITS(from, 2, 2, to, 0) ! returns to = 00000111
```
NAMELIST

Statement: Associates a name with a list of variables. This group name can be referenced in some input/output operations.

Syntax

NAMELIST /group/ var-list[, ] /group/ var-list]...

group

var-list

Is the name of the group.

Is a list of variables (separated by commas) that are to be associated with the preceding group name. The variables can be of any data type.

Description

The namelist group name is used by namelist I/O statements instead of an I/O list. The unique group name identifies a list whose entities can be modified or transferred.

A variable can appear in more than one namelist group.

Each variable in var-list must be accessed by use or host association, or it must have its type, type parameters, and shape explicitly or implicitly specified in the same scoping unit. If the variable is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

You cannot specify an assumed-size array in a namelist group.

Only the variables specified in the namelist can be read or written in namelist I/O. It is not necessary for the input records in a namelist input statement to define every variable in the associated namelist.

The order of variables in the namelist controls the order in which the values appear on namelist output. Input of namelist values can be in any order.

If the group name has the PUBLIC attribute, no item in the variable list can have the PRIVATE attribute.

The group name can be specified in more than one NAMELIST statement in a scoping unit. The variable list following each successive appearance of the group name is treated as a continuation of the list for that group name.

Example

In the following example, D and E are added to the variables A, B, and C for group name LIST:

\[
\text{NAMELIST /LIST/ A, B, C} \\
\text{NAMELIST /LIST/ D, E}
\]

In the following example, two group names are defined:

\[
\text{CHARACTER*30 NAME(25)} \\
\text{NAMELIST /INPUT/ NAME, GRADE, DATE /OUTPUT/ TOTAL, NAME}
\]

Group name INPUT contains variables NAME, GRADE, and DATE. Group name OUTPUT contains variables TOTAL and NAME.
The following shows another example:

```
NAMELIST /example/ i1, l1, r4, r8, z8, z16, c1, c10, iarray
! The corresponding input statements could be:
&example
i1  = 11
l1  = .TRUE.
r4  = 24.0
r8  = 28.0d0
z8  = (38.0, 0.0)
z16 = (316.0d0, 0.0d0)
c1  = 'A'
c10 = 'abcdefghij'
iarray(8) = 41, 42, 43
/
```

A sample program, NAMELIST.F90, is included in the `<install-dir>/samples` subdirectory.

### NARGS

**Inquiry Intrinsic Function (Specific):** Returns the total number of command-line arguments, including the command. This function cannot be passed as an actual argument.

**Syntax**

```
result = NARGS()
```

**Results**

The result type is INTEGER(4). The result is the number of command-line arguments, including the command. For example, NARGS returns 4 for the command-line invocation of `PROG1 -g -c -a`.

**Example**

```
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END

! MYPROG.F90 responds to command switches -r, -c, ! and/or -d
INTEGER(4) count, num, i, status
CHARACTER(80) buf
REAL r1 / 0.0 /
COMPLEX c1 / (0.0,0.0) /
REAL(8) d1 / 0.0 /

num = 5
count = NARGS()
DO i = 1, count-1
   CALL GETARG(i, buf, status)
   IF (status .lt. 0) THEN
      WRITE (*,*) 'GETARG error - exiting'
      EXIT
   END IF
ENDDO
```
IF (buf(2:status) .EQ.'r') THEN
   r1 = REAL(num)
   WRITE (*,*) 'r1 = ', r1
ELSE IF (buf(2:status) .EQ.'c') THEN
   cl = CMPLX(num)
   WRITE (*,*) 'cl = ', cl
ELSE IF (buf(2:status) .EQ.'d') THEN
   dl = DBLE(num)
   WRITE (*,*) 'dl = ', dl
ELSE
   WRITE(*,*) 'Invalid command switch: ', buf (1:status)
END IF
END DO
END

NEAREST

Elemental Intrinsic Function (Generic): Returns the nearest different number (representable on the processor) in a given direction.

Syntax

result = NEAREST (x, s)

x (Input) Must be of type real.

s (Input) Must be of type real and nonzero.

Results

The result type and kind is the same as x. The result has a value equal to the machine representable number that is different from and nearest to x, in the direction of the infinity with the same sign as s.

Example

If 3.0 and 2.0 are REAL(4) values, NEAREST (3.0, 2.0) has the value 3 + 2 \times 2^{-22}, which equals approximately 3.0000002. (For more information on the model for REAL(4), see Model for Real Data.

The following shows another example:

REAL(4) r1
REAL(8) r2, result
r1 = 3.0
result = NEAREST (r1, -2.0)
WRITE(*,*) result ! writes 2.999999761581421

! When finding nearest to REAL(8), can't see
! the difference unless output in HEX
r2 = 111502.07D0
result = NEAREST(r2, 2.0)
WRITE(*,'(1x,Z16)') result ! writes 40FB38E11EB851ED
result = NEAREST(r2, -2.0)
WRITE(*,'(1x,Z16)') result ! writes 40FB38E11EB851EB
END

EPSILON

NEW_LINE
Inquiry Intrinsic Function (Generic): Returns a new line character.

Syntax
result = NEW_LINE(a)

Input) Must be of type default character. It may be a scalar or an array.

Results
The result is a character scalar of length one with the same kind type parameter as a.
The result value is the ASCII newline character ACHAR(10).

NINT
Elemental Intrinsic Function (Generic): Returns the nearest integer to the argument.

Syntax
result = NINT(a [, kind])

Input) Must be of type real.

kind (Input; optional) Must be a scalar integer initialization expression.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind;
otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent
the result value in the kind of the result, the result is undefined.

If a is greater than zero, NINT(a) has the value INT(a + 0.5); if a is less than or equal to zero, NINT(a) has
the value INT(a - 0.5).

¹ Or JNINT.

² Or JNINT.
Specific Name | Argument Type | Result Type
---|---|---
2 The setting of compiler options specifying integer size can affect NINT, IDNINT, and IQNINT.
3 Or JIDNNT. For compatibility with older versions of Fortran, IDNINT can also be specified as a generic function.
4 Or JIQNNT. For compatibility with older versions of Fortran, IQNINT can also be specified as a generic function.

Example

NINT (3.879) has the value 4.
NINT (-2.789) has the value -3.
The following shows another example:

```
INTEGER(4) i1, i2
i1 = NINT(2.783) ! returns 3
i2 = IDNINT(-2.783D0) ! returns -3
```

NLSEnumCodepages (W*S)

**NLS Function:** Returns an array containing the codepages supported by the system, with each array element describing one valid codepage.

Module

USE IFNLS

Syntax

```
ptr => NLSEnumCodepages()
```

Results

The result is a pointer to an array of codepages, with each element describing one supported codepage.

**NOTE**

After use, the pointer returned by NLSEnumCodepages should be deallocated with the DEALLOCATE statement.

See Also

NLSEnumLocales (W*S)
DEALLOCATE

NLSEnumLocales (W*S)

**NLS Function:** Returns an array containing the language and country combinations supported by the system, in which each array element describes one valid combination.

Module

USE IFNLS
Syntax

ptr => NLSEnumLocales()

Results

The result is a pointer to an array of locales, in which each array element describes one supported language and country combination. Each element has the following structure:

```fortran
TYPE NLS$EnumLocale
   CHARACTER*(NLS$MaxLanguageLen)  Language
   CHARACTER*(NLS$MaxCountryLen)   Country
   INTEGER(4)                      DefaultWindowsCodepage
   INTEGER(4)                      DefaultConsoleCodepage
END TYPE
```

If the application is a Windows or QuickWin application, NLS$DefaultWindowsCodepage is the codepage used by default for the given language and country combination. If the application is a console application, NLS$DefaultConsoleCodepage is the codepage used by default for the given language and country combination.

**NOTE**

After use, the pointer returned by NLSEnumLocales should be deallocated with the DEALLOCATE statement.

See Also

NLSEnumCodepages (W*S)
DEALLOCATE

NLSFormatCurrency (W*S)

**NLS Function:** Returns a correctly formatted currency string for the current locale.

Module

USE IFNLS

Syntax

result = NLSFormatCurrency(outstr, instr[, flags])

*outstr*  
(Output) Character*(*). String containing the correctly formatted currency for the current locale. If *outstr* is longer than the formatted currency, it is blank-padded.

*instr*  
(Input) Character*(*). Number string to be formatted. Can contain only the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

*flags*  
(Input; optional) INTEGER(4). If specified, modifies the currency conversion. If you omit *flags*, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
Results

The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - outstr buffer is too small
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorInvalidInput - instr has an illegal value

Example

```fortran
USE IFNLS
CHARACTER(40) str
INTEGER(4) i

i = NLSFormatCurrency(str, "1.23")
print *, str  ! prints $1.23
i = NLSFormatCurrency(str, "1000000.99")
print *, str  ! prints $1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatCurrency(str, "1.23")
print *, str  ! prints 1 Pts
i = NLSFormatCurrency(str, "1000000.99")
print *, str  ! prints 1.000.001 Pts
```

See Also

NLSFormatNumber (W*S)
NLSFormatDate (W*S)
NLSFormatTime (W*S)

**NLSFormatDate (W*S)**

*NLS Function: Returns a correctly formatted string containing the date for the current locale.*

Module

USE IFNLS

Syntax

```
result = NLSFormatDate (outstr [, intime] [, flags])
```

- **outstr** (Output) Character*(*). String containing the correctly formatted date for the current locale. If outstr is longer than the formatted date, it is blank-padded.

- **intime** (Input; optional) INTEGER(4). If specified, date to be formatted for the current locale. Must be an integer date such as the packed time created with PACKTIMEQQ. If you omit intime, the current system date is formatted and returned in outstr.

- **flags** (Input; optional) INTEGER(4). If specified, modifies the date conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:
  - NLS$Normal - No special formatting
  - NLS$NoUserOverride - Do not use user overrides
  - NLS$UseAltCalendar - Use the locale's alternate calendar
  - NLS$LongDate - Use local long date format
• NLS$ShortDate - Use local short date format

Results
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

• NLS$ErrorInsufficentBuffer - outstr buffer is too small
• NLS$ErrorInvalidFlags - flags has an illegal value
• NLS$ErrorInvalidInput - intime has an illegal value

Example
USE IFNLS
INTEGER(4) i
CHARACTER(40) str
i = NLSFORMATDATE(str, FLAGS=NLS$NORMAL)           ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$USEALTCALENDAR)   ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$LONGDATE)         ! Sunday, August 1, 2010
i = NLSFORMATDATE(str, FLAGS=NLS$SHORTDATE)        ! 8/1/10
END

NLSFormatTime (W*S)
NLSFormatCurrency (W*S)
NLSFormatNumber (W*S)

NLSFormatNumber (W*S)

**NLS Function:** Returns a correctly formatted number string for the current locale.

Module
USE IFNLS

Syntax
result = NLSFormatNumber (outstr, instr [, flags])

outstr (Output) Character*(*). String containing the correctly formatted number for the current locale. If outstr is longer than the formatted number, it is padded with blanks.

instr (Input) Character*(*). Number string to be formatted. Can only contain the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

flags (Input; optional) INTEGER(4). If specified, modifies the number conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

• NLS$Normal - No special formatting
• NLS$NoUserOverride - Do not use user overrides

Results
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:
Example

USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatNumber(str, "1.23")
print *, str                       ! prints 1.23
i = NLSFormatNumber(str, "1000000.99")
print *, str                       ! prints 1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatNumber(str, "1.23")
print *, str                       ! prints 1,23
i = NLSFormatNumber(str, "1000000.99")
print *, str                       ! prints 1.000.000,99
END

See Also
NLSFormatTime (W*S)
NLSFormatCurrency (W*S)
NLSFormatDate (W*S)

NLSFormatTime (W*S)

NLS Function: Returns a correctly formatted string containing the time for the current locale.

Module
USE IFNLS

Syntax
result = NLSFormatTime (outstr [, intime] [, flags])

outstr
(Output) Character(*). String containing the correctly formatted time for the current locale. If outstr is longer than the formatted time, it is blank-padded.

intime
(Input; optional) INTEGER(4). If specified, time to be formatted for the current locale. Must be an integer time such as the packed time created with PACKTIMEQQ. If you omit intime, the current system time is formatted and returned in outstr.

flags
(Input; optional) INTEGER(4). If specified, modifies the time conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
- NLS$NoMinutesOrSeconds - Do not return minutes or seconds
- NLS$NoSeconds - Do not return seconds
- NLS$NoTimeMarker - Do not add a time marker string
- NLS$Force24HourFormat - Return string in 24 hour format
**Results**

The result type is INTEGER(4). The result is the number of characters written to `outstr` (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - `outstr` buffer is too small
- NLS$ErrorInvalidFlags - `flags` has an illegal value
- NLS$ErrorInvalidInput - `intime` has an illegal value

**Example**

```fortran
USE IFNLS
INTEGER(4) i
CHARACTER(20) str
i = NLSFORMATTIME(str, FLAGS=NLS$NORMAL) ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOMINUTESORSECONDS) ! 11 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOTIMEMARKER) ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=IOR(NLS$FORCE24HOURFORMAT, &
   NLS$NOSECONDS)) ! 23:38 PM
END
```

**See Also**

- NLSFormatCurrency (W*S)
- NLSFormatDate (W*S)
- NLSFormatNumber (W*S)

**NLSGetEnvironmentCodepage (W*S)**

**NLS Function:** Returns the codepage number for the system (Window) codepage or the console codepage.

**Module**

USE IFNLS

**Syntax**

```fortran
result = NLSGetEnvironmentCodepage (flags)
```

**flags**

(Input) INTEGER(4). Tells the function which codepage number to return. Available values (defined in *IFNLS.F90*) are:

- NLS$ConsoleEnvironmentCodepage - Gets the codepage for the console
- NLS$WindowsEnvironmentCodepage - Gets the current Windows codepage

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, it returns one of the following error codes:

- NLS$ErrorInvalidFlags - `flags` has an illegal value.
- NLS$ErrorNoConsole - There is no console associated with the given application. So, operations with the console codepage are not possible.

**See Also**

- NLSSetEnvironmentCodepage (W*S)
**NLSGetLocale (W*S)**

**NLS Subroutine:** Returns the current language, country, or codepage.

**Module**

USE IFNLS

**Syntax**

CALL NLSGetLocale (language [,country] [,codepage])

- `language` (Output; optional) Character*(*) . Current language.
- `country` (Output; optional) Character*(*) . Current country.
- `codepage` (Output; optional) INTEGER(4) . Current codepage.

NLSGetLocale returns a valid codepage in `codepage`. It does not return one of the NLS$... symbolic constants that can be used with NLSSetLocale.

**Example**

USE IFNLS
CHARACTER(50) cntry, lang
INTEGER(4) code
CALL NLSGetLocale (lang, cntry, code)  ! get all three
CALL NLSGetLocale (CODEPAGE = code)    ! get the codepage
CALL NLSGetLocale (COUNTRY = cntry, CODEPAGE =code) ! get country
              ! and codepage

**See Also**

NLSSetLocale (W*S)

**NLSGetLocaleInfo (W*S)**

**NLS Function:** Returns information about the current locale.

**Module**

USE IFNLS

**Syntax**

result = NLSGetLocaleInfo (type, outstr)

- `type` (Input) INTEGER(4) . NLS parameter requested. A list of parameter names is provided in NLS LocaleInfo Parameters.
- `outstr` (Output) Character*(*) . Parameter setting for the current locale. All parameter settings placed in `outstr` are character strings, even numbers. If a parameter setting is numeric, the ASCII representation of the number is used. If the requested parameter is a date or time string, an explanation of how to interpret the format in `outstr` is provided in NLS Date and Time Format.

**Results**

The result type is INTEGER(4). The result is the number of characters written to `outstr` if successful, or if `outstr` has 0 length, the number of characters required to hold the requested information. Otherwise, the result is one of the following error codes (defined in IFNLS.F90):

```plaintext
1637
```
• NLS$ErrorInvalidLIType - The given type is invalid
• NLS$ErrorInsufficientBuffer - The outstr buffer was too small, but was not 0 (so that the needed size would be returned)

The NLS$LI parameters are used for the argument type and select the locale information returned by NLSGetLocaleInfo in outstr. You can perform an inclusive OR with NLS$NoUserOverride and any NLS$LI parameter. This causes NLSGetLocaleInfo to bypass any user overrides and always return the system default value.

The following table lists and describes the NLS$LI parameters.

### NLS LocaleInfo Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NLS$LI_ILANGUAGE</td>
<td>An ID indicating the language.</td>
</tr>
<tr>
<td>NLS$LI_SLANGUAGE</td>
<td>The full localized name of the language.</td>
</tr>
<tr>
<td>NLS$LI_SENGLANGUAGE</td>
<td>The full English name of the language from the ISO Standard 639. This will always be restricted to characters that map into the ASCII 127 character subset.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVLANGNAME</td>
<td>The abbreviated name of the language, created by taking the 2-letter language abbreviation as found in ISO Standard 639 and adding a third letter as appropriate to indicate the sublanguage.</td>
</tr>
<tr>
<td>NLS$LI_SNATIVELANGNAME</td>
<td>The native name of the language.</td>
</tr>
<tr>
<td>NLS$LI_ICOUNTRY</td>

<tr>
<td>NLS$LI_SMONTHNAME1 - NLS$LI_SMONTHNAME13</td>
<td>Native name for each month. 1 = January, 2 = February, etc. 13 = the 13th month, if it exists in the locale.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVMONTHNAME1 - NLS$LI_SABBREVMONTHNAME13</td>
<td>Native abbreviated name for each month. 1 = Jan, 2 = Feb, etc. 13 = the 13th month, if it exists in the locale.</td>
</tr>
</tbody>
</table>

When NLSGetLocaleInfo (type, outstr) returns information about the date and time formats of the current locale, the value returned in outstr can be interpreted according to the following tables. Any text returned within a date and time string that is enclosed within single quotes should be left in the string in its exact form; that is, do not change the text or the location within the string.

*Day*

The day can be displayed in one of four formats using the letter "d". The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Day of the month as digits without leading zeros for single-digit days</td>
</tr>
<tr>
<td>dd</td>
<td>Day of the month as digits with leading zeros for single-digit days</td>
</tr>
<tr>
<td>ddd</td>
<td>Day of the week as a three-letter abbreviation (SABBREVDAYNAME)</td>
</tr>
<tr>
<td>dddd</td>
<td>Day of the week as its full name (SDAYNAME)</td>
</tr>
</tbody>
</table>

*Month*

The month can be displayed in one of four formats using the letter "M". The uppercase "M" distinguishes months from minutes. The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Month as digits without leading zeros for single-digit months</td>
</tr>
<tr>
<td>MM</td>
<td>Month as digits with leading zeros for single-digit months</td>
</tr>
<tr>
<td>MMM</td>
<td>Month as a three-letter abbreviation (SABBREVMONTHNAME)</td>
</tr>
<tr>
<td>MMMM</td>
<td>Month as its full name (SMONTHNAME)</td>
</tr>
</tbody>
</table>

*Year*

The year can be displayed in one of three formats using the letter "y". The following table shows the three variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>Year represented by only the last digit</td>
</tr>
<tr>
<td>yy</td>
<td>Year represented by only the last two digits</td>
</tr>
<tr>
<td>yyyy</td>
<td>Year represented by the full 4 digits</td>
</tr>
</tbody>
</table>

*Period/Era*

The period/era string is displayed in a single format using the letters "gg".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gg</td>
<td>Period/Era string</td>
</tr>
</tbody>
</table>

*Time*
The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker. The following table shows the numerous variations of the time format. Lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The lowercase "m" distinguishes minutes from months.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>Hours without leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>hh</td>
<td>Hours with leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>H</td>
<td>Hours without leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>HH</td>
<td>Hours with leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>m</td>
<td>Minutes without leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>mm</td>
<td>Minutes with leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>s</td>
<td>Seconds without leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>ss</td>
<td>Seconds with leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>t</td>
<td>One-character time marker string</td>
</tr>
<tr>
<td>tt</td>
<td>Multicharacter time marker string</td>
</tr>
</tbody>
</table>

**Example**

```fortran
USE IFNLS
INTEGER(4) strlen
CHARACTER(40) str
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str  ! prints Monday if language is English
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str  ! prints Tuesday if language is English
```

**See Also**

NLSGetLocale (W*S)
NLSFormatDate (W*S)
NLSFormatTime (W*S)
NLSSetLocale (W*S)
NLSSetEnvironmentCodepage (W*S)

**NLSSetEnvironmentCodepage (W*S)**

**NLS Function:** Sets the codepage for the current console. The specified codepage affects the current console program and any other programs launched from the same console. It does not affect other open consoles or any consoles opened later.

**Module**

USE IFNLS

**Syntax**

```fortran
result = NLSSetEnvironmentCodepage (codepage, flags)
```

- `codepage`  
  (Input) INTEGER(4). Number of the codepage to set as the console codepage.

- `flags`  
  (Input) INTEGER(4). Must be set to NLS$ConsoleEnvironmentCodepage.
Results

The result type is INTEGER(4). The result is zero if successful. Otherwise, returns one of the following error codes defined in IFNLS.F90:

- NLS$ErrorInvalidCodepage - codepage is invalid or not installed on the system
- NLS$ErrorInvalidFlags - flags is not valid
- NLS$ErrorNoConsole - There is no console associated with the given application. So operations, with the console codepage are not possible

The flags argument must be a NLS$ConsoleEnvironmentCodepage; it cannot be a NLS$WindowsEnvironmentCodepage. NLSSetEnvironmentCodepage does not affect the Windows* codepage.

See Also

NLSSetEnvironmentCodepage (W*S)

NLSSetLocale (W*S)

**NLS Function:** Sets the current language, country, or codepage.

Module

USE IFNLS

Syntax

result = NLSSetLocale (language[, country] [,codepage])

- language (Input) Character*(*). One of the languages supported by the Windows* OS NLS APIs.
- country (Input; optional) Character*(*). If specified, characterizes the language further. If omitted, the default country for the language is set.
- codepage (Input; optional) INTEGER(4). If specified, codepage to use for all character-oriented NLS functions. Can be any valid supported codepage or one of the following predefined values defined in IFNLS.F90:
  - NLS$CurrentCodepage - The codepage is not changed. Only the language and country settings are altered by the function.
  - NLS$ConsoleEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for console programs.
  - NLS$ConsoleLanguageCodepage - The codepage is changed to the default console codepage for the language and country combination specified.
  - NLS$WindowsEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for Windows* OS programs.
  - NLS$WindowsLanguageCodepage - The codepage is changed to the default Windows OS codepage for the language and country combination specified.

If you omit codepage, it defaults to NLS$WindowsLanguageCodepage. At program startup, NLS$WindowsEnvironmentCodepage is used to set the codepage.

Results

The result type is INTEGER(4). The result is zero if successful. Otherwise, one of the following error codes (defined in IFNLS.F90) may be returned:
• NLS$ErrorInvalidLanguage - _language_ is invalid or not supported
• NLS$ErrorInvalidCountry - _country_ is invalid or is not valid with the language specified
• NLS$ErrorInvalidCodepage - _codepage_ is invalid or not installed on the system

**NOTE**
NLSSetLocale works on installed locales only. Many locales are supported, but they must be installed through the system Control Panel/International menu.

When doing mixed-language programming with Fortran and C, calling NLSSetLocale with a codepage other than the default environment Windows OS codepage causes the codepage in the C run-time library to change by calling C's setmbcp( ) routine with the new codepage. Conversely, changing the C run-time library codepage does not change the codepage in the Fortran NLS library.

Calling NLSSetLocale has no effect on the locale used by C programs. The locale set with C's setlocale( ) routine is independent of NLSSetLocale.

Calling NLSSetLocale with the default environment console codepage, NLS$ConsoleEnvironmentCodepage, causes an implicit call to the Windows OS API SetFileApisToOEM( ). Calling NLSSetLocale with any other codepage causes a call to SetFileApisToANSI( ).

**See Also**
NLSSetLocale (W*S)

**NOFREEFORM**

**Statement:** Specifies that source code is in fixed-form format.

**See Also**
See FREEFORM and NOFREEFORM.

**NOFUSION**

**General Compiler Directive:** Prevents a loop from fusing with adjacent loops.

**Syntax**

```fortran
!DIR$ NOFUSION
```

The NOFUSION directive lets you fine tune your program on a loop-by-loop basis.

This directive should be placed immediately before the DO statement of the loop that should not be fused.

**Example**

Consider the following example that demonstrates use of the NOFUSION directive:

```fortran
subroutine sub (b,a,n)
  real a(n), b(n)
  do i=1,n
    a(i) = a(i) + b(i)
  enddo
!DIR$ NOFUSION
  do i=1,n
    a(i) = a(i) + 1
  enddo
end
```
The following shows the same example, but it uses Standard Fortran array assignments, which allow implicit arrays:

```fortran
subroutine sub (b,a,n)
    real a(n), b(n)
    a = a + b
!DIR$ NOFUSION
    a = a + 1
end
```

**NOOPTIMIZE**

*Statement:* Disables optimizations.

See Also
See OPTIMIZE and NOOPTIMIZE.

**NOPREFETCH**

*Statement:* Disables data prefetching.

See Also
See PREFETCH and NOPREFETCH.

**NORM2**

*Transformational Intrinsic Function (Generic):* Returns the $L_2$ norm of an array.

*Syntax*

```fortran
result = NORM2 (x [, dim])
```

*x*  
(Input) Must be a real array.

*dim*  
(Input; optional) Must be a scalar integer with a value in the range $1 \leq dim \leq n$, where $n$ is the rank of $x$.

The corresponding actual argument must not be an optional dummy argument.

*Results*

The result is of the same type and kind parameters as $x$.

The result is a scalar if *dim* is omitted; otherwise, the result has rank $n - 1$ and shape $[d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ... , d_n]$, where $n$ is the rank of $x$ and $[d_1, d_2, ..., d_n]$ is the shape of $x$.

The result of NORM2 ($x$) has a value equal to a processor-dependent approximation to the generalized $L_2$ norm of $x$, which is the square root of the sum of the squares of the elements of $x$.

The result of NORM2 ($x$, DIM=*dim*) has a value equal to that of NORM2 ($x$) if $x$ has rank one.

Otherwise, the value of element $(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ... , s_n)$ of the result is equal to NORM2 ($x$ $(s_1, s_2, ..., s_{dim-1}, ; s_{dim+1}, ... , s_n)$).

It is recommended that the processor compute the result without undue overflow or underflow.
Example
The value of NORM2 ([3.0, 4.0]) is 5.0 (approximately).

If X has the value:

\[
\begin{bmatrix}
  1.0 & 2.0 \\
  3.0 & 4.0
\end{bmatrix}
\]

then the value of NORM2 (X, DIM=1) is approximately [3.162, 4.472] and the value of NORM2 (X, DIM=2) is approximately [2.236, 5.0].

NOSTRICT

Statement: Enables language features not found in the language standard specified on the command line.

See Also
See STRICT and NOSTRICT.

NOT

Elemental Intrinsic Function (Generic): Returns the logical complement of the argument.

Syntax

\[
\text{result} = \text{NOT} \ (i)
\]

\(i\) (Input) Must be of type integer.

Results

The result type and kind is the same as \(i\). The result value is obtained by complementing \(i\) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>(\text{NOT} \ (i))</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BNOT</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>INOT(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JNOT</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KNOT</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or HNOT.

Example

If I has a value equal to 10101010 (base 2), NOT (I) has the value 01010101 (base 2).

The following shows another example:

\[
\begin{align*}
\text{INTEGER}(2) & \ i(2), \ j(2) \\
& \ i = (/4, 132/) \quad ! \ i(1) = 0000000000000100 \\
& \quad ! \ i(2) = 0000000010000100 \\
& \ j = \text{NOT}(i) \quad ! \text{returns} \ (-5,-133) \\
& \quad ! \ j(1) = 11111111111111011 \\
& \quad ! \ j(2) = 11111111011111011
\end{align*}
\]

ISHFTC

**NOUNROLL**

*Statement:* Disables the unrolling of a DO loop.

See Also
See UNROLL and NOUNROLL.

**NOUNROLL_AND_JAM**

*Statement:* Hints to the compiler to disable loop unrolling and jamming.

See Also
See UNROLL_AND_JAM and NOUNROLL_AND_JAM.

**NOVECTOR**

*Statement:* Disables vectorization of a DO loop.

See Also
See VECTOR and NOVECTOR.

**NOWAIT Clause**

*Parallel Directive Clause:* Specifies that threads may resume execution before the execution of the region completes.

**Syntax**

NOWAIT

When you specify this clause, it removes the synchronization barrier implied at the end of the region.

Note that NOWAIT can also be specified as a keyword in several directives.

At most one NOWAIT clause or keyword can appear in a directive that allows the clause or keyword.

**NULL**

*Transformational Intrinsic Function (Generic):*

Initializes a pointer as disassociated when it is declared.

**Syntax**

result = NULL ([ mold])
mold

(Optional) Must be a pointer; it can be of any type. Its pointer association status can be associated, disassociated, or undefined. If its status is associated, the target does not have to be defined with a value.

Results

The result type and kind is the same as mold, if present; otherwise, it is determined as follows:

<table>
<thead>
<tr>
<th>If NULL ( ) Appears...</th>
<th>Type is Determined From...</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the right side of pointer assignment</td>
<td>The pointer on the left side</td>
</tr>
<tr>
<td>As initialization for an object in a declaration</td>
<td>The object</td>
</tr>
<tr>
<td>As default initialization for a component</td>
<td>The component</td>
</tr>
<tr>
<td>In a structure constructor</td>
<td>The corresponding component</td>
</tr>
<tr>
<td>As an actual argument</td>
<td>The corresponding dummy argument</td>
</tr>
<tr>
<td>In a DATA statement</td>
<td>The corresponding pointer object</td>
</tr>
</tbody>
</table>

The result is a pointer with disassociated association status.

**CAUTION**

If you use module IFWIN or IFWINTY, you will have a name conflict if you use the NULL intrinsic. To avoid this problem, rename the integer parameter constant NULL to something else; for example:

```
USE IFWIN, NULL0 => NULL
```

This example lets you use both NULL0 and NULL( ) in the same program unit with no conflict.

Example

Consider the following:

```
INTEGER, POINTER :: POINT1 => NULL( )
```

This statement defines the initial association status of POINT1 to be disassociated.

**NULLIFY**

*Statement*: Disassociates a pointer from a target.

**Syntax**

```
NULLIFY (pointer-object[,pointer-object]...)
```

*pointer-object* Is a structure component or the name of a variable; it must be a pointer (have the POINTER attribute).

**Description**

The initial association status of a pointer is undefined. You can use NULLIFY to initialize an undefined pointer, giving it disassociated status. Then the pointer can be tested using the intrinsic function ASSOCIATED.

**Example**

The following is an example of the NULLIFY statement:

```
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR_A(:), PTR_B(:)
PTR_A => TAR
PTR_B => NULL
```
PTR_B => TAR
...
NULLIFY(PTR_A)

After these statements are executed, PTR_A will have disassociated status, while PTR_B will continue to be
associated with variable TAR.

The following shows another example:

```fortran
!    POINTER2.F90    Pointing at a Pointer and Target
!DIR$ FIXEDFORMLINESIZE:80

REAL, POINTER :: arrow1 (:)
REAL, POINTER :: arrow2 (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:)

ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye
arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1

arrow2 => arrow1
IF (ASSOCIATED(arrow2)) WRITE (*','/(a/)') ' ARROW2 is pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow2

NULLIFY (arrow2)
IF (.NOT.ASSOCIATED(arrow2)) WRITE (*','/(a/)') ' ARROW2 is not pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow1
WRITE (*,'/(1x,a,7f8.0)') 'target ',bullseye

END
```

**NUM_IMAGES**

*Transformational Intrinsic Function (Generic):*

*Returns the number of images.*

**Syntax**

```fortran
result = NUM_IMAGES()
```

**Results**

The result type is default integer. The result is the number of images.

You can specify a compiler option or environment variable to modify the number of images. If both are
specified, the environment variable setting overrides the compiler option setting.

A compiler option must be specified to enable coarrays. If it is not specified and you use this intrinsic
function, an error occurs.
Example

In the following example, image 1 is used to read data. The other images then copy the data:

```fortran
REAL :: R[*]
IF (THIS_IMAGE()==1) THEN
   READ (7,*) R
   DO I = 2, NUM_IMAGES()
      R[I] = R
   END DO
END IF
SYNC ALL
```

O to P

OBJCOMMENT

**General Compiler Directive:** Specifies a library search path in an object file.

**Syntax**

```fortran
!DIR$ OBJCOMMENT LIB: library
```

*library* is a character constant specifying the name and, if necessary, the path of the library that the linker is to search.

The linker searches for the library named in OBJCOMMENT as if you named it on the command line, that is, before default library searches. You can place multiple library search directives in the same source file. Each search directive appears in the object file in the order it is encountered in the source file.

If the OBJCOMMENT directive appears in the scope of a module, any program unit that uses the module also contains the directive, just as if the OBJCOMMENT directive appeared in the source file using the module.

If you want to have the OBJCOMMENT directive in a module, but do not want it in the program units that use the module, place the directive outside the module that is used.

Example

```fortran
! MOD1.F90
MODULE a
!DIR$ OBJCOMMENT LIB: "opengl32.lib"
END MODULE a

! MOD2.F90
!DIR$ OBJCOMMENT LIB: "graftools.lib"
MODULE b
!
END MODULE b

! USER.F90
PROGRAM go
   USE a   ! library search contained in MODULE a
   ! included here
   USE b   ! library search not included
END
```
OFFLOAD

**OFFLOAD Compiler Directive:** Enables statements to execute on the target. This directive only applies to Intel® MIC Architecture.

Syntax

```c
!DIR$ [OMP] OFFLOAD clause[|, clause...]
```

**clause**

Can be any of the following:

- **TARGET** *(target-name [:target-number]*)
- **IF** *(if-specifier)*
  
  An optional clause. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.

  Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

- **SIGNAL** *(tag)*
  
  An optional clause. Include it to enable the CPU to continue execution after initiating the OFFLOAD.

  If this clause is used, the computation performed by the offload and any data transfers occur concurrently with the CPU execution of the code after the directive.

  If this clause is not used, then the entire offload and associated data transfers are executed synchronously: the CPU will not continue execution past the directive until the computation performed by the offload has completed.

  SIGNAL is device specific; if you use this clause, you must specify a target-number =0 in the TARGET clause.

- **WAIT** *(tag [, tag, ...]*)
  
  An optional clause. Include it to specify a wait for completion of a previously initiated asynchronous data transfer or asynchronous computation.

  WAIT is device specific; if you use this clause, you must specify a target-number =0 in the TARGET clause.

- **MANDATORY**
  
  An optional clause. Include it to specify that execution on the coprocessor is required. Execution on the CPU is not allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message.

  You cannot specify both MANDATORY and OPTIONAL since they are opposites.
If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **OPTIONAL**

  An optional clause. Include it to specify that execution on the coprocessor is requested but not required. Execution on the CPU is allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program is executed on the CPU, not the TARGET.

  You cannot specify both MANDATORY and OPTIONAL since they are opposites.

  If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **STATUS (var)**

  An optional clause. Include it to determine the status of the execution of an offloading construct. When used with the OPTIONAL or MANDATORY clause, the STATUS clause also lets you modify the action to take upon failure.

  var is of derived type offload_status defined in mic_lib.mod. This status variable can be queried for details about the offload. The module mic_lib.mod is provided and contains the following definitions:

  ```fortran
  use, intrinsic :: iso_c_binding
  enum , bind (C) 
    enumerator :: OFFLOAD_SUCCESS         = 0
    enumerator :: OFFLOAD_DISABLED        = 1  ! offload is disabled
    enumerator :: OFFLOAD_UNAVAILABLE     = 2  ! card is not available
    enumerator :: OFFLOAD_OUT_OF_MEMORY   = 3  ! not enough memory on device
    enumerator :: OFFLOAD_PROCESS_DIED    = 4  ! target process has died
    enumerator :: OFFLOAD_ERROR           = 5  ! unspecified error
  end enum

  type, bind (C) :: offload_status
    integer(kind=c_int) ::  result        = OFFLOAD_DISABLED   ! result, see enum above
    integer(kind=c_int) ::  device_number = -1  ! device number
    integer(kind=c_int) ::  data_sent     =  0  ! number of bytes sent to the target
    integer(kind=c_int) ::  data_received =  0  ! number of bytes received by host
  end type offload_status
  ```

  When you specify STATUS with the MANDATORY clause, and the offload cannot be performed, the construct is not automatically executed on the host. The program continues execution. You should examine var for the cause of the offload failure and take appropriate action. Note that if no STATUS clause is specified, then the program is terminated.

  When you specify STATUS with the OPTIONAL clause, and the offload cannot be performed, the construct is executed on the host processor. You can examine the var in the STATUS clause to determine the cause of the offload failure.
• `offload-parameter [[,] offload-parameter]`
  One or more data movement clauses (see below).

The following arguments are used in the above `clause` items:

- **target-name**
  Is an identifier that represents the target. The only allowable target name is MIC.

- **target-number**
  (Required for SIGNAL and WAIT) Is an integer expression whose value is interpreted as shown in the following table.
  When `target-number` is specified, the implicit MANDATORY offload is overridden and execution on the CPU is allowed when either the OPTIONAL clause is also specified or optional is also specified in the `[Q]offload` option.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>This value specifies execution on the coprocessor. The runtime system chooses the specific coprocessor. Execution on the CPU is not allowed.</td>
</tr>
<tr>
<td></td>
<td>If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option <code>[q or Q]offload</code>.</td>
</tr>
<tr>
<td></td>
<td>This value is not allowed if you specify the SIGNAL or WAIT clause.</td>
</tr>
<tr>
<td>&gt;= 0</td>
<td>A value greater than or equal to zero specifies execution on a specific coprocessor. The number of the specific coprocessor is determined as follows:</td>
</tr>
<tr>
<td></td>
<td><code>coprocessor = MOD (target-number, number_of_coprocs)</code></td>
</tr>
<tr>
<td></td>
<td>If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option <code>[q or Q]offload</code>.</td>
</tr>
<tr>
<td>&lt; -1</td>
<td>These values are reserved.</td>
</tr>
</tbody>
</table>
If you don’t specify the target-number argument, the runtime system executes the code on the coprocessor, and if multiple coprocessors are available, on which coprocessor. If no coprocessor is available, the program fails with an error message.

For example, in a system with 4 coprocessors:

- Specifying 2 or 6 tells the runtime systems to use coprocessor 2 for the transfer, because both MOD(2,4) and MOD(6,4) equal 2.
- Specifying 1000 tells the runtime systems to use coprocessor 0 for the transfer, because MOD(1000,4) = 0.

**NOTE**
Leaving data values on the coprocessor from one execution of offloaded code to another is called "data persistence". In a system with multiple coprocessors, you need to specify a target-number to reliably use data persistence. When you use ALLOC_IF or FREE_IF to implement data persistence on the coprocessor, but do not specify a target-number, the runtime system randomly chooses a coprocessor, so the chosen coprocessor could be one on which the data is not available.

**if-specifier**
Is a Boolean expression.
If the expression evaluates to true, then the program attempts to offload the statement. If the specified target coprocessor is absent from the system or not available at that time because it is fully loaded, then the offloaded code executes on the CPU.
If the expression evaluates to false, then the offloaded code executes on the CPU and none of the other OFFLOAD clauses have any effect.

**tag**
Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.
When used with SIGNAL, tag is an integer value associated with an asynchronous computation or an asynchronous data transfer. tag can be used in subsequent WAIT clauses in other OFFLOAD, OFFLOAD_TRANSFER, or OFFLOAD_WAIT directives.
When used with WAIT, tag is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same tag that you specified in the SIGNAL clause that started the asynchronous computation or data transfer with the OFFLOAD or OFFLOAD_TRANSFER directive.

**offload-parameter**
Can be any of the following data movement clauses:
- IN ( identifier[, identifier…] [: modifier[, modifier… ] ] )
- OUT ( identifier[, identifier…] [: modifier[, modifier… ] ] )
- INOUT ( identifier[, identifier…] [: modifier[, modifier… ] ] )
- NOCOPY ( identifier[, identifier…] [: modifier[, modifier… ] ] )

When a program runs in a heterogeneous environment, program variables are copied back and forth between the CPU and the target. The offload-parameter is a specification for controlling the direction in which variables are copied, and for pointers, the amount of data that is copied.
The data selected for transfer is a combination of variables implicitly transferred because they are lexically referenced within offload constructs, and variables explicitly listed in an offload-parameter.

<table>
<thead>
<tr>
<th>IN</th>
<th>This indicates that the variable is strictly an input to the target region and it is copied from the CPU to the coprocessor. Its value is not copied back from the coprocessor to the CPU after the region completes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUT</td>
<td>This indicates that the variable is strictly an output of the target region. The host CPU does not copy the variable to the target coprocessor. It is copied from the coprocessor to the CPU.</td>
</tr>
<tr>
<td>INOUT</td>
<td>This indicates that the variable is both copied from the CPU to the target coprocessor and back from the coprocessor to the CPU.</td>
</tr>
<tr>
<td>NOCOPY</td>
<td>This indicates that the variable should not be copied.</td>
</tr>
<tr>
<td></td>
<td>A variable whose value is reused from the last target execution or a variable that is used entirely within the offloaded code section can be named in a NOCOPY clause to avoid any copying.</td>
</tr>
<tr>
<td></td>
<td>If the NOCOPY clause is being used to retain values across offload instances (data persistence), then currently values of non-scalar variables with automatic storage allocation (stack variables) are not preserved across offload instances. However, all statically allocated variables are preserved, and non-scalar variables with automatic allocation are also preserved across offload instances.</td>
</tr>
<tr>
<td></td>
<td>If the NOCOPY clause is being used merely to suppress data transfer between the CPU and the target, then variables of all memory allocation types are supported.</td>
</tr>
</tbody>
</table>

An IN or OUT element-count-expr expression (see description below within modifier) is evaluated at a point in the program before the statement or clause in which it is used.
An array variable whose size is known from its declaration is copied in its entirety. If a subset of an array is to be processed, use the name of the starting element of the subset and the `element-count-expr` to transfer the array subset.

Because a data pointer variable not listed in an IN clause is uninitialized within the offload region, it must be assigned a value on the target before it can be referenced.

**identifier**

Is a variable, a subscripted variable, an array slice, or a component reference. The variable or the component reference may have the ALLOCATABLE or POINTER attribute. An array slice may be contiguous or non-contiguous.

**modifier**

Is one of the following:

- `LENGTH (element-count-expr)`
  
  where `element-count-expr` is an integer expression, computed at runtime. Use it with:
  
  - Integer pointer variables (not Fortran 90 POINTERS)
    
    Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host CPU and the target. Instead, objects that an integer pointer points to are copied to or from the target, and the value of the pointer variable is recreated. By default, a single element is copied.
    
    Use `element-count-expr` to specify how many elements pointed to should be considered as data. If the expression value is zero or negative, the program fails with an error message.
  
  - Arrays (including assumed-size)
    
    `element-count-expr` specifies a number of elements copied between the CPU and target.
    
    A Fortran array variable can be one of four major types: explicit-shape, assumed-shape, deferred-shape and assumed-size. The runtime descriptor for the first three types makes that array variable's size known at compile time or at runtime. The last dimension of an assumed-size array is the length of its variable.
    
    By default, the compiler copies explicit-shape, assumed-shape and deferred-shape arrays in their entirety. They do not need an `element-count-expr`. However, you can use an optional `element-count-expr` to specify the total number of elements to copy, which limits the number of elements copied back and forth in the last dimension of the array.
    
    You must specify an assumed-size array with an `element-count-expr` specification, because the compiler does not know the total size of the array. The value of the `element-count-expr` is the total number of elements of the array to be copied.
  
  - `ALLOC_IF (condition) | FREE_IF (condition)`
    
    where `condition` is a Boolean expression.
    
    The ALLOC_IF modifier specifies a Boolean condition that controls whether the allocatable variables in the IN clause will be allocated a new block of memory on the target when the offload is executed on the
target. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused (data persistence). You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a FREE_IF(.FALSE.) clause on an earlier offload.

The FREE_IF modifier specifies a Boolean condition that controls whether to deallocate the memory allocated for the allocatable variables in an IN clause. If the expression evaluates to true, the memory pointed to by each variable listed in the clause is deallocated. If the condition evaluates to false, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

The following are the default settings for ALLOC_IF and FREE_IF:

<table>
<thead>
<tr>
<th></th>
<th>ALLOC_IF</th>
<th>FREE_IF</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>INOUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>OUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>NOCOPY</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

For more information, see Managing Memory Allocation for Pointer Variables.

• ALIGN \( (\text{expression}) \) where the value of \text{expression} should be a power of two.

This modifier applies to pointer variables and requests the specified minimum alignment for pointer data allocated on the target.

• ALLOC \( (\text{array-subscript-list}) \) where \text{array-subscript-list} is a list of array section triplets that specifies a set of elements of an array that need allocation. The \text{array-subscript-list} takes the following form:

\[ \text{start-element} : \text{end-element} [ : \text{stride}] [ , \text{start-element} : \text{end-element} [ : \text{stride}] ]... \]

This modifier can only be used in IN and OUT clauses and only one identifier must be listed in the clause. A one to one correspondence is established between the identifier in the IN or OUT clause and the base variable that will be allocated with \text{array-subscript-list} dimensions.

When ALLOC is specified, the allocation on the target is the same shape as \text{array-subscript-list}. The variable being transferred or allocated must be the same variable used in the ALLOC modifier (\text{identifier or into-identifier}). Only unit strides are allowed in \text{array-subscript-list}. When \text{array-subscript-list} has rank greater than one, the second and subsequent subscript triplet must specify all elements at that dimension. Therefore, \text{array-subscript-list} must describe an array that is simply contiguous. (See CONTIGUOUS.)

Data is transferred into that portion of the array specified by the IN or OUT clauses. Therefore, memory allocation and the data transfer can use separate array slice references.
When the lower bound of the first dimension of array-subscript-list in the ALLOC is greater than the lower bound of the first dimension of identifier, then the memory allocation begins with that element. The memory below the lower bound is unallocated and should not be referenced by the program. This allows a smaller section of the array to be transferred to the target without requiring that the entire array be allocated.

For more information, see Allocating Memory for Parts of Arrays.

• INTO (into-identifier)

where into-identifier is a variable, a subscripted variable, an array slice, or a component reference with the same form, rank, dimensions, and kind type parameters as the identifier in the clause.

This modifier can only be used in IN and OUT clauses and only one identifier must be listed in the clause. When INTO is specified, data can be transferred from one variable on the CPU to another on the target, and vice versa. This establishes a one to one correspondence between a single source variable and a single destination variable.

You can specify ALLOC, ALLOC_IF, and FREE_IF modifiers along with the INTO modifier.

When INTO is used in an IN clause, data is copied from the CPU object identifier to the target object into-identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the into-identifier in the INTO clause.

When INTO is used in an OUT clause, data is copied from the target object into-identifier to the CPU object identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the identifier in the OUT expression.

When this modifier is used, the source expression generates a stream of elements to be copied into the memory range specified by the INTO expression.

If overlap occurs between the source and destination variables, it causes undefined behavior (although with disjoint memories it will work as expected). No ordering can be assumed between transfers from different IN or OUT clauses.

For more information, see Moving Data from One Variable to Another.

The OFFLOAD directive both transfers data and offloads computation.

The OMP is optional in the syntax. When it is present, the next line, other than a comment, must be an OpenMP* PARALLEL, PARALLEL SECTIONS, or PARALLEL DO directive. Otherwise the compiler issues an error.

When OMP is not present in the syntax, the OFFLOAD directive must be followed by one of the following or the compiler issues an error:

• An OpenMP* PARALLEL, PARALLEL SECTIONS, or PARALLEL DO directive
  This specifies remote execution of that top-level OpenMP* construct.
• A CALL statement
  This specifies remote execution of that single procedure call.
• An assignment statement where the right side only executes a function
  This specifies remote execution of that single function invocation.
You can choose whether to offload a statement based on runtime conditions, such as the size of a data set. The IF (if-specifier) clause lets you specify the condition.

The SIGNAL and WAIT clauses refer to a specific target device, so you must specify target-number in the TARGET clause. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

If the if-specifier evaluates to false and a SIGNAL (tag) clause is used in the directive, then the SIGNAL is undefined and any WAIT on this SIGNAL has undefined behavior.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.

For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.

In the data movement clauses (IN, OUT, INOUT, and NOCOPY) and the modifiers ALLOC and INTO, you can specify an array slice of any rank. For an assumed-size dummy array, you can specify the following syntax, interchangeably:

- var:length(k), where k is a scalar integer expression computed at runtime representing the number of elements of var to be moved.
- var(section-subscript-list), where section-subscript-list is a comma-separated list of subscript triplets of the form [ subscripts ] : [ subscripts ] [ : stride ]

**NOTE**

Do not use the __MIC__ preprocessor symbol inside a statement following an OMP OFFLOAD directive. However, you can use it in a subprogram called from the directive.

Conceptually, this is the sequence of events when a statement marked for offload is encountered:

1. If there is no IF clause, go to step 3.
2. On the host, evaluate the IF expression. If it evaluates to true, go to step 3. Otherwise, execute the region on the host and go to step 17.
3. Attempt to acquire the target. If successful, go to step 4. Otherwise:
   - If there is no MANDATORY clause, execute the region on the host and go to step 17.
   - If there is a STATUS clause, set the var to indicate the error and go to step 17.
   - Otherwise, terminate the program with an appropriate error message.
4. On the host, compute all ALLOC_IF, FREE_IF, and element-count-expr expressions used in IN and OUT clauses.
5. On the host, gather all variable values that are inputs to the offload.
6. Send the input values from the host to the target.
7. On the target, allocate memory for variable-length OUT variables.
8. On the target, copy input values into corresponding target variables.
9. On the target, execute the offloaded region.
10. On the target, compute all element-count-expr expressions used in OUT clauses.
11. On the target, gather all variable values that are outputs of the offload.
12. Send output values back from the target to the host.
13. On the host, copy values received into corresponding host variables.
14. If no error occurred on the target, go to step 17.
15. If there is a STATUS clause, set the var to indicate the error and go to step 17.
16. Otherwise, terminate the program with an appropriate error message.
17. Continue processing the program on the host.

Example

The following example demonstrates offloading a CALL statement or assignment statement. Note that !DIR$ OFFLOAD TARGET (MIC) prefixes the statement designated for offload.

! Offload call of routine calc
!DIR$ OFFLOAD TARGET(MIC)
CALL calc(...)

! Offload call of function recalc
!DIR$ OFFLOAD TARGET(MIC)
X = recalc(...)
real, allocatable :: in1(:), in2(:), out1(:), out2(:)

!dir$ end options

integer :: sin1, sin2, sout1, sout2

contains

!dir$ attributes offload:mic ::compute
subroutine compute(x, y)
real, allocatable :: x(:), y(:)
integer :: i

!dir$ omp parallel do num_threads(96) private(i)
do i = 1, count
  y(i) = x(i) * x(i)
end do
end subroutine compute

subroutine do_async_in()

integer :: i

! prime loop with initial in1 transfer to target

!dir$ offload_transfer target(mic:0) signal(sin1) &
in( in1 : alloc_if(.false.) free_if(.false.) )
do i = 1, iter
  if (mod(i,2) == 0) then
    ! initiate another in1 data transfer to target, skip if last iteration
    !dir$ offload_transfer target(mic:0) if(i /= iter) signal(sin1) &
    ! in( in1 : alloc_if(.false.) free_if(.false.) )
  ! wait for in2 transfer to complete, then offload computation
    !dir$ offload target(mic:0) wait(sin2) &
    ! nocopy(in2) &
    ! out( out2 : alloc_if(.false.) free_if(.false.) )
call compute(in2, out2);
  ! use out2 results on host
  call use_result(out2);
  else
    ! initiate another in2 data transfer to target, skip if last iteration

end program main

The following example demonstrates the tag argument:

module mmod
!dir$ attributes offload : mic :: x, y
real :: x (1000) = 1.1
real :: y(1000) = 2.2
integer :: gtag = 1
end module mmod

program mmain
!            compile with symbol name "doGLOB" defined to use a global tag
!            compile with symbol name "doGLOB" undefined to use a local tag
use mmod
integer :: ktag = 2
call f (ktag)
call g (ktag)
print *, (y (j),j=1,1000,100) ! print every 100th element == 5.1
end program mmain

subroutine f (kktag)
use mmod
integer :: kktag
#ifdef doGLOB
!dir$ offload_transfer target (mic:0) signal (gtag) IN(x) ! copy X to MIC, signal when done
#else
!dir$ offload_transfer target (mic:0) signal (kktag) IN(x) ! copy X to MIC, signal when done
#endif
end subroutine f
subroutine g (kktag)
use mmod
integer :: kktag

#ifdef doGLOB
!dir$ offload begin target (mic:0) wait (gtag) OUT (y) ! wait for offload_transfer in f to copy x
#else
!dir$ offload begin target (mic:0) wait (kktag) OUT (y) ! wait for offload_transfer in f to copy x
#endif

y = x + 4                   ! y is all 5.1s
!dir$ end offload
end subroutine g

The following examples demonstrate using the STATUS clause.

Example 1

use mic_lib

type (offload_status) :: stat

!dir$ offload target (mic:1) status (stat)
_                   ! code to be offloaded to the coprocessor
!dir$ end offload

if (stat%result .ne. OFFLOAD_SUCCESS) then
  _                   ! handle the error condition
end if

Example 2

use mic_lib

type (offload_status) :: stat
real :: p (20), q (20)
integer :: my_mic

!dir$ offload_transfer target (mic), status (stat), in (p, q)
if (stat%result == OFFLOAD_OUT_OF_MEMORY) then
  _                   ! memory could not be allocated
else
  _                   ! data has been transferred, can continue using coprocessor
  my_mic = stat%device_number
  !dir$ offload target (mic:my_mic), status (stat)
  _                   ! do offload computation on device that was obtained
end if

Subscript Triplets

**OFFLOAD BEGIN and END OFFLOAD**

**OFFLOAD Compiler Directives:** Enable a group of statements to execute on the target. These directives only apply to Intel® MIC Architecture.

**Syntax**

```fortran
!DIR$ OFFLOAD BEGIN clause[[], clause...]  
block
!DIR$ END OFFLOAD
```

- **clause**
  See the description of all clauses in **OFFLOAD**.

- **block**
  Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

These directives provide the same functionality as the OFFLOAD directive, except that they let you offload a block of code that includes any number of Fortran statements, including DO, CALL and any assignments, but not OpenMP* directives.

The OFFLOAD BEGIN directive must be paired with a closing END OFFLOAD directive. See **OFFLOAD** for complete details on clauses and behavior.

**Example**

In the following example, the DO loop is designated for offloading.

```fortran
subroutine sample()
 ...
!DIR$ OFFLOAD BEGIN TARGET(MIC)
   do i = 1, n
      a(i) = b(i) ** 2.0
   enddo
!DIR$ END OFFLOAD
 ...
end subroutine sample
```

See **OFFLOAD** for further examples.

**OFFLOAD_TRANSFER**

**OFFLOAD Compiler Directive:** Initiates asynchronous data transfer, or initiates and completes synchronous data transfer. The action performed depends on the whether SIGNAL is specified. This directive only applies to Intel® MIC Architecture.

**Syntax**

```fortran
!DIR$ OFFLOAD_TRANSFER clause[[], clause...]  
```

- **clause**
  Can be any of the following:
  - `TARGET (target-name [:target-number])`
  - `IF (if-specifier)`

  An optional clause. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.
Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

- **SIGNAL** *(tag)*
  
  An optional clause. Include it to enable asynchronous data transfer, meaning that data transfers are initiated, and the CPU can continue executing after initiating the OFFLOAD_TRANSFER. When you don’t include it, data transfer is synchronous.
  
  SIGNAL is device specific; if you use this clause, you must specify a *target-number* >=0 in the TARGET clause.

- **WAIT** *(tag [, tag, ...]*)
  
  An optional clause. Include it to specify a wait for completion of a previously initiated asynchronous data transfer or asynchronous computation.
  
  WAIT is device specific; if you use this clause, you must specify a *target-number* >=0 in the TARGET clause.

- **MANDATORY**
  
  An optional clause. Include it to specify that execution on the coprocessor is required. Execution on the CPU is not allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message.
  
  You cannot specify both MANDATORY and OPTIONAL since they are opposites.
  
  If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **OPTIONAL**
  
  An optional clause. Include it to specify that execution on the coprocessor is requested but not required. Execution on the CPU is allowed. If the correct target hardware needed to run the offloaded code is not available on the system, the program is executed on the CPU, not the TARGET.
  
  You cannot specify both MANDATORY and OPTIONAL since they are opposites.
  
  If OPTIONAL is not specified for this directive and it is not specified in option [q or Q]offload, then MANDATORY is implied. You can explicitly specify MANDATORY to reinforce this implied default.

- **STATUS** *(var)*
  
  An optional clause. Include it to determine the status of the execution of an offloading construct. When used with the OPTIONAL or MANDATORY clause, the STATUS clause also lets you modify the action to take upon failure.
  
  *var* is of derived type *offload_status* defined in *mic_lib.mod*. This status variable can be queried for details about the offload. The module *mic_lib.mod* is provided and contains the following definitions:

```fortran
use, intrinsic :: iso_c_binding
enum , bind (C)
```
<table>
<thead>
<tr>
<th>Enumerator</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD_SUCCESS</td>
<td>0</td>
</tr>
<tr>
<td>OFFLOAD_DISABLED</td>
<td>1</td>
</tr>
<tr>
<td>OFFLOAD_UNAVAILABLE</td>
<td>2</td>
</tr>
<tr>
<td>OFFLOAD_OUT_OF_MEMORY</td>
<td>3</td>
</tr>
<tr>
<td>OFFLOAD_PROCESS_DIED</td>
<td>4</td>
</tr>
<tr>
<td>OFFLOAD_ERROR</td>
<td>5</td>
</tr>
</tbody>
</table>

```fortran
type, bind (C) :: offload_status
  integer(kind=integer) :: result = OFFLOAD_DISABLED ! result, see enum above
  integer(kind=integer) :: device_number = -1 ! device number
  integer(kind=integer) :: data_sent = 0 ! number of bytes sent to the target
  integer(kind=integer) :: data_received = 0 ! number of bytes received by host
end type offload_status
```

When you specify STATUS with the MANDATORY clause, and the offload cannot be performed, the construct is not automatically executed on the host. The program continues execution. You should examine var for the cause of the offload failure and take appropriate action. Note that if no STATUS clause is specified, then the program is terminated.

When you specify STATUS with the OPTIONAL clause, and the offload cannot be performed, the construct is executed on the host processor. You can examine the var in the STATUS clause to determine the cause of the offload failure.

- `offload-parameter [*,] offload-parameter`
  One or more data movement clauses (see below).

The following arguments are used in the above `clause` items:

- **target-name**
  Is an identifier that represents the target. The only allowable target name is MIC.

- **target-number**
  (Required for SIGNAL and WAIT) Is an integer expression whose value is interpreted as shown in the following table.

When `target-number` is specified, the implicit MANDATORY offload is overridden and execution on the CPU is allowed when either the OPTIONAL clause is also specified or optional is also specified in option [q or Q] offload.

-1

This value specifies execution on the coprocessor. The runtime system chooses the specific coprocessor. Execution on the CPU is not allowed.

If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL
clause is also specified or optional
is also specified in option [q or Q]offload.

This value is not allowed if you specify the SIGNAL or WAIT clause.

\[ \geq 0 \]

A value greater than or equal to zero specifies execution on a specific coprocessor. The number of the specific coprocessor is determined as follows:

\[ \text{coprocessor} = \text{MOD} (\text{target-number}, \text{number_of_copros}) \]

If the correct target hardware needed to run the offloaded code is not available on the system, the program fails with an error message. Execution on the CPU is allowed when the OPTIONAL clause is also specified or optional is also specified in option [q or Q]offload.

\[ < -1 \]

These values are reserved.

If you don’t specify the target-number argument, the runtime system executes the code on the coprocessor, and if multiple coprocessors are available, on which coprocessor. If no coprocessor is available, the program fails with an error message.

For example, in a system with 4 coprocessors:

- Specifying 2 or 6 tells the runtime systems to use coprocessor 2 for the transfer, because both MOD(2,4) and MOD(6,4) equal 2.
- Specifying 1000 tells the runtime systems to use coprocessor 0 for the transfer, because MOD(1000,4) = 0.

**if-specifier**

Is a Boolean expression.

If the expression evaluates to true, then the data transfer specified by the directive occurs. If the specified target coprocessor is absent from the system or not available at that time because it is fully loaded, then no action is taken.

If the expression evaluates to false, then no action is taken and none of the other offload clauses have any effect.

**tag**

Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.

When used with SIGNAL, tag is an integer value associated with an asynchronous computation or an asynchronous data transfer. tag can be used in subsequent WAIT clauses in other OFFLOAD, OFFLOAD_TRANSFER, or OFFLOAD_WAIT directives.
When used with WAIT, tag is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same tag that you specified in the SIGNAL clause that started the asynchronous computation or data transfer with the OFFLOAD or OFFLOAD_TRANSFER directive.

**offload-parameter**

Can be any of the following data movement clauses:

- **IN** (identifier[, identifier...] [: modifier[[], modifier...] ] )
- **OUT** (identifier[, identifier...] [: modifier[[], modifier...] ] )
- **NOCOPY** (identifier[, identifier...] [: modifier[[], modifier...] ] )

When a program runs in a heterogeneous environment, program variables are copied back and forth between the CPU and the target. The **offload-parameter** is a specification for controlling the direction in which variables are copied, and for pointers, the amount of data that is copied.

<table>
<thead>
<tr>
<th><strong>IN</strong></th>
<th>This indicates that the variable is strictly an input to the target region and it is copied from the CPU to the coprocessor. Its value is not copied back from the coprocessor to the CPU after the region completes.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OUT</strong></td>
<td>This indicates that the variable is strictly an output of the target region. The host CPU does not copy the variable to the target coprocessor. It is copied from the coprocessor to the CPU.</td>
</tr>
<tr>
<td><strong>NOCOPY</strong></td>
<td>This indicates that the variable should not be copied. A variable whose value is reused from the last target execution or one that is used entirely within the offloaded code section may be named in a NOCOPY clause to avoid any copying. Memory is allocated on the coprocessor for the variable.</td>
</tr>
</tbody>
</table>

This clause is required. It must not contain both an IN clause and an OUT clause.

An **IN** or **OUT** **element-count-exp** expression (see description below within **modifier**) is evaluated at a point in the program before the statement or clause in which it is used.

An array variable whose size is known from its declaration is copied in its entirety. If a subset of an array is to be processed, use the name of the starting element of the subset and the **element-count-exp** to transfer the array subset.
identifier

Is a variable, a subscripted variable, an array slice, or a component reference. The variable or the component reference may have the ALLOCATABLE or POINTER attribute. An array slice may be contiguous or non-contiguous.

modifier

Is one of the following:

- **LENGTH** (element-count-expr)

  where element-count-expr is an integer expression, computed at runtime. Use it with:

  - Integer pointer variables (not Fortran 90 POINTERs)

    Pointer variable values themselves are never copied across the host/target interface because there is no correspondence between the memory addresses of the host CPU and the target. Instead, objects that an integer pointer points to are copied to or from the target, and the value of the pointer variable is recreated. By default, a single element is copied.

    Use element-count-expr to specify how many elements pointed to should be considered as data. If the expression value is zero or negative, the program fails with an error message.

  - Arrays (including assumed-size)

    element-count-expr specifies a number of elements copied between the CPU and target.

    A Fortran array variable can be one of four major types: explicit-shape, assumed-shape, deferred-shape and assumed-size. The runtime descriptor for the first three types makes that array variable's size known at compile time or at runtime. The last dimension of an assumed-size array is the length of its variable.

    By default, the compiler copies explicit-shape, assumed-shape and deferred-shape arrays in their entirety. They do not need an element-count-expr. However, you can use an optional element-count-expr to specify the total number of elements to copy, which limits the number of elements copied back and forth in the last dimension of the array.

    You must specify an assumed-size array with an element-count-expr specification, because the compiler does not know the total size of the array. The value of the element-count-expr is the total number of elements of the array to be copied.

- **ALLOC_IF** (condition) | **FREE_IF** (condition)

  where condition is a Boolean expression.

  The ALLOC_IF modifier specifies a Boolean condition that controls whether the allocatable variables in the IN clause will be allocated a new block of memory on the target when the offload is executed on the target. If the expression evaluates to true, a new memory allocation is performed for each variable listed in the clause. If the condition evaluates to false, the existing allocated values on the target are reused. You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a FREE_IF(.FALSE.) clause on an earlier offload.

  The FREE_IF modifier specifies a Boolean condition that controls whether to deallocate the memory allocated for the allocatable variables in an IN clause. If the expression evaluates to true, the memory pointed to by
each variable listed in the clause is deallocated. If the condition evaluates to false, no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory (data persistence).

The following are the default settings for ALLOC_IF and FREE_IF:

<table>
<thead>
<tr>
<th></th>
<th>ALLOC_IF</th>
<th>FREE_IF</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>INOUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>OUT</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>NOCOPY</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

For more information, see Managing Memory Allocation for Pointer Variables.

- **ALIGN** *(expression)*

  where the value of expression should be a power of two.

  This modifier applies to pointer variables and requests the specified minimum alignment for pointer data allocated on the target.

- **ALLOC** *(array-subscript-list)*

  where array-subscript-list is a list of array section triplets that specifies a set of elements of an array that need allocation. The array-subscript-list takes the following form:

  \[
  \text{start-element : end-element [ : stride] [ , start-element : end-element [ : stride] ]...}
  \]

  This modifier can only be used in IN and OUT clauses and only one identifier must be listed in the clause. A one to one correspondence is established between the identifier in the IN or OUT clause and the base variable that will be allocated with array-subscript-list dimensions.

  When ALLOC is specified, the allocation on the target is the same shape as array-subscript-list. The variable being transferred or allocated must be the same variable used in the ALLOC modifier (identifier or into-identifier). Only unit strides are allowed in array-subscript-list. When array-subscript-list has rank greater than one, the second and subsequent subscript triplet must specify all elements at that dimension. Therefore, array-subscript-list must describe an array that is simply contiguous. (See CONTIGUOUS.)

  Data is transferred into that portion of the array specified by the IN or OUT clauses. Therefore, memory allocation and the data transfer can use separate array slice references.

  When the lower bound of the first dimension of array-subscript-list in the ALLOC is greater than the lower bound of the first dimension of identifier, then the memory allocation begins with that element. The memory below the lower bound is unallocated and should not be referenced by the program. This allows a smaller section of the array to be transferred to the target without requiring that the entire array be allocated.

  For more information, see Allocating Memory for Parts of Arrays.

- **INTO** *(into-identitier)*
where into-identifier is a variable, a subscripted variable, an array slice, or a component reference with the same form, rank, dimensions, and kind type parameters as the identifier in the clause.

This modifier can only be used in IN and OUT clauses and only one identifier must be listed in the clause. When INTO is specified, data can be transferred from one variable on the CPU to another on the target, and vice versa. This establishes a one to one correspondence between a single source variable and a single destination variable.

You can specify ALLOC, ALLOC_IF, and FREE_IF modifiers along with the INTO modifier.

When INTO is used in an IN clause, data is copied from the CPU object identifier to the target object into-identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the into-identifier in the INTO clause.

When INTO is used in an OUT clause, data is copied from the target object into-identifier to the CPU object identifier. If the ALLOC_IF, FREE_IF, or ALLOC modifier is specified, it applies only to the identifier in the OUT expression.

When this modifier is used, the source expression generates a stream of elements to be copied into the memory range specified by the INTO expression.

If overlap occurs between the source and destination variables, it causes undefined behavior (although with disjoint memories it will work as expected). No ordering can be assumed between transfers from different IN or OUT clauses.

For more information, see Moving Data from One Variable to Another.

This directive initiates asynchronous data transfer if SIGNAL is specified. If SIGNAL is not specified, it initiates and completes synchronous data transfer.

You can choose whether to offload a statement based on runtime conditions, such as the size of a data set. The IF (if-specifier) clause lets you specify the condition.

Use SIGNAL (tag) to start the asynchronous computation.

The SIGNAL and WAIT clauses refer to a specific target device, so you must specify target-number in the TARGET clause. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

If the if-specifier evaluates to false and a SIGNAL (tag) clause is used in the directive, then the SIGNAL is undefined and any WAIT on this SIGNAL has undefined behavior.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.

See Example 2 in the OFFLOAD Examples section for an example showing how to use offload_status to identify the target-number value when using -1, or when target-number is not specified.

For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.
In the data movement clauses (IN, OUT, INOUT, and NOCOPY) and the modifiers ALLOC and INTO, you can specify an array slice of any rank. For an assumed-size dummy array, you can specify the following syntax, interchangeably:

- `var:length(k)`, where `k` is a scalar integer expression computed at runtime representing the number of elements of `var` to be moved.
- `var(section-subscript-list)`, where `section-subscript-list` is a comma-separated list of subscript triplets of the form `[ subscript ] : [ subscript ] [ : stride ]`

OFFLOAD

OFFLOAD_WAIT

About Asynchronous Data Transfer

About Asynchronous Computation

Writing Target-Specific Code Using a Directive

Dealing with Multiple Coprocessors in a System

Subscript Triplets

**OFFLOAD_WAIT**

**OFFLOAD Compiler Directive:** Specifies a wait for a previously initiated asynchronous activity. This directive only applies to Intel® MIC Architecture.

**Syntax**

```
!DIR$ OFFLOAD_WAIT clause[[,] clause...]
```

`clause` Can be any of the following:

- **TARGET** `(target-name :target-number)`
- **IF** `(if-specifier)`
  
  An optional `clause`. Include it to allow a test at execution time for whether or not the executable should try to offload the statement.

  Use the IF clause to control whether the offload is enabled. All OFFLOAD directives that have data dependencies should use the IF clause in a coordinated fashion, so that either all or none of the related offloads are enabled.

- **WAIT** `(tag [, tag, ...])`
  
  A required `clause`. It specifies a wait until a previously initiated asynchronous data transfer or asynchronous computation is completed.

  `WAIT` is device specific; if you use this clause, you must specify a `target-number >=0` in the TARGET clause.

- **STATUS** `(var)`
  
  An optional `clause`. Include it to determine the status of the execution of an offloading construct.
var is of derived type offload_status defined in mic_lib.mod. This status variable can be queried for details about the offload. The module mic_lib.mod is provided and contains the following definitions:

```fortran
use, intrinsic :: iso_c_binding
enum , bind (C)
    enumerator :: OFFLOAD_SUCCESS         = 0
    enumerator :: OFFLOAD_DISABLED        = 1  ! offload is disabled
    enumerator :: OFFLOAD_UNAVAILABLE     = 2  ! card is not available
    enumerator :: OFFLOAD_OUT_OF_MEMORY   = 3  ! not enough memory on device
nenumber :: OFFLOAD_PROCESS_DIED       = 4  ! target process has died
    enumerator :: OFFLOAD_ERROR           = 5  ! unspecified error
end enum

type, bind (C) :: offload_status
    integer(kind=c_int) ::  result        = OFFLOAD_DISABLED   ! result, see enum above
    integer(kind=c_int) ::  device_number = -1  ! device number
    integer(kind=c_int) ::  data_sent     =  0  ! number of bytes sent to the target
    integer(kind=c_int) ::  data_received =  0  ! number of bytes received by host
end type offload_status
```

The following arguments are used in the above clause items:

**target-name**

Is an identifier that represents the target. The only allowable target name is MIC.

**target-number**

Is a required integer expression whose value is interpreted as follows:

- **>= 0**
  
  A value greater than or equal to zero specifies execution on a specific coprocessor. The number of the specific coprocessor is determined as follows:

  \[ \text{coprocessor} = \text{MOD} \left( \text{target-number}, \text{number_of_copros} \right) \]

- **<= -1**
  
  These values are reserved.

For example, in a system with 4 coprocessors:

- Specifying 2 or 6 tells the runtime systems to use coprocessor 2 for the transfer, because both MOD(2,4) and MOD(6,4) equal 2.
- Specifying 1000 tells the runtime systems to use coprocessor 0 for the transfer, because MOD(1000,4) = 0.

**if-specifier**

Is a Boolean expression.

If the expression evaluates to true, then execution waits for the completion of a previously initiated asynchronous data transfer or asynchronous computation. If the specified target coprocessor is absent from the system or not available at that time because it is fully loaded, then no action is taken.
If the expression evaluates to false, then no action is taken and none of the other offload clauses have any effect.

tag

Is a scalar integer expression. Its value is used to coordinate an asynchronous computation or an asynchronous data transfer.

When used with WAIT, tag is an integer value associated with a previously initiated asynchronous computation or asynchronous data transfer. Use the same tag that you specified in the SIGNAL clause that started the asynchronous computation or data transfer with the OFFLOAD or OFFLOAD_TRANSFER directive.

The OFFLOAD_WAIT directive specifies a wait for the completion of a previously initiated asynchronous data transfer performed by the OFFLOAD_TRANSFER directive, or an asynchronous computation and return data transfer, if any, performed by the OFFLOAD directive.

The WAIT clause refers to a specific target device, so you must specify target-number in the TARGET clause. The signal associated with tag is cleared following completion of the previously initiated asynchronous data transfer or asynchronous computation. If you query a signal before the signal has been initiated, it results in undefined behavior and a runtime abort of the application. For example, if you query a signal (SIG1) on target device 0 that was initiated for target device 1, it results in a runtime abort of the application. This is because the signal (SIG1) was initiated for target device 1, so there is no signal (SIG1) associated with target device 0.

When you specify the STATUS clause, it affects the behavior of optional and mandatory offloads differently when the offload request is not successful:

- For an optional offload, the computation is performed on the CPU and the status variable has an appropriate value.
- For a mandatory offload, there is no CPU fallback. The program does not terminate. You must examine the value of the status variable, determine the reason the offload failed, and decide what action to take.

For both optional and mandatory offloads, when offload is successful, the status variable has the value OFFLOAD_SUCCESS.

Example

See the examples in OFFLOAD.

OPEN

Statement: Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.

Syntax

OPEN ([UNIT=] io-unit[, FILE= name] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var], slist)
io-unit

Is an external unit specifier.

name

Is a character or numeric expression specifying the name of the file to be connected. For more information, see FILE Specifier.

label

Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

msg-var

Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

i-var

Is a scalar integer variable that is defined as a positive integer (the number of the error message) if an error occurs, a negative integer if an end-of-file record is encountered, and zero if no error occurs. For more information, see I/O Status Specifier.

slist

Is one or more of the following OPEN specifiers in the form specifier= value or specifier (each specifier can appear only once):

<table>
<thead>
<tr>
<th>SPECIFIER</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>ACTION</td>
<td>DEFAULTFILE</td>
</tr>
<tr>
<td>ASSOCIATIVEVAR</td>
<td>DELIM</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>DISPOSE</td>
</tr>
<tr>
<td>BLANK</td>
<td>ENCODING</td>
</tr>
<tr>
<td>BLOCKSIZE</td>
<td>FILE</td>
</tr>
<tr>
<td>BUFFERCOUNT</td>
<td>FORM</td>
</tr>
<tr>
<td>BUFFERED</td>
<td>IOFOCUS</td>
</tr>
<tr>
<td>CARRIAGECONTROL</td>
<td>MAXREC</td>
</tr>
<tr>
<td>CONVERT</td>
<td>MODE</td>
</tr>
<tr>
<td>CONVERSION</td>
<td>RECL</td>
</tr>
<tr>
<td>STATUS</td>
<td>RECURRENTSIZE</td>
</tr>
<tr>
<td>TITLE</td>
<td>USEROPEN</td>
</tr>
</tbody>
</table>

The OPEN specifiers and their acceptable values are summarized in the OPEN Statement Overview.

The control specifiers that can be specified in an OPEN statement are discussed in I/O Control List in the Language Reference.

Description

The control specifiers ([UNIT=] io-unit, ERR= label, and IOSTAT= i-var) and OPEN specifiers can appear anywhere within the parentheses following OPEN. However, if the UNIT specifier is omitted, the io-unit must appear first in the list.

If you specify BLANK=, DECIMAL=, PAD=, ROUND=, or SIGN=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Specifier values that are scalar numeric expressions can be any integer or real expression. The value of the expression is converted to integer data type before it is used in the OPEN statement.
If the NEWUNIT= specifier does not appear, an io-unit must be specified. If the keyword UNIT= is omitted, the io-unit must be first in the control list.

If the NEWUNIT= specifier appears, an io-unit must not be specified.

If the NEWUNIT= specifier appears, either the FILE= specifier or the STATUS=SCRATCH specifier must also appear.

Only one unit at a time can be connected to a file, but multiple OPENs can be performed on the same unit. If an OPEN statement is executed for a unit that already exists, the following occurs:

- If FILE is not specified, or FILE specifies the same file name that appeared in a previous OPEN statement, the current file remains connected.
  
  If the file names are the same, the values for the BLANK, CARRIAGECONTROL, CONVERT, DELIM, DISPOSE, ERR, IOSTAT, and PAD specifiers can be changed. Other OPEN specifier values cannot be changed, and the file position is unaffected.

- If FILE specifies a different file name, the previous file is closed and the new file is connected to the unit.

The ERR and IOSTAT specifiers from any previously executed OPEN statement have no effect on any currently executing OPEN statement. If an error occurs, no file is opened or created.

Secondary operating system messages do not display when IOSTAT is specified. To display these messages, remove IOSTAT or use a platform-specific method.

**Example**

You can specify character values at run time by substituting a character expression for a specifier value in the OPEN statement. The character value can contain trailing blanks but not leading or embedded blanks; for example:

```fortran
CHARACTER*6 FINAL / ' '/
...
IF (expr) FINAL = 'DELETE'
   OPEN (UNIT=1, STATUS='NEW', DISP=FINAL)
```

The following statement creates a new sequential formatted file on unit 1 with the default file name fort.1:

```fortran
OPEN (UNIT=1, STATUS='NEW', ERR=100)
```

The following example opens the existing file /usr/users/someone/test.dat:

```fortran
OPEN (unit=10, DEFAULTFILE='/usr/users/someone/', FILE='test.dat',
     FORM='FORMATTED', STATUS='OLD')
```

The following example opens a new file:

```fortran
! Prompt user for a filename and read it:
CHARACTER*64 filename
WRITE (*, '(A)') ' enter file to create: '
READ (*, '(A)') filename
! Open the file for formatted sequential access as unit 7.
! Note that the specified access need not have been specified,
! since it is the default (as is "formatted").
OPEN (7, FILE = filename, ACCESS = 'SEQUENTIAL', STATUS = 'NEW')
```

The following example opens an existing file called DATA3.TXT:

```fortran
! Open a file created by an editor, "DATA3.TXT", as unit 3:
OPEN (3, FILE = 'DATA3.TXT')
```

CLOSE  
FORMAT
OPTIONAL

Statement and Attribute: Permits dummy arguments to be omitted in a procedure reference.

Syntax

The OPTIONAL attribute can be specified in a type declaration statement or an OPTIONAL statement, and takes one of the following forms:

Type Declaration Statement:

\[ \text{type},\{\text{att-ls},\} \text{ OPTIONAL } [\{,\text{att-ls}\} :: \text{d-arg}, \text{d-arg}] \ldots \]

Statement:

\[ \text{OPTIONAL } [:: \text{d-arg}, \text{d-arg}] \ldots \]

- \text{type} is a data type specifier.
- \text{att-ls} is an optional list of attribute specifiers.
- \text{d-arg} is the name of a dummy argument.

Description

The OPTIONAL attribute can only appear in the scoping unit of a subprogram or an interface body, and can only be specified for dummy arguments. It cannot be specified for arguments that are passed by value.

A dummy argument is "present" if it associated with an actual argument that is itself present. A dummy argument that is not optional must be present. You can use the PRESENT intrinsic function to determine whether an optional dummy argument is associated with an actual argument.

To call a procedure that has an optional argument, you must use an explicit interface.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Example

The following example shows a type declaration statement specifying the OPTIONAL attribute:

```plaintext
SUBROUTINE TEST(A)
REAL, OPTIONAL, DIMENSION(-10:2) :: A
END SUBROUTINE
```

The following is an example of the OPTIONAL statement:

```plaintext
SUBROUTINE TEST(A, B, L, X)
  INTEGER A, B, L, X
  IF (PRESENT(B)) THEN        ! Printing of B is conditional
    PRINT *, A, B, L, X       ! on its presence
  ELSE
    PRINT *, A, L, X
  ENDIF
END SUBROUTINE
```

INTERFACE

```plaintext
SUBROUTINE TEST(ONE, TWO, THREE, FOUR)
```

```plaintext
39
```

```plaintext
1681
```
INTEGER ONE, TWO, THREE, FOUR
OPTIONAL :: TWO
END SUBROUTINE
END INTERFACE

INTEGER I, J, K, L
I = 1
J = 2
K = 3
L = 4
CALL TEST(I, J, K, L) ! Prints: 1 2 3 4
CALL TEST(I, THREE=K, FOUR=L) ! Prints: 1 3 4
END

Note that in the second call to subroutine TEST, the second positional (optional) argument is omitted. In this case, all following arguments must be keyword arguments.

The following shows another example:

SUBROUTINE ADD (a, b, c, d)
  REAL a, b, d
  REAL, OPTIONAL :: c
  IF (PRESENT(c)) THEN
    d = a + b + c + d
  ELSE
    d = a + b + d
  END IF
END SUBROUTINE

Consider the following:

SUBROUTINE EX (a, b, c)
  REAL, OPTIONAL :: b, c

This subroutine can be called with any of the following statements:

CALL EX (x, y, z) !All 3 arguments are passed.
CALL EX (x) !Only the first argument is passed.
CALL EX (x, c=z) !The first optional argument is omitted.

Note that you cannot use a series of commas to indicate omitted optional arguments, as in the following example:

CALL EX (x,,z) !Invalid statement.

This results in a compile-time error.

Type Declarations

OPTIONS Statement
Statement: Overrides or confirms the compiler options in effect for a program unit.

Syntax
OPTIONS option[option...]
The OPTIONS statement must be the first statement in a program unit, preceding the PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

OPTIONS statement options override compiler options, but only until the end of the program unit for which they are defined. If you want to override compiler options in another program unit, you must specify the OPTIONS statement before that program unit.

**Example**

The following are valid OPTIONS statements:

```
OPTIONS /CHECK=ALL/F77
OPTIONS /I4
```

**See Also**

OPEN Statement CONVERT Method
OPTIONS Statement Method

For details on compiler options, see your *Compiler Options* reference

**OPTIMIZE and NOOPTIMIZE**

*General Compiler Directive: Enables or disables optimizations for the program unit.*
Syntax

!DIR$ OPTIMIZE[: n]

!DIR$ NOOPTIMIZE

Is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options 00, 01, 02, and 03. If n is omitted, the default is 2, which corresponds to option 02.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to −O0 (Linux* OS and OS X*) and /Od (Windows* OS).

The procedure is compiled with an optimization level equal to the smaller of n and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with compiler option 03, this procedure is compiled at 00 while the rest of the program is compiled at 03.

Syntax Rules for Compiler Directives
O

OPTIONS Directive

General Compiler Directive: Affects data alignment and warnings about data alignment. Also controls whether a target attribute is assigned to a section of program declarations.

Syntax

!DIR$ OPTIONS option[option]

...

!DIR$ END OPTIONS

Is one (or more) of the following:

/  
OFFLOAD_ATTRIBUTE  
_TARGET=target-name

Controls whether a target attribute is assigned to a section of program declarations. The declarations can contain interface definitions and variable declarations. The directive option must appear within each INTERFACE block. This option enables statements to execute on the target.

Currently, the only supported value for target-name is mic.

This option is useful for properly declaring variables and function names used in offloaded code within the subprogram in which the directive appears. You cannot use it for offloading a complete routine.
WARN=[NO]ALIGNMENT

Controls whether warnings are issued by the compiler for data that is not naturally aligned. By default, you receive compiler messages when misaligned data is encountered (/WARN=ALIGNMENT).

/[NO]ALIGN=[p]

Controls alignment of fields in record structures and data items in common blocks. The fields and data items can be naturally aligned (for performance reasons) or they can be packed together on arbitrary byte boundaries.

p

Is a specifier with one of the following forms:

[class=]rule

[class= rule,...]

ALL

NONE

class

Is one of the following keywords:

• COMMONS: For common blocks
• RECORDS: For records
• STRUCTURES: A synonym for RECORDS

rule

Is one of the following keywords:

PACK

Packs fields in records or data items in common blocks on arbitrary byte boundaries.

ED

NATURAL

Naturally aligns fields in records and data items in common blocks on up to 64-bit boundaries (inconsistent with the Standard Fortran).
This keyword causes the compiler to naturally align all data in a common block, including INTEGER(KIND =8), REAL(KIND=8), and all COMPLEX data.

**STANDARD** Naturally aligns data items in common blocks on up to 32-bit boundaries (consistent with the Standard Fortran).

This keyword only applies to common blocks; so, you can specify / ALIGN=COMMONS=STANDARD, but you cannot specify / ALIGN=STANDARD.

**ALL** Is the same as specifying OPTIONS / ALIGN, OPTIONS / ALIGN=NATURAL, and OPTIONS / ALIGN=(RECORDS=NATURAL,COMMONS=NATURAL).

**NONE** Is the same as specifying OPTIONS / NOALIGN, OPTIONS / ALIGN=PACKED, and OPTIONS / ALIGN=(RECORDS=PACKED,COMMONS=PACKED).
The OPTIONS (and accompanying END OPTIONS) directives must come after OPTIONS, SUBROUTINE, FUNCTION, and BLOCK DATA statements (if any) in the program unit, and before the executable part of the program unit.

The OPTIONS directive supersedes compiler option align.

For performance reasons, Intel® Fortran aligns local data items on natural boundaries. However, EQUIVALENCE, COMMON, RECORD, and STRUCTURE data declaration statements can force misaligned data. If /WARN=NOALIGNMENT is specified, warnings will not be issued if misaligned data is encountered.

**NOTE**

Misaligned data significantly increases the time it takes to execute a program. As the number of misaligned fields encountered increases, so does the time needed to complete program execution. Specifying /ALIGN (or compiler option align) minimizes misaligned data.

If you want aligned data in common blocks, do one of the following:

- Specify OPTIONS /ALIGN=COMMONS=STANDARD for data items up to 32 bits in length.
- Specify OPTIONS /ALIGN=COMMONS=NATURAL for data items up to 64 bits in length.
- Place source data declarations within the common block in descending size order, so that each data item is naturally aligned.

If you want packed, unaligned data in a record structure, do one of the following:

- Specify OPTIONS /ALIGN=RECORDS=PACKED.
- Place source data declarations in the record structure so that the data is naturally aligned.

**Example**

```fortran
! directives can be nested up to 100 levels
!DIR$ OPTIONS /ALIGN=PACKED     ! Start of Group A
declarations
!DIR$ OPTIONS /ALIGN=RECO=NATU     ! Start of nested Group B
more declarations
!DIR$ END OPTIONS                  ! End of Group B
still more declarations
!DIR$ END OPTIONS               ! End of Group A
```

The OPTIONS specification for Group B only applies to RECORDS; common blocks within Group B will be PACKED. This is because COMMONS retains the previous setting (in this case, from the Group A specification).

In the following example that applies to Intel® MIC Architecture only, the target attribute is passed to function h and real variables a and b.

```fortran
SUBROUTINE f(x)
REAL x
INTERFACE
    SUBROUTINE g(y)
    REAL y
    END SUBROUTINE g
END INTERFACE
!DIR$ OPTIONS /OFFLOAD_ATTRIBUTE_TARGET=mic
INTERFACE
    FUNCTION h (z)
    REAL z
    END FUNCTION h
END INTERFACE
REAL a, b
```
The following example demonstrates incorrect usage of the Intel® MIC Architecture directive.

```
!DIR$ OPTIONS /OFFLOAD_ATTRIBUTE_TARGET=mic
SUBROUTINE INVALID()
...
END SUBROUTINE INVALID
!DIR$ END OPTIONS
```

qoffload-attribute-target, Qoffload-attribute-target compiler option

OR

**Elemental Intrinsic Function (Generic):** Performs a bitwise inclusive OR on its arguments.

**Example**

```fortran
INTEGER i
i = OR(3, 10)   ! returns 11
```

See Also

See IOR.

ORDERED

**OpenMP® Fortran Compiler Directive:** Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.

**Syntax**

```
!$OMP ORDERED [clause [,[,] clause ]]  
block  
!$OMP END ORDERED
```

clause

Is an optional clause. It can be one or more of the following:

- **SIMD**
  Applies an ordered region inside a SIMD loop.
- **THREADS**
  Applies an ordered region inside a PARALLEL DO loop. If no clause is specified, the directive behaves as if THREADS was specified.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The binding thread set for an ORDERED construct is the current team. An ordered region binds to the innermost enclosing loop region.

An ORDERED directive with no clause or with the THREADS clause specified can appear only in the dynamic extent of a DO or PARALLEL DO directive. The DO directive to which the ordered section binds must have the ORDERED clause specified.
An iteration of a loop using a DO directive must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.

One thread is allowed in an ordered section at a time. Threads are allowed to enter in the order of the loop iterations. No thread can enter an ordered section until it can be guaranteed that all previous iterations have completed or will never execute an ordered section. This sequentializes and orders code within ordered sections while allowing code outside the section to run in parallel.

Ordered sections that bind to different DO directives are independent of each other.

If the SIMD clause is specified, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

**Example**

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
END DO
... 
SUBROUTINE WORK(K)
!$OMP ORDERED
WRITE(*,*) K
!$OMP END ORDERED
```

**OUTGTEXT (W*S)**

_Graphics Subroutine_: In graphics mode, sends a string of text to the screen, including any trailing blanks.

**Module**

USE IFQWIN

**Syntax**

CALL OUTGTEXT (text)

_text_ (Input) Character*(*). String to be displayed.

Text output begins at the current graphics position, using the current font set with SETFONT and the current color set with SETCOLORRGB or SETCOLOR. No formatting is provided. After it outputs the text, OUTGTEXT updates the current graphics position.

Before you call OUTGTEXT, you must call the INITIALIZEFONTS function.

Because OUTGTEXT is a graphics function, the color of text is affected by the SETCOLORRGB function, not by SETTEXTCOLORRGB.

**Example**

! build as a QuickWin App.
USE IFQWIN
INTEGER(2) result
INTEGER(4) i
TYPE (xycoord) xys
result = INITIALIZEFONTS()
result = SETFONT('t''Arial''h18w10pvib')
do i=1,6
  CALL MOVETO(INT2(0),INT2(30*(i-1)),xys)
gstat=SETCOLOR(INT2(i))
  CALL OUTGTEXT('This should be ')
  SELECT CASE (i)
  CASE (1)
    CALL OUTGTEXT('Blue')
  CASE (2)
    CALL OUTGTEXT('Green')
  CASE (3)
    CALL OUTGTEXT('Cyan')
  CASE (4)
    CALL OUTGTEXT('Red')
  CASE (5)
    CALL OUTGTEXT('Magenta')
  CASE (6)
    CALL OUTGTEXT('Orange')
  END SELECT
end do
end

WRITE Statement
WRAPON (W*S)

PACK Function
Transformational Intrinsic Function (Generic):
Takes elements from an array and packs them into a
rank-one array under the control of a mask.

Syntax
result = PACK (array, mask[, vector])

array (Input) Must be an array. It may be of any data type.

mask (Input) Must be of type logical and conformable with array. It determines
which elements are taken from array.

vector (Input; optional) Must be a rank-one array with the same type and type
parameters as array. Its size must be at least t, where t is the number of
true elements in mask. If mask is a scalar with value true, vector must
have at least as many elements as there are in array.

Elements in vector are used to fill out the result array if there are not
enough elements selected by mask.

Results
The result is a rank-one array with the same type and kind parameters as array. If vector is present, the size
of the result is that of vector. Otherwise, the size of the result is the number of true elements in mask, or the
number of elements in array (if mask is a scalar with value true).

Elements in array are processed in array element order to form the result array. Element i of the result is the
element of array that corresponds to the ith true element of mask. If vector is present and has more
elements than there are true values in mask, any result elements that are empty (because they were not
true according to mask) are set to the corresponding values in vector.

Example
N is the array

[ 0  8  0 ]
[ 0  0  0 ]
[ 7  0  0 ].

PACK (N, MASK=N .NE. 0, VECTOR=(/1, 3, 5, 9, 11, 13/)) produces the result (7, 8, 5, 9, 11, 13).

PACK (N, MASK=N .NE. 0) produces the result (7, 8).

The following shows another example:

INTEGER array(2, 3), vec1(2), vec2(5)
LOGICAL mask (2, 3)
array = RESHAPE((/7, 0, 0, -5, 0, 0/), (/2, 3/))
mask = array .NE. 0
! array is  7  0 0  and mask is  T F F
!            0 -5 0               F T F
VEC1 = PACK(array, mask)      ! returns ( 7, -5 )
VEC2 = PACK(array, array .GT. 0, VECTOR= (/1,2,3,4,5/))
! returns ( 7, 2, 3, 4, 5 )

See Also
UNPACK

PACK Directive

General Compiler Directive: Specifies the memory
alignment of derived-type items (and record structure
items).

Syntax
!DIR$ PACK[: {1 | 2 | 4 | 8} ]

Items of derived types, unions, and structures are aligned in memory on the smaller of two sizes: the size of
the type of the item, or the current alignment setting. The current alignment setting can be 1, 2, 4, or 8
bytes. The default initial setting is 8 bytes (unless compiler option vms or align rec n bytes is specified). By
reducing the alignment setting, you can pack variables closer together in memory.

The PACK directive lets you control the packing of derived-type or record structure items inside your program
by overriding the current memory alignment setting.

For example, if PACK:1 is specified, all variables begin at the next available byte, whether odd or even.
Although this slightly increases access time, no memory space is wasted. If PACK:4 is specified, INTEGER(1),
LOGICAL(1), and all character variables begin at the next available byte, whether odd or even. INTEGER(2)
and LOGICAL(2) begin on the next even byte; all other variables begin on 4-byte boundaries.

If the PACK directive is specified without a number, packing reverts to the compiler option setting (if any), or
the default setting of 8.

The directive can appear anywhere in a program before the derived-type definition or record structure
definition. It cannot appear inside a derived-type or record structure definition.

Example

! Use 4-byte packing for this derived type
! Note PACK is used outside of the derived type definition
!DIR$ PACK:4
TYPE pair
  INTEGER a, b
END TYPE
! revert to default or compiler option
!DIR$ PACK

Equivalent Compiler Options
PACKTIMEQQ

**Portability Subroutine:** Packs time and date values.

**Module**
USE IFPORT

**Syntax**

CALL PACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

- **timedate**  
  (Output) INTEGER(4). Packed time and date information.

- **iyr**  
  (Input) INTEGER(2). Year (xxxxAD).

- **imon**  
  (Input) INTEGER(2). Month (1 - 12).

- **iday**  
  (Input) INTEGER(2). Day (1 - 31)

- **ihr**  
  (Input) INTEGER(2). Hour (0 - 23)

- **imin**  
  (Input) INTEGER(2). Minute (0 - 59)

- **isec**  
  (Input) INTEGER(2). Second (0 - 59)

The input values are interpreted as being in the time zone set on the local computer and following the daylight savings rules for that time zone.

The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

**Example**

USE IFPORT
INTEGER(2) year, month, day, hour, minute, second, hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour, minute, second)
END

**See Also**
UNPACKTIMEQQ
SETFILETIMEQQ

**PARALLEL Directive (OpenMP* API)**

**OpenMP* Fortran Compiler Directive:** Defines a parallel region.

**Syntax**

!$OMP PARALLEL [clause[, clause] ... ]
    block
!$OMP END PARALLEL
clause

Is one or more of the following:

- COPYIN (list)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- FIRSTPRIVATE (list)
- IF (expression)
- NUM_THREADS (scalar_integer_expression)

Specifies the number of threads to be used in a parallel region. The scalar_integer_expression must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive.

- PRIVATE (list)
- PROC_BIND (MASTER | CLOSE | SPREAD)

Specifies a method for mapping the threads in the team to the "places" in the current partition.

Once a thread is assigned to a place, the OpenMP* implementation should not move it to another place.

MASTER instructs the execution environment to assign every thread in the team to the same place as the master thread. CLOSE instructs the execution environment to assign the threads to places close to the place of the parent thread. SPREAD creates a sparse distribution for a team of T threads among the P places of the parent's place partition.

For CLOSE and SPREAD, the threads with the smallest numbers are assigned starting with the place of the master thread. For CLOSE, threads are packed into consecutive places within the parent's partition. For SPREAD, the partition of the master thread is sub-divided and threads in the team are assigned round-robin to those subpartitions.

Only a single PROC_BIND clause can appear in the directive.

- REDUCTION (operator | intrinsic : list)
- SHARED (list)

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The PARALLEL and END PARALLEL directive pair must appear in the same routine in the executable section of the code.

The END PARALLEL directive denotes the end of the parallel region. There is an implied barrier at this point. Only the master thread of the team continues execution at the end of a parallel region.

The number of threads in the team can be controlled by the NUM_THREADS clause, the environment variable OMP_NUM_THREADS, or by calling the run-time library routine OMP_SET_NUM_THREADS from a serial portion of the program.

NUM_THREADS supersedes the OMP_SET_NUM_THREADS routine, which supersedes the OMP_NUM_THREADS environment variable. Subsequent parallel regions, however, are not affected unless they have their own NUM_THREADS clauses.

Once specified, the number of threads in the team remains constant for the duration of that parallel region.

If the dynamic threads mechanism is enabled by an environment variable or a library routine, then the number of threads requested by the NUM_THREADS clause is the maximum number to use in the parallel region.

The code contained within the dynamic extent of the parallel region is executed on each thread, and the code path can be different for different threads.
If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes the master of that new team. By default, nested parallel regions are always serialized and executed by a team of one thread.

**Example**

You can use the PARALLEL directive in coarse-grain parallel programs. In the following example, each thread in the parallel region decides what part of the global array X upon which to work based on the thread number:

```
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,NPOINTS)
   IAM = OMP_GET_THREAD_NUM( )
   NP = OMP_GET_NUM_THREADS( )
   IPOINTS = NPOINTS/NP
   CALL SUBDOMAIN(X,IAM,IPOINTS)
!$OMP END PARALLEL
```

Assuming you previously used the environment variable OMP_NUM_THREADS to set the number of threads to six, you can change the number of threads between parallel regions as follows:

```
CALL OMP_SET_NUM_THREADS(3)
 !$OMP PARALLEL
   ...
 !$OMP END PARALLEL
CALL OMP_SET_NUM_THREADS(4)
 !$OMP PARALLEL DO
   ...
 !$OMP END PARALLEL DO
```

PARALLEL DO
SHARED Clause
Parallel Processing Model for information about Binding Sets

**PARALLEL and NOPARALLEL Loop Directives**

**General Compiler Directives:** PARALLEL facilitates auto-parallelization by assisting the compiler’s dependence analysis of the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.

**Syntax**

```
!DIR$ PARALLEL [clause[,[, clause] ... ]

!DIR$ NOPARALLEL
```

*clause* is one or more of the following:

- **ALWAYS [ASSERT]**
- **FIRSTPRIVATE (list)**

Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different iterations are initialized to the value the variable had upon entering the parallel loop.

- **LASTPRIVATE (list)**
Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel loop is exited, each variable has the value that resulted from the sequentially last iteration of the parallel loop.

- NUM_THREADS (scalar_integer_expression)
  Specifies the number of threads to be used to parallelize the immediately following DO loop. The scalar_integer_expression must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive. Once specified, the number of threads used remains constant for the duration of that parallelized DO loop.

- PRIVATE (list)
  Declares specified variables to be private to each thread in a team. The declared variables become private to a task.

  list
  Is one or more items in the form: var [:expr].... Each list item must be separated by a comma.

  var
  Is a scalar or array variable. The following rules apply:
  - Assumed-size arrays cannot appear in a PRIVATE clause.
  - A variable that is part of another variable (for example, as an array or structure element) cannot appear in a PRIVATE clause.
  - A variable that appears in a PRIVATE clause must either be definable, or an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
  - Variables that appear in namelist statements, in variable format expressions, and in expressions for statement function definitions, cannot appear in a PRIVATE clause.

  expr
  Is an integer expression denoting the number of array elements to privatize. When expr is specified, var must be an array or a pointer variable. The following rules also apply:
  - If var is an array, then only its first expr elements are privatized. If expr is omitted, the entire array is privatized.
  - If var is a pointer, then the first expr elements are privatized (element size is provided by the pointer's target type). If expr is omitted, only the pointer variable itself is privatized.
  - Program behavior is undefined if expr evaluates to a non-positive value, or if it exceeds the array size.

PARALLEL helps the compiler to resolve dependencies, facilitating auto-parallelization of the immediately following DO loop. It instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the loop. However, if dependencies are proven, they are not ignored.

In addition, PARALLEL ALWAYS overrides the compiler heuristics that estimate the likelihood that parallelization of a loop will increase performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

NOPARALLEL prevents auto-parallelization of the immediately following DO loop.

These directives take effect only if you specify the compiler option that enables auto-parallelization.
CAUTION
The directive PARALLEL ALWAYS should be used with care. Overriding the heuristics of the compiler should only be done if you are absolutely sure the parallelization will improve performance.

Example

program main
parameter (n=100)
integer x(n), a(n), k
!DIR$ NOPARALLEL
    do i=1,n
       x(i) = i
    enddo
!DIR$ PARALLEL LASTPRIVATE (k)
    do i=1,n
       a( x(i) ) = i
       k = x(i)
    enddo
    print *, k     ! print 100, the value of x(n)
end

PARALLEL DO

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single DO directive.

Syntax

!$OMP PARALLEL DO [clause[,,] clause] ... ]

    do-loop

[!$OMP END PARALLEL DO]

clause

Can be any of the clauses accepted by the DO or PARALLEL directives.

do-loop

Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

You cannot branch out of a DO loop associated with a DO directive.

If the END PARALLEL DO directive is not specified, the PARALLEL DO is assumed to end with the DO loop that immediately follows the PARALLEL DO directive. If used, the END PARALLEL DO directive must appear immediately after the end of the DO loop.

The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a DO directive.
Example

In the following example, the loop iteration variable is private by default and it is not necessary to explicitly declare it. The END PARALLEL DO directive is optional:

```fortran
!$OMP PARALLEL DO
   DO I=1,N
       B(I) = (A(I) + A(I-1)) / 2.0
   END DO
!$OMP END PARALLEL DO
```

The following example shows how to use the REDUCTION clause in a PARALLEL DO directive:

```fortran
!$OMP PARALLEL DO DEFAULT(PRIVATE) REDUCTION(+: A,B)
   DO I=1,N
       CALL WORK(ALOCAL,BLOCAL)
       A = A + ALOCAL
       B = B + BLOCAL
   END DO
!$OMP END PARALLEL DO
```

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL DO SIMD

**OpenMP* Fortran Compiler Directive:** Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.

Syntax

```fortran
!$OMP PARALLEL DO SIMD [clause[, clause] ... ]
   do-loop
[!$OMP END PARALLEL DO SIMD]
```

**clause**

Can be any of the clauses accepted by the PARALLEL, DO, or SIMD directives.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END PARALLEL DO SIMD directive is not specified, an END PARALLEL DO SIMD directive is assumed at the end of **do-loop**.

You cannot specify NOWAIT in a PARALLEL DO SIMD directive.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL SECTIONS

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.

Syntax

```fortran
 !$OMP PARALLEL SECTIONS [clause[,, clause] ... ]
 [ !$OMP SECTION
   block
 [ !$OMP SECTION
   block ] ...
 !$OMP END PARALLEL SECTIONS
```  

clause Can be any of the clauses accepted by the PARALLEL or SECTIONS directives.

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The last section ends at the END PARALLEL SECTIONS directive.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```fortran
 !$OMP PARALLEL SECTIONS
 !$OMP SECTION
   CALL XAXIS
 !$OMP SECTION
   CALL YAXIS
 !$OMP SECTION
   CALL ZAXIS
 !$OMP END PARALLEL SECTIONS
```

PARALLEL WORKSHARE

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.

Syntax

```fortran
 !$OMP PARALLEL WORKSHARE [clause[,, clause] ... ]
   block
 !$OMP END PARALLEL WORKSHARE
```
**clause**
Can be any of the clauses accepted by the `PARALLEL` directive.

**block**
Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

OpenMP® Fortran Compiler Directives
Syntax Rules for Compiler Directives

---

**PARAMETER**

**Statement and Attribute:** Defines a named constant.

**Syntax**
The PARAMETER attribute can be specified in a type declaration statement or a PARAMETER statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls,] PARAMETER [, att-ls] :: c = expr[, c = expr] ...
```

**Statement:**

```
PARAMETER [()]c = expr[, c = expr] ... [()]
```

- **type**
  Is a data type specifier.

- **att-ls**
  Is an optional list of attribute specifiers.

- **c**
  Is the name of the constant.

- **expr**
  Is an initialization expression. It can be of any data type.

**Description**
The type, type parameters, and shape of the named constant are determined in one of the following ways:

- By an explicit type declaration statement in the same scoping unit.
- By the implicit typing rules in effect for the scoping unit. If the named constant is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

For example, consider the following statement:

```
PARAMETER (MU=1.23)
```

According to implicit typing, MU is of integer type, so MU=1. For MU to equal 1.23, it should previously be declared REAL in a type declaration or be declared in an IMPLICIT statement.

A named constant must not appear in a format specification or as the character count for Hollerith constants. For compilation purposes, writing the name is the same as writing the value.

If the named constant is used as the length specifier in a CHARACTER declaration, it must be enclosed in parentheses.

The name of a constant cannot appear as part of another constant, although it can appear as either the real or imaginary part of a complex constant.

You can only use the named constant within the scoping unit containing the defining PARAMETER statement. Any named constant that appears in the initialization expression must have been defined previously in the same type declaration statement (or in a previous type declaration statement or PARAMETER statement), or made accessible by use or host association.

An entity with the PARAMETER attribute must not be a variable, a coarray, or a procedure.
The use of parentheses is optional and can be controlled by using compiler option [no]altparam.

Example

The following example shows a type declaration statement specifying the PARAMETER attribute:

```fortran
REAL, PARAMETER :: C = 2.9979251, Y = (4.1 / 3.0)
```

The following is an example of the PARAMETER statement:

```fortran
REAL(4) PI, PIOV2
REAL(8) DPI, DPIOV2
LOGICAL FLAG
CHARACTER*(*) LONGNAME
PARAMETER (PI=3.1415927, DPI=3.141592653589793238D0)
PARAMETER (PIOV2=PI/2, DPIOV2=DPI/2)
PARAMETER (FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS')
```

The following shows other examples:

```fortran
! implicit integer type
PARAMETER (nbblocks = 10)
!
! implicit real type
IMPLICIT REAL (L-M)
PARAMETER (loads = 10.0, mass = 32.2)
!
! typed by PARAMETER statement
! Requires compiler option
PARAMETER mass = 47.3, pi = 3.14159
PARAMETER bigone = 'This constant is larger than forty characters'
!
! PARAMETER in attribute syntax
REAL, PARAMETER :: mass=47.3, pi=3.14159, loads=10.0, mass=32.2
```

Alternative Syntax for the PARAMETER Statement
altparam

PARITY

Transformational Intrinsic Function (Generic):
Reduces an array by using an exclusive OR (.NEQV.) operation.

Syntax

```fortran
result = PARITY (mask[, dim])
```

- `mask` (Input) Must be an array of type logical.
- `dim` (Input; optional) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of mask. The corresponding actual argument must not be an optional dummy argument.
Results

The result has the same type and kind parameters as `mask`. It is scalar if `dim` does not appear; otherwise, the result has rank `n - 1` and shape `[d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n]` where `[d_1, d_2, ..., d_n]` is the shape of `mask`.

The result of `PARITY(mask)` has the value `.TRUE.` if an odd number of the elements of `mask` are true; otherwise, `.FALSE.`.

If `mask` has rank one, `PARITY(mask, dim)` is equal to `PARITY(mask)`. Otherwise, the value of element `(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)` of `PARITY(mask, dim)` is equal to `PARITY(mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n))`.

Example

If `A` is the array

```
[ T  F  T ]
[ T  T  F ]
```

and `T` has the value `.TRUE. and `F` has the value `.FALSE.`, then

`PARITY(A, DIM=1)` has the value `[F, T, T]` and `PARITY(A, DIM=2)` has the value `[F, F]`.

PASSDIRKEYSQQ (W*S)

QuickWin Function: Determines the behavior of direction and page keys in a QuickWin application.

Module

USE IFQWIN

Syntax

```fortran
result = PASSDIRKEYSQQ(val)
```

val

(Input) INTEGER(4) or LOGICAL(4).

A value of `.TRUE.` causes direction and page keys to be input as normal characters (the PassDirKeys flag is turned on). A value of `.FALSE.` causes direction and page keys to be used for scrolling.

The following constants, defined in IFQWIN.F90, can be used as integer arguments:

- **PASS_DIR_FALSE** - Turns off any special handling of direction keys. They are not passed to the program by GETCHARQQ.
- **PASS_DIR_TRUE** - Turns on special handling of direction keys. That is, they are passed to the program by GETCHARQQ.
- **PASS_DIR_INSDEL** - INSERT and DELETE are also passed to the program by GETCHARQQ
- **PASS_DIR_CNTRLC** - Only needed for a QuickWin application, but harmless if used with a Standard Graphics application that already passes CTRL+C.

This value allows CTRL+C to be passed to a QuickWin program by GETCHARQQ if the following is true: the program must have removed the File menu EXIT item by using DELETEMENUQQ.

This value also passes direction keys and INSERT and DELETE.

Results

The return value indicates the previous setting of the PassDirKeys flag.
The return data type is the same as the data type of \textit{val}; that is, either INTEGER(4) or LOGICAL(4).

When the PassDirKeys flag is turned on, the mouse must be used for scrolling since the direction and page keys are treated as normal input characters.

The \texttt{PASSDIRKEYSQQ} function is meant to be used primarily with the \texttt{GETCHARQQ} and \texttt{INCHARQQ} functions. Do not use normal input statements (such as \texttt{READ}) with the PassDirKeys flag turned on, unless your program is prepared to interpret direction and page keys.

\textbf{Example}

\begin{verbatim}
use IFQWIN

logical*4 res
character*1 ch, ch1

Print *,"Type X to exit, S to scroll, D to pass Direction keys"

123 continue
ch = getcharqq( )
! check for escapes
! 0x00 0x?? is a function key
! 0xE0 0x?? is a direction key
if (ichar(ch) .eq. 0) then
  ch1 = getcharqq()
  print *,"function key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
  goto 123
else if (ichar(ch) .eq. 224) then
  ch1 = getcharqq()
  print *,"direction key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
  goto 123
else
  print *,ichar(ch)," ",ch
if(ch .eq. 'S') then
  res = passdirkeysqq(.false.)
  print *, "Entering Scroll mode ",res
endif
if(ch .eq. 'D')  then
  res = passdirkeysqq(.true.)
  print *, "Entering Direction keys mode ",res
endif
if(ch .ne. 'X')  go to 123
endif
end
\end{verbatim}

The following example uses an integer constant as an argument to \texttt{PASSDIRKEYSQQ}:

\begin{verbatim}
c=======================================================================
c
c dirkeys4.for

c=======================================================================
c
  Compile/Load Input Line for Standard Graphics Full Screen Window

c
  ifort /libs:qwins dirkeys4.for

c
  Compile/Load Input Line for QuickWin Graphics
\end{verbatim}
Program to illustrate how to get almost every character from the keyboard in QuickWin or Standard Graphics mode. Comment out the deletemenu line for Standard Graphics mode.

If you are doing a standard graphics application, control C will come in as a '03' without further effort.

In a QuickWin application, the File menu Exit item must be deleted, and PassDirKeysQQ called with PASS_DIR_CNTRLC to get control C.

```
use IFQWIN
integer(4) status
character*1 key1,key2,ch1
write(*,*) 'Initializing'
c----don't do this for a Standard Grapics application
c remove File menu Exit item.
status = deletemenuqq(1,3) ! stop QuickWin from getting control C
c----set up to pass all keys to window including control c.
status  = passdirkeysqq(PASS_DIR_CNTRLC)
c read and print characters
c
10 key1 = getcharqq()
c----first check for control+c
if(ichar(key1) .eq. 3) then
   write(*,*) 'Control C Received'
   write(*,*) "Really want to quit?"
   write(*,*) "Type Y <cr> to exit, or any other char <cr> to continue."
   read(*,*) ch1
   if(ch1.eq."y" .or. ch1.eq."Y") goto 30
   goto 10
endif
if(ichar(key1).eq.0) then ! function key?
key2 = getcharqq()
write(*,15) ichar(key1),ichar(key2),key2
15 format(1x,2i12,1x,a1,' function key')
else
   if(ichar(key1).eq.224) then ! direction key?
key2 = getcharqq()
write(*,16) ichar(key1),ichar(key2),key2
16 format(1x,2i12,1x,a1,' direction key')
else
   write(*,20) key1,ichar(key1) ! normal key
20 format(1x,a1,i11)
endif
```

INCHARQQ (W*S)

PAUSE

**Statement:** Temporarily suspends program execution
and lets you execute operating system commands
during the suspension. The PAUSE statement is a
deleted feature in the Fortran Standard. Intel® Fortran
fully supports features deleted in the Fortran
Standard.

**Syntax**

```fortran
PAUSE [pause-code]
```

*pause-code* (Optional) Is an optional message. It can be either of the following:

- A scalar character constant of type default character.
- A string of up to six digits; leading zeros are ignored. (Standard Fortran
  limits digits to five.)

If you specify *pause-code*, the PAUSE statement displays the specified message and then displays the default prompt.

If you do not specify *pause-code*, the system displays the following default message:

```
FORTRAN PAUSE
```

The following prompt is then displayed:

- **On Windows* systems:**
  ```fortran
  Fortran Pause - Enter command<CR> or <CR> to continue.
  ```
- **On Linux* and OS X* systems:**
  ```fortran
  PAUSE prompt>
  ```

For alternate methods of pausing while reading from and writing to a device, see **READ** and **WRITE**.

**Effect on Windows* OS**
The program waits for input on stdin. If you enter a blank line, execution resumes at the next executable statement.

Anything else is treated as a DOS command and is executed by a system() call. The program loops, letting you execute multiple DOS commands, until a blank line is entered. Execution then resumes at the next executable statement.

**Effect on Linux* OS and OS X**
The effect of PAUSE differs depending on whether the program is a foreground or background process, as follows:

- If a program is a foreground process, the program is suspended until you enter the CONTINUE command. Execution then resumes at the next executable statement.
  Any other command terminates execution.
- If a program is a background process, the behavior depends on stdin, as follows:
If stdin is redirected from a file, the system displays the following (after the pause code and prompt):

```
To continue from background, execute 'kill -15 n'
```

In this message, \texttt{n} is the process id of the program.

If stdin is not redirected from a file, the program becomes a suspended background job, and you must specify \texttt{fg} to bring the job into the foreground. You can then enter a command to resume or terminate processing.

Example

The following examples show valid PAUSE statements:

```
PAUSE 701
PAUSE 'ERRONEOUS RESULT DETECTED'
```

The following shows another example:

```
CHARACTER*24 filename
PAUSE 'Enter DIR to see available files or press RETURN' &
&' if you already know filename.'
READ(*,'(A\)') filename
OPEN(1, FILE=filename)
```

PEEKCHARQQ

\textbf{Run-Time Function:} Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.

Module

USE IFCORE

Syntax

```
result = PEEKCHARQQ( )
```

Results

The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..

To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ to .FALSE..

Example

```
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
   WRITE(*,*) 'Press any key'
   pressed = PEEKCHARQQ ( )
END DO
END
```

PERERROR

Run-Time Subroutine: Sends a message to the
standard error stream, preceded by a specified string,
for the last detected error.

Module
USE IFCORE

Syntax
CALL PERROR (string)

string (Input) Character*(*) - Message to precede the standard error message.

The string sent is the same as that given by GERROR.

Example
USE IFCORE
character*24 errtext
errtext = 'In my opinion, '
...!
 any error message generated by errtext is
! preceded by 'In my opinion, '
Call PERROR (errtext)

See Also
GERROR
IERRNO

PIE, PIE_W (W*S)

Graphics Functions: Draw a pie-shaped wedge in
the current graphics color.

Module
USE IFQWIN

Syntax
result = PIE (i, x1, y1, x2, y2, x3, y3, x4, y4)
result = PIE_W (i, wx1, wy1, wx2, wy2, wx3, y3, wx4, wy4)

i (Input) INTEGER(2) - Fill flag. One of the following symbolic constants
defined in IFQWIN.F90:

- $GFILLINTERIOR - Fills the figure using the current color and fill mask.
- $GBORDER - Does not fill the figure.

x1, y1 (Input) INTEGER(2) - Viewport coordinates for upper-left corner of bounding rectangle.
$x_2, y_2$ (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

$x_3, y_3$ (Input) INTEGER(2). Viewport coordinates of start vector.

$x_4, y_4$ (Input) INTEGER(2). Viewport coordinates of end vector.

$wx_1, wy_1$ (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

$wx_2, wy_2$ (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

$wx_3, wy_3$ (Input) REAL(8). Window coordinates of start vector.

$wx_4, wy_4$ (Input) REAL(8). Window coordinates of end vector.

**Results**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the pie is clipped or partially out of bounds, the pie is considered successfully drawn and the return is 1. If the pie is drawn completely out of bounds, the return is 0.

The border of the pie wedge is drawn in the current color set by SETCOLORRGB.

The PIE function uses the viewport-coordinate system. The center of the arc is the center of the bounding rectangle, which is specified by the viewport-coordinate points $(x_1, y_1)$ and $(x_2, y_2)$. The arc starts where it intersects an imaginary line extending from the center of the arc through $(x_3, y_3)$. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through $(x_4, y_4)$.

The PIE_W function uses the window-coordinate system. The center of the arc is the center of the bounding rectangle specified by the window-coordinate points $(wx_1, wy_1)$ and $(wx_2, wy_2)$. The arc starts where it intersects an imaginary line extending from the center of the arc through $(wx_3, wy_3)$. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through $(wx_4, wy_4)$.

The fill flag option $GFILLINTERIOR$ is equivalent to a subsequent call to FLOODFILLRGB using the center of the pie as the starting point and the current graphics color (set by SETCOLORRGB) as the fill color. If you want a fill color different from the boundary color, you cannot use the $GFILLINTERIOR$ option. Instead, after you have drawn the pie wedge, change the current color with SETCOLORRGB and then call FLOODFILLRGB. You must supply FLOODFILLRGB with an interior point in the figure you want to fill. You can get this point for the last drawn pie or arc by calling GETARCINFO.

If you fill the pie with FLOODFILLRGB, the pie must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**NOTE**
The PIE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Pie routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Pie.

**Example**

```fortran
! build as Graphics App.
USE IFQWIN
INTEGER(2) status, dummy
INTEGER(2) x1, y1, x2, y2, x3, y3, x4, y4
```
x1 = 80; y1 = 50
x2 = 180; y2 = 150
x3 = 110; y3 = 80
x4 = 90; y4 = 180

status = SETCOLOR(INT2(4))
dummy = PIE( $GFILLINTERIOR, x1, y1, x2, y2, &
    x3, y3, x4, y4)
END

This figure shows the coordinates used to define PIE and PIE_W:

POINTER - Fortran

Statement and Attribute: Specifies that an object or a procedure is a pointer (a dynamic variable). A pointer does not contain data, but points to a scalar or array variable where data is stored. A pointer has no initial storage set aside for it; memory storage is created for the pointer as a program runs.

Syntax
The POINTER attribute can be specified in a type declaration statement or a POINTER statement, and takes one of the following forms:

Type Declaration Statement:

type,[att-ls,] POINTER [, att-ls] :: ptr[(d-spec)][ , ptr[(d-spec)]]...

Statement:

POINTER [::]ptr[(d-spec)][ , ptr[(d-spec)]] ...

\[\text{type-spec}\]
Is a data type specifier.

\[\text{att-ls}\]
Is an optional list of attribute specifiers.
**Description**

No storage space is created for a data pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target.

Each pointer has an association status, which tells whether the pointer is currently associated with a target object. When a pointer is initially declared, its status is undefined. You can use the ASSOCIATED intrinsic function to find the association status of a pointer if the pointer’s association status is defined.

Entities with the POINTER attribute can be associated with different data objects or procedures during execution of a program.

A data pointer must not be referenced or defined unless it is pointer associated with a target object that can be referenced or defined. A procedure pointer must not be referenced unless it is pointer associated with a target procedure.

If the data pointer is an array, and it is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

A pointer cannot be specified in an EQUIVALENCE or NAMELIST statement. A pointer in a DATA statement can only be associated with NULL().

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

An entity with the POINTER attribute must not have the ALLOCATABLE, INTRINSIC, or TARGET attribute, and it must not be a coarray.

Fortran pointers are not the same as integer pointers. For more information, see the **POINTER - Integer** statement.

**Example**

The following example shows type declaration statements specifying the POINTER attribute:

```
TYPE(SYSTEM), POINTER :: CURRENT, LAST
REAL, DIMENSION(:,,:), POINTER :: I, J, REVERSE
```

The following is an example of the POINTER statement:

```
TYPE(SYSTEM) :: TODAYS
POINTER :: TODAYS, A(:,:)
```

The following shows another example:

```
REAL, POINTER :: arrow (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:,:)
!
! The following statement associates the pointer with an unused ! block of memory.
!
ALLOCATE (arrow (1:8), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(1x,a)') 'ARROW allocated'
arrow = 5.
WRITE (*,'(1x,8f8.0/)') arrow
ALLOCATE (bullseye (1:8,3), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(a)') 'BULLSEYE allocated'
bullseye = 1.
bullseye (1:8:2,2) = 10.
WRITE (*,'(1x,8f8.0/)') bullseye
```
The following association breaks the association with the first target, which being unnamed and unassociated with other pointers, becomes lost. ARROW acquires a new shape.

```
arrow => bullseye (2:7,2)
WRITE (*,'(/1x,a)') 'ARROW is repointed & resized, all the 5s are lost'
WRITE (*,'(1x,8f8.0)') arrow

NULLIFY (arrow)
IF (.NOT.ASSOCIATED(arrow)) WRITE (*,'(/a/)') ' ARROW is not pointed'
DEALLOCATE (bullseye, STAT = ierr)
IF (ierr.eq.0) WRITE (*,*) 'Deallocation successful.'
END
```

NULLIFY
TARGET Statement
Deferred-Shape Specifications
Pointer Assignments
Pointer Association
PointerType: Establishes pairs of objects and pointers, in which each pointer contains the address of its paired object. This statement is different from the Fortran POINTER statement.

**Syntax**

```
POINTER (pointer, pointee) [, (pointer, pointee)] . . .
```

**pointer**

Is a variable whose value is used as the address of the **pointee**.

**pointee**

Is a variable; it can be an array name or array specification. It can also be a procedure named in an EXTERNAL statement or in a specific (non-generic) procedure interface block.

The following are **pointer** rules and behavior:

- Two pointers can have the same value, so pointer aliasing is allowed.
- When used directly, a pointer is treated like an integer variable. On 1A-32 architecture, a pointer occupies one numeric storage unit, so it is a 32-bit quantity (INTEGER(4)). On Intel® 64 architecture, a pointer occupies two numeric storage units, so it is a 64-bit quantity (INTEGER(8)).
- A pointer cannot be a pointee.
- A pointer cannot appear in an ASSIGN statement and cannot have the following attributes:
A pointer can appear in a DATA statement with integer literals only.

- Integers can be converted to pointers, so you can point to absolute memory locations.
- A pointer variable cannot be declared to have any other data type.
- A pointer cannot be a function return value.
- You can give values to pointers by doing the following:
  - Retrieve addresses by using the LOC intrinsic function (or the %LOC built-in function)
  - Allocate storage for an object by using the MALLOC intrinsic function (or by using malloc(3f) on Linux* and OS X* systems)

For example:

```fortran
Using %LOC:

INTEGER I(10)
INTEGER I1(10) /10*10/
POINTER (P,I)
P = %LOC(I1)
I(2) = I(2) + 1
```

```fortran
Using MALLOC:

INTEGER I(10)
POINTER (P,I)
P = MALLOC(40)
I(2) = I(2) + 1
```

- The value in a pointer is used as the pointee's base address.

The following are pointee rules and behavior:

- A pointee is not allocated any storage. References to a pointee look to the current contents of its associated pointer to find the pointee's base address.
- A pointee cannot be data-initialized or have a record structure that contains data-initialized fields.
- A pointee can appear in only one integer POINTER statement.
- A pointee array can have fixed, adjustable, or assumed dimensions.
- A pointee cannot appear in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement, and it cannot have the following attributes:

```fortran
ALLOCATABLE   OPTIONAL   SAVE
EXTERNAL      PARAMETER   STATIC
EXTERNAL      PARAMETER   TARGET
```

- A pointee cannot be:
  - A dummy argument
  - A function return value
  - A record field or an array element
  - Zero-sized
  - An automatic object
  - The name of a generic interface block
- If a pointee is of derived type, it must be of sequence type.

Example

```fortran
POINTER (p, k)
INTEGER j(2)

! This has the same effect as j(1) = 0, j(2) = 5
p = LOC(j)
k = 0
p = p + SIZEOF(k) ! 4 for 4-byte integer
k = 5
```

**POLYBEZIER, POLYBEZIER_W (W*S)**

**Graphics Functions:** Draw one or more Bezier curves.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{POLYBEZIER} \ (lppoints, cpoints) \\
\text{result} = \text{POLYBEZIER_W} \ (lppoints, cpoints)
\]

\(lppoints\) (Input) Derived type \(xycoord\). Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type \(xycoord\) is defined in \(IFQWIN.F90\) as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

\(cpoints\) (Input) INTEGER(2). Number of points in \(lppoints\).

**Results**

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point must be given for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, \(cpoints\) should contain 4 for one curve, 7 for 2 curves, 10 for 3 curves, and so forth.

POLYBEZIER does not use or change the current graphics position.

**Example**

```
Program Bezier
use IFQWIN
! Shows how to use POLYBEZIER, POLYBEZIER_W, 
! POLYBEZIERTO, and POLYBEZIERTO_W,

END PROGRAM Bezier

See Also
POLYBEZIERTO, POLYBEZIERTO_W (W*S)

POLYBEZIERTO, POLYBEZIERTO_W (W*S)

Graphics Functions: Draw one or more Bezier curves.

Module
USE IFQWIN

Syntax
result = POLYBEZIERTO (lppoints, cpoints)
result = POLYBEZIERTO_W (lppoints, cpoints)

lppoints (Input) Derived type xycoord. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

cpoints (Input) INTEGER(2). Number of points in ppoints or lppoints.

Results
The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.
A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point is the current graphics position as set by MOVETO for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, cpoints should contain 3 for one curve, 6 for 2 curves, 9 for 3 curves, and so forth.

POLYBEZIERTO moves the current graphics position to the ending point of the last curve drawn.

**Example**

See the example in POLYBEZIER, POLYBEZIER_W (W*S).

**See Also**

POLYBEZIER, POLYBEZIER_W (W*S)

MOVETO, MOVETO_W (W*S)

**POLYGON, POLYGON_W (W*S)**

*Graphics Functions:* Draw a polygon using the current graphics color, logical write mode, and line style.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{POLYGON} \left( \text{control}, \text{lppoints}, \text{cpoints} \right)
\]

\[
\text{result} = \text{POLYGON_W} \left( \text{control}, \text{lppoints}, \text{cpoints} \right)
\]

**control**

(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90:

- $\text{GFILLINTERIOR}$ - Draws a solid polygon using the current color and fill mask.
- $\text{GBORDER}$ - Draws the border of a polygon using the current color and line style.

**lppoints**

(Input) Derived type xycoord. Array of derived types defining the polygon vertices in viewport coordinates. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

**cpoints**

(Input) INTEGER(2). Number of polygon vertices.

**Results**

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

The border of the polygon is drawn in the current graphics color, logical write mode, and line style, set with SETCOLORRGB, SETWRITEMODE, and SETLINESTYLE, respectively. The POLYGON routine uses the viewport-coordinate system (expressed in xycoord derived types), and the POLYGON_W routine uses real-valued window coordinates (expressed in xycoord types).

The argument lppoints is an array whose elements are xycoord derived types. Each element specifies one of the polygon’s vertices. The argument cpoints is the number of elements (the number of vertices) in the lppoints array.
Note that POLYGON draws between the vertices in their order in the array. Therefore, when drawing outlines, skeletal figures, or any other figure that is not filled, you need to be careful about the order of the vertices. If you don't want lines between some vertices, you may need to repeat vertices to make the drawing backtrack and go to another vertex to avoid drawing across your figure. Also, POLYGON draws a line from the last specified vertex back to the first vertex.

If you fill the polygon using FLOODFILLRGB, the polygon must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE
The POLYGON routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Polygon routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Polygon.

Example

! Build as a Graphics App.

! Draw a skeletal box

USE IFQWIN

INTEGER(2) status

TYPE (xycoord) poly(12)

! Set up box vertices in order they will be drawn, &
! repeating some to avoid unwanted lines across box

poly(1)%xcoord = 50
poly(1)%ycoord = 80
poly(2)%xcoord = 85
poly(2)%ycoord = 35
poly(3)%xcoord = 185
poly(3)%ycoord = 35
poly(4)%xcoord = 150
poly(4)%ycoord = 80
poly(5)%xcoord = 50
poly(5)%ycoord = 80
poly(6)%xcoord = 50
poly(6)%ycoord = 180
poly(7)%xcoord = 185
poly(7)%ycoord = 180
poly(8)%xcoord = 185
poly(8)%ycoord = 135
poly(9)%xcoord = 185
poly(9)%ycoord = 35
poly(10)%xcoord = 150
poly(10)%ycoord = 80
poly(11)%xcoord = 150
poly(11)%ycoord = 180
poly(12)%xcoord = 150
poly(12)%ycoord = 80

status = SETCOLORRGB(Z'0000FF')
status = POLYGON($GBORDER, poly, INT2(12))
END

See Also
SETCOLORRGB (W*S)
SETFILLMASK (W*S)
POLYLINEQQ (W*S)

*Graphics Function:* Draws a line between each successive x, y point in a given array.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{POLYLINEQQ} (\text{points}, \text{cnt})
\]

- **points** (Input) An array of DF_POINT objects. The derived type DF_POINT is defined in IFQWIN.F90 as:
  
  ```
  type DF_POINT
  sequence
  integer(4) x
  integer(4) y
  end type DF_POINT
  ```

- **cnt** (Input) INTEGER(4). Number of elements in the points array.

**Results**

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, zero.

POLYLINEQQ uses the viewport-coordinate system.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

The current graphics position is not used or changed as it is in the LINETO function.

**Example**

```fortran
! Build for QuickWin or Standard Graphics
USE IFQWIN
TYPE(DF_POINT) points(12)
integer(4) result
integer(4) cnt, i

! load the points
do i = 1,12,2
  points(i).x = 20*i
  points(i).y = 10
  points(i+1).x = 20*i
  points(i+1).y = 60
end do

! A sawtooth pattern will appear in the upper left corner
result = POLYLINEQQ(points, 12)
```

**POPCNT**

*Elemental Intrinsic Function (Generic):* Returns the number of 1 bits in the integer argument.

**Syntax**

\[\text{result} = \text{POPCNT}(i)\]

\[i\] (Input) Must be of type integer or logical.

**Results**

The result type and kind is the same as \(i\). The result value is the number of 1 bits in the binary representation of the integer \(i\).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

If the value of \(I\) is \(B'0...00011010110'\), the value of POPCNT(I) is 5.

**POPPAR**

*Elemental Intrinsic Function (Generic):* Returns the parity of the integer argument.

**Syntax**

\[\text{result} = \text{POPPAR}(i)\]

\[i\] (Input) Must be of type integer or logical.

**Results**

The result type and kind is the same as \(i\). The result value is 1 if there are an odd number of 1 bits in the binary representation of the integer \(i\). The result value is zero if there are an even number.

\(\text{POPPAR}(i)\) is the same as \(1 \cdot \text{AND. POPCNT}(i)\).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

If the value of \(I\) is \(B'0...00011010110'\), the value of POPPAR(I) is 1.

**PRECISION**

*Inquiry Intrinsic Function (Generic):* Returns the decimal precision in the model representing real numbers with the same kind parameter as the argument.

**Syntax**

\[\text{result} = \text{PRECISION}(x)\]
Results
The result is a scalar of type default integer. The result has the value \( \text{INT}((\text{DIGITS}(x) - 1) \times \log_{10}(\text{RADIX}(x))) \). If \( \text{RADIX}(x) \) is an integral power of 10, 1 is added to the result.

Example
If \( X \) is a REAL(4) value, \( \text{PRECISION}(X) \) has the value 6. The value 6 is derived from \( \text{INT} ((24-1) \times \log_{10}(2.)) = \text{INT} (6.92...) \). For more information on the model for REAL(4), see Model for Real Data.

PREFETCH and NOPREFETCH

General Compiler Directives: PREFETCH hints to the compiler to prefetch data into closer levels of cache. Prefetching data can minimize the effects of memory latency. NOPREFETCH disables data prefetching. These directives give fine-level control to the programmer to influence the prefetches generated by the compiler. These directives are only available on Intel® MIC Architecture.

Syntax

\[
!\text{DIR$} \text{ PREFETCH} \ [\text{var}1[: \text{hint}1[: \text{distance}1]] [,\text{var}2[: \text{hint}2[: \text{distance}2]]]...]
\]

\[
!\text{DIR$} \text{ NOPREFETCH} \ [\text{var}1[,\text{var}2]...]
\]

\text{var} \quad \text{Is an optional memory reference.}

\text{hint} \quad \text{Is an optional integer initialization expression with the integer value 0, 1, 2, or 3. These are the same as the defined values FOR_K_PREFETCH_T0, FOR_K_PREFETCH_T1, FOR_K_PREFETCH_T2, or FOR_K_PREFETCH_NTA for \text{hint} in the intrinsic subroutine MM_PREFETCH. To use this argument, you must also specify \text{var}.}

\text{distance} \quad \text{Is an optional integer initialization expression with a value greater than 0. It indicates the number of (possibly vectorized) loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify \text{var} and \text{hint}.}

To use these directives, compiler option \( [q \text{ or Q}]\text{opt-prefetch} \) must be set. Note that this option is turned on by default if the compiler general optimization level is O2 or higher.

This directive affects the DO loop it precedes.

If you specify PREFETCH *, the \text{hint} and optional \text{distance} are used to prefetch all array accesses in the DO loop.

If you specify NOPREFETCH with no arguments, the following occurs:

- All arrays accessed in the DO loop will NOT be prefetched.
- It negates all other PREFETCH directives for the following DO loop.

If a loop includes expression \( A(j) \), placing \( !\text{DIR$} \text{ PREFETCH} A:0:d \) in front of the loop instructs the compiler to insert a \text{vprefetch}0 instruction for \( A \) within the loop that is \( d \) iterations ahead.

The \text{PREFETCH} directive takes precedence over the \( [q \text{ or Q}]\text{opt-prefetch-distance} \) options.

The variables in a NOPREFETCH or PREFETCH directive take precedence over PREFETCH *.
A NOPREFETCH directive with no arguments negates all other PREFETCH directives for the following DO loop.

**Example**

```plaintext
! Issue no prefetches for A
! Issue vector prefetch from L2 and higher caches for B with a distance
!   of 16 vectorized iterations ahead
! Issue vector prefetch from L1 and higher caches for B with a distance
!   of 4 vectorized iterations ahead
!DIR$ NOPREFETCH A1
!DIR$ PREFETCH B:1:16
!DIR$ PREFETCH B:0:4
  DO J = 1,N
    A1(J) = B(J-1) + B(J+1)
  END DO

In the following example, array A will be prefetched with hint 0 and distance 5, arrays B and C will be prefetched with hint 1 and distance 10, and array D will not be prefetched:

```plaintext
!DIR$ PREFETCH *:1:10
!DIR$ PREFETCH A:0:5
!DIR$ NOPREFETCH D
  DO J = 1, N
    A(J) = B(J) + C(J) + D(J)
  END DO
```

qopt-prefetch-distance, Qopt-prefetch-distance compiler option

**PRESENT**

*Inquiry Intrinsic Function (Generic):* Returns whether or not an optional dummy argument is present, that is, whether it has an associated actual argument.

**Syntax**

```
result = PRESENT (a)
```

*a* (Input) Must be an argument of the current procedure and must have the OPTIONAL attribute. An explicit interface for the current procedure must be visible to its caller; for more information, see *Procedure Interfaces*.

**Results**

The result is a scalar of type default logical. The result is .TRUE. if *a* is present; otherwise, the result is .FALSE..

**Example**

Consider the following:

```plaintext
MODULE MYMOD
CONTAINS
SUBROUTINE CHECK (X, Y)
  REAL X, Z
  REAL, OPTIONAL :: Y
  ...
```
IF (PRESENT (Y)) THEN
    Z = Y
ELSE
    Z = X * 2
END IF
END SUBROUTINE CHECK
END MODULE MYMOD

USE MYMOD
CALL CHECK (15.0, 12.0) ! Causes Z to be set to 12.0
CALL CHECK (15.0) ! Causes Z to be set to 30.0

The following shows another example:
CALL who( 1, 2 ) ! prints "A present" "B present"
CALL who( 1 ) ! prints "A present"
CALL who( b = 2 ) ! prints "B present"
CALL who( ) ! prints nothing
CONTAINS
    SUBROUTINE who( a, b )
        INTEGER(4), OPTIONAL :: a, b
        IF (PRESENT(a)) PRINT *, 'A present'
        IF (PRESENT(b)) PRINT *, 'B present'
    END SUBROUTINE who
END

OPTIONAL
Optional Arguments

PRINT
Statement: Displays output on the screen. TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.

Syntax
The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using environment variable FOR_PRINT.

A PRINT statement takes one of the following forms:

Formated:
PRINT form[, io-list]

Formatted - List-Directed:
PRINT *[, io-list]

Formatted - Namelist:
PRINT nml

form Is the nonkeyword form of a format specifier (no FMT=).

io-list Is an I/O list.

* Is the format specifier indicating list-directed formatting.

nml Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.
Example

In the following example, one record (containing four fields of data) is printed to the implicit output device:

<table>
<thead>
<tr>
<th>CHARACTER*16 NAME, JOB</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRINT 400, NAME, JOB</td>
</tr>
<tr>
<td>400 FORMAT ('NAME=', A, 'JOB=', A)</td>
</tr>
</tbody>
</table>

The following shows another example:

```
! The following statements are equivalent:
PRINT '(A11)', 'Abbottsford'
WRITE (*, '(A11)') 'Abbottsford'
TYPE '(A11)', 'Abbottsford'
```

PRIVATE Statement

**Statement and Attribute:** Specifies that entities in a module can be accessed only within the module itself.

**Syntax**

The PRIVATE attribute can be specified in a type declaration statement or a PRIVATE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] PRIVATE [, att-ls] :: entity[, entity]...
```

**Statement:**

```
PRIVATE [::] entity[, entity] ...
```

- **type**
  - Is a data type specifier.

- **att-ls**
  - Is an optional list of attribute specifiers.

- **entity**
  - Is one of the following:
    - A variable name
    - A procedure name
    - A derived type name
    - A named constant
    - A namelist group name
  - In statement form, an entity can also be a generic identifier (a generic name, defined operator, or defined assignment).

**Description**

The PRIVATE attribute can only appear in the scoping unit of a module.

Only one PRIVATE statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module.
If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility. Entities with PUBLIC accessibility can be accessed from outside the module by means of a USE statement.

If a derived type is declared PRIVATE in a module, its components are also PRIVATE. The derived type and its components are accessible to any subprograms within the defining module through host association, but they are not accessible from outside the module.

If the derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the definition.

Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```fortran
REAL,   PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
PRIVATE RESTRICTED_DATA
END MODULE
```

The following derived-type declaration statement indicates that the type is restricted to the module:

```fortran
TYPE, PRIVATE :: DATA
...
END TYPE DATA
```

The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
  TYPE ELEMENTS
  PRIVATE
  INTEGER C, D
END TYPE
...
END MODULE MATTER
```
In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```fortran
!LENGTH in module VECTRLLEN calculates the length of a 2-D vector.
!The module contains both private and public procedures
MODULE VECTRLLEN
  PRIVATE SQUARE
  PUBLIC LENGTH
  CONTAINS
  SUBROUTINE LENGTH(x,y,z)
    REAL,INTENT(IN) x,y
    REAL,INTENT(OUT) z
    CALL SQUARE(x,y)
    z = SQRT(x + y)
    RETURN
  END SUBROUTINE
  SUBROUTINE SQUARE(x1,y1)
    REAL x1,y1
    x1 = x1**2
    y1 = y1**2
    RETURN
  END SUBROUTINE
END MODULE
```

PRIVATE Clause

**Parallel Directive Clause:** Declares one or more variables to be private to each thread in a team.

**Syntax**

```
PRIVATE (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

This clause allows each thread to have its own copy of the variable and makes it a local variable to the thread.

The following occurs when variables are declared in a PRIVATE clause:

- A new object of the same type is declared once for each thread in the team (or for each implicit task in a region) and it is used by each thread (or task) inside the scope of the directive construct instead of the original variable. The new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
• Variables defined as PRIVATE are undefined for each thread upon entering the construct and the corresponding shared variable is undefined when the parallel construct is exited. Within a parallel, worksharing, or task region, the initial status of a private pointer is undefined.

The value and allocation status of the original variable will change only in the following cases:

• If it is accessed and modified by means of a pointer
• If it is accessed in the region but outside of the construct
• As a side effect of directives or clauses
• If accessed and modified via construct association.

If a variable has the ALLOCATABLE attribute, the following rules apply:

• If the variable is not currently allocated, the new list item will have an initial state of "unallocated".
• If the variable is allocated, the new list item will have an initial state of allocated with the same array bounds.

A variable that appears in a PRIVATE clause may be storage-associated with other variables when the PRIVATE clause is encountered by constructs such as EQUIVALENCE or COMMON. If A is a variable appearing in a PRIVATE clause and B is a variable that is storage-associated with A, then the following applies:

• The contents, allocation, and association status of B are undefined on entry to the parallel or task region.
• Any definition of A, or any definition of its allocation or association status, causes the contents, allocation, and association status of B to become undefined.
• Any definition of B, or any definition of its allocation or association status, causes the contents, allocation, and association status of A to become undefined.
• A list item that appears in a private clause can be a selector in an ASSOCIATE construct. If the ASSOCIATE construct association is established before entry to a parallel region, the association between the associate name and the original PRIVATE list item will be retained in the parallel region.

The following are restrictions for the PRIVATE clause:

• A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
• A variable that appears in a PRIVATE clause must either be definable or it must be an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
• Assumed-size arrays must not appear in a PRIVATE clause.
• A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a PRIVATE clause. This restriction does not apply to the FIRSTPRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

Variables in a list can appear in other clauses as follows:

• Variables that appear in a PRIVATE, FIRSTPRIVATE, or REDUCTION clause in a parallel construct can also appear in a PRIVATE clause in an enclosed parallel, task, or worksharing construct.
• Variables that appear in a PRIVATE or FIRSTPRIVATE clause in a task construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.
• Variables that appear in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clause in a worksharing construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.

**NOTE**

Variables that are used as counters for explicit or implicit DO loops or FORALL commands, or common blocks that are specified to be THREADPRIVATE become automatically private to each thread, even though they are not explicitly included inside a PRIVATE clause at the beginning of the scope of the parallel region.
Example

Consider the following:

```sh
!$OMP PARALLEL PRIVATE(A, B)
```

In this simple case, each thread will have its own copy of variables A and B. The variables can have different values in each thread because the variables are local to the thread.

FIRSTPRIVATE
LASTPRIVATE

PROCEDURE

**Statement:** Declares procedure pointers, dummy procedures, and external procedures.

**Syntax**

```
PROCEDURE ( [proc-interface] ) [ , proc-attr-spec ] ... :: proc-decl-list
```

**proc-interface**

(Optional) Is the name of an interface, an intrinsic type specifier, or a derived-type TYPE statement.

If an interface name is specified, it must be the name of an abstract interface, a procedure that has an explicit interface, or a procedure pointer. It must have been previously declared and it cannot be the same as a keyword that specifies an intrinsic type.

If `proc-interface` is a type specifier, the declared procedures or procedure pointers are functions that have implicit interfaces and the specified result type. If a type is specified for an external function, its function definition must specify the same result type and type parameters.

**proc-attr-spec**

(Optional) Is one of the following attributes:

- PUBLIC
- PRIVATE
- BIND (C [ , NAME = init-expr])
  This is also called a language-binding-spec. The `init-expr` is a scalar character initialization expression of default character kind. If `NAME=` is specified, there can only be one `proc-decl` item, which cannot have the POINTER attribute or be a dummy procedure.
- INTENT(INOUT)
- OPTIONAL
- POINTER
- SAVE

Each `proc-attr-spec` gives the corresponding attribute to all procedures declared in that statement. If a procedure entity has the INTENT attribute or SAVE attribute, it must also have the POINTER attribute.

**proc-decl-list**

Is one or more of the following:

```
procedure-name [=> null-init]
```

where `null-init` is a reference to intrinsic function NULL with no arguments. If `=>` null-init appears, the procedure must have the POINTER attribute.
Description

A PROCEDURE statement is allowed only in an interface block that has a generic name.

You cannot use the PROCEDURE statement to identify a BLOCK DATA subprogram.

If => null-init appears, it specifies that the initial association status of the corresponding procedure entity is disassociated. It also implies the SAVE attribute.

You can also declare procedures by using an EXTERNAL statement or a procedure component definition statement.

If the BIND attribute is specified for a procedure, each dummy argument must be:

• An interoperable procedure or a variable that is interoperable
• Assumed shape
• Assumed rank
• Assumed type
• Or of assumed character length or has the ALLOCATABLE or POINTER attribute

If the BIND attribute is specified for a function, the function result must be an interoperable scalar variable.

A Fortran procedure is interoperable if it has the BIND attribute; that is, if its interface is specified with a language-binding-spec.

The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a procedure that has a BIND attribute.

A dummy argument of a procedure that has a BIND attribute must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that has a BIND attribute must be of interoperable type or assumed type.

When a procedure whose interface has the BIND attribute is called, any actual argument corresponding to a dummy argument with the ALLOCATABLE or POINTER attribute is passed by C descriptor. Similarly, if a Fortran procedure with a BIND attribute has such dummy arguments, they are received by C descriptor.

Example

Consider the following:

PROCEDURE (NAME_TEMP) :: NAME37

The above declares NAME37 to be a procedure with an identical interface to that of NAME_TEMP.

The following are equivalent:

PROCEDURE (INTEGER) X
INTEGER, EXTERNAL :: X

Consider the following:

ABSTRACT INTERFACE
 FUNCTION SIM_FUNC (X)
   REAL, INTENT (IN) :: X
   REAL :: SIM_FUNC
 END FUNCTION SIM_FUNC
END INTERFACE

INTERFACE
 SUBROUTINE SUB2 (X)
   REAL, INTENT (IN) :: X
 END SUBROUTINE SUB2
END INTERFACE
The following shows external and dummy procedures with explicit interfaces:

```
PROCEDURE (SIM_FUNC) :: VMAC, KAPPA
PROCEDURE (SUB2) :: PRINGLES
```

The following shows procedure pointers with an explicit interface, one initialized to NULL():

```
PROCEDURE (SIM_FUNC), POINTER :: P1, R1 => NULL()
PROCEDURE (SIM_FUNC), POINTER :: KAPPA_POINTER
```

The following shows a derived type with a procedure pointer component:

```fortran
TYPE MEMO_TYPE
  PROCEDURE (SIM_FUNC), POINTER :: COMPONENT
END TYPE MEMO_TYPE
```

The following shows a variable of the above type:

```fortran
TYPE (MEMO_TYPE) :: STRUCTA
```

The following shows an external or dummy function with an implicit interface:

```
PROCEDURE (INTEGER) :: PHIL0
```

**PROCESSOR Clause**

**Parallel Directive Clause:** Tells the compiler to create a vector version of the routine for the specified processor. When running on a processor that does not match "cpuid", a scalar version will be invoked multiple times based on vector length.

**Syntax**

```
PROCESSOR (cpuid)
```

`cpuid` is one of the following keywords:

- `atom` Intel® Atom™ processors with Supplemental Streaming SIMD Extensions 3 (SSSE3)
- `atom_sse4_2` Intel® Atom™ processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)
- `atom_sse4_2_movbe` Intel® Atom™ processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) with MOVBE instructions enabled
- `core_2_duo_sse4_1` Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture processors with Intel® Streaming SIMD Extensions 4.1 (Intel® SSE4.1)
- `core_2_duo_ssse3` Intel® Core™2 Duo processors and Intel® Xeon® processors with Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)

DECLARE SIMD
ATTRIBUTES VECTOR

PRODUCT
Transformational Intrinsic Function (Generic):
Returns the product of all the elements in an entire array or in a specified dimension of an array.

Syntax

\[
\text{result} = \text{PRODUCT} (\text{array}[\text{,dim}] [\text{,mask}])
\]

- **array** (Input) Must be an array of type integer, real, or complex.
- **dim** (Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{array} \).
- **mask** (Input; optional) Must be of type logical and conformable with \( \text{array} \).

Results

The result is an array or a scalar of the same data type as \( \text{array} \).

The result is a scalar if \( \text{dim} \) is omitted or \( \text{array} \) has rank one.

The following rules apply if \( \text{dim} \) is omitted:

- If \( \text{PRODUCT} (\text{array}) \) is specified, the result is the product of all elements of \( \text{array} \). If \( \text{array} \) has size zero, the result is 1.
- If \( \text{PRODUCT} (\text{array}, \text{MASK} = \text{mask}) \) is specified, the result is the product of all elements of \( \text{array} \) corresponding to true elements of \( \text{mask} \). If \( \text{array} \) has size zero, or every element of \( \text{mask} \) has the value \( .\text{FALSE} \), the result is 1.

The following rules apply if \( \text{dim} \) is specified:

- If \( \text{array} \) has rank one, the value is the same as \( \text{PRODUCT} (\text{array}[\text{,MASK} = \text{mask}]) \).
- An array result has a rank that is one less than \( \text{array} \), and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \( \text{array} \).
- The value of element \((s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of \( \text{PRODUCT} (\text{array}, \text{dim}[\text{,mask}]) \) is equal to \( \text{PRODUCT} (\text{array}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n) [\text{,MASK} = \text{mask}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)]) \).

Example

\( \text{PRODUCT} ((/2, 3, 4/)) \) returns the value 24 (the product of 2 * 3 * 4). \( \text{PRODUCT} ((/2, 3, 4/), \text{DIM}=1) \) returns the same result.

\( \text{PRODUCT} (\text{C}, \text{MASK} = \text{C} \cdot \text{LT} \cdot 0.0) \) returns the product of the negative elements of \( \text{C} \).

\( \text{A} \) is the array

\[
\begin{pmatrix}
1 & 4 & 7 \\
2 & 3 & 5 \\
\end{pmatrix}
\]

\( \text{PRODUCT} (\text{A}, \text{DIM}=1) \) returns the value (2, 12, 35), which is the product of all elements in each column. 2 is the product of 1 * 2 in column 1. 12 is the product of 4 * 3 in column 2, and so forth.

\( \text{PRODUCT} (\text{A}, \text{DIM}=2) \) returns the value (28, 30), which is the product of all elements in each row. 28 is the product of 1 * 4 * 7 in row 1. 30 is the product of 2 * 3 * 5 in row 2.

If \( \text{array} \) has shape (2, 2, 2), \( \text{mask} \) is omitted, and \( \text{dim} \) is 1, the result is an array result with shape (2, 2) whose elements have the following values.
<table>
<thead>
<tr>
<th>Resultant array element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>result(1, 1)</td>
<td>array(1, 1, 1) * array(2, 1, 1)</td>
</tr>
<tr>
<td>result(2, 1)</td>
<td>array(1, 2, 1) * array(2, 2, 1)</td>
</tr>
<tr>
<td>result(1, 2)</td>
<td>array(1, 1, 2) * array(2, 1, 2)</td>
</tr>
<tr>
<td>result(2, 2)</td>
<td>array(1, 2, 2) * array(2, 2, 2)</td>
</tr>
</tbody>
</table>

The following shows another example:

```fortran
INTEGER array (2, 3)
INTEGER AR1(3), AR2(2)
array = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2,3/))
! array is  1 2 3
!           4 5 6
AR1 = PRODUCT(array, DIM = 1) ! returns [ 4 10 18 ]
AR2 = PRODUCT(array, MASK = array .LT. 6, DIM = 2)
! returns [ 6 20 ]
END
```

See Also
- SUM

**PROGRAM**

**Statement:** Identifies the program unit as a main program and gives it a name.

**Syntax**

```fortran
[PROGRAM name]
  [specification-part]
  [execution-part]
[CONTAINS
  internal-subprogram-part]
END[PROGRAM [name]]
```

- **name**
  - Is the name of the program.

- **specification-part**
  - Is one or more specification statements, except for the following:
    - INTENT (or its equivalent attribute)
    - OPTIONAL (or its equivalent attribute)
    - PUBLIC and PRIVATE (or their equivalent attributes)
    An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

- **execution-part**
  - Is one or more executable constructs or statements, except for ENTRY or RETURN statements.

- **internal-subprogram-part**
  - Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

The PROGRAM statement is optional. Within a program unit, a PROGRAM statement can be preceded only by comment lines or an OPTIONS statement.
The END statement is the only required part of a program. If a name follows the END statement, it must be the same as the name specified in the PROGRAM statement.

The program name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A main program must not reference itself (either directly or indirectly).

Example

The following is an example of a main program:

```fortran
PROGRAM TEST
   INTEGER C, D, E(20,20) ! Specification part
   CALL SUB_1 ! Executable part
...
CONTAINS
   SUBROUTINE SUB_1 ! Internal subprogram
   ...
END SUBROUTINE SUB_1
END PROGRAM TEST
```

The following shows another example:

```fortran
PROGRAM MyProg
   PRINT *, 'hello world'
END
```

PROTECTED

Statement and Attribute: Specifies limitations on the use of module entities.

Syntax

The PROTECTED attribute can be specified in a type declaration statement or a PROTECTED statement, and takes one of the following forms:

Type Declaration Statement:

```fortran
  type, [att-ls, ] PROTECTED [, att-ls] :: entity[, entity] ...
```

Statement:

```fortran
  PROTECTED [:]entity[, entity] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `entity` Is the name of an entity in a module.

The PROTECTED attribute can only appear in the specification part of a module.

The PROTECTED attribute can only be specified for a procedure pointer or named variable that is not in a common block.

A non-pointer object that has the PROTECTED attribute and is accessed by use association can not appear in a variable definition or as the target in a pointer assignment statement.

A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as any of the following:

- A `pointer-object` in a NULLIFY statement
- A `pointer-object` in a pointer assignment statement
• An object in an ALLOCATE or DEALLOCATE statement
• An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following restrictions apply outside of the module in which the entity has been given the PROTECTED attribute:

• A non-pointer entity may not be defined or redefined.
• A pointer entity may not have its association status changed through the pointer.

Example
The following example shows a type declaration statement specifying the PROTECTED attribute:

```fortran
INTEGER, PROTECTED :: D, E
```

Consider the following example:

```fortran
MODULE counter_mod
    INTEGER, PROTECTED :: current = 0
    CONTAINS
    INTEGER FUNCTION next()
        current = current + 1    ! current can be modified here
        next = current
        RETURN
    END FUNCTION next
END MODULE counter_mod

PROGRAM test_counter
    USE counter_mod
    PRINT *, next()             ! Prints 1
    current = 42                 ! Error: variable is protected
END PROGRAM test_counter
```

Type Declarations
Type Declarations
Pointer Assignments

PSECT

General Compiler Directive: Modifies characteristics of a common block.

Syntax

```
!DIR$ PSECT /common-name/ a[,a] ...
```

**common-name**

Is the name of the common block. The slashes (/) are required.

**a**

Is one of the following:

• **ALIGN= val or ALIGN= keyword**

  Specifies minimum alignment for the common block. ALIGN only has an effect when specified on Windows* and Linux* systems.

  The val is a constant ranging from 0 through 6 on Windows* systems and 0 through 4 on Linux* systems. The specified number is interpreted as a power of 2. The value of the expression is the alignment in bytes.
The *keyword* is one of the following:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to val</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>0</td>
</tr>
<tr>
<td>WORD</td>
<td>1</td>
</tr>
<tr>
<td>LONG</td>
<td>2</td>
</tr>
<tr>
<td>QUAD</td>
<td>3</td>
</tr>
<tr>
<td>OCTA</td>
<td>4</td>
</tr>
<tr>
<td>PAGE</td>
<td>On IA-32 architecture: range is 0 through 13 for Windows* OS; 0 through 12 for Linux* OS</td>
</tr>
</tbody>
</table>

- **[NO]WRT**
  
  Determines whether the contents of a common block can be modified during program execution.

If one program unit changes one or more characteristics of a common block, all other units that reference that common block must also change those characteristics in the same way.

The defaults are ALIGN=OCTA and WRT.

General Compiler Directives
Syntax Rules for Compiler Directives

**PUBLIC**

*Statement and Attribute:* Specifies that entities in a module can be accessed from outside the module (by specifying a USE statement).

**Syntax**

The PUBLIC attribute can be specified in a type declaration statement or a PUBLIC statement, and takes one of the following forms:

**Type Declaration Statement:**

type,[att-ls] PUBLIC [, att-ls] :: entity [, entity]...

**Statement:**

PUBLIC [::] entity [, entity] ...

*type*  
Is a data type specifier.

*att-ls*  
Is an optional list of attribute specifiers.

*entity*  
Is one of the following:
- A variable name
- A procedure name
- A derived type name
- A named constant
- A namelist group name
In statement form, an entity can also be a generic identifier (a generic name, defined operator, or defined assignment).

Description

The PUBLIC attribute can only appear in the scoping unit of a module.

Only one PUBLIC statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility.

If a derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module through use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the definition.

Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```fortran
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
PRIVATE RESTRICTED_DATA
END MODULE
```

The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.
The following shows another example:

! LENGTH in module VECTRLEN calculates the length of a 2-D vector.
! The module contains both private and public procedures
MODULE VECTRLEN
  PRIVATE SQUARE
  PUBLIC LENGTH
  CONTAINS
  SUBROUTINE LENGTH(x,y,z)
    REAL, INTENT(IN) x, y
    REAL, INTENT(OUT) z
    CALL SQUARE(x,y)
    z = SQRT(x + y)
    RETURN
  END SUBROUTINE
  SUBROUTINE SQUARE(x1,y1)
    REAL x1, y1
    x1 = x1**2
    y1 = y1**2
    RETURN
  END SUBROUTINE
END MODULE

PURE
Keyword: Asserts that a user-defined procedure has no side effects.

Description
This kind of procedure is specified by using the prefix PURE (or ELEMENTAL) in a FUNCTION or SUBROUTINE statement.

A pure procedure has no side effects. It has no effect on the state of the program, except for the following:

- For functions: It returns a value.
- For subroutines: It modifies INTENT(OUT) and INTENT(INOUT) parameters.

The following intrinsic and library procedures are implicitly pure:

- All intrinsic functions
- The elemental intrinsic subroutine MVBITS
- The intrinsic subroutine MOVE_ALLOC

A statement function is pure only if all functions that it references are pure.

Except for procedure arguments and pointer arguments, the following intent must be specified for all dummy arguments in the specification part of the procedure:

- For functions: INTENT(IN)
- For subroutines: any INTENT (IN, OUT, or INOUT)
A local variable declared in a pure procedure (including variables declared in any internal procedure) must not:

- Specify the SAVE attribute
- Be initialized in a type declaration statement or a DATA statement

The following variables have restricted use in pure procedures (and any internal procedures):

- Global variables
- Dummy arguments with INTENT(IN) (or no declared intent)
- Objects that are storage associated with any part of a global variable

They must not be used in any context that does either of the following:

- Causes their value to change. For example, they must not be used as:
  - The left side of an assignment statement or pointer assignment statement
  - An actual argument associated with a dummy argument with INTENT(OUT), INTENT(INOUT), or the POINTER attribute
  - An index variable in a DO or FORALL statement, or an implied-DO clause
  - The variable in an ASSIGN statement
  - An input item in a READ statement
  - An internal file unit in a WRITE statement
  - An object in an ALLOCATE, DEALLOCATE, or NULLIFY statement
  - An IOSTAT or SIZE specifier in an I/O statement, or the STAT specifier in a ALLOCATE or DEALLOCATE statement
- Creates a pointer to that variable. For example, they must not be used as:
  - The target in a pointer assignment statement
  - The right side of an assignment to a derived-type variable (including a pointer to a derived type) if the derived type has a pointer component at any level

A pure procedure must not contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement or an ERROR STOP statement
- An image control statement
- An OpenMP* directive

A pure procedure can be used in contexts where other procedures are restricted; for example:

- It can be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It can be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, or finalization.
- It can be passed as an actual argument to a pure procedure.

If a procedure is used in any of these contexts, its interface must be explicit and it must be declared pure in that interface.

**Example**

Consider the following:

```fortran
PURE FUNCTION DOUBLE(X)
  REAL, INTENT(IN) :: X
  DOUBLE = 2 * X
END FUNCTION DOUBLE
```
The following shows another example:

```fortran
PURE INTEGER FUNCTION MANDELBROT(X)
   COMPLEX, INTENT(IN) :: X
   COMPLEX__:: XTMP
   INTEGER__:: K
   ! Assume SHARED_DEFS includes the declaration
   ! INTEGER ITOL
   USE .SHARED.DEFS
   
   K = 0
   XTMP = -X
   DO WHILE (ABS(XTMP) < 2.0 .AND. K < ITOL)
      XTMP = XTMP**2 - X
      K = K + 1
   END DO
   MANDELBROT = K
END FUNCTION
```

The following shows the preceding function used in an interface block:

```fortran
INTERFACE
   PURE INTEGER FUNCTION MANDELBROT(X)
      COMPLEX, INTENT(IN) :: X
   END FUNCTION MANDELBROT
END INTERFACE
```

The following shows a FORALL construct calling the MANDELBROT function to update all the elements of an array:

```fortran
FORALL (I = 1:N, J = 1:M)
   A(I,J) = MANDELBROT(COMPLEX((I-1)*1.0/(N-1), (J-1)*1.0/(M-1))
END FORALL
```

**PUTC**

*Portability Function*: Writes a character to Fortran external unit number 6.

**Module**

USE IFPORT

**Syntax**

```fortran
result = PUTC (char)
```

*char*  
(Input) Character. Character to be written to external unit 6.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

**Example**

```fortran
use IFPORT
integer(4) i4
character*1 char1
```
do i = 1,26
   char1 = char(123-i)
   i4 = putc(char1)
   if (i4.ne.0) iflag = 1
enddo

PUTIMAGE, PUTIMAGE_W (W*S)

Graphics Subroutines: Transfer the image stored in memory to the screen.

Module
USE IFQWIN

Syntax

CALL PUTIMAGE (x, y, image, action)
CALL PUTIMAGE_W (wx, wy, image, action)

x, y
   (Input) INTEGER(2). Viewport coordinates for upper-left corner of the image when placed on the screen.
wx, wy
   (Input) REAL(8). Window coordinates for upper-left corner of the image when placed on the screen.
image
action
   (Input) INTEGER(2). Interaction of the stored image with the existing screen image. One of the following symbolic constants defined in IFQWIN.F90:

- $GAND - Forms a new screen display as the logical AND of the stored image and the existing screen display. Points that have the same color in both the existing screen image and the stored image remain the same color, while points that have different colors are joined by a logical AND.
- $GOR - Superimposes the stored image onto the existing screen display. The resulting image is the logical OR of the image.
- $GPRESET - Transfers the data point-by-point onto the screen. Each point has the inverse of the color attribute it had when it was taken from the screen by GETIMAGE, producing a negative image.
- $GPSET - Transfers the data point-by-point onto the screen. Each point has the exact color attribute it had when it was taken from the screen by GETIMAGE.
- $GXOR - Causes points in the existing screen image to be inverted wherever a point exists in the stored image. This behavior is like that of a cursor. If you perform an exclusive OR of an image with the background twice, the background is restored unchanged. This allows you to move an object around without erasing the background. The $GXOR constant is a special mode often used for animation.
- In addition, the following ternary raster operation constants can be used (described in the online documentation for the Windows* API BitBlt):
- $GSRCCOPY (same as $GPSET)
- $GSRCPAINT (same as $GOR)
- $GSRCAND (same as $GAND)
- $GSRCINVERT (same as $GXOR)
- $GSRCERASE
- $GNOTSRCCOPY (same as $GPRESET)
- $GNOTSRCERASE
- $GMERGECOPY
- $GMERGEPAINT
- $GPATCOPY
- $GPATPAINT
- $GPATINVERT
- $GDSTINVERT
- $GBLACKNESS
- $GWHITENESS

PUTIMAGE places the upper-left corner of the image at the viewport coordinates \((x, y)\). PUTIMAGE_W places the upper-left corner of the image at the window coordinates \((wx, wy)\).

**Example**

```fortran
! Build as a Graphics App.
USE IFQWIN
INTEGER(1), ALLOCATABLE :: buffer(:)
INTEGER(2) status, x
INTEGER(4) imsize

status = SETCOLOR(INT2(4))

! draw a circle
status = ELLIPSE($GFILLINTERIOR,INT2(40),INT2(55),    &
INT2(70),INT2(85))

imsize = IMAGESIZE (INT2(39),INT2(54),INT2(71), &
INT2(86))
ALLOCATE (buffer(imsize))
CALL GETIMAGE(INT2(39),INT2(54),INT2(71),INT2(86), &
buffer)

! copy a row of circles beneath it
DO x = 5, 395, 35
  CALL PUTIMAGE(x, INT2(90), buffer, $GPSET)
END DO
DEALLOCATE(buffer)
END
```

**PXF(type)GET**

POSIX Subroutine: Gets the value stored in a component (or field) of a structure.

**Module**

USE IFPOSIX
Syntax

CALL PXF(type)GET (jhandle, compname, value, ierror)
CALL PXF(type)GET (jhandle, compname, value, ilen, ierror) ! syntax when (type) is STR

(type) A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*</td>
<td>PXFSTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFINT8GET</td>
</tr>
</tbody>
</table>

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

value (Output) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). Stores the value of the component (or field).

ilen (Output) INTEGER(4). This argument can only be used when (type) is STR (PXFSTRGET). Stores the length of the returned string.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXF(type)GET subroutines retrieve the value from component (or field) compname of the structure associated with handle jhandle into variable value.

Example

See the example in PXFTIMES (which shows PXFINTGET and PXFINT8GET)

See Also

PXF(type)SET

POSIX Subroutine: Sets the value of a component (or field) of a structure.

Module

USE IFPOSIX

Syntax

CALL PXF(type)SET (jhandle, compname, value, ierror)
CALL PXF(type)SET (jhandle, compname, value, ilen, ierror) ! syntax when (type) is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFSTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFIN8SET</td>
</tr>
</tbody>
</table>

jhandle  
(Input) INTEGER(4). A handle of a structure.

compname  
(Input) Character. The name of the component (or field) of the structure to write data to.

value  
(Input) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). The value for the component (or field).

ilen  
(Input) INTEGER(4). This argument can only be used when (type) is STR (PXFSTRSET). The length of the string in value.

ierror  
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Example
See the example in PXFSTRUCTCREATE (which shows PXFSTRSET)

See Also
PXF(type)GET

PXFA(type)GET

POSIX Subroutine: Gets the array values stored in a component (or field) of a structure.

Module
USE IFPOSIX

Syntax
CALL PXFA(type)GET (jhandle, compname, value, ilen, ierror)

CALL PXFA(type)GET (jhandle, compname, value, ilen, ilen, ierror) ! syntax when (type) is STR

A placeholder for one of the following values:
<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFAINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFAREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFALGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*(*)</td>
<td>PXFASTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFACHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8GET</td>
</tr>
</tbody>
</table>

**jhandle**
(Input) INTEGER(4). A handle of a structure.

**compname**
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value**
(Output) An array, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).

**ialen**
(Input) INTEGER(4). The size of array value.

**ilen**
(Output) INTEGER(4). This argument can only be used when (type) is STR (PXFASTRGET). An array that stores the lengths of elements of array value.

**ierror**
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**See Also**
PXFA(type)SET
PXF(type)GET

**PXFA(type)SET**

** POSIX Subroutine:** Sets the value of an array component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFA(type)SET (jhandle, compname, value, ialen, ierror)

CALL PXFA(type)SET (jhandle, compname, value, ialen, ilen, ierror) ! syntax when (type) is STR
(type) A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFAINTSET</td>
</tr>
<tr>

PXFACCESS
POSIX Subroutine: Determines the accessibility of a file.

Module
USE IFPOSIX

Syntax
CALL PXFACCESS (path, ilen, iamode, ierror)
### PXFALARM

**POSIX Subroutine:** Schedules an alarm.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFALARM (iseconds, isecleft, ierror)

- **iseconds** *(Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.*

- **isecleft** *(Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered.*

  *It is set to zero if there was no previously scheduled alarm signal.*

- **ierror** *(Output) INTEGER(4). The error status.*

  *If successful, ierror is set to zero; otherwise, an error code.

The PXFALARM subroutine arranges for a SIGALRM signal to be delivered to the process in seconds iseconds.

On Linux* and OS X* systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

PXFCALLSUBHANDLE

**POSIX Subroutine:** Calls the associated subroutine.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCALLSUBHANDLE (jhandle2, ival, ierror)

- **jhandle2** (Input) INTEGER(4). A handle to the subroutine.
- **ival** (Input) INTEGER(4). The argument to the subroutine.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine.
PXGETSUBHANDLE should be used to obtain a subroutine handle.

**NOTE**
The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

See Also
PXGETSUBHANDLE

PXFCFGETISPEED (L*X, M*X)

**POSIX Subroutine:** Returns the input baud rate from a termios structure.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCFGETISPEED (jtermios, iospeed, ierror)

- **jtermios** (Input) INTEGER(4). A handle of structure termios.
- **iospeed** (Output) INTEGER(4). The returned value of the input baud rate from the structure associated with handle **jtermios**.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
NOTE
To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also
PXFSTRUCTCREATE

PXFCHMOD

**POSIX Subroutine:** Changes the ownership mode of the file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCHMOD (path, ilen, imode, ierror)

path (Input) Character. The path to the file.

ilen (Input) INTEGER(4). The length of the path string.

imode (Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++ Installation in the \include directory under sys\stat.h for the values of imode. On Linux* and OS X* systems, use octal file-access mode.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**NOTE**
On Linux* and OS X* systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

PXFCHOWN (L*X, M*X)

**POSIX Subroutine:** Changes the owner and group of a file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCHOWN (path, ilen, iowner, igroup, ierror)

path (Input) Character. The path to the file.

ilen (Input) INTEGER(4). The length of the path string.

iowner (Input) INTEGER(4). The owner UID.

igroup (Input) INTEGER(4). The group GID.
ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFCLEARENV

POSIX Subroutine: Clears the process environment.

Module
USE IFPOSIX

Syntax
CALL PXFCLEARENV (ierror)

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

After a call to PXFCLEARENV, no environment variables are defined.

PXFCLOSE

POSIX Subroutine: Closes the file associated with the descriptor.

Module
USE IFPOSIX

Syntax
CALL PXFCLOSE (fd,ierror)

fd

(Input) INTEGER(4). A file descriptor.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also
PXFOPEN

PXFCLOSEDIR

POSIX Subroutine: Closes the directory stream.

Module
USE IFPOSIX

Syntax
CALL PXFCLOSEDIR (idirid,ierror)

idirid

(Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with idirid.
See Also
PXFOPENDIR

PXFCREATE

POSIX Subroutine: Creates a new file or rewrites an existing file.

Module
USE IFPOSIX

Syntax
CALL PXFCREAT (path, ilen, imode, ifildes, ierror)

path (Input) Character. The pathname of the file.
ilen (Input) INTEGER(4). The length of path string.
imode
(Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* and OS X* systems, use octal file-access mode.

ifildes
(Output) INTEGER(4). The returned file descriptor.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**PXFCTERMID (L*X, M*X)**

**POSIX Subroutine:** Generates a terminal pathname.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFCTERMID (s,ilen,ierror)

s
(Output) Character. The returned pathname of the terminal.

ilen
(Output) INTEGER(4). The length of the returned value in the s string.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine returns a string that refers to the current controlling terminal for the current process.

**PXFDUP, PXFDUP2**

**POSIX Subroutine:** Duplicates an existing file descriptor.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFDUP (ifildes,ifid,ierror)
CALL PXFDUP2 (ifildes,ifildes2,ierror)

ifildes
(Input) INTEGER(4). The file descriptor to duplicate.

ifid
(Output) INTEGER(4). The returned new duplicated file descriptor.

ifildes2
(Input) INTEGER(4). The number for the new file descriptor.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFDUP subroutine creates a second file descriptor for an opened file.

The PXFDUP2 subroutine copies the file descriptor associated with ifildes. Integer number ifildes2 becomes associated with this new file descriptor, but the value of ifildes2 is not changed.
PXFE(type)GET

**POSIX Subroutine:** Gets the value stored in an array element component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFE(type)GET (jhandle, compname, index, value, ierr)

CALL PXFE(type)GET (jhandle, compname, index, value, ilen, ierr) ! syntax when (type) is STR

(type) A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8GET</td>
</tr>
</tbody>
</table>

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

index (Input) INTEGER(4). The index of the array element to get data for.

value (Output) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). Stores the value of the component (or field).

ilen (Output) INTEGER(4). This argument can only be used when (type) is STR (PXFESTRGET). Stores the length of the returned string.

ierr (Output) INTEGER(4). The error status.

If successful, ierr is set to zero; otherwise, an error code.

The PXFE(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)GET subroutines are used, the array element with index index is accessed (read from the component or field).

**See Also**

PXFE(type)SET
PXF(type)GET
**PXFE(type)SET**

**POSIX Subroutine:** Sets the value of an array element component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFE(type)SET (jhandle, compname, index, value, ierror)

CALL PXFE(type)SET (jhandle, compname, index, value, ilen, ierror) ! syntax when (type) is STR

(type)

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8SET</td>
</tr>
</tbody>
</table>

jhandle  
(Input) INTEGER(4). A handle of a structure.

compname  
(Input) Character. The name of the component (or field) of the structure to write data to.

index  
(Input) INTEGER(4). The index of the array element to write data to.

value  
(Input) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). The value for the component (or field).

ilen  
(Input) INTEGER(4). This argument can only be used when (type) is STR (PXFESTRSET). The length of the string value.

ierror  
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFE(type)SET subroutines are similar to the PXF(type)SET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)SET subroutines are used, the array element with index index is accessed (written to the component or field).

**See Also**

PXFE(type)GET  
PXF(type)SET
PXFEXECV

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFEXECV (path, lenpath, argv, lenargv, iargc, ierror)

- **path** (Input) Character. The path to the new executable process.
- **lenpath** (Input) INTEGER(4). The length of path string.
- **argv** (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
- **lenargv** (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.
- **iargc** (Input) INTEGER(4). The number of command-line arguments.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. If execution is successful, no return is made to the calling process.

**See Also**
PXFEXECVE
PXFEXECVP

**PXFEXECVE**

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFEXECVE (path, lenpath, argv, lenargv, iargc, env, lenenv, ienvc, ierror)

- **path** (Input) Character. The path to the new executable process.
- **lenpath** (Input) INTEGER(4). The length of path string.
- **argv** (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
- **lenargv** (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.
- **iargc** (Input) INTEGER(4). The number of command-line arguments.
- **env** (Input) Character array. Environment variables.
- **lenenv** (Input) INTEGER(4). An array of lengths for each corresponding environment variable.
- **ienvc** (Input) INTEGER(4). The number of environment variables.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. If execution is successful, no return is made to the calling process.
env

(Input) An array of character strings. Contains the environment settings for the new process.

lenenv

(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in env.

ienvc

(Input) INTEGER(4). The number of environment settings in env.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array and environment settings specified in the env array.

See Also
PXFEXECV
PXFEXECVP

PXFEXECVP

POSIX Subroutine: Executes a new process by passing command-line arguments.

Module
USE IFPOSIX

Syntax
CALL PXFEXECVP (file, lenfile, argv, lenargv, iargc, ierror)

file

(Input) Character. The filename of the new executable process.

lenfile

(Input) INTEGER(4). The length of file string.

argv

(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

lenargv

(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

iargc

(Input) INTEGER(4). The number of command-line arguments.

ierror

(Input) Character. The filename of the new executable process.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVP subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. It uses the PATH environment variable to find the file to execute.

See Also
PXFEXECV
PXFEXECVE

PXFEXIT, PXFFASTEXIT

POSIX Subroutine: Exits from a process.

Module
USE IFPOSIX
**Syntax**

CALL PXFEXIT (istatus)

CALL PXFFASTEXIT (istatus)

`istatus`  
**Input** INTEGER(4). The exit value.

The PXFEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions `atexit` and `onexit`, and flushes all file buffers before terminating the process. The `istatus` value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing `atexit` or `onexit`, and without flushing stream buffers.

**Example**

```fortran
program t1
use ifposix

integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
  print *, "I am a child process"
  print *, "My child's pid is", IPID_RET
call PXFGETPPID(IPID_RET,IERROR)
  print *, "The pid of my parent is", IPID_RET
  print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
  print *, "I am a parent process"
  print *, "My parent pid is ", IPID_RET
  print *, "I am creating the process with pid", IPID
  print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *, "The child with pid ", IPID_RET," has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, "The child exited normally"
    istat_ret = IPXFEXITSTATUS(ISTAT)
    print 10, "The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program
```

**PXFFCNTL (L*X, M*X)**

**POSIX Subroutine:** Manipulates an open file descriptor.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFCNTL (ifildes, icmd, iargin, iargout, ierror)

`ifildes`  
**Input** INTEGER(4). A file descriptor.
icmd  (Input) INTEGER(4). Defines an action for the file descriptor.

iargin  (Input; output) INTEGER(4). Interpretation of this argument depends on the value of icmd.

iargout  (Output) INTEGER(4). Interpretation of this argument depends on the value of icmd.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in icmd, can be obtained by using the values of predefined macros in C header fcntl.h, or by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_DUPFD</td>
<td>Returns into iargout the lowest available unopened file descriptor greater than or equal to iargin. The new file descriptor refers to the same open file as ifildes and shares any locks. The system flag FD_CLOEXEC for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.</td>
</tr>
<tr>
<td>F_GETFD</td>
<td>Returns into iargout the value of system flag FD_CLOEXEC associated with ifildes. In this case, iargin is ignored.</td>
</tr>
<tr>
<td>F_SETFD</td>
<td>Sets or clears the system flag FD_CLOEXEC for file descriptor ifildes. The PXFEXEC family of functions will close all file descriptors with the FD_CLOEXEC flag set. The value for FD_CLOEXEC is obtained from argument iargin.</td>
</tr>
</tbody>
</table>
| F_GETFL  | Returns the file status flags for file descriptor ifildes. Unlike F_GETFD, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for PXFCONST or IPXFCONST, can be returned:  
  - O_APPEND - Specifies the file is opened in append mode.  
  - O_NONBLOCK - Specifies when the file is opened, it does not block waiting for data to become available.  
  - O_RDONLY - Specifies the file is opened for reading only.  
  - O_RDWR - Specifies the file is opened for both reading and writing.  
  - O_WRONLY - Specifies the file is opened for writing only. |
<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_SETFL</td>
<td>Sets the file status flags from iargin for file descriptor ifildes. Only O_APPEND or O_NONBLOCK flags can be modified. In this case, iargout is ignored.</td>
</tr>
<tr>
<td>F_GETLK</td>
<td>Gets information about a lock. Argument iargin must be a handle of structure flock. This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle iargin. If there are no locks in place that would prevent the lock from being locked, field l_type in the structure is set to the value of the constant with symbolic name F_UNLCK.</td>
</tr>
<tr>
<td>F_SETLK</td>
<td>Sets or clears a lock. Argument iargin must be a handle of structure flock. The lock is set or cleared according to the value of structure field l_type. If the lock is busy, an error is returned.</td>
</tr>
<tr>
<td>F_SETLKW</td>
<td>Sets or clears a lock, but causes the process to wait if the lock is busy. Argument iargin must be a handle of structure flock. The lock is set or cleared according to the value of structure field l_type. If the lock is busy, PXFCNTL waits for an unlock.</td>
</tr>
</tbody>
</table>

**NOTE**
To get a handle for an instance of the flock structure, use PXFSTRUCTCREATE with the string 'flock' for the structure name.

**See Also**
PXFSTRUCTCREATE
IPXFCONST
PXFFDOPEN

**POSIX Subroutine:** Opens an external unit.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFDOPEN (ifildes,iunit,access,ierror)

ifildes   (Input) INTEGER(4). The file descriptor of the opened file.
iunit     (Input) INTEGER(4). The Fortran logical unit to connect to file descriptor ifildes.
(Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Possible Values</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NEWLINE'</td>
<td>'YES' or 'NO'</td>
<td>I/O type</td>
<td>'YES'</td>
</tr>
<tr>
<td>'BLANK'</td>
<td>'NULL' or 'ZERO'</td>
<td>Interpretation of blanks</td>
<td>'NULL'</td>
</tr>
<tr>
<td>'STATUS'</td>
<td>'OLD', 'SCRATCH', or 'UNKNOWN'</td>
<td>File status at open</td>
<td>'UNKNOWN'</td>
</tr>
<tr>
<td>'FORM'</td>
<td>'FORMATTED' or 'UNFORMATTED'</td>
<td>Format type</td>
<td>'FORMATTED'</td>
</tr>
</tbody>
</table>

Keywords should be separated from their values by the equals ('=') character; for example:

```fortran
call PXFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN', IERROR)
```

ierror

(Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by `iunit` to a file descriptor `ifildes`. If unit is already connected to a file, the file should be closed before using PXFFDOPEN.

**NOTE**

On Windows* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

**See Also**

PXFPOSIXIO

PXFFFLUSH

**POSIX Subroutine:** Flushes a file directly to disk.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFFFLUSH (lunit, ierror)
```

lunit (Input) INTEGER(4). A Fortran logical unit.

ierror (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFFFLUSH subroutine writes any buffered output to the file connected to unit `lunit`. 
PXFFGETC

**POSIX Subroutine:** Reads a character from a file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFGETC (lunit, char, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **char** (Input) Character. The character to be read.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFFGETC subroutine reads a character from a file connected to unit **lunit**.

**See Also**

PXFFPUTC

PXFFILENO

**POSIX Subroutine:** Returns the file descriptor associated with a specified unit.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFILENO (lunit, fd, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **fd** (Output) INTEGER(4). The returned file descriptor.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code. Possible error codes are:

- **EINVAL**: **lunit** is not an open unit.
- **EBADF**: **lunit** is not connected with a file descriptor.

The PXFFILENO subroutine returns in **fd** the file descriptor associated with **lunit**.

**NOTE**

On Windows* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

**See Also**

PXFPOSIXIO
PXFFORK (L*X, M*X)

**POSIX Subroutine:** Creates a child process that differs from the parent process only in its PID.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFORK (ipid, ierror)

**ipid**

(Output) INTEGER(4). The returned PID of the new child process.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent’s thread of execution, and a zero is returned in the child’s thread of execution. Otherwise, a -1 is returned in the parent's context and no child process is created.

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *, "I am a child process"
   print *, "My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *, "The pid of my parent is",IPID_RET
   print *, "Now I have exited with code 0xABCD"
   call PXFEXIT(Z'ABCD')
else
   print *, "I am a parent process"
   print *, "My parent pid is ", IPID_RET
   print *, "I am creating the process with pid", IPID
   print *, "Now I am waiting for the end of the child process"
   call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *, "The child with pid ", IPID_RET," has exited"
   if( PXFMIFEXITED(ISTAT) ) then
      print *, "The child exited normally"
      istat_ret = IPXFEXITSTATUS(ISTAT)
      print 10,"The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program
```

**See Also**

IPXFEXITSTATUS (L*X, M*X)

PXFFPATHCONF

**POSIX Subroutine:** Gets the value for a configuration option of an opened file.
Module
USE IFPOSIX

Syntax
CALL PXFFPATHCONF (ifildes, name, ival, ierror)

ifildes  
(Input) INTEGER(4). The file descriptor of the opened file.

name  
(Input) INTEGER(4). The configurable option.

ival  
(Output) INTEGER(4). The value of the configurable option.

ierror  
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor ifildes.

The configuration option, defined in name, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If ifildes refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON1</td>
<td>Returns the maximum length of a formatted input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT1</td>
<td>Returns the maximum length of an input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in ifildes that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when ifildes is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the file descriptor ifildes must refer to a pipe or FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED1</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If ifildes refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC1</td>
<td>Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE1</td>
<td>Returns nonzero if special character processing can be disabled; the file descriptor ifildes must refer to a terminal.</td>
</tr>
</tbody>
</table>

1L*X, M*X
On Linux* and OS X* systems, the corresponding macros are defined in <unistd.h>. The values for name can be obtained by using PXFCNST or IPXFCNST when passing the string names of predefined macros in <unistd.h>. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>_POSIX_PATH_MAX</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>_POSIX_CHOWN_RESTRICTED</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NO_TRUNC</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
</tbody>
</table>

PXFPATHCONF

PXFFPUTC

**POSIX Subroutine:** Writes a character to a file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFPUTC (lunit, char, ierror)

lunit (Input) INTEGER(4). A Fortran logical unit.
char (Input) Character. The character to be written.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit lunit.

PXFFGETC

PXFFSEEK

**POSIX Subroutine:** Modifies a file position.

**Module**
USE IFPOSIX
**Syntax**

CALL PXFFSEEK (lunit, ioffset, iwhence, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **ioffset** (Input) INTEGER(4). The number of bytes away from iwhence to place the pointer.
- **iwhence** (Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in stdio.h):
  - SEEK_SET = 0 Offset from the beginning of the file.
  - SEEK_CUR = 1 Offset from the current position of the file pointer.
  - SEEK_END = 2 Offset from the end of the file.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. Possible error codes are:
- EINVAL: No file is connected to lunit, iwhence is not a proper value, or the resulting offset is invalid.
- ESPIPE: lunit is a pipe or FIFO.
- EEND: The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit lunit.

**PXFFSTAT**

**POSIX Subroutine: Gets a file's status information.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFSTAT (ifildes, jstat, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor for an opened file.
- **jstat** (Input) INTEGER(4). A handle of structure stat.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with ifildes into the structure associated with handle jstat.

**NOTE**

To get a handle for an instance of the stat structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

**See Also**

PXFSTRUCTCREATE
**PXFFTELL**

**POSIX Subroutine:** Returns the relative position in bytes from the beginning of the file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFTELL (lunit, ioffset, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **ioffset** (Output) INTEGER(4). The returned relative position in bytes from the beginning of the file.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

**PXGETARG**

**POSIX Subroutine:** Gets the specified command-line argument.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFGETARG (argnum, str, istr, ierror)

- **argnum** (Input) INTEGER(4). The number of the command-line argument.
- **str** (Output) Character. The returned string value.
- **istr** (Output) INTEGER(4). The length of the returned string; it is zero if an error occurs.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFGETARG subroutine places the command-line argument with number **argnum** into character string **str**. If **argnum** is equal to zero, the value of the argument returned is the command name of the executable file.

**See Also**
IPXFARGC

**PXGETC**

**POSIX Subroutine:** Reads a character from standard input unit 5.

**Module**
USE IFPOSIX
**Syntax**

CALL PXFGETC (nextcar, ierror)

*nextcar* (Output) Character. The returned character that was read.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**See Also**

PXFPUTC

**PXFGETCWD**

*POSIX Subroutine:* Returns the path of the current working directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETCWD (buf, ilen, ierror)

*buf* (Output) Character. The returned pathname of the current working directory.

*ilen* (Output) INTEGER(4). The length of the returned pathname.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of *buf* is insufficient.

**PXFGETEGID (L*X, M*X)**

*POSIX Subroutine:* Gets the effective group ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETEGID (iegid, ierror)

*iegid* (Output) INTEGER(4). The returned effective group ID.

*ierror* (Output) INTEGER(4). The error status.

**Description**

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.
**PXGETENV**

**POSIX Subroutine:** Gets the setting of an environment variable.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETENV (name, lenname, value, lenval, ierror)

- **name** (Input) Character. The name of the environment variable.
- **lenname** (Input) INTEGER(4). The length of name.
- **value** (Output) Character. The returned value of the environment variable.
- **lenval** (Output) INTEGER(4). The returned length of value. If an error occurs, it returns zero.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**See Also**

PXGETENV

**PXGETEUID (L*X, M*X)**

**POSIX Subroutine:** Gets the effective user ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETEUID (ieuid, ierror)

- **ieuid** (Output) INTEGER(4). The returned effective user ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

**PXGETGID (L*X, M*X)**

**POSIX Subroutine:** Gets the real group ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETGID (igid, ierror)
$igid$  (Output) INTEGER(4). The returned real group ID.

$ierror$  (Output) INTEGER(4). The error status.

If successful, $ierror$ is set to zero; otherwise, an error code.
The real ID corresponds to the ID of the calling process.

Example
See the example in PXFGETGROUPS

See Also
PXFSETGID (L*X, M*X)

PXFGETGRGID (L*X, M*X)

**POSIX Subroutine:** Gets group information for the specified GID.

Module
USE IFPOSIX

Syntax
CALL PXFGETGRGID ($jgid$, $jgroup$, $ierror$)

$jgid$  (Input) INTEGER(4). The group ID to retrieve information about.

$jgroup$  (Input) INTEGER(4). A handle of structure $group$.

$ierror$  (Output) INTEGER(4). The error status.

If successful, $ierror$ is not changed; otherwise, an error code.
The PXFGETGRGID subroutine stores the group information from /etc/group for the entry that matches the group GID $jgid$ in the structure associated with handle $jgroup$.

**NOTE**
To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

Example
See the example in PXFGETGROUPS

See Also
PXFSTRUCTCREATE

PXFGETGRNAM (L*X, M*X)

**POSIX Subroutine:** Gets group information for the named group.

Module
USE IFPOSIX

Syntax
CALL PXFGETGRNAM (name, ilen, $jgroup$, $ierror$)
name  (Input) Character. The name of the group to retrieve information about.
ilen  (Input) INTEGER(4). The length of the name string.
jgroup  (Input) INTEGER(4). A handle of structure group.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is not changed; otherwise, an error code.

The PXFGETGRNAM subroutine stores the group information from /etc/group for the entry that matches the group name name in the structure associated with handle jgroup.

NOTE
To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

See Also
PXFSTRUCTCREATE

PXFGETGROUPS (L*X, M*X)

POSIX Subroutine: Gets supplementary group IDs.

Module
USE IFPOSIX

Syntax
CALL PXFGETGROUPS (igidsetsize, igrouplist, ngroups, ierror)

igidsetsize  (Input) INTEGER(4). The number of elements in the igrouplist array.
igrouplist  (Output) INTEGER(4). The array that has the returned supplementary group IDs.
ngroups  (Output) INTEGER(4). The total number of supplementary group IDs for the process.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFGETGROUPS subroutine returns, up to size igidsetsize, the supplementary group IDs in array igrouplist. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

Example
program test5
use ifposix
implicit none
integer(4) number_of_groups, ierror, isize,i,igid
integer(4),allocatable,dimension(:):: igrouplist
integer(JHANDLE_SIZE) jgroup

! Get total number of groups in system
! call PXFGETGROUPS with 0
CALL PXFGETGROUPS(0, igrouplist, number_of_groups, ierror)
IF(ierror.NE.0) STOP 'Error: first call of PXFGETGROUPS fails'
PRINT *, "The number of groups in system ", number_of_groups

! Get Group IDs
isize = number_of_groups
ALLOCATE(igrouplist(isize))
CALL PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
IF(ierror.NE.0) THEN
  DEALLOCATE(igrouplist)
  STOP 'Error: first call of PXFGETGROUPS fails'
END IF

PRINT *, "Create an instance for structure 'group'"
CALL PXFSTRUCTCREATE("group", jgroup, ierror)
IF(ierror.NE.0) THEN
  DEALLOCATE(igrouplist)
  STOP 'Error: PXFSTRUCTCREATE failed to create an instance of group'
END IF

DO i = 1, number_of_groups
  CALL PXFGETGRGID(igrouplist(i), jgroup, ierror)
  IF(ierror.NE.0) THEN
    DEALLOCATE(igrouplist)
    CALL PXFSTRUCTFREE(jgroup, ierror)
    PRINT *, 'Error: PXFGETGRGID failed for i=', i, " gid=", igrouplist(i)
    STOP 'Abnormal termination'
  END IF
  CALL PRINT_GROUP_INFO(jgroup)
END DO

CALL PXFGETGID(igid, ierror)
IF(ierror.NE.0) THEN
  DEALLOCATE(igrouplist)
  CALL PXFSTRUCTFREE(jgroup, ierror)
  PRINT *, 'Error: PXFGETGID failed'
  STOP 'Abnormal termination'
END IF

CALL PXFGETGRGID(igid, jgroup, ierror)
IF(ierror.NE.0) THEN
  DEALLOCATE(igrouplist)
  CALL PXFSTRUCTFREE(jgroup, ierror)
  PRINT *, 'Error: PXFGETGRGID failed for gid=', igid
  STOP 'Abnormal termination'
END IF

CALL PRINT_GROUP_INFO(jgroup)
DEALLOCATE(igrouplist)
CALL PXFSTRUCTFREE(jgroup, ierror)
PRINT *, "Program will normal terminated"
CALL PXFEXIT(0)
END

**PXFGETLOGIN**

**POSIX Subroutine:** Gets the name of the user.

**Module**

USE IFPOSIX
Syntax

CALL PXFGETLOGIN (s, ilen, ierror)

s 
(Output) Character. The returned user name.

ilen 
(Output) INTEGER(4). The length of the string stored in s.

ierror 
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**PXFGETPGRP (L*X, M*X)**

POSIX Subroutine: Gets the process group ID of the calling process.

Module

USE IFPOSIX

Syntax

CALL PXFGETPGRP (ipgrp, ierror)

ipgrp 
(Output) INTEGER(4). The returned process group ID.

ierror 
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Each process group is a member of a session and each process is a member of the session in which its process group is a member.

**PXFGETPID**

POSIX Subroutine: Gets the process ID of the calling process.

Module

USE IFPOSIX

Syntax

CALL PXFGETPID (ipid, ierror)

ipid 
(Output) INTEGER(4). The returned process ID.

ierror 
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *, "I am a child process"
print *, "My child's pid is", IPID_RET
call PXFGETPPID(IPID_RET, IERROR) —
print *, "The pid of my parent is", IPID_RET
print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
print *, "I am a parent process"
print *, "My parent pid is ", IPID_RET
print *, "I am creating the process with pid", IPID
print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
print *, "The child with pid ", IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
    print *, "The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10,"The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

PXFGETPPID

POSIX Subroutine: Gets the process ID of the parent of the calling process.

Module

USE IFPOSIX

Syntax

CALL PXFGETPPID (ippid, ierror)

ippid (Output) INTEGER(4). The returned process ID.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
    print *, "I am a child process"
    print *, "My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET, IERROR)
    print *, "The pid of my parent is", IPID_RET
    print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
    print *, "I am a parent process"
    print *, "My parent pid is", IPID_RET
    print *, "I am creating the process with pid", IPID
    print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *, "The child with pid", IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
  print *, " The child exited normally"
  istat_ret = IPXFWEXITSTATUS(ISTAT)
  print 10," The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

PXGETPWNAM (L*X, M*X)

**POSIX Subroutine:** Gets password information for a specified name.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETPWNAM (name, ilen, jpasswd, ierror)

- **name** (Input) Character. The login name of the user to retrieve information about. For example, a login name might be "j smith", while the actual name is "John Smith".
- **ilen** (Input) INTEGER(4). The length of the name string.
- **jpasswd** (Input) INTEGER(4). A handle of structure compnam.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is not changed; otherwise, an error code.

The **PXGETPWNAM** subroutine stores the user information from /etc/passwd for the entry that matches the user name **name** in the structure associated with handle **jpasswd**.

**NOTE**

To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

**See Also**

PXFSTRUCTCREATE

PXGETPWUID (L*X, M*X)

**POSIX Subroutine:** Gets password information for a specified UID.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETPWUID (iuid, jpasswd, ierror)

- **iuid** (Input) INTEGER(4). The user ID to retrieve information about.
jpasswd  (Output) INTEGER(4). A handle of structure compnam.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFGETPWUID subroutine stores the user information from /etc/passwd for the entry that matches the user ID iuid in the structure associated with handle jpasswd.

NOTE
To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

See Also
PXFSTRUCTCREATE

PXFGETSUBHANDLE
POSIX Subroutine: Returns a handle for a subroutine.

Module
USE IFPOSIX

Syntax
CALL PXFGETSUBHANDLE (sub, jhandle1, ierror)

sub  (Input) The Fortran subroutine to get a handle for.

jhandle1  (Output) INTEGER(4). The returned handle for the subroutine.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE
The argument sub cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

PXFGETUID (L*X, M*X)
POSIX Subroutine: Gets the real user ID of the current process.

Module
USE IFPOSIX

Syntax
CALL PXFGETUID (iuid, ierror)

iuid  (Output) INTEGER(4). The returned real user ID.

ierror  (Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

See Also
PXFSETUID (L*X, M*X)

PXFISATTY (L*X, M*X)
**POSIX Subroutine:** Tests whether a file descriptor is connected to a terminal.

Module
USE IFPOSIX

Syntax
CALL PXFISATTY (ifildes, isatty, ierror)

ifildes (Input) INTEGER(4). The file descriptor.
isatty (Output) LOGICAL(4). The returned value.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

If file descriptor ifildes is open and connected to a terminal, isatty returns .TRUE.; otherwise, .FALSE..

See Also
PXFOPEN

PXFISBLK
**POSIX Function:** Tests for a block special file.

Module
USE IFPOSIX

Syntax
result = PXFISBLK (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a block special file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFISCHR

PXFISCHR
**POSIX Function:** Tests for a character file.

Module
USE IFPOSIX
Syntax
result = PXFISCHR (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a character file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFISBLK
PXFISCONST

PXFISCONST
POSIX Function: Tests whether a string is a valid constant name.

Module
USE IFPOSIX

Syntax
result = PXFISCONST (s)

s (Input) Character. The name of the constant to test.

Results
The result type is logical. The PXFISCONST function confirms whether the argument is a valid constant name that can be passed to functions PXFCONST and IPXFCONST. It returns .TRUE. only if IPXFCONST will return a valid value for name s.

See Also
IPXFCONST
PXFCONST

PXFISDIR
POSIX Function: Tests whether a file is a directory.

Module
USE IFPOSIX

Syntax
result = PXFISDIR (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a directory, the result value is .TRUE.; otherwise, .FALSE..

PXFISFIFO
POSIX Function: Tests whether a file is a special FIFO file.
Module
USE IFPOSIX

Syntax
result = PXFISFIFO (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical.
The PXFISFIFO function tests whether the file is a special FIFO file created by PXFMKFIFO. If the file is a special FIFO file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFMKFIFO (L*X, M*X)
PXFISREG

PXFISREG
POSIX Function: Tests whether a file is a regular file.

Module
USE IFPOSIX

Syntax
result = PXFISREG (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results
The result type is logical. If the file is a regular file, the result value is .TRUE.; otherwise, .FALSE..

See Also
PXFMKFIFO (L*X, M*X)
PXFKILL

PXFKILL
POSIX Subroutine: Sends a signal to a specified process.

Module
USE IFPOSIX

Syntax
CALL PXFKILL (ipid, isig, ierror)

ipid (Input) INTEGER(4). The process to kill. It is determined by one of the following values:

> 0                       Kills the specific process.
< 0          Kills all processes in the group.
== 0         Kills all processes in the group except special processes.
== pid_t-1   Kills all processes.

isig          (Input) INTEGER(4). The value of the signal to be sent.
ierror        (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFKILL subroutine sends a signal with value isig to a specified process. On Windows* systems, only the ipid for the current process can be used.

PXFLINK (L*X, M*X)

POSIX Subroutine: Creates a link to a file or a directory.

Module
USE IFPOSIX

Syntax
CALL PXFLINK (existing, lenexist, new, lennew, ierror)

existing      (Input) Character. The path to the file or directory that you want to link to.
lenexist      (Input) INTEGER(4). The length of the existing string.
new           (Input) Character. The name of the new link file.
lennew        (Input) INTEGER(4). The length of the new string.
ierror        (Output) INTEGER(4). The error status.

If successful, ierror is not changed; otherwise, an error code.

The PXFLINK subroutine creates a new link (also known as a hard link) to an existing file or directory. This new name can be used exactly as the old one for any operation. Both names refer to the same entity (so they have the same permissions and ownership) and it is impossible to tell which name was the "original".

PXFLOCALTIME

POSIX Subroutine: Converts a given elapsed time in seconds to local time.

Module
USE IFPOSIX

Syntax
CALL PXFLOCALTIME (isecnds, iatime, ierror)
**iseconds**

(Input) INTEGER(4). The elapsed time in seconds since 00:00:00 Greenwich Mean Time, January 1, 1970.

**iatime**

(Output) INTEGER(4). One-dimensional array with 9 elements containing numeric time data. The elements of iatime are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>iatime(1)</td>
<td>Seconds (0-59)</td>
</tr>
<tr>
<td>iatime(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>iatime(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>iatime(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>iatime(5)</td>
<td>Month (1-12)</td>
</tr>
<tr>
<td>iatime(6)</td>
<td>Gregorian year (for example, 1990)</td>
</tr>
<tr>
<td>iatime(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>iatime(8)</td>
<td>Day of year (1-366)</td>
</tr>
<tr>
<td>iatime(9)</td>
<td>Daylight savings flag (1 if daylight savings time is in effect; otherwise, 0)</td>
</tr>
</tbody>
</table>

**ierror**

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFLOCALTIME subroutine converts the time (in seconds since epoch) in the iseconds argument to the local date and time as described by the array iatime above.

---

**PXFSEEK**

*POSIX Subroutine: Positions a file a specified distance in bytes.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSEEK (ifildes, ioffset, iwhence, iposition, ierror)

**ifildes**

(Input) INTEGER(4). A file descriptor.

**ioffset**

(Input) INTEGER(4). The number of bytes to move.

**iwhence**

(Input) INTEGER(4). The starting position. The value must be one of the following:

- SEEK_SET = 0
  
  Sets the offset to ioffset bytes.

- SEEK_CUR = 1
Sets the offset to its current location plus \textit{ioffset} bytes.

- \texttt{SEEK\_END = 2}
  
  Sets the offset to the size of the file plus \textit{ioffset} bytes.

\textit{iposition} (Output) INTEGER(4). The ending position; the resulting offset location as measured in bytes from the beginning of the file.

\textit{ierror} (Output) INTEGER(4). The error status.

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFLSEEK subroutine repositions the offset of file descriptor \texttt{ifildes} to the argument \textit{ioffset} according to the value of argument \textit{iwhence}.

PXFLSEEK allows the file offset to be set beyond the end of the existing end-of-file. If data is later written at this point, subsequent reads of the data in the gap return bytes of zeros (until data is actually written into the gap).

\textbf{PXFMKDIR}

\textit{POSIX Subroutine: Creates a new directory.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFMKDIR (path, ilen, imode, ierror)

\textit{path} (Input) Character. The path for the new directory.

\textit{ilen} (Input) INTEGER(4). The length of \textit{path} string.

\textit{imode} (L*X only) (Input) INTEGER(4). The mode mask. Octal file-access mode.

\textit{ierror} (Output) INTEGER(4). The error status.

If successful, \textit{ierror} is set to zero; otherwise, an error code.

\textbf{See Also}

PXFRMDIR
PXFCHDIR

\textbf{PXFMKFIFO (L*X, M*X)}

\textit{POSIX Subroutine: Creates a new FIFO.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFMKFIFO (path, ilen, imode, ierror)

\textit{path} (Input) Character. The path for the new FIFO.

\textit{ilen} (Input) INTEGER(4). The length of \textit{path} string.
**PXFMKFIFO**

**(Input) INTEGER(4).** The mode mask; specifies the FIFO's permissions. Octal file-access mode.

**ierror** *(Output) INTEGER(4).** The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFMKFIFO subroutine creates a FIFO special file with name *path*. A FIFO special file is similar to a pipe, except that it is created in a different way. Once a FIFO special file is created, any process can open it for reading or writing in the same way as an ordinary file.

However, the FIFO file has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks it until some other process opens the same FIFO for writing, and vice versa.

**See Also**

PXFISFIFO

**PXOPEN**

**POSIX Subroutine:** Opens or creates a file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXOPEN (path, ilen, iopenflag, imode, ifildes, ierror)

path *(Input) Character.** The path of the file to be opened or created.

ilen *(Input) INTEGER(4).** The length of *path* string.

iopenflag *(Input) INTEGER(4).** The flags for the file. (For possible constant names that can be passed to PXFCONST or IPXFCONST, see below.)

imode *(Input) INTEGER(4).** The permissions for a new file. This argument should always be specified when *iopenflag=*O_CREAT; otherwise, it is ignored. (For possible permissions, see below.)

ifildes *(Output) INTEGER(4).** The returned file descriptor for the opened or created file.

ierror *(Output) INTEGER(4).** The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

For *iopenflag*, you should specify one of the following constant values:

- O_RDONLY (read only)
- O_WRONLY (write only)
- O_RDWR (read and write)

In addition, you can also specify one of the following constant values by using a bitwise inclusive OR (IOR):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>O_CREAT</td>
<td>Creates a file if the file does not exist.</td>
</tr>
<tr>
<td>Value</td>
<td>Action</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>O_EXCL</td>
<td>When used with O_CREAT, it causes the open to fail if the file already exists. In this case, a symbolic link exists, regardless of where it points to.</td>
</tr>
<tr>
<td>O_NOCTTY&lt;sup&gt;1&lt;/sup&gt;</td>
<td>If <code>path</code> refers to a terminal device, it prevents it from becoming the process's controlling terminal even if the process does not have one.</td>
</tr>
<tr>
<td>O_TRUNC</td>
<td>If the file already exists, it is a regular file, and <code>imode</code> allows writing (its value is O_RDWR or O_WRONLY), it causes the file to be truncated to length 0.</td>
</tr>
<tr>
<td>O_APPEND</td>
<td>Opens the file in append mode. Before each write, the file pointer is positioned at the end of the file, as if with PXFLSEEK.</td>
</tr>
<tr>
<td>O_NONBLOCK (or O_NDELAY)&lt;sup&gt;1&lt;/sup&gt;</td>
<td>When possible, opens the file in non-blocking mode. Neither the open nor any subsequent operations on the file descriptor that is returned will cause the calling process to wait. This mode need not have any effect on files other than FIFOs.</td>
</tr>
<tr>
<td>O_SYNC</td>
<td>Opens the file for synchronous I/O. Any writes on the resulting file descriptor will block the calling process until the data has been physically written to the underlying hardware.</td>
</tr>
<tr>
<td>O_NOFOLLOW&lt;sup&gt;1&lt;/sup&gt;</td>
<td>If <code>path</code> is a symbolic link, it causes the open to fail.</td>
</tr>
<tr>
<td>O_DIRECTORY&lt;sup&gt;1&lt;/sup&gt;</td>
<td>If <code>path</code> is not a directory, it causes the open to fail.</td>
</tr>
<tr>
<td>O_LARGEFILE&lt;sup&gt;1&lt;/sup&gt;</td>
<td>On 32-bit systems that support the Large Files System, it allows files whose sizes cannot be represented in 31 bits to be opened.</td>
</tr>
<tr>
<td>O_BINARY&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Opens the file in binary (untranslated) mode.</td>
</tr>
<tr>
<td>O_SHORT_LIVED&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Creates the file as temporary. If possible, it does not flush to the disk.</td>
</tr>
<tr>
<td>O_TEMPORARY&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Creates the file as temporary. The file is deleted when last file handle is closed.</td>
</tr>
<tr>
<td>O_RANDOM&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Specifies primarily random access from the disk.</td>
</tr>
<tr>
<td>O_SEQUENTIAL&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Specifies primarily sequential access from the disk.</td>
</tr>
<tr>
<td>O_TEXT&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Opens the file in text (translated) mode.</td>
</tr>
<tr>
<td>&lt;sup&gt;1&lt;/sup&gt;L*X only</td>
<td></td>
</tr>
<tr>
<td>&lt;sup&gt;2&lt;/sup&gt;W*S</td>
<td></td>
</tr>
<tr>
<td>&lt;sup&gt;2&lt;/sup&gt;W*S</td>
<td></td>
</tr>
</tbody>
</table>

<sup>3</sup>For more information, see "Text and Binary Modes" in the Visual C++ programmer's guide.
Argument *imode* specifies the permissions to use if a new file is created. The permissions only apply to future accesses of the newly created file. The value for *imode* can be any of the following constant values (which can be obtained by using PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_IRWXU</td>
<td>user (file owner) has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRUSR, S_IWRITE</td>
<td>user has write permission.</td>
</tr>
<tr>
<td>S_IWUSR, S_IEXEC</td>
<td>user has execute permission.</td>
</tr>
<tr>
<td>S_IRWXG</td>
<td>group has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRGRP</td>
<td>group has read permission.</td>
</tr>
<tr>
<td>S_IWGRP</td>
<td>group has execute permission.</td>
</tr>
<tr>
<td>S_IXGRP</td>
<td>group has execute permission.</td>
</tr>
<tr>
<td>S_IRWXO</td>
<td>others have read, write and execute permission.</td>
</tr>
<tr>
<td>S_IROTH</td>
<td>others have read permission.</td>
</tr>
<tr>
<td>S_IWOTH</td>
<td>others have write permission.</td>
</tr>
<tr>
<td>S_IXOTH</td>
<td>others have execute permission.</td>
</tr>
</tbody>
</table>

| 1L*X only        | |

### Example

The following call opens a file for writing only and if the file does not exist, it is created:

```fortran
  call PXFOPEN( "OPEN.OUT", &
               8, &
               IOR( IPXFCONST(O_WRONLY), IPXFCONST(O_CREAT) ), &
               IOR( IPXFCONST(S_IREAD), IPXFCONST(S_IWRITE) ) )
```

### See Also

PXFCLOSE
PXFCONST
PXFCOPEN

**PXFOPENDIR**

**POSIX Subroutine:** Opens a directory and associates a stream with it.

### Module

USE IFPOSIX

### Syntax

```fortran
CALL PXFOPENDIR (dirname, lendirname, opendirid, ierror)

dirname             (Input) Character. The directory name.
```
lendirname  (Input) INTEGER(4). The length of dirname string.
opendirid (Output) INTEGER(4). The returned ID for the directory.
ierror       (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine opens a directory pointed to by the dirname argument and returns the ID of the directory into opendirid. After the call, this ID can be used by functions PXFREADDR, PXFREWINDDIR, PXFCLOSEDIR.

See Also
PXFCLOSEDIR
PXFREADDR
PXFREWINDDIR

PXFPATHCONF
POSIX Subroutine: Gets the value for a configuration option of an opened file.

Module
USE IFPOSIX

Syntax
CALL PXFPATHCONF (path, ilen, name, ival, ierror)

path  (Input) Character. The path to the opened file.
ilen  (Input) INTEGER(4). The length of path.
name  (Input) INTEGER(4). The configurable option.
ival  (Input) INTEGER(4). The value of the configurable option.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPATHCONF subroutine gets a value for the configuration option named for the opened file with path path.

The configuration option, defined in name, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If path refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>Returns the maximum length of a formatted input line; the path must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>Returns the maximum length of an input line; the path must refer to a terminal.</td>
</tr>
</tbody>
</table>
### Constant

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in <em>path</em> that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when <em>path</em> is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the <em>path</em> must refer to a FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED(^1)</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If <em>path</em> refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC(^1)</td>
<td>Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE(^1)</td>
<td>Returns nonzero if special character processing can be disabled; the <em>path</em> must refer to a terminal.</td>
</tr>
</tbody>
</table>

\(^{1}\)L\(^{*}\), M\(^{*}\)

On Linux\(^{*}\) and OS X\(^{*}\) systems, the corresponding macros are defined in `<unistd.h>`. The values for *name* can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in `<unistd.h>`. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>_POSIX_PATH_MAX</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>

IPXFCONST
PXFCONST
PXFFPATHCONF

**PXFPause**

*POSIX Subroutine:* Suspending process execution.

**Module**
USE IFPOSIX
Syntax
CALL PXFPause (ierror)

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPause subroutine causes the invoking process (or thread) to sleep until a signal is received that either terminates it or causes it to call a signal-catching function.

PXFPIPE (L*X, M*X)
POSIX Subroutine: Creates a communications pipe between two processes.

Module
USE IFPOSIX

Syntax
CALL PXFPIPE (ireadfd, iwritefd, ierror)

ireadfd (Output) INTEGER(4). The file descriptor for reading.

iwritefd (Output) INTEGER(4). The file descriptor for writing.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPIPE subroutine returns a pair of file descriptors, pointing to a pipe inode, and places them into ireadfd for reading and into iwritefd for writing.

PXFPOSIXIO
POSIX Subroutine: Sets the current value of the POSIX I/O flag.

Module
USE IFPOSIX

Syntax
CALL PXFPOSIXIO (new, old, ierror)

new (Input) INTEGER(4). The new value for the POSIX I/O flag.

old (Output) INTEGER(4). The previous value of the POSIX I/O flag.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine sets the current value of the Fortran POSIX I/O flag and returns the previous value of the flag. The initial state of the POSIX I/O flag is unspecified.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is 1, the unit is accessed as if the records are newline delimited, even if the file does not contain records that are delimited by a new line character.
If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is zero, a connection to a file descriptor is not assumed and the records in the file are not required to be accessed as if they are newline delimited.

**PXFPUTC**

*POSIX Subroutine:* Outputs a character to logical unit 6 (stdout).

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPUTC (ch,ierror)

ch  (Input) Character. The character to be written.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

**See Also**

PXFGETC

**PXFREAD**

*POSIX Subroutine:* Reads from a file.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREAD (ifildes,buf,nbyte,nread,ierror)

ifildes  (Input) INTEGER(4). The file descriptor of the file to be read from.

buf  (Output) Character. The buffer that stores the data read from the file.

nbyte  (Input) INTEGER(4). The number of bytes to read.

nread  (Output) INTEGER(4). The number of bytes that were read.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFREAD subroutine reads nbyte bytes from the file specified by ifildes into memory in buf. The subroutine returns the total number of bytes read into nread. If no error occurs, the value of nread will equal the value of nbyte.

**See Also**

PXFWRITE

**PXFREADDR**

*POSIX Subroutine:* Reads the current directory entry.
Module
USE IFPOSIX

Syntax
CALL PXFREADDIR (idirid, jdirent, ierror)

idirid (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.

jdirent (Output) INTEGER(4). A handle of structure dirent.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFREADDIR subroutine reads the entry of the directory associated with idirid into the structure associated with handle jdirent.

NOTE
To get a handle for an instance of the dirent structure, use PXFSTRUCTCREATE with the string 'dirent' for the structure name.

See Also
PXFOPEN
PXFREWINDDIR

PXFRENAME
POSIX Subroutine: Changes the name of a file.

Module
USE IFPOSIX

Syntax
CALL PXFRENAME (old, lenold, new, lennew, ierror)

old (Input) Character. The name of the file to be renamed.

lenold (Input) INTEGER(4). The length of old string.

new (Input) Character. The new file name.

lennew (Input) INTEGER(4). The length of new string.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFREWINDDIR
POSIX Subroutine: Resets the position of the stream to the beginning of the directory.

Module
USE IFPOSIX
**Syntax**

CALL PXFREWINDDIR (idirid,ierror)

- **idirid**  
  (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**PXFRMDIR**

*POSIX Subroutine: Removes a directory.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFRMDIR (path,ilen,ierror)

- **path**  
  (Input) Character. The directory to be removed. It must be empty.

- **ilen**  
  (Input) INTEGER(4). The length of `path` string.

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**See Also**

PXFMKDIR  
PXFCHDIR

**PXFSETENV**

*POSIX Subroutine: Adds a new environment variable or sets the value of an environment variable.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSETENV (name,lenname,new,lennew,ioverwrite,ierror)

- **name**  
  (Input) Character. The name of the environment variable.

- **lenname**  
  (Input) INTEGER(4). The length of `name`.

- **new**  
  (Input) Character. The value of the environment variable.

- **lennew**  
  (Input) INTEGER(4). The length of `new`.

- **ioverwrite**  
  (Input) INTEGER(4). A flag indicating whether to change the value of the environment variable if it exists.

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

If `name` does not exist, `PXFSETENV` adds it with value `new`.
If `name` exists, PXFSETENV sets its value to `new` if `ioverwrite` is a nonzero number. If `ioverwrite` is zero, the value of `name` is not changed.

If `lennew` is equal to zero, PXFSETENV sets the value of the environment variable to a string equal to `new` after removing any leading or trailing blanks.

**Example**

```
program test2
use ifposix
character*10 name, new
integer lenname, lennew, ioverwrite, ierror
name = "FOR_NEW"
lenname = 7
new = "ON"
lennew = 2
ioverwrite = 1

CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
print *, "name= ", name
print *, "lenname= ", lenname
print *, "new= ", lenname
print *, "lennew= ", lenname
print *, "ierror= ", ierror
end
```

**See Also**

PXFGETENV

**PXFSETGID (L*X, M*X)**

**POSIX Subroutine:** Sets the effective group ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFSETGID (igid, ierror)
```

- `igid` (Input) INTEGER(4). The group ID.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

If the caller is the superuser, the real and saved group ID's are also set. This feature allows a program other than root to drop all of its group privileges, do some un-privileged work, and then re-engage the original effective group ID in a secure manner.

**CAUTION**

If the user is root then special care must be taken. PXFSETGID checks the effective gid of the caller. If it is the superuser, all process-related group ID's are set to gid. After this has occurred, it is impossible for the program to regain root privileges.

**See Also**

PXFGETGID (L*X, M*X)
**PXFSETPGID (L*X, M*X)**

*POSIX Subroutine:* Sets the process group ID.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSETPGID (ipid, ipgid, ierror)

- **ipid** (Input) INTEGER(4). The process group ID to change.
- **ipgid** (Input) INTEGER(4). The new process group ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETPGID subroutine sets the process group ID of the process specified by *ipid* to *ipgid*.

If *ipid* is zero, the process ID of the current process is used. If *ipgid* is zero, the process ID of the process specified by *ipid* is used.

PXFSETPGID can be used to move a process from one process group to another, but both process groups must be part of the same session. In this case, *ipgid* specifies an existing process group to be joined and the session ID of that group must match the session ID of the joining process.

**PXFSETSID (L*X, M*X)**

*POSIX Subroutine:* Creates a session and sets the process group ID.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSETSID (isid, ierror)

- **isid** (Output) INTEGER(4). The session ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETSID subroutine creates a new session if the calling process is not a process group leader.

The calling process is the leader of the new session and the process group leader for the new process group.

The calling process has no controlling terminal.

The process group ID and session ID of the calling process are set to the PID of the calling process. The calling process will be the only process in this new process group and in this new session.

**PXFSETUID (L*X, M*X)**

*POSIX Subroutine:* Sets the effective user ID of the current process.

**Module**

USE IFPOSIX
**Syntax**

CALL PXFSETUID (iuid, ierror)

iuid  (Output) INTEGER(4). The session ID.

ierror  (Output) INTEGER(4). The user status.

If successful, ierror is set to zero; otherwise, an error code.

If the effective user ID of the caller is root, the real and saved user ID's are also set. This feature allows a program other than root to drop all of its user privileges, do some un-privileged work, and then re-engage the original effective user ID in a secure manner.

**CAUTION**

If the user is root then special care must be taken. PXFSETUID checks the effective uid of the caller. If it is the superuser, all process-related user ID's are set to uid. After this has occurred, it is impossible for the program to regain root privileges.

---

**See Also**

PXFGETUID (L*X, M*X)

PXFSIGACTION (L*X, M*X)

**POSIX Subroutine:** Changes the action associated with a specific signal. It can also be used to examine the action of a signal.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGACTION (isig, jsigact, josigact, ierror)

isig  (Input) INTEGER(4). The signal number whose action should be changed.

jsigact  (Input) INTEGER(4). A handle of structure sigaction. Specifies the new action for signal isig.

josigact  (Output) INTEGER(4). A handle of structure sigaction. Stores the previous action of the specified signal isig.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The signal specified in isig can be any valid signal except SIGKILL and SIGSTOP.

If jsigact is nonzero, the new action for signal isig is installed from the structure associated with handle jsigact. If josigact is nonzero, the previous action of the specified signal is saved in the structure associated with handle josigact where it can be examined.

**NOTE**

To get a handle for an instance of the sigaction structure, use PXFSTRUCTCREATE with the string 'sigaction' for the structure name.
See Also
PXFSTRUCTCREATE

**PXFSIGADDSET (L*X, M*X)**

**POSIX Subroutine:** Adds a signal to the signal set.

**Module**
USE IFPOSIX

**Syntax**

CALL PXFSIGADDSET (jsigset, isigno, ierror)

- **jsigset** (Input) INTEGER(4). A handle of structure sigset. This is the set to add the signal to.
- **isigno** (Input) INTEGER(4). The signal number to add to the set.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGADDSET subroutine adds signal number *isigno* to the set of signals associated with handle *jsigset*. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

**NOTE**
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGDELESET (L*X, M*X)
PXFSIGACTION (L*X, M*X)

**PXFSIGDELESET (L*X, M*X)**

**POSIX Subroutine:** Deletes a signal from the signal set.

**Module**
USE IFPOSIX

**Syntax**

CALL PXFSIGDELESET (jsigset, isigno, ierror)

- **jsigset** (Input) INTEGER(4). A handle of structure sigset. This is the set to delete the signal from.
- **isigno** (Input) INTEGER(4). The signal number to delete from the set.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFSIGDELSET subroutine removes signal number isigno from the set of signals associated with handle jsigset. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGADDSET (L*X, M*X)
PXFSIGACTION (L*X, M*X)

PXFSIGEMPTYSET (L*X, M*X)
POSIX Subroutine: Empties a signal set.

Module
USE IFPOSIX

Syntax
CALL PXFSIGEMPTYSET (jsigset, ierror)

jsigset (Input) INTEGER(4). A handle of structure sigset. This is the set to empty.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, nonzero.

The PXFSIGEMPTYSET subroutine initializes the signal set associated with handle jsigset to empty; all signals are excluded from the set. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGFILLSET (L*X, M*X)
PXFSIGACTION (L*X, M*X)

PXFSIGFILLSET (L*X, M*X)
POSIX Subroutine: Fills a signal set.

Module
USE IFPOSIX
Syntax

CALL PXFSIGFILLSET (jsigset,ierror)

jsigset (Input) INTEGER(4). A handle of structure sigset. This is the set to fill.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGFILLSET subroutine initializes the signal set associated with handle jsigset to full; all signals are included into the set. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string ‘sigset’ for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGEMPTYSET (L*X, M*X)
PXFSIGACTION (L*X, M*X)
PXFSIGISMEMBER (L*X, M*X)

POSIX Subroutine: Tests whether a signal is a member of a signal set.

Module
USE IFPOSIX

Syntax

CALL PXFSIGISMEMBER (jsignset,isigno,ismember,ierror)

jsignset (Input) INTEGER(4). A handle of structure sigset. This is the set the signal will be tested in.

isigno (Input) INTEGER(4). The signal number to test for membership.

ismember (Output) Logical. The returned result.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGISMEMBER subroutine tests whether isigno is a member of the set associated with handle jsignset. If the signal is a member of the set, ismember is set to .TRUE.; otherwise, .FALSE.. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.
NOTE
To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also
PXFSTRUCTCREATE
PXFSIGACTION (L*X, M*X)

PXFSIGPENDING (L*X, M*X)
POSIX Subroutine: Examines pending signals.

Module
USE IFPOSIX

Syntax
CALL PXFSIGPENDING (jsigset, ierror)

jsigset (Input) INTEGER(4). A handle of structure sigaction. The signals to examine.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGPENDING subroutine is used to examine pending signals (ones that have been raised while blocked). The signal mask of the pending signals is stored in the signal set associated with handle jsigset.

PXFSIGPROCMASK (L*X, M*X)
POSIX Subroutine: Changes the list of currently blocked signals.

Module
USE IFPOSIX

Syntax
CALL PXFSIGPROCMASK (ihow, jsigset, josigset, ierror)

ihow (Input) INTEGER(4). Defines the action for jsigset.

jsigset (Input) INTEGER(4). A handle of structure sigset. The signals to examine.

josigset (Input) INTEGER(4). A handle of structure sigset. Stores the previous mask of blocked signals.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The argument ihow indicates the way in which the set is to be changed, and consists of one of the following constant names:
<table>
<thead>
<tr>
<th>Constant 1</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIG_BLOCK</td>
<td>The resulting set of blocked signals will be the union of the current signal set and the jsigset signal set.</td>
</tr>
<tr>
<td>SIG_UNBLOCK</td>
<td>The resulting set of blocked signals will be the current set of blocked signals with the signals in jsigset removed. It is legal to attempt to unblock a signal that is not blocked.</td>
</tr>
<tr>
<td>SIG_SETMASK</td>
<td>The resulting set of blocked signals will be the jsigset signal set.</td>
</tr>
</tbody>
</table>

1 These names can be used in PXCONST or IPXCONST.

If josigset is non-zero, the previous value of the signal mask is stored in the structure associated with handle josigset.

See Also
IPXCONST
PXCONST

PXFSIGSUSPEND (L*X, M*X)

POSIX Subroutine: Suspends the process until a signal is received.

Module
USE IFPOSIX

Syntax
CALL PXFSIGSUSPEND (jsigset, ierror)

jsigset  (Input) INTEGER(4). A handle of structure sigset. Specifies a set of signals.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFSIGSUSPEND temporarily replaces the signal mask for the process with that given by the structure associated with the jsigset handle; it then suspends the process until a signal is received.

PXFSLEEP

POSIX Subroutine: Forces the process to sleep.

Module
USE IFPOSIX

Syntax
CALL PXFSLEEP (iseconds, isecleft, ierror)

iseconds  (Input) INTEGER(4). The number of seconds to sleep.

isecleft  (Output) INTEGER(4). The number of seconds left to sleep.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSLEEP subroutine forces the current process to sleep until seconds iseconds have elapsed or a signal arrives that cannot be ignored.

**PXFSLEEP**

**POSIX Subroutine: Gets a file's status information.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSLEEP (path,ilen,jstat,ierror)

path (Input) Character. The path to the file.

ilen (Input) INTEGER(4). The length of path string.

jstat (Input) INTEGER(4). A handle of structure stat.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSLEEP subroutine puts the status information for the file specified by path into the structure associated with handle jstat.

---

**NOTE**

To get a handle for an instance of the stat structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

---

**See Also**

PXFSTRUCTCREATE

**PXFSTRUCTCOPY**

**POSIX Subroutine: Copies the contents of one structure to another.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSTRUCTCOPY (structname,jhandle1,jhandle2,ierror)

structname (Input) Character. The name of the structure.

jhandle1 (Input) INTEGER(4). A handle to the structure to be copied.

jhandle2 (Input) INTEGER(4). A handle to the structure that will receive the copy.

ierror (Output) INTEGER(4). The error status.
If successful, `ierror` is set to zero; otherwise, an error code.

**Example**

See the example in PXFSTRUCTCREATE

---

**PXFSTRUCTCREATE**

**POSIX Subroutine:** Creates an instance of the specified structure.

---

**Module**

USE IFPOSIX

---

**Syntax**

CALL PXFSTRUCTCREATE (structname, jhandle, ierror)

- **structname** (Input) Character. The name of the structure.
  
  As for any character string, the name must be specified in single or double quotes; for example, the structure `sigaction` would be specified as `‘sigaction’`. For more information on available structures, see the table below.

- **jhandle** (Output) INTEGER(4). The handle of the newly-created structure.

- **ierror** (Output) INTEGER(4). The error status.

  If successful, `ierror` is set to zero; otherwise, an error code.

If your application passes information to the system, you should call one of the PXF(type)SET subroutines. If your application needs to get information from the structure, you should call one of the PXF(type)GET subroutines.

The following table shows:

- The structures that are available in the Fortran POSIX library
- The fields within each structure
- The subroutines you must use to access the structure fields

^L*X only

As for any character string, you must use single or double quotes when specifying a field name in a PXF(type)GET or PXF(type)SET subroutine. For example, field name sysname (in structure _utsname_) must be specified as 'sysname'.

**Example**

```fortran
program test4
  use ifposix
  implicit none
  integer(jhandle_size) jhandle1, jhandle2
  integer(4) ierror, ilen1

  print *, "Create a first instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname", jhandle1, ierror)
  if(ierror.NE.0) STOP 'Error: cannot create structure for jhandle1'

  print *, "Create a second instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname", jhandle2, ierror)
  if(ierror.NE.0) then
    call PXFSTRUCTFREE(jhandle1, ierror)
    STOP 'test failed - cannot create structure for jhandle2'
  end if

  print *, "Fill the structure associated with jhandle1 with arbitrary data"
  call PXFSTRSET(jhandle1, "sysname", "00000000000000", 14, ierror)

PXFSTRUCTFREE
PXFTIMES

PXFSTRUCTFREE

**POSIX Subroutine:** Deletes the instance of a structure.

**Module**
USE IFPOSIX

**Syntax**

CALL PXFSTRUCTFREE (jhandle, ierror)
**Example**

See the example in PXFSTRUCTCREATE, the example in PXFTIMES

**PXFSYSCONF**

**POSIX Subroutine:** Gets values for system limits or options.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSYSCONF (name, ival, ierror)

- **name** (Input) INTEGER(4). The system option you want information about.
- **ival** (Output) INTEGER(4). The returned value.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

PXFSYSCONF lets you determine values for system limits or system options at runtime.

The value for **name** can be any of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SC_ARG_MAX(^1)</td>
<td>Indicates the maximum length of the arguments to the PXFEXEC family of routines.</td>
</tr>
<tr>
<td>_SC_CHILD_MAX(^1)</td>
<td>Indicates the number of simultaneous processes per user ID.</td>
</tr>
<tr>
<td>_SCCLK_TCK</td>
<td>Indicates the number of clock ticks per second.</td>
</tr>
<tr>
<td>_SC_STREAM_MAX(^2)</td>
<td>Indicates the maximum number of streams that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_TZNAME_MAX</td>
<td>Indicates the maximum number of bytes in a timezone name.</td>
</tr>
<tr>
<td>_SC_OPEN_MAX</td>
<td>Indicates the maximum number of files that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_JOB_CONTROL(^1)</td>
<td>Indicates whether POSIX-style job control is supported.</td>
</tr>
<tr>
<td>_SC_SAVED_IDS(^1)</td>
<td>Indicates whether a process has a saved set-user-ID and a saved set-group-ID.</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_SC_VERSION¹</td>
<td>Indicates the year and month the POSIX.1 standard was approved in the format YYYYMM; the value 199009L indicates the most recent revision, 1990.</td>
</tr>
<tr>
<td>_SC_BC_BASE_MAX¹</td>
<td>Indicates the maximum obase value accepted by the bc(1) utility.</td>
</tr>
<tr>
<td>_SC_BC_DIM_MAX¹</td>
<td>Indicates the maximum value of elements that bc(1) permits in an array.</td>
</tr>
<tr>
<td>_SC_BC_SCALE_MAX¹</td>
<td>Indicates the maximum scale value allowed by bc(1).</td>
</tr>
<tr>
<td>_SC_BC_STRING_MAX¹</td>
<td>Indicates the maximum length of a string accepted by bc(1).</td>
</tr>
<tr>
<td>_SC_COLL_WEIGHTS_MAX¹</td>
<td>Indicates the maximum numbers of weights that can be assigned to an entry of the LC_COLLATE order keyword in the locale definition file.</td>
</tr>
<tr>
<td>_SC_EXPR_NEST_MAX¹,³</td>
<td>Indicates the maximum number of expressions that can be nested within parentheses by expr(1).</td>
</tr>
<tr>
<td>_SC_LINE_MAX¹</td>
<td>Indicates the maximum length of a utility’s input line length, either from standard input or from a file. This includes the length for a trailing newline.</td>
</tr>
<tr>
<td>_SC_RE_DUP_MAX¹</td>
<td>Indicates the maximum number of repeated occurrences of a regular expression when the interval notation {m,n} is used.</td>
</tr>
<tr>
<td>_SC_2_VERSION¹</td>
<td>Indicates the version of the POSIX.2 standard; it is in the format YYYYMM.</td>
</tr>
<tr>
<td>_SC_2_DEV¹</td>
<td>Indicates whether the POSIX.2 C language development facilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_DEV¹</td>
<td>Indicates whether the POSIX.2 FORTRAN language development utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_RUN¹</td>
<td>Indicates whether the POSIX.2 FORTRAN runtime utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_LOCALEDEF¹</td>
<td>Indicates whether the POSIX.2 creation of locates via localedef(1) is supported.</td>
</tr>
<tr>
<td>_SC_2_SW_DEV¹</td>
<td>Indicates whether the POSIX.2 software development utilities option is supported.</td>
</tr>
<tr>
<td>_SC_PAGESIZE (or _SC_PAGE_SIZE)</td>
<td>Indicates the size of a page (in bytes).</td>
</tr>
<tr>
<td>_SC_PHYS_PAGES⁴</td>
<td>Indicates the number of pages of physical memory. Note that it is possible for the product of this value and the value of _SC_PAGE_SIZE to overflow.</td>
</tr>
<tr>
<td>_SC_AVPHYS_PAGES⁴</td>
<td>Indicates the number of currently available pages of physical memory.</td>
</tr>
</tbody>
</table>

¹L*X only
The corresponding macros are defined in `<bits/confname.h>` on Linux* systems; `<unistd.h>` on OS X* systems. The values for argument name can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in the appropriate .h file.

PXFCONST

**PXFTCDRAIN (L*X, M*X)**

*POSIX Subroutine:* Waits until all output written has been transmitted.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFTCDRAIN (ifildes, ierror)

- *ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**PXFTCFLOW (L*X, M*X)**

*POSIX Subroutine:* Suspends the transmission or reception of data.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFTCFLOW (ifildes, iaction, ierror)

- *ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.
- *iaction* (Input) INTEGER(4). The action to perform.
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCFLOW subroutine suspends or resumes transmission or reception of data from the terminal referred to by *ifildes*. The action performed depends on the value of *iaction*, which must be one of the following constant names:
<table>
<thead>
<tr>
<th>Constant ¹</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCOOFF</td>
<td>Output is suspended.</td>
</tr>
<tr>
<td>TCOON</td>
<td>Output is resumed.</td>
</tr>
<tr>
<td>TCIOFF</td>
<td>A STOP character is transmitted. This should cause the terminal to stop transmitting data to the system.</td>
</tr>
<tr>
<td>TCION</td>
<td>A START character is transmitted. This should cause the terminal to resume transmitting data to the system.</td>
</tr>
</tbody>
</table>

PXFTCFLUSH (L*X, M*X)
POSIX Subroutine: Discards terminal input data, output data, or both.

Module
USE IFPOSIX

Syntax
CALL PXFTCFLUSH (ifildes, iaction, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.

iaction  (Input) INTEGER(4). The action to perform.

ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The action performed depends on the value of iaction, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant ¹</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCIFLUSH</td>
<td>Discards all data that has been received but not read.</td>
</tr>
<tr>
<td>TCOFLUSH</td>
<td>Discards all data that has been written but not transmitted.</td>
</tr>
<tr>
<td>TCIOFLUSH</td>
<td>Discards both data received but not read and data written but not transmitted. (Performs TCIFLUSH and TCOFLUSH actions.)</td>
</tr>
</tbody>
</table>

¹These names can be used in PXFCONST or IPXCONST.

**PXFTCGETATTR (L*X, M*X)**

**POSIX Subroutine:** Reads current terminal settings.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCGETATTR (ifildes, jtermios, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **jtermios** (Output) INTEGER(4). A handle for structure termios. Stores the terminal settings.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**NOTE**

To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

**See Also**

PXFSTRUCTCREATE
PXFTCSETATTR (L*X, M*X)

**PXFTCGETPGRP (L*X, M*X)**

**POSIX Subroutine:** Gets the foreground process group ID associated with the terminal.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCGETPGRP (ifildes, ipgid, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **ipgid** (Output) INTEGER(4). The returned process group ID.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**See Also**

PXFTCSETPGRP (L*X, M*X)
PXFTCSENDBREAK (L*X, M*X)

**PXFTCSENDBREAK (L*X, M*X)**

**POSIX Subroutine:** Sends a break to the terminal.

**Module**

USE IFPOSIX
**Syntax**

CALL PXFTCSENDBREAK (ifildes, iduration, ierror)

*ifildes*  
(Input) INTEGER(4). The file descriptor associated with the terminal.

*iduration*  
(Input) INTEGER(4). Indicates how long the break should be.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCSENDBREAK subroutine sends a break (a ‘\0’ with a framing error) to the terminal associated with *ifildes*.

**PXFTCSETATTR (L*X, M*X)**

*POSIX Subroutine: Writes new terminal settings.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCSETATTR (ifildes, ioptacts, jtermios, ierror)

*ifildes*  
(Input) INTEGER(4). The file descriptor associated with the terminal.

*ioptacts*  
(Input) INTEGER(4). Specifies when the terminal changes take effect.

*jtermios*  
(Input) INTEGER(4). A handle for structure termios. Contains the new terminal settings.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCSETATTR subroutine copies all terminal parameters from structure termios into the terminal associated with *ifildes*. When the terminal settings will change depends on the value of *ioptacts*, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant 1</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCSANOW</td>
<td>The changes occur immediately.</td>
</tr>
<tr>
<td>TCSADRAIN</td>
<td>The changes occur after all output written to <em>ifildes</em> has been transmitted.</td>
</tr>
<tr>
<td>TCSAFLUSH</td>
<td>The changes occur after all output written to <em>ifildes</em> has been transmitted, and all input that had been received but not read has been discarded.</td>
</tr>
</tbody>
</table>

1These names can be used in PXFCONST or IPXFCONST.

**NOTE**

To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.
See Also
PXFSSTRUCTCREATE
PXFTCGETATTR (L*X, M*X)

PXFTCSETPGRP (L*X, M*X)

POSIX Subroutine: Sets the foreground process group ID associated with the terminal.

Module
USE IFPOSIX

Syntax
CALL PXFTCSETPGRP (ifildes, ipgid, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.
ipgid    (Input) INTEGER(4). The foreground process group ID for ifildes.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also
PXFTCGETPGRP (L*X, M*X)

PXFTIME

POSIX Subroutine: Returns the current system time.

Module
USE IFPOSIX

Syntax
CALL PXFTIME (itime, ierror)

itime    (Output) INTEGER(4). The returned system time.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFTIME subroutine returns the number of seconds since Epoch (00:00:00 UTC, January 1, 1970).

Example
See the example in PXFTIMES.

PXFTIMES

POSIX Subroutine: Returns process times.

Module
USE IFPOSIX

Syntax
CALL PXFTIMES (jtms, itime, ierror)
**jtms**

(Output) INTEGER(4). A handle of structure *tms*.

**itime**

(Output) INTEGER(4). The returned time since system startup.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTIMES subroutine fills the fields of structure *tms* associated with handle *jtms* with components of time that was spent by the current process. The structure fields are:

- *tms_utime* - User CPU time
- *tms_stime* - System CPU time
- *tms_cutime* - User time of child process
- *tms_cstime* - System time of child process

All members are measured in system clocks. The values can be converted to seconds by dividing by value *ival* returned from the following call:

```
PXFSYSCONF(IPFXCONST('_SC_CLK_TCK'), ival, ierror)
```

User time is the time charged for the execution of user instructions of the calling process. System time is the time charged for execution by the system on behalf of the calling process.

**NOTE**

To get a handle for an instance of the *tms* structure, use PXFSTRUCTCREATE with the string 'tms' for the structure name.

---

### Example

```fortran
program test_uname
  use ifposix
  implicit none
  integer(jhandle_size) jtms1, jtms2
  integer(4) ierror,i
  integer(4),parameter :: n=10000000
  integer(SIZEOF_CLOCK_T) itime,time1,time2, user_time1,user_time2
  integer(SIZEOF_CLOCK_T) system_time1,system_time2
  integer(4) clocks_per_sec, iname
  real(8) s, PI
  real(8) seconds_user, seconds_system

  print *,"Create a first instance for structure 'tms'"
  call PXFSTRUCTCREATE("tms",jtms1,ierror)
  if(ierror.NE.0) STOP 'Error: cannot create structure for handle jtms1'
  print *,"Create a second instance for structure 'tms'"
  call PXFSTRUCTCREATE("tms",jtms2,ierror)
  if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    STOP 'Error: cannot create structure for handle jtms2'
  end if

  print *, 'Do some calculations'
  call PXFTIMES(jtms1, itime,ierror)

PXFSTRUCTCREATE
PXFTTYNAME (L*X, M*X)

**POSIX Subroutine:** Gets the terminal pathname.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTTYNAME (ifildes, s, ilen, ierror)

*ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.

*s* (Output) Character. The returned terminal pathname.

*ilen* (Output) INTEGER(4). The length of the string stored in *s*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFUCOMPARE

**POSIX Subroutine:** Compares two unsigned integers.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUCOMPARE (i1, i2, icmpr, idiff)

*i1, i2* (Input) INTEGER(4). The two unsigned integers to compare.

*icmpr* (Output) INTEGER(4). The result of the comparison; one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>If <em>i1</em> &lt; <em>i2</em></td>
</tr>
<tr>
<td>0</td>
<td>If <em>i1</em> = <em>i2</em></td>
</tr>
<tr>
<td>1</td>
<td>If <em>i1</em> &gt; <em>i2</em></td>
</tr>
</tbody>
</table>

*idiff* (Output) INTEGER(4). The absolute value of the difference.

The PXFUCOMPARE subroutine compares two unsigned integers and returns the absolute value of their difference into *idiff*.

PXFUMASK

**POSIX Subroutine:** Sets a new file creation mask and gets the previous one.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUMASK (icmask, iprevcmask, ierror)
**icmask**  
(Input) INTEGER(4). The new file creation mask.

**iprevcmask**  
(Output) INTEGER(4). The previous file creation mask.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**PXFUNAME**

**POSIX Subroutine:** Gets the operation system name.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUNAME (jutsname, ierror)

**jutsname**  
(Input) INTEGER(4). A handle of structure utsname.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFUNAME subroutine provides information about the operation system. The information is stored in the structure associated with handle *jutsname*.

**Example**

See the example in PXFSTRUCTCREATE

---

**PXFUNLINK**

**POSIX Subroutine:** Removes a directory entry.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUNLINK (path, ilen, ierror)

**path**  
(Input) Character. The name of the directory entry to remove.

**ilen**  
(Input) INTEGER(4). The length of *path* string.

**ierror**  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**PXFUTIME**

**POSIX Subroutine:** Sets file access and modification times.

**Module**

USE IFPOSIX
Syntax

CALL PXFUTIME (path, ilen, jutimbuf, ierror)

path  (Input) Character. The path to the file.
ilen  (Input) INTEGER(4). The length of path string.
jutimbuf  (Input) INTEGER(4). A handle of structure utimbuf.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFUTIME subroutine sets access and modification times for the file pointed to by path. The time values are retrieved from structure utimbuf.

PXFWAIT (L*X, M*X)

POSIX Subroutine: Waits for a child process.

Module

USE IFPOSIX

Syntax

CALL PXFWAIT (istat, iretpid, ierror)

istat  (Output) INTEGER(4). The returned status of the child process.
iretpid  (Output) INTEGER(4). The process ID of the stopped child process.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFWAIT subroutine suspends execution of the current process until a child has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The subroutine returns in iretpid the value of the process ID of the child that exited, or zero if no child was available. The returned value in istat can be used in subroutines IPXFWEXITSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWIFEXITED, PXFWIFSIGNALED, and PXFWIFSTOPPED.

Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, " the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
    print *, " I am a child process"
    print *, " My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET,IERROR)
    print *, " The pid of my parent is",IPID_RET
    print *, " Now I have exited with code 0xABCDE"
call PXFEXIT(Z'ABCD')
else
print *, "I am a parent process"
print *, "My parent pid is ", IPID_RET
print *, "I am creating the process with pid ", IPID
print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
print *, "The child with pid ", IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
  print *, "The child exited normally"
  istat_ret = IPXFWEXITSTATUS(ISTAT)
  print 10,"The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

See Also
PXFWAITPID (L*X, M*X)
IPXFWEXITSTATUS (L*X, M*X)
IPXFWSTOPSIG (L*X, M*X)
IPXFWTERMSIG (L*X, M*X)
PXFWIFEXITED (L*X, M*X)
PXFWIFSIGNALED (L*X, M*X)
PXFWIFSTOPPED (L*X, M*X)

PXFWAITPID (L*X, M*X)

**POSIX Subroutine:** Waits for a specific PID.

Module
USE IFPOSIX

Syntax
CALL PXFWAITPID (ipid, istat, ioptions, iretpid, ierror)

**ipid**
(Input) INTEGER(4). The PID to wait for. One of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; -1</td>
<td>Specifies to wait for any child process whose process group ID is equal to the absolute value of ipid.</td>
</tr>
<tr>
<td>-1</td>
<td>Specifies to wait for any child process; this is the same behavior as PXFWAIT.</td>
</tr>
<tr>
<td>0</td>
<td>Specifies to wait for any child process whose process group ID is equal to that of the calling process.</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>Specifies to wait for the child whose process ID is equal to the value of ipid.</td>
</tr>
</tbody>
</table>

**istat**
(Output) INTEGER(4). The returned status of the child process.
**ioptions**

(Input) INTEGER(4). One or more of the following constant values (which can be passed to PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WNOHANG</td>
<td>Specifies to return immediately if no child process has exited.</td>
</tr>
<tr>
<td>WUNTRACED</td>
<td>Specifies to return for child processes that have stopped, and whose status has not been reported.</td>
</tr>
</tbody>
</table>

**iretpid**

(Output) INTEGER(4). The PID of the stopped child process.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFWAITPID subroutine suspends execution of the current process until the child specified by *ipid* has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child specified by *ipid* has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The returned value in *istat* can be used in subroutines PXFWEXITSTATUS, PXFWSTOPSIG, PXFWTERMSIG, PXFWIFEXITED, PXFWIFSIGNALED, and PXFWIFSTOPPED.

IPFWTERMSIG (L*X, M*X)
PXFWIFEXITED (L*X, M*X)
PXFWIFSIGNALED (L*X, M*X)
PXFWIFSTOPPED (L*X, M*X)

**PXFWIFEXITED (L*X, M*X)**

**POSIX Function:** Determines if a child process has exited.

**Module**

USE IFPOSIX

**Syntax**

```fortran
result = PXFWIFEXITED (istat)
```

**istat**

(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results**

The result type is logical. The result value is .TRUE. if the child process has exited normally; otherwise, .FALSE..

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
```
print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
   print *, "I am a child process"
   print *, "My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET, IERROR)
   print *, "The pid of my parent is", IPID_RET
   print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
   print *, "I am a parent process"
   print *, "My parent pid is", IPID_RET
   print *, "I am creating the process with pid", IPID
   print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *, "The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, "The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10, "The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program

See Also
PXFWIFSIGNALED (L*X, M*X)
PXFWIFSTOPPED (L*X, M*X)

PXFWIFSIGNALED (L*X, M*X)

**POSIX Function**: Determines if a child process has exited because of a signal.

**Module**
USE IFPOSIX

**Syntax**
result = PXFWIFSIGNALED (istat)

`istat` (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results**
The result type is logical. The result value is .TRUE. if the child process has exited because of a signal that was not caught; otherwise, .FALSE..

See Also
PXFWIFEXITED (L*X, M*X)
PXFWIFSTOPPED (L*X, M*X)

PXFWIFSTOPPED (L*X, M*X)

**POSIX Function**: Determines if a child process has stopped.

**Module**
USE IFPOSIX
Syntax

\[
\text{result} = \text{PXFWIFSTOPPED} \ (\text{istat})
\]

\textit{istat} \quad \text{(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).}

Results

The result type is logical. The result value is .TRUE. if the child process has stopped; otherwise, .FALSE..

See Also

PXFWIFEXITED \ ((L*X, M*X))
PXFWIFSIGNALED \ ((L*X, M*X))

\textbf{PXFWRITE}

\textit{POSIX Subroutine:} Writes to a file.

Module

\textbf{USE IFPOSIX}

Syntax

\textbf{CALL PXFWRITE} \ (\textit{ifildes, buf, nbyte, nwritten, ierror})

\textit{ifildes} \quad \text{(Input) INTEGER(4). The file descriptor for the file to be written to.}

\textit{buf} \quad \text{(Input) Character. The buffer that contains the data to write into the file.}

\textit{nbyte} \quad \text{(Input) INTEGER(4). The number of bytes to write.}

\textit{nwritten} \quad \text{(Output) INTEGER(4). The returned number of bytes written.}

\textit{ierror} \quad \text{(Output) INTEGER(4). The error status.}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFWRITE subroutine writes \textit{nbyte} bytes from the storage \textit{buf} into a file specified by file descriptor \textit{ifildes}. The subroutine returns the total number of bytes read into \textit{nwritten}. If no error occurs, the value of \textit{nwritten} will equal the value of \textit{nbyte}.

Q to R

Q to R

\textbf{QCMPLX}

\textit{Elemental Intrinsic Function (Specific):} Converts an argument to COMPLEX(16) type. This function cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{QCMPLX} \ (x[,y])
\]
$x$  (Input) Must be of type integer, real, or complex.

$y$  (Input; optional) Must be of type integer or real. It must not be present if $x$ is of type complex.

**Results**

The result type is COMPLEX(16) (or COMPLEX*32).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If $y$ is not specified and $x$ is complex, the result value is CMPLX(REAL($x$), AIMAG($x$)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

QCMPLX($x$, $y$) has the complex value whose real part is REAL($x$, kind=16) and whose imaginary part is REAL($y$, kind=16).

**Example**

QCMPLX(-3) has the value (-3.0Q0, 0.0Q0).

QCMPLX(4.1, 2.3) has the value (4.1Q0, 2.3Q0).

See Also

CMPLX
DCMPLX
FLOAT
INT
IFIX
REAL Function
SNGL

**QEXT**

*Elemental Intrinsic Function (Generic):* Converts a number to quad precision (REAL(16)) type.

**Syntax**

result = QEXT(a)

$a$  (Input) Must be of type integer, real, or complex.

**Results**

The result type is REAL(16) (REAL*16). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If $a$ is of type REAL(16), the result is the value of the $a$ with no conversion (QEXT(a) = a).

If $a$ is of type integer or real, the result has as much precision of the significant part of $a$ as a REAL(16) value can contain.

If $a$ is of type complex, the result has as much precision of the significant part of the real part of $a$ as a REAL(16) value can contain.

</tr>
</tbody>
</table>

¹These specific functions cannot be passed as actual arguments.

### Example

QEXT (4) has the value 4.0 (rounded; there are 32 places to the right of the decimal point).

QEXT ((3.4, 2.0)) has the value 3.4 (rounded; there are 32 places to the right of the decimal point).

### QFLOAT

*Elemental Intrinsic Function (Generic):* Converts an integer to quad precision (REAL(16)) type.

#### Syntax

```fortran
result = QFLOAT (a)
```

*a*  (Input) Must be of type integer.

#### Results

The result type is REAL(16) (REAL*16).

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

#### Example

QFLOAT (-4) has the value -4.0 (rounded; there are 32 places to the right of the decimal point).

### QNUM

*Elemental Intrinsic Function (Specific):* Converts a character string to a REAL(16) value. This function cannot be passed as an actual argument.

#### Syntax

```fortran
result = QNUM (i)
```

*i*  (Input) Must be of type character.

#### Results

The result type is REAL(16). The result value is the real value represented by the character string *i*.
Example
QNUM ("-174.23") has the value -174.23 of type REAL(16).

QRANSET
**Portability Subroutine:** Sets the seed for a sequence of pseudo-random numbers.

**Module**
USE IFPORT

**Syntax**
CALL QRANSET (rseed)

*rseed* 
(Input) INTEGER(4). The reset value for the seed.

QREAL
**Elemental Intrinsic Function (Specific):** Converts the real part of a COMPLEX(16) argument to REAL(16) type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**
result = QREAL (a)

*a* 
(Input) Must be of type COMPLEX(16) (or COMPLEX*32).

**Results**
The result type is quad-precision real (REAL(16) or REAL*16).

**Example**
QREAL ((2.0q0, 3.0q0)) has the value 2.0q0.

**See Also**
REAL Function
DREAL

QSORT
**Portability Subroutine:** Performs a quick sort on an array of rank one.

**Module**
USE IFPORT

**Syntax**
CALL QSORT (array, len, isize, compar)

*array* 
(Input) Any type. One-dimensional array to be sorted.

If the data type does not conform to one of the predefined interfaces for QSORT, you may have to create a new interface (see below).
**Example**

```fortran
! program showing how to call 'QSORT' on
! a user-defined type.
!
! Define the type to be shared.
!
module share_type
  type element_type
    integer       :: data
    character(10) :: key
  end type
end module
!

! Main program calls QSORT.
!
program main
  use IFPORT       ! To get QSORT
  use share_type   ! To get shared type
  
  ! Define an overload of the default QSORT signature
  ! with a signature using the shared type.
```

**NOTE**

If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module's source file, `IFPORT.F90`. 

---

*Input* INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in `array`.

*isize* (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Size, in bytes, of a single element of `array`:

- 4 if array is of type REAL(4)
- 8 if array is of type REAL(8) or complex
- 16 if array is of type COMPLEX(8)

*compar* (Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of `compar` takes the form:

```fortran
INTEGER(2) FUNCTION compar(arg1, arg2)
```

where `arg1` and `arg2` have the same type as `array` (above). Once you have created an ordering scheme, implement your sorting function so that it returns the following:

- Negative if `arg1` should precede `arg2`
- Zero if `arg1` is equivalent to `arg2`
- Positive if `arg1` should follow `arg2`

Dummy argument `compar` must be declared as external.

In place of an INTEGER kind, you can specify the constant `SIZEOF_SIZE_T`, defined in `IFPORT.F90`, for argument `len` or `isize`. Use of this constant ensures correct compilation.
39
!
interface
subroutine QSORT_element_types(array, len, isize, comp)
use share_type
type(element_type) array(len)
integer len, isize
integer(2), external :: comp
!
! Hook the overload to the real thing but be careful
! to connect to the correct qsort: the Fortran one, not
! the C one!
!
! We need to call the _Fortran_ qsort, not the _C_ one, or
! there will be errors from the 1-origin vs. 0-origin indexing
! and the row-major vs. column-major ordering.
!
! The symptom is that "OrderCharCI" is called with pointer values
! which are outside the bounds of the array to be sorted.
!

PROGRAM SORTQ
USE IFPORT
integer(2), external :: cmp_function
integer(2) insort(26), i
integer (SIZEOF_SIZE_T) array_len, array_size
array_len = 26
array_size = 2
do i=90,65,-1
   insort(i-64)=91 - i
end do
print *, "Before: ", insort
CALL qsort(insort,array_len,array_size,cmp_function)
print *, "After: ", insort
END

! integer(2) function cmp_function(a1, a2)
   integer(2) a1, a2
   cmp_function=a1-a2
end function

RADIX

Inquiry Intrinsic Function (Generic): Returns the base of the model representing numbers of the same type and kind as the argument.

Syntax
result = RADIX (x)

x (Input) Must be of type integer or real; it can be scalar or array valued.

Results
The result is a scalar of type default integer. For an integer argument, the result has the value r (as defined in Model for Integer Data). For a real argument, the result has the value b (as defined in Model for Real Data).

Example
If X is a REAL(4) value, RADIX (X) has the value 2.

Data Representation Models

RAISEQQ

Portability Function: Sends a signal to the executing program.

Module
USE IFPORT

Syntax
result = RAISEQQ (sig)

sig
(Input) INTEGER(4). Signal to raise. One of the following constants (defined in IFPORT.F90):

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+C signal
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

If a signal-handling routine for sig has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).

SIGNALQQ
SIGNAL
KILL

RAN

Nonelemental Intrinsic Function (Specific):
Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = RAN (i)

i
(Input; output) Must be an INTEGER(4) variable or array element.
It should initially be set to a large, odd integer value. The RAN function stores a value in the argument that is later used to calculate the next random number.

There are no restrictions on the seed, although it should be initialized with different values on separate runs to obtain different random numbers.

**Results**

The result type is REAL(4). The result is a floating-point number that is uniformly distributed in the range between 0.0 inclusive and 1.0 exclusive. It is set equal to the value associated with the argument $i$.

RAN is not a pure function.

**Example**

In RAN (1), if variable I has the value 3, RAN has the value 4.8220158E-05.

**See Also**

RANDOM Subroutine
RANDOM_NUMBER

**RAND, RANDOM**

*Portability Functions:* Return real random numbers in the range 0.0 to 1.0, not including the end points.

**Module**

USE IFPORT

**Syntax**

```
result = RAND ([ iflag])
result = RANDOM (iflag)
```

* `iflag` (Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

**Results**

The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 to 1.0, not including the end points.

<table>
<thead>
<tr>
<th>Value of <code>iflag</code></th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using <code>iflag</code>, restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

When RAND is called without an argument, the following applies:

- The value of `iflag` is assumed to be 0.
- You must specify USE IFPORT.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them.
The intrinsic functions RANDOM_NUMBER and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

You can use SRAND to restart the pseudorandom number generator used by RAND.

NOTE
RANDOM is available as a function or subroutine.

Example
The following example shows how to use both the RANDOM function and the RANDOM subroutine:

```fortran
use ifport
real(4) ranval
call seed(1995) ! initialize
call random(ranval) ! get next random number
print *,ranval
ranval = random(1) ! initialize
ranval = random(0) ! get next random number
print *,ranval
end
```

See Also
RANDOM_NUMBER
RANDOM_SEED
SRAND

RANDOM Subroutine

**Portability Subroutine:** Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.

Module

USE IFPORT

Syntax

CALL RANDOM (ranval)

ranval (Output) REAL(4). Pseudorandom number, 0 \( \leq \text{ranval} < 1 \), from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFCORE.F90) to SEED before the first call to RANDOM.

The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.
Example

USE IFPORT
REAL(4) ran

CALL SEED(1995)
CALL RANDOM(ran)

The following example shows how to use both the RANDOM subroutine and the RANDOM function:

use ifport
real(4) ranval
! from libifcore.lib
call seed(1995) ! initialize
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number

print *,ranval
! from libifport.lib
ranval = random(1) ! initialize
! same
ranval = random(0) ! get next random number

print *,ranval
end

RANDOM_NUMBER
SEED
DRAND, DRANDM
IRAND, IRANDM
RAN
RAND, RANDOM

RANDOM_NUMBER
Intrinsic Subroutine: Returns one pseudorandom number or an array of such numbers.

Syntax
CALL RANDOM_NUMBER (harvest)

harvest (Output) Must be of type real. It can be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution within the range 0 <= x < 1.

The seed for the pseudorandom number generator used by RANDOM_NUMBER can be set or queried with RANDOM_SEED. If RANDOM_SEED is not used, the processor sets the seed for RANDOM_NUMBER to a processor-dependent value.

The RANDOM_NUMBER generator uses two separate congruential generators together to produce a period of approximately 10**18, and produces real pseudorandom results with a uniform distribution in (0,1). It accepts two integer seeds, the first of which is reduced to the range [1, 2147483562]. The second seed is reduced to the range [1, 2147483398]. This means that the generator effectively uses two 31-bit seeds.

For more information on the algorithm, see the following:

Example

Consider the following:

```fortran
REAL Y, Z (5, 5)
! Initialize Y with a pseudorandom number
CALL RANDOM_NUMBER (HARVEST = Y)
CALL RANDOM_NUMBER (Z)
```

Y and Z contain uniformly distributed random numbers.

The following shows another example:

```fortran
REAL x, array1 (5, 5)
CALL RANDOM_SEED()
CALL RANDOM_NUMBER(x)
CALL RANDOM_NUMBER(array1)
```

The following shows another example:

```fortran
program testrand
  intrinsic random_seed, random_number
  integer size, seed(2), gseed(2), hiseed(2), zseed(2)
  real harvest(10)
  data seed /123456789, 987654321/
  data hiseed /-1, -1/
  data zseed /0, 0/
  call random_seed(SIZE=size)
  print *, "size ",size
  call random_seed(PUT=hiseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "hiseed gseed ", hiseed, gseed
  call random_seed(PUT=zseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "zseed gseed ", zseed, gseed
  call random_seed(PUT=seed(1:size))
  call random_seed(GET=gseed(1:size))
  call random_number(HARVEST=harvest)
  print *, "seed gseed ", seed, gseed
  print *, "harvest"
  print *, harvest
  call random_seed(GET=gseed(1:size))
  print *, "gseed after harvest ", gseed
end program testrand
```

RAND, RANDOM

RANDOM_SEED

Intrinsic Subroutine (Generic): Changes or queries the seed (starting point) for the pseudorandom number generator used by intrinsic subroutine RANDOM_NUMBER. Intrinsic subroutines cannot be passed as actual arguments.
Syntax

CALL RANDOM_SEED ([size] [,put] [,get])

size  (Output; optional) Must be scalar and of type integer. Set to the number of
      integers (N) that the processor uses to hold the value of the seed.

put  (Input; optional) Must be an integer array of rank one and size greater than
      or equal to N. It is used to reset the value of the seed.

get  (Output; optional) Must be an integer array of rank one and size greater
      than or equal to N. It is set to the current value of the seed.

No more than one argument can be specified. If no argument is specified, a random number based on the
date and time is assigned to the seed.

You can determine the size of the array the processor uses to store the seed by calling RANDOM_SEED with
the size argument (see the second example below).

Example

Consider the following:

```
CALL RANDOM_SEED                        ! Processor initializes the
!   seed randomly from the date          ! and time
CALL RANDOM_SEED (SIZE = M)             ! Sets M to N
CALL RANDOM_SEED (PUT = SEED (1 : M))   ! Sets user seed
CALL RANDOM_SEED (GET = OLD (1 : M))    ! Reads the current seed
```

The following shows another example:

```
INTEGER I
INTEGER, ALLOCATABLE :: new (:), old(:)
CALL RANDOM_SEED ( )  ! Processor reinitializes the seed
!   randomly from the date and time
CALL RANDOM_SEED (SIZE = I)  ! I is set to the size of
!   the seed array
ALLOCATE (new(I))
ALLOCATE (old(I))
CALL RANDOM_SEED (GET=old(1:I)) ! Gets the current seed
WRITE(*,*) old
new = 5
CALL RANDOM_SEED (PUT=new(1:I)) ! Sets seed from array
    new
END
```

RANDOM_NUMBER
SEED
SRAND

RANDU

**Intrinsic Subroutine (Generic):** Computes a
pseudorandom number as a single-precision value.
Intrinsic subroutines cannot be passed as actual
arguments.

Syntax

CALL RANDU (i1,i2,x)
ii, i2 (Input; output) Must be scalars of type INTEGER(2) or INTEGER(4). They contain the seed for computing the random number. These values are updated during the computation so that they contain the updated seed.

x (Output) Must be a scalar of type REAL(4). This is where the computed random number is returned.

The result is returned in x, which must be of type REAL(4). The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for i1 and i2.

The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for i1 and i2.

If i1 = 0 and i2 = 0, the generator base is set as follows:

\[ x(n + 1) = 2^{16} + 3 \]

Otherwise, it is set as follows:

\[ x(n + 1) = (2^{16} + 3) \cdot x(n) \mod 2^{32} \]

The generator base x(n + 1) is stored in i1, i2. The result is x(n + 1) scaled to a real value y(n + 1), for 0.0 <= y(n + 1) < 1.

Example

Consider the following:

```fortran
REAL X
INTEGER(2) I, J
...
CALL RANDU (I, J, X)
```

If I and J are values 4 and 6, X has the value 5.4932479E-04.

**RANF Intrinsic Procedure**

**Elemental Intrinsic Function (Generic):** Generates a random number between 0.0 and RAND_MAX. This function must not be passed as an actual argument. RANF can be used as an intrinsic procedure or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

**Syntax**

```fortran
result = RANF ()
```

**Results**

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and (2**31) - 1.

The initial seed is set by the following:

```fortran
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

The intrinsic function RANF generates a different sequence of random numbers than the RANF portability function generates for the same seed. The intrinsic function RANF used inside a loop can be vectorized into one call that returns four results, but the portability function RANF cannot be so optimized.

**See Also**

RANDOM_NUMBER
RANF Portability Routine

SRAND

RANF Portability Routine

**Portability Function:** Generates a random number between 0.0 and RAND_MAX. RANF can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

```
result = RANF()
```

Results

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and 
\((2^{31}) - 1\).

The initial seed is set by the following:

```
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

See Also

RANDOM_NUMBER
RANF Intrinsic Procedure
SRAND

RANGE

**Inquiry Intrinsic Function (Generic):** Returns the decimal exponent range in the model representing numbers with the same kind parameter as the argument.

Syntax

```
result = RANGE(x)
```

\(x\) (Input) Must be of type integer, real, or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

For an integer argument, the result has the value \(\text{INT}(\log_{10}(\text{HUGE}(x)))\). For information on the integer model, see Model for Integer Data.

For a real or complex argument, the result has the value \(\text{INT}(\min(\log_{10}(\text{HUGE}(x)), -\log_{10}(\text{TINY}(x))))\). For information on the real model, see Model for Real Data.

Example

If \(X\) is a REAL(4) value, RANGE \((X)\) has the value 37. (\(\text{HUGE}(X) = (1 - 2^{-24}) \times 2^{128}\) and \(\text{TINY}(X) = 2^{-126}\))

See Also

HUGE
TINY
RANGET
Portability Subroutine: Returns the current seed.

Module
USE IFPORT

Syntax
CALL RANGET (seed)

seed (Output) INTEGER(4). The current seed value.

RANK
Inquiry Intrinsic Function (Generic): Returns the rank of a data object.

Syntax
result = RANK (a)

a (Input) Is a data object. It can be of any type.

Results
The result type is default integer scalar. The result value is the rank of a.

Example
If object C is an assumed-rank dummy argument and its associated argument is an array of rank 5, RANK(C) returns the value 5.
If D is an array declared DIMENSION (2, 3, 4), RANK(D) returned the value 3.

See Also
Assumed-Rank Specifications

RANSET
Portability Subroutine: Sets the seed for the random number generator.

Module
USE IFPORT

Syntax
CALL RANSET (seed)

seed (Input) REAL(4). The reset value for the seed.

READ Statement
Statement: Transfers input data from external sequential, direct-access, or internal records.

Syntax
Sequential
Formatted:
READ form[, io-list]

Formatted - List-Directed:
READ *[, io-list]

Formatted - Namelist:
READ nml

Unformatted:

Direct-Access

Formatted:

Unformatted:

Internal
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]

Internal Namelist
READ (iunit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]

eunit Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if eunit is not the first specifier in the list.

format Is a format specifier. It is optionally prefaced by FMT= if format is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

For internal READs, an asterisk (*) indicates list-directed formatting. For direct-access READs, an asterisk is not permitted.

advance Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

blank Is a blank control specifier (BLANK = blnk). If the value of blnk is 'NULL', all blanks are ignored. If the value is 'ZERO', all blanks are treated as zeros. The default value is 'NULL'.

decimal  Is a decimal mode specifier (DECIMAL=dmode) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.

id  Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

pad  Is a blank padding specifier (PAD = pd). If the value of pad is 'YES', the record will be padded with blanks when necessary. If the value is 'NO', the record will not be padded with blanks. The default value is 'YES'.

pos  Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

round  Is a rounding specifier (ROUND=rmode) that determines the I/O rounding mode for this READ statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.

size  Is a character count specifier (SIZE=i-var). It can only be specified for nonadvancing READ statements.

iostat  Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

err, end, eor  Are branch specifiers if an error (ERR=label), end-of-file (END=label), or end-of-record (EOR=label) condition occurs. EOR can only be specified for nonadvancing READ statements.

iomsg  Is an I/O message specifier (IOMSG=msg-var).

io-list  Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

If an item in io-list is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as eunit.

If I/O is to or from a formatted device, io-list cannot contain derived-type variables, but it can contain components of derived types. If I/O is to a binary or unformatted device, io-list can contain either derived type components or a derived type variable.

form  Is the nonkeyword form of a format specifier (no FMT=).

*  Is the format specifier indicating list-directed formatting. (It can also be specified as FMT=*)

nml-group  Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if nml-group is not the second I/O specifier. For more information, see Namelist Specifier.
nml  Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist I/O.

rec  Is the cell number of a record to be accessed directly. It must be prefaced by REC=.

iunit  Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if iunit is not the first specifier in the list. It must be a character variable. It must not be an array section with a vector subscript.

If you specify EOR= or SIZE=, you must also specify ASYNCHRONOUS='NO'.
If you specify BLANK=, DECIMAL=, PAD=, or ROUND=, you must also specify FMT= or NML=.
If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

CAUTION
The READ statement can disrupt the results of certain graphics text functions (such as SETTEXTWINDOW) that alter the location of the cursor. You can avoid the problem by getting keyboard input with the GETCHARQQ function and echoing the keystrokes to the screen using OUTTEXT. Alternatively, you can use SETTEXTPOSITION to control cursor location.

Example
DIMENSION ia(10,20)
! Read in the bounds for the array.
! Then read in the array in nested implied-DO lists
! with input format of 8 columns of width 5 each.
READ (6, 990) il, jl, ((ia(i,j), j = 1, jl), i =1, il)
990 FORMAT (2I5, /, (8I5))

! Internal read gives a variable string-represented numbers
CHARACTER*12 str
str = '123456'
READ (str, '(*i6)') i

! List-directed read uses no specified format
REAL x, y
INTEGER i, j
READ (*,*) x, y, i, j

I/O Formatting Overview

REAL Statement
Statement: Specifies the REAL data type.

Syntax
REAL
REAL([KIND=] n)

REAL* n

DOUBLE PRECISION

n Is an initialization expression that evaluates to kind 4, 8 or 16.

**Description**

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

REAL(4) and REAL*4 (single precision) are the same data type. REAL(8), REAL*8, and DOUBLE PRECISION are the same data type.

**Example**

```fortran
! type declarations with attribute specifiers
REAL (8), PARAMETER :: testval=50.d0
REAL, SAVE :: a(10), b(20,30)
REAL, PARAMETER :: x = 100.

! attribute statements to declare the same entities
REAL x, a, b, testval*8
DIMENSION a(10), b(20,30)
SAVE a, b
PARAMETER (x = 100., testval=50.d0)
```

**See Also**

DOUBLE PRECISION

REAL Directive

Real Data Types

General Rules for Real Constants

General Rules for Real Constants

General Rules for Real Constants

Model for Real Data

**REAL Directive**

*General Compiler Directive: Specifies the default real kind.*

**Syntax**

```fortran
!DIR$ REAL:{ 4 | 8 | 16 }
```

The REAL directive selects a size of 4 (KIND=4), 8 (KIND=8), or 16 (KIND=16) bytes for default real numbers. When the directive is in effect, all default real and complex variables are of the kind specified in the directive. Only numbers specified or implied as REAL without KIND are affected.

The REAL directive can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. REAL cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.
**Example**

```
REAL r              ! a 4-byte REAL
WRITE(*,*) KIND(r)
CALL REAL8( )
WRITE(*,*) KIND(r)  ! still a 4-byte REAL
                   ! not affected by setting in subroutine
END

SUBROUTINE REAL8( )
  !DIR$ REAL:8
  REAL s ! an 8-byte REAL
  WRITE(*,*) KIND(s)
END SUBROUTINE
```

**See Also**
REAL Statement
COMPLEX Statement
General Compiler Directives
Syntax Rules for Compiler Directives

**REAL Function**

*Elemental Intrinsic Function (Generic):* Converts a value to real type.

**Syntax**

```
result = REAL (a[,kind])
```

- `a`  
  (Input) Must be of type integer, real, or complex.

- `kind`  
  (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is real. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

If `a` is integer or real, the result is equal to an approximation of `a`. If `a` is complex, the result is equal to an approximation of the real part of `a`.

1 These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying real size can affect FLOAT, REAL, and SNGL.

3 Or FLOATJ. For compatibility with older versions of Fortran, FLOAT is generic, allowing any kind of INTEGER argument, and returning a default real result.

4 For compatibility with older versions of Fortran, SNGL is generic, allowing any kind of REAL argument, and returning a default real result.

If the argument is a boz-constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

REAL (-4) has the value -4.0.

REAL (Y) has the same kind parameter and value as the real part of complex variable Y.

DFLOAT
DREAL
DBLE
assume compiler option

**RECORD**

**Statement:** Declares a record structure as an entity with a name.

**Syntax**

RECORD /structure-name/record-namelist [, /structure-name/record-namelist]...

structure-name Is the name of a previously declared structure.

record-namelist Is a list of one or more variable names, array names, or array specifications, separated by commas. All of the records named in this list have the same structure and are allocated separately in memory.

You can use record names in COMMON and DIMENSION statements, but not in DATA or NAMELIST statements.

Records initially have undefined values unless you have defined their values in structure declarations.

STRUCTURE and RECORD constructs have been replaced by derived types, which should be used in writing new code. See Derived Data Types.

**Example**

```fortran
STRUCTURE /address/
  LOGICAL*2    house_or_apt
  INTEGER*2    apt
  INTEGER*2    housenumber
  CHARACTER*30 street
  CHARACTER*20 city
```
character*2 state
integer*4 zip
end structure

record /address/ mailing_addr(20), shipping_addr(20)

the following shows another example:

record /t1/ a, b, /t2/ c, /t3/ d, e, f

record structures

rectangle, rectangle_w (w*s)

graphics functions: draw a rectangle using the current graphics color, logical write mode, and line style.

module
use ifqwin

syntax
result = rectangle (control, x1, y1, x2, y2)
result = rectangle_w (control, wx1, wy1, wx2, wy2)

control (input) integer(2). fill flag. one of the following symbolic constants defined in ifqwin.f90:

- $gfillinterior - draws a solid figure using the current color and fill mask.
- $gborder - draws the border of a rectangle using the current color and line style.

x1, y1 (input) integer(2). viewport coordinates for upper-left corner of rectangle.

x2, y2 (input) integer(2). viewport coordinates for lower-right corner of rectangle.

wx1, wy1 (input) real(8). window coordinates for upper-left corner of rectangle.

wx2, wy2 (input) real(8). window coordinates for lower-right corner of rectangle.

results
the result type is integer(2). the result is nonzero if successful; otherwise, 0.

the rectangle function uses the viewport-coordinate system. the viewport coordinates (x1, y1) and (x2, y2) are the diagonally opposed corners of the rectangle.

the rectangle_w function uses the window-coordinate system. the window coordinates (wx1, wy1) and (wx2, wy2) are the diagonally opposed corners of the rectangle.

setcolorrgb sets the current graphics color. setfillmask sets the current fill mask. by default, filled graphic shapes are filled solid with the current color.
If you fill the rectangle using FLOODFILLRGB, the rectangle must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**NOTE**
The RECTANGLE routine described here is a QuickWin routine. If you are trying to use the Microsoft Platform SDK version of the Rectangle routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Rectangle.

**Example**
This program draws the rectangle shown below.

```fortran
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
dummy = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
END
```

**RECURSIVE**

*Keyword:* Specifies that a subroutine or function can call itself directly or indirectly. Recursion is permitted if the keyword is specified in a FUNCTION or SUBROUTINE statement, or if RECURSIVE is specified as a compiler option or in an OPTIONS statement.

**Description**
If a function is directly recursive and array valued, the keywords RECURSIVE and RESULT must both be specified in the FUNCTION statement.

The procedure interface is explicit within the subprogram in the following cases:

- When RECURSIVE is specified for a subroutine
- When RECURSIVE and RESULT are specified for a function

The keyword RECURSIVE must be specified if any of the following applies (directly or indirectly):
• The subprogram invokes itself.
• The subprogram invokes a subprogram defined by an ENTRY statement in the same subprogram.
• An ENTRY procedure in the same subprogram invokes one of the following:
  • Itself
  • Another ENTRY procedure in the same subprogram
  • The subprogram defined by the FUNCTION or SUBROUTINE statement

Example

```fortran
! RECURS.F90
!
i = 0
CALL Inc (i)
END
RECURSIVE SUBROUTINE Inc (i)
i = i + 1
CALL Out (i)
IF (i.LT.20) CALL Inc (i) ! This also works in OUT
END SUBROUTINE Inc

SUBROUTINE Out (i)
WRITE (*,*) i
END SUBROUTINE Out
```

REDUCTION

**Parallel Directive Clause:** Performs a reduction operation on the specified variables.

Syntax

```fortran
REDUCTION (operator| intrinsic: list)
```

- **operator**
  Is one of the following: +, *, -, .AND., .OR., .EQV., or .NEQV.

- **intrinsic**
  Is one of the following: MAX, MIN, IAND, IOR, or IEOR.

- **list**
  Is the name of one or more variables of intrinsic type that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma. Deferred-shape and assumed-size arrays, and procedure pointers are not allowed.

Variables that appear in a REDUCTION clause must be SHARED in the enclosing context. A private copy of each variable in list is created for each thread as if the PRIVATE clause had been used. The private copy is initialized according to the operator (see the table below). A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a REDUCTION clause.
At the end of the REDUCTION, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the operator specified. The reduction operators are all associative (except for subtraction), and the compiler can freely reassociate the computation of the final value; the partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the REDUCTION construct.

However, if the REDUCTION clause is used in a construct to which NOWAIT is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all the threads complete the REDUCTION clause.

The REDUCTION clause must be used in a region or worksharing construct where the reduction variable is used only in a reduction statement having one of the following forms:

\[
\begin{align*}
  x &= x \text{ operator } \text{expr} \\
  x &= \text{expr} \text{ operator } x \text{ (except for subtraction)} \\
  x &= \text{intrinsic} (x, \text{expr}) \\
  x &= \text{intrinsic} (\text{expr}, x)
\end{align*}
\]

Some reductions can be expressed in other forms. For instance, a MAX reduction can be expressed as follows:

\[
\text{IF } (x .LT. \text{expr}) x = \text{expr}
\]

Alternatively, the reduction might be hidden inside a subroutine call. Be careful that the operator you specify in the REDUCTION clause matches the reduction operation.

The following table lists the operators and intrinsics and their initialization values. The actual initialization value will be consistent with the data type of the reduction variable.

**Initialization Values for REDUCTION Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Initialization Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>0</td>
</tr>
<tr>
<td>*</td>

</tr>
</tbody>
</table>

If a directive allows reduction clauses, the number you can specify is not limited. However, each variable name can appear in only one of the clauses.

%REF

**Built-in Function:** Changes the form of an actual argument. Passes the argument by reference. In Intel® Fortran, passing by reference is the default.

**Syntax**

%REF (a)

a  
(Input) An expression, record name, procedure name, array, character array section, or array element.

You must specify %REF in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following table lists the Intel® Fortran defaults for argument passing, and the allowed uses of %REF:

<table>

<td>Yes</td>
</tr>
</tbody>
</table>

1 A character argument is passed by address and hidden length.
2 In Intel® Fortran record structures

The %REF and %VAL functions override related !DIR$ ATTRIBUTE settings.

### Example

```fortran
CHARACTER(LEN=10) A, B
CALL SUB(A, %REF(B))
```

Variable A is passed by address and hidden length. Variable B is passed by reference.

Note that on Windows* systems, compiler option iface determines how the character argument for variable B is passed.

iface

### REGISTERMOUSEEVENT (W*S)

**QuickWin Function:** Registers the application-supplied callback routine to be called when a specified mouse event occurs in a specified window.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = REGISTERMOUSEEVENT (unit, mouseevents, callbackroutine)
```

- **unit** (Input) INTEGER(4). Unit number of the window whose callback routine on mouse events is to be registered.

- **mouseevents** (Input) INTEGER(4). One or more mouse events to be handled by the callback routine to be registered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:
  - MOUSE$LBUTTONDOWN - Left mouse button down
  - MOUSE$LBUTTONUP - Left mouse button up
  - MOUSE$LBUTTONDBLCLK - Left mouse button double-click
  - MOUSE$RBUTTONDOWN - Right mouse button down
  - MOUSE$RBUTTONUP - Right mouse button up
  - MOUSE$RBUTTONDBLCLK - Right mouse button double-click
  - MOUSE$MOVE - Mouse moved

- **callbackroutine** (Input) Routine to be called on the specified mouse event in the specified window. It must be declared EXTERNAL.
Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE$BADEVENT - The event specified is not supported.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system's CONTROL PANEL/MOUSE.

Example

The following example registers the routine CALCULATE, to be called when the user double-clicks the left mouse button while the mouse cursor is in the child window opened as unit 4:

```
USE IFQWIN
INTEGER(4) result
OPEN (4, FILE= 'USER')
...
result = REGISTERMOUSEEVENT (4, MOUSE$LBUTTONDBLCLK, CALCULATE)
```

See Also

UNREGISTERMOUSEEVENT (W*S)
WAITONMOUSEEVENT (W*S)

REMAPALLPALETTERGB, REMAPPALETTERGB (W*S)

*Graphics Functions:* REMAPALLPALETTERGB remaps a set of Red-Green-Blue (RGB) color values to indexes recognized by the video hardware. REMAPPALETTERGB remaps one color index to an RGB color value.

Module

USE IFQWIN

Syntax

```
result = REMAPALLPALETTERGB (colors)
result = REMAPPALETTERGB (index, colors)
```

- **colors** (Input) INTEGER(4). Ordered array of RGB color values to be mapped in order to indexes. Must hold 0-255 elements.
- **index** (Input) INTEGER(4). Color index to be reassigned an RGB color.
- **color** (Input) INTEGER(4). RGB color value to assign to a color index.

Results

The result type is INTEGER(4). REMAPALLPALETTERGB returns 0 if successful; otherwise, -1. REMAPPALETTERGB returns the previous color assigned to the index.

The REMAPALLPALETTERGB function remaps all of the available color indexes simultaneously (up to 236; 20 indexes are reserved by the operating system). The colors argument points to an array of RGB color values. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in IFQWIN.F90.
The number of colors mapped can be fewer than 236 if the number of colors supported by the current video mode is fewer, but at most 236 colors can be mapped by REMAPALLPALETTERGB. Most Windows* OS graphics drivers support a palette of 256K colors or more, of which only a few can be mapped into the 236 palette indexes at a time. To access and use all colors on the system, bypass the palette and use direct RGB color functions such as SETCOLORRGB and SETPIXELSRGB.

Any RGB colors can be mapped into the 236 palette indexes. Thus, you could specify a palette with 236 shades of red.

In each RGB color value, each of the three colors, red, green and blue, is represented by an eight-bit value (2 hex digits). In the values you specify with REMAPALLPALETTERGB or REMAPPALETTERGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z’008080’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

**Example**

```
! Build as QuickWin or Standard Graphics App.

USE IFQWIN
INTEGER(4) colors(3)
INTEGER(2) status
colors(1) = Z'00FFFF' ! yellow
colors(2) = Z'FFFFFF' ! bright white
colors(3) = 0 ! black

status = REMAPALLPALETTERGB(colors)
status = REMAPPALETTERGB(INT2(47), Z'45A315')
END
```

**See Also**

SETBKCOLORRGB (W*S)
SETCOLORRGB (W*S)
SETBKCOLOR (W*S)
SETCOLOR (W*S)
RENAME

Portability Function: Renames a file.

Module

USE IFPORT

Syntax

result = RENAME (from, to)

from (Input) Character*(*). Path of an existing file.

to (Input) Character*(*). The new path for the file (see Caution note below).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

- EACCES - The file or directory specified by to could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
- ENOENT - The file or path specified by from could not be found.
- EXDEV - Attempt to move a file to a different device.

CAUTION

This routine can cause data to be lost. If the file specified in to already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.

The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).

Example

use IFPORT
integer(4) istatus
character*12 old_name, new_name
print *, "Enter file to rename: ", old_name
read *, old_name
print *, "Enter new name: ", new_name
read *, new_name
ISTATUS = RENAME (old_name, new_name)

See Also

RENAMEFILEQQ

RENAMEFILEQQ

Portability Function: Renames a file.

Module

USE IFPORT

Syntax

result = RENAMEFILEQQ (oldname, newname)

oldname (Input) Character*(*). Current name of the file to be renamed.
**newname** *(Input) Character*(*). New name of the file to be renamed.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the *newname* parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$ACCES - Permission denied. The file's permission setting does not allow the specified access.
- ERR$EXIST - The file already exists.
- ERR$NOENT - File or path specified by *oldname* not found.
- ERR$XDEV - Attempt to move a file to a different device.

**Example**

```fortran
USE IFPORT
USE IFCORE
INTEGER(4) len
CHARACTER(80) oldname, newname
LOGICAL(4) result

WRITE(*,')' ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,')' ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END
```

**See Also**
FINDFILEQQ
RENAME
GETLASTERRORQQ

**REPEAT**

*Transformational Intrinsic Function (Generic):*  
Concatenates several copies of a string.

**Syntax**

```
result = REPEAT (string, ncopies)
```

- **string** *(Input) Must be scalar and of type character.*
- **ncopies** *(Input) Must be scalar and of type integer. It must not be negative.*

**Results**

The result is a scalar of type character and length *ncopies* x LEN( *string*). The kind parameter is the same as *string*. The value of the result is the concatenation of *ncopies* copies of *string*.

**Example**

REPEAT ('S', 3) has the value SSS.
REPEAT ('ABC', 0) has the value of a zero-length string.
The following shows another example:

```fortran
CHARACTER(6) str
str = REPEAT('HO', 3) ! returns HOHOHO
```

**See Also**

SPREAD

RESHAPE

*Transformational Intrinsic Function (Generic):*

*Constructs an array with a different shape from the argument array.*

**Syntax**

```fortran
result = RESHAPE (source, shape[, pad] [, order])
```

- **source** (Input) Must be an array. It may be of any data type. It supplies the elements for the result array. Its size must be greater than or equal to \( \text{PRODUCT(shape)} \) if `pad` is omitted or has size zero.

- **shape** (Input) Must be an integer array of up to 31 elements, with rank one and constant size. It defines the shape of the result array. Its size must be positive; its elements must not have negative values.

- **pad** (Input; optional) Must be an array with the same type and kind parameters as `source`. It is used to fill in extra values if the result array is larger than `source`.

- **order** (Input; optional) Must be an integer array with the same shape as `shape`. Its elements must be a permutation of \((1,2,...,n)\), where \(n\) is the size of `shape`. If `order` is omitted, it is assumed to be \((1,2,...,n)\).

**Results**

The result is an array of shape `shape` with the same type and kind parameters as `source`. The size of the result is the product of the values of the elements of `shape`.

In the result array, the array elements of `source` are placed in the order of dimensions specified by `order`. If `order` is omitted, the array elements are placed in normal array element order.

The array elements of `source` are followed (if necessary) by the array elements of `pad` in array element order. If necessary, additional copies of `pad` follow until all the elements of the result array have values.

**NOTE**

In standard Fortran array element order, the first dimension varies fastest. For example, element order in a two-dimensional array would be \((1,1), (2,1), (3,1)\) and so on. In a three-dimensional array, each dimension having two elements, the array element order would be \((1,1,1), (2, 1, 1), (1, 2, 1), (2, 2, 1), (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2)\).

RESHAPE can be used to reorder a Fortran array to match C array ordering before the array is passed from a Fortran to a C procedure.

**Example**

RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 3/)) has the value

```
[ 3  5  7 ]
[ 4  6  8 ].
```
RESHAPE (/(3, 4, 5, 6, 7, 8/), (/2, 4/), (/1, 1/), (/2, 1/)) has the value

```
[ 3 4 5 6 ]
[ 7 8 1 1 ].
```

The following shows another example:

```fortran
INTEGER AR1(2, 5)
REAL F(5,3,8)
REAL C(8,3,5)
AR1 = RESHAPE((/1,2,3,4,5,6/),(/2,5/),(/0,0/),(/2,1/))
! returns 1 2 3 4 5
! 6 0 0 0 0
!
! Change Fortran array order to C array order
C = RESHAPE(F, (/8,3,5/), ORDER = (/3, 2, 1/))
END
```

See Also
PACK Function
SHAPE
TRANSPOSE
Array Assignment Statements

**RESULT**

*Keyword: Specifies a name for a function result.*

**Description**

Normally, a function result is returned in the function's name, and all references to the function name are references to the function result.

However, if you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. In this case, all references to the function name are recursive calls, and the function name must not appear in specification statements.

The RESULT name must be different from the name of the function.

**Example**

The following shows an example of a recursive function specifying a RESULT variable:

```fortran
RECURSIVE FUNCTION FACTORIAL(P) RESULT(L)
    INTEGER, INTENT(IN) :: P
    INTEGER L
    IF (P == 1) THEN
        L = 1
    ELSE
        L = P * FACTORIAL(P - 1)
    END IF
END FUNCTION
```

The following shows another example:

```fortran
recursive function FindSame(Aindex,Last,Used) &
& result(FindSameResult)
type(card) Last
integer Aindex, i
logical matched, used(5), FindSameResult
if( Aindex > 5 ) then
    FindSameResult = .true.
    return
endif
...
RETURN

Statement: Transfers control from a subprogram to the calling program unit.

Syntax

RETURN [expr]

expr Is a scalar expression that is converted to an integer value if necessary.

The expr is only allowed in subroutines; it indicates an alternate return. (An alternate return is an obsolescent feature in Standard Fortran.)

Description

When a RETURN statement is executed in a function subprogram, control is transferred to the referencing statement in the calling program unit.

When a RETURN statement is executed in a subroutine subprogram, control is transferred to the first executable statement following the CALL statement that invoked the subroutine, or to the alternate return (if one is specified).

Example

The following shows how alternate returns can be used in a subroutine:

CALL CHECK(A, B, +10, +20, C)
...
10 ...
20 ...
   SUBROUTINE CHECK(X, Y, +, +, C)
   ...
50   IF (X) 60, 70, 80
60   RETURN
70   RETURN 1
80   RETURN 2
END

The value of X determines the return, as follows:

• If X < 0, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the calling program.
• If X == 0, the first alternate return (RETURN 1) occurs and control is transferred to the statement identified with label 10.
• If X > 0, the second alternate return (RETURN 2) occurs and control is transferred to the statement identified with label 20.

Note that an asterisk (+) specifies the alternate return. An ampersand (&) can also specify an alternate return in a CALL statement, but not in a subroutine’s dummy argument list.

The following shows another example:

SUBROUTINE Loop
   CHARACTER in
10   READ (*, '(A)') in
   IF (in .EQ. 'Y') RETURN
  GOTO 10
The following example shows alternate returns:

```fortran
CALL AltRet (i, *10, *20, *30)
WRITE (*, *) 'normal return'
GOTO 40
10 WRITE (*, *) 'I = 10'
GOTO 40
20 WRITE (*, *) 'I = 20'
GOTO 40
30 WRITE (*, *) 'I = 30'
40 CONTINUE
END
SUBROUTINE AltRet (i, *, *, *)
IF (i .EQ. 10) RETURN 1
IF (i .EQ. 20) RETURN 2
IF (i .EQ. 30) RETURN 3
END
```

In the above example, RETURN 1 specifies the list's first alternate-return label, which is a symbol for the actual argument *10 in the CALL statement. RETURN 2 specifies the second alternate-return label, and RETURN 3 specifies the third alternate-return label.

CALL
CASE

**REWIND**

Statement: Positions a sequential or direct access file at the beginning of the file (the initial point). It takes one of the following forms:

Syntax

```
REWIND ([UNIT=] io-unit[, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

Rewind io-unit

- `io-unit` (Input) Is an external unit specifier.
- `label` Is the label of the branch target statement that receives control if an error occurs.
- `msg-var` (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
- `i-var` (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The unit number must refer to a file on disk or magnetic tape, and the file must be open for sequential, direct, or append access.

If a REWIND is done on a direct access file, the NEXTREC specifier is assigned a value of 1.

If a file is already positioned at the initial point, a REWIND statement has no effect.

If a REWIND statement is specified for a unit that is not open, it has no effect.
Example
The following statement repositions the file connected to I/O unit 3 to the beginning of the file:

REWIND 3

Consider the following statement:

REWIND (UNIT=9, IOSTAT=IOS, ERR=10)

This statement positions the file connected to unit 9 at the beginning of the file. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

The following shows another example:

WRITE (7, '(I10)') int
REWIND (7)
READ (7, '(I10)') int

See Also
OPEN
READ Statement
WRITE Statement
Data Transfer I/O Statements Overview
Branch Specifiers (END=, EOR=, ERR=)

REWRITE

Statement: Rewrites the current record.

Syntax

Formatted:

REWRITE (eunit, format[, iostat] [, err]) [io-list]

Unformatted:

REWRITE (eunit[, iostat][, err]) [io-list]

eunit Is an external unit specifier ([UNIT]=io-unit).

format Is a format specifier ([FMT]=format).

iostat Is a status specifier (IOSTAT=i-var).

erp Is a branch specifier (ERR=label) if an error condition occurs.

io-list Is an I/O list.

Description

In the REWRITE statement, data (translated if formatted; untranslated if unformatted) is written to the current (existing) record in a file with direct access.

The current record is the last record accessed by a preceding, successful sequential or direct-access READ statement.

Between a READ and REWRITE statement, you should not specify any other I/O statement (except INQUIRE) on that logical unit. Execution of any other I/O statement on the logical unit destroys the current-record context and causes the current record to become undefined.

Only one record can be rewritten in a single REWRITE statement operation.

The output list (and format specification, if any) must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)
If the number of characters specified by the I/O list (and format, if any) do not fill a record, blank characters are added to fill the record.

Example

In the following example, the current record (contained in the relative organization file connected to logical unit 3) is updated with the values represented by NAME, AGE, and BIRTH:

```fortran
REWRITE (3, 10, ERR=99) NAME, ,AGE, BIRTH
10 FORMAT (A16, I2, A8)
```

**RGBTOINTEGER (W’S)**

*QuickWin Function:* Converts three integers specifying red, green, and blue color intensities into a four-byte RGB integer for use with RGB functions and subroutines.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = RGBTOINTEGER (red, green, blue)
```

*red*  
(Input) INTEGER(4). Intensity of the red component of the RGB color value. Only the lower 8 bits of *red* are used.

*green*  
(Input) INTEGER(4). Intensity of the green component of the RGB color value. Only the lower 8 bits of *green* are used.

*blue*  
(Input) INTEGER(4). Intensity of the blue component of the RGB color value. Only the lower 8 bits of *blue* are used.

**Results**

The result type is INTEGER(4). The result is the combined RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value returned with RGBTOINTEGER, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B</td>
<td>G G G G G G G G</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

**Example**

```fortran
! Build as a QuickWin App.
USE IFQWIN
INTEGER r, g, b, rgb, result
INTEGER(2) status
r = Z’F0’
g = Z’F0’
b = 0
rgb = RGBTOINTEGER(r, g, b)
result = SETCOLORRGB(rgb)
```
status = ELLIPSE($GFILLINTERIOR, INT2(40), INT2(55), &
    INT2(90), INT2(85))

END

SETTEXTCOLORRGB (W*S)

RINDEX

Portability Function: Locates the index of the last occurrence of a substring within a string.

Module
USE IFPORT

Syntax
result = RINDEX(string, substr)

string (Input) Character*(*). Original string to search.
substr (Input) Character*(*). String to search for.

Results
The result type is INTEGER(4). The result is the starting position of the final occurrence of substr in string. The result is zero if substring does not occur in string.

Example
USE IFPORT
character*80 mainstring
character*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring, shortstr)
! where is 19

See Also
INDEX

RNUM

Elemental Intrinsic Function (Specific): Converts a character string to a REAL(4) value. This function cannot be passed as an actual argument.

Syntax
result = RNUM (i)

i (Input) Must be of type character.

Results
The result type is REAL(4). The result value is the real value represented by the character string i.
Example

RNUM ("821.003") has the value 821.003 of type REAL(4).

RRSPACING

*Elemental Intrinsic Function (Generic):* Returns the reciprocal of the relative spacing of model numbers near the argument value.

**Syntax**

\[
\text{result} = \text{RRSPACING}(x)
\]

\(x\) (Input) Must be of type real.

**Results**

The result type and kind is the same as \(x\). The result has the value \(|x| \cdot b^{-e} \cdot x \cdot p\). Parameters \(b, e, p\) are defined in [Model for Real Data](#).

**Example**

If -3.0 is a REAL(4) value, RRSPACING (-3.0) has the value 0.75 \(\times 2^{24}\).

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = RRSPACING(3.0) ! returns 1.258291E+07
res4 = RRSPACING(-3.0) ! returns 1.258291E+07
r2 = 487923.3
res8 = RRSPACING(r2) ! returns 8.382458680573952E+15
END
```

SPACING

Data Representation Models

RSHIFT

*Elemental Intrinsic Function (Generic):* Shifts the bits in an integer right by a specified number of positions. This is the same as specifying ISHFT with a negative shift.

**See Also**

See ISHFT.

RTC

*Portability Function:* Returns the number of seconds elapsed since a specific Greenwich mean time.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{RTC}()
\]
Results
The result type is REAL(8). The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

Example
USE IFPORT
  real(8) s, s1, time_spent
  INTEGER(4) i, j
  s = RTC( )
  call sleep(4)
  s1 = RTC( )
  time_spent = s1 - s
  PRINT *, 'It took ',time_spent, 'seconds to run.'

See Also
DATE_AND_TIME
TIME Portability Routine

RUNQQ
*Portability Function:* Executes another program and waits for it to complete.

Module
USE IFPORT

Syntax
result = RUNQQ (filename, commandline)

filename (Input) Character*(*). File name of a program to be executed.
commandline (Input) Character*(*). Command-line arguments passed to the program to be executed.

Results
The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the exit code of that program is returned to the program that launched it. If the program fails, -1 is returned.

The RUNQQ function executes a new process for the operating system using the same path, environment, and resources as the process that launched it. The launching process is suspended until execution of the launched process is complete.

Example
USE IFPORT
  INTEGER(2) result
  result = RUNQQ('myprog', '-c -r')
END

See also the example in NARGS.

See Also
NARGS
SYSTEM
NARGS
SAME_TYPE_AS

Inquiry Intrinsic Function (Generic): Inquires whether the dynamic type of one object is the same as the dynamic type of another object.

Syntax

result = SAME_TYPE_AS (a, b)

a (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

b (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.

Results

The result type is default logical scalar. The result is true only if the dynamic type of a is the same as the dynamic type of b.

SAVE

Statement and Attribute: Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.

Syntax

The SAVE attribute can be specified in a type declaration statement or a SAVE statement, and takes one of the following forms:

Type Declaration Statement:

type, [att-ls,] SAVE [, att-ls] :: entity[ , entity] ...

Statement:

SAVE [[::]entity [, entity] ...]

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

entity Is the name of an object, the name of a procedure pointer, or the name of a common block enclosed in slashes (/common-block-name/).

Description

In Intel® Fortran, certain variables are given the SAVE attribute, or not, by default:

- The following variables are not saved by default:
  - Scalar local variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL without default initialization
  - Variables that are declared AUTOMATIC
  - Local variables that are allocatable arrays
• Derived-type variables that are data initialized by default initialization of any of their components
• RECORD variables that are data initialized by default initialization specified in its STRUCTURE declaration
• The following variables are saved by default:
  • COMMON variables
  • Scalar local variables not of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL of non-recursive subprograms
  • Non-scalar local variables of non-recursive subprograms
  • Module or submodule variables
  • Data initialized by DATA statements
• Local variables that are not described in the preceding two lists are saved by default.

NOTE
Certain compiler options (such as options [Q]save and automatic) and the use of OpenMP* features can change the defaults.

To enhance portability and avoid possible compiler warning messages, Intel recommends that you use the SAVE statement to name variables whose values you want to preserve between subprogram invocations. When a SAVE statement does not explicitly contain a list, all allowable items in the scoping unit are saved.

A SAVE statement cannot specify the following (their values cannot be saved):
• A blank common
• An object in a common block
• A procedure
• A dummy argument
• A function result
• An automatic object
• A PARAMETER (named) constant

Even though a common block can be included in a SAVE statement, individual variables within the common block can become undefined (or redefined) in another scoping unit.

If a common block is saved in any scoping unit of a program (other than the main program), it must be saved in every scoping unit in which the common block appears.

A SAVE statement has no effect in a main program.

Example
The following example shows a type declaration statement specifying the SAVE attribute:

```fortran
SUBROUTINE TEST()
   REAL, SAVE :: X, Y
```

The following is an example of the SAVE statement:

```fortran
SAVE A, /BLOCK_B/, C, /BLOCK_D/, E
```

The following shows another example:

```fortran
SUBROUTINE MySub
   COMMON /z/ da, in, a, idum(10)
   REAL(8) x,y
   ...

   SAVE x, y, /z/
   ! alternate declaration
   REAL(8), SAVE :: x, y
   SAVE /z/
```

Graphics Functions: Save an image from a specified portion of the screen into a Windows bitmap file.

Module
USE IFQWIN

Syntax
result = SAVEIMAGE (filename, ulxcoord, ulycoord, lrxcoord, lrycoord)
result = SAVEIMAGE_W (filename, ulwxcoord, ulwycoord, lrwxcoord, lrwycoord)

filename (Input) Character*(*). Path of the bitmap file.
ulxcoord, ulycoord (Input) INTEGER(4). Viewport coordinates for upper-left corner of the screen image to be captured.
lrxcoord, lrycoord (Input) INTEGER(4). Viewport coordinates for lower-right corner of the screen image to be captured.
ulwxcoord, ulwycoord (Input) REAL(8). Window coordinates for upper-left corner of the screen image to be captured.
lrxcoord, lrycoord (Input) REAL(8). Window coordinates for lower-right corner of the screen image to be captured.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The SAVEIMAGE function captures the screen image within a rectangle defined by the upper-left and lower-right screen coordinates and stores the image as a Windows bitmap file specified by filename. The image is stored with a palette containing the colors displayed on the screen.
SAVEIMAGE defines the bounding rectangle in viewport coordinates. SAVEIMAGE_W defines the bounding rectangle in window coordinates.

See Also

PUTIMAGE, PUTIMAGE_W (W*S)
**SCALE**

*Elemental Intrinsic Function (Generic):* Returns the value of the exponent part (of the model for the argument) changed by a specified value.

**Syntax**

\[
\text{result} = \text{SCALE} \left( x, i \right)
\]

- \( x \) (Input) Must be of type real.
- \( i \) (Input) Must be of type integer.

**Results**

The result type and kind is the same as \( x \). The result has the value \( x \times b^i \). Parameter \( b \) is defined in Model for Real Data.

**Example**

If 3.0 is a REAL(4) value, SCALE (3.0, 2) has the value 12.0 and SCALE (3.0, 3) has the value 24.0.

The following shows another example:

```fortran
REAL r
r = SCALE(5.2, 2)     ! returns 20.8
```

**See Also**

LSHIFT
Data Representation Models

**SCAN**

*Elemental Intrinsic Function (Generic):* Scans a string for any character in a set of characters.

**Syntax**

\[
\text{result} = \text{SCAN} \left( \text{string}, \text{set}[, \text{back}][, \text{kind}] \right)
\]

- \( \text{string} \) (Input) Must be of type character.
- \( \text{set} \) (Input) Must be of type character with the same kind parameter as \( \text{string} \).
- \( \text{back} \) (Input; optional) Must be of type logical.
- \( \text{kind} \) (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \( \text{back} \) is omitted (or is present with the value false) and \( \text{string} \) has at least one character that is in \( \text{set} \), the value of the result is the position of the leftmost character of \( \text{string} \) that is in \( \text{set} \).

If \( \text{back} \) is present with the value true and \( \text{string} \) has at least one character that is in \( \text{set} \), the value of the result is the position of the rightmost character of \( \text{string} \) that is in \( \text{set} \).

If no character of \( \text{string} \) is in \( \text{set} \) or the length of \( \text{string} \) or \( \text{set} \) is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.
Example

SCAN ("ASTRING", 'ST') has the value 2.
SCAN ("ASTRING", 'ST', BACK=.TRUE.) has the value 3.
SCAN ("ASTRING", 'CD') has the value zero.

The following shows another example:

```
INTEGER i
INTEGER array(2)
i = SCAN ("FORTRAN", 'TR')          ! returns 3
i = SCAN ("FORTRAN", 'TR', BACK = .TRUE.)  ! returns 5
i = SCAN ("FORTRAN", 'GHA')          ! returns 6
i = SCAN ("FORTRAN", 'ora')          ! returns 0
array = SCAN ((/"FORTRAN","VISUALC"/),(/'A', 'A'/))
       ! returns (6, 5)
```

! Note that when using SCAN with arrays, the string ! elements must be the same length. When using string ! constants, blank pad to make strings the same length. ! For example:

```
array = SCAN ((/"FORTRAN","MASM "/),(/'A', 'A'/))
       ! returns (6, 2)
```

END

See Also

VERIFY

SCANENV

**Portability Subroutine:** Scans the environment for the value of an environment variable.

Module

USE IFPORT

Syntax

CALL SCANENV (envname, envtext, envvalue)

- **envname**
  - (Input) Character*. Contains the name of an environment variable you need to find the value for.

- **envtext**
  - (Output) Character*. Set to the full text of the environment variable if found, or to '' if nothing is found.

- **envvalue**
  - (Output) Character*. Set to the value associated with the environment variable if found or to '' if nothing is found.

SCANENV scans for an environment variable that matches envname and returns the value or string it is set to.

SCROLLTEXTWINDOW (W*S)

**Graphics Subroutine:** Scrolls the contents of a text window.

Module

USE IFQWIN
**Syntax**

CALL SCROLLTEXTWINDOW (rows)

*rows*  
(Input) INTEGER(2). Number of rows to scroll.

The SCROLLTEXTWINDOW subroutine scrolls the text in a text window (previously defined by SETTEXTWINDOW). The default text window is the entire window.

The `rows` argument specifies the number of lines to scroll. A positive value for `rows` scrolls the window up (the usual direction); a negative value scrolls the window down. Specifying a number larger than the height of the current text window is equivalent to calling CLEARSCREEN ($GWINDOW). A value of 0 for `rows` has no effect.

**Example**

```fortran
! Build as QuickWin or Standard Graphics app.
USE IFQWIN INTEGER(2) row, istat
CHARACTER(18) string
TYPE (rccoord) oldpos

CALL SETTEXTWINDOW (INT2(1), INT2(0), INT2(25), INT2(80))
CALL CLEARSCREEN ( $GCLEARSCREEN )
CALL SETTEXTPOSITION (INT2(1), INT2(1), oldpos)
DO row = 1, 6
   string = 'Hello, World # '
   CALL SETTEXTPOSITION( row, INT2(1), oldpos )
   WRITE(string(15:16), '(I2)') row
   CALL OUTTEXT( string )
END DO
istat  = displaycursor($GCURSORON)
WRITE(*,'(1x,A")') 'Hit ENTER'
READ (*,*)
! wait for ENTER
! Scroll window down 4 lines
CALL SCROLLTEXTWINDOW(INT2( -4) )
CALL SETTEXTPOSITION (INT2(10), INT2(18), oldpos)
WRITE(*,'(1x,A")') "Hit ENTER"
READ( *,*) ! wait for ENTER
! Scroll window up 5 lines
CALL SCROLLTEXTWINDOW( INT2(5 ) )
END
```

**See Also**

SETTEXTWINDOW (W*S)  
WRAPON (W*S)

**SCWRQQ**

*Portability Subroutine:* Returns the floating-point processor control word.
Module
USE IFPORT

Syntax
CALL SCWRQQ (control)

control (Output) INTEGER(2). Floating-point processor control word.

SCRWQQ performs the same function as the run-time subroutine GETCONTROLFPQQ, and is provided for compatibility.

Example
See the example in LCWRQQ.

See Also
GETCONTROLFPQQ
LCWRQQ

SECNDS Intrinsic Procedure

Elemental Intrinsic Function (Generic): Provides the system time of day, or elapsed time, as a floating-point value in seconds. SECNDS can be used as an intrinsic function or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

Syntax
This function must not be passed as an actual argument. It is not a pure function, so it cannot be referenced inside a FORALL construct.

result = SECNDS (x)

x (Input) Must be of type real.

Results
The result type and kind is the same as x.

If x is zero, the result value is the time in seconds since the most recent midnight (in local time).

If x is not zero, it is compared to now: the value that would be returned if x had been zero. If x is less than now, then the result value is now - x. If x is more than now, the function assumes that x is the result of a call to SECONDS made the previous day and returns the value between that time and now.

This function cannot detect a delay of more than one day between calls. For timing intervals longer than 24 hours, use DCLOCK.

This function does not account for daylight savings changes in either direction.

The value of SECNDS is accurate to 0.01 second, which is the resolution of the system clock.

The 24 bits of precision provide accuracy to the resolution of the system clock for about one day. However, loss of significance can occur if you attempt to compute very small elapsed times late in the day.

Example
The following shows how to use SECNDS to perform elapsed-time computations:

C    START OF TIMED SEQUENCE
T1 = SECNDS(0.0)
See Also
DATE_AND_TIME
RTC
SYSTEM_CLOCK
TIME Intrinsic Procedure
SECNDS Portability Routine
DCLOCK

SECNDS Portability Routine

Portability Function: Returns the number of seconds that have elapsed since midnight, less the value of its argument. SECNDS can be used as a portability function or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module
USE IFPORT

Syntax
result = SECNDS (time)

time (Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.

Results
The result type is REAL(4). The result value is the number of seconds that have elapsed since midnight, minus time, with a precision of a hundredth of a second (0.01).

To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

Example
USE IFPORT
REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
   J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ', s, ' seconds to run.'

SECTIONS

OpenMP* Fortran Compiler Directive: Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.

Syntax

```fortran
!$OMP SECTIONS [clause[, clause] ... ]

[!$OMP SECTION]
  block
[!$OMP SECTION
  block]...

!$OMP END SECTIONS[NOWAIT]
```

clause

Is one of the following:

- FIRSTPRIVATE (list)
- LASTPRIVATE (list)
- PRIVATE (list)
- REDUCTION (operator | intrinsic : list)

block

Is a structured block (section) of statements or constructs. Any constituent section must also be a structured block.

You cannot branch into or out of the block.

The binding thread set for a SECTIONS construct is the current team. A SECTIONS region binds to the innermost enclosing parallel region.

Each section of code is preceded by a SECTION directive, although the directive is optional for the first section. The SECTION directives must appear within the lexical extent of the SECTIONS and END SECTIONS directive pair.

The last section ends at the END SECTIONS directive. Threads that complete execution of their SECTIONs encounter an implied barrier at the END SECTIONS directive unless NOWAIT is specified.

SECTIONS directives must be encountered by all threads in a team or by none at all.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```fortran
!$OMP PARALLEL
!$OMP SECTIONS
!$OMP SECTION
  CALL XAXIS
!$OMP SECTION
  CALL YAXIS
!$OMP SECTION
  CALL ZAXIS
!$OMP END SECTIONS
!$OMP END PARALLEL
```

SEED

**Portability Subroutine:** Changes the starting point of the pseudorandom number generator.

### Module
USE IFPORT

### Syntax
CALL SEED (iseed)

*iseed* (Input) INTEGER(4). Starting point for RANDOM.

SEED uses *iseed* to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.

This routine is not thread-safe.

### Example
USE IFPORT
REAL myrand
CALL SEED(7531)
CALL RANDOM(myrand)

### See Also
RANDOM Subroutine
RANDOM_SEED
RANDOM_NUMBER

**SELECT CASE and END SELECT**

**Statement:** Transfers program control to a selected block of statements according to the value of a controlling expression.

### Example
CHARACTER*1 cmdchar

```fortran
... Files: SELECT CASE (cmdchar)
    CASE ('0')
        WRITE (*, *) "Must retrieve one to nine files"
    CASE ('1':'9')
        CALL RetrieveNumFiles (cmdchar)
    CASE ('A', 'a')
        CALL AddEntry
    CASE ('D', 'd')
        CALL DeleteEntry
    CASE ('H', 'h')
        CALL Help
    CASE DEFAULT
        WRITE (*, *) "Command not recognized; please re-enter"
END SELECT Files
```

### See Also
See **CASE**.
SELECT TYPE

**Statement:** Marks the beginning of a SELECT TYPE construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the dynamic type of a specified expression.

**Syntax**

```
[name:] SELECT TYPE ([ assoc-name => ] selector)

[type-guard-stmt

   block]...

END SELECT [name]
```

(name) Is the name of the SELECT TYPE construct.

(assoc-name) Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct. If selector is not a named variable, assoc-name => must appear.

(selector) Is an expression or variable. It must be polymorphic. It is evaluated when the SELECT TYPE statement is executed.

(type-guard-stmt) (Optional) Is one of the following:

- TYPE IS (type) [name]
- CLASS IS (type) [name]
- CLASS DEFAULT [name]

CLASS DEFAULT can be specified only once in the construct. The same type and kind parameter values can only be specified in one TYPE IS statement and one CLASS IS statement.

(type) Is an intrinsic type specifier or a derived-type specifier. It must specify that each length type parameter is assumed. It cannot be a sequence derived type or a type with the BIND attribute.

(block) (Optional) Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified at the beginning of a SELECT TYPE statement, the same name must appear in the corresponding END SELECT statement and any type-guard-stmt. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT TYPE statement, you cannot specify one following the END SELECT statement or any type-guard-stmt.

Execution of a SELECT TYPE construct whose selector is not a variable causes the selector expression to be evaluated.

A SELECT TYPE construct selects at most one block to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector.

The following steps determine which block is selected for execution:

1. If a TYPE IS statement matches the selector, the block following that statement is executed. A TYPE IS statement matches the selector if the dynamic type and type parameter values of the selector are the same as those specified by the statement.
2. Otherwise, if exactly one CLASS IS statement matches the selector, the block following that statement is executed. A CLASS IS statement matches the selector if the dynamic type of the selector is an extension of the type specified by the statement and the kind type parameters specified by the statement are the same as the corresponding type parameters of the dynamic type of the selector.

3. Otherwise, if several CLASS IS statements match the selector, one of these statements must specify a type that is an extension of all the types specified in the others. In this case, the block following that statement is executed.

4. Otherwise, if there is a CLASS DEFAULT statement, the block following that statement is executed.

Within the block following a TYPE IS statement, the associating entity is not polymorphic, it has the type named in the TYPE IS statement, and has the type parameters of the selector.

Within the block following a CLASS IS statement, the associating entity is polymorphic and has the declared type named in the CLASS IS statement. The type parameters of the associating entity are the corresponding type parameters of the selector.

Within the block following a CLASS DEFAULT statement, the associating entity is polymorphic and has the same declared type as the selector. The type parameters of the associating entity are those of the declared type of the selector.

If the declared type of the selector is M, specifying CLASS DEFAULT has the same effect as specifying CLASS IS (M).

Within a SELECT TYPE construct, each associating entity has the same rank as its associated selector.

A type-guard-stmt cannot be a branch target statement. You can branch to an END SELECT statement only from within its SELECT TYPE construct.

Example

The following example shows a SELECT TYPE construct:

```fortran
TYPE POINT
  REAL :: X, Y
END TYPE POINT
TYPE, EXTENDS(POINT) :: POINT_3D
  REAL :: Z
END TYPE POINT_3D
TYPE, EXTENDS(POINT) :: COLOR_POINT
  INTEGER :: COLOR
END TYPE COLOR_POINT
TYPE(POINT), TARGET :: P
TYPE(POINT_3D), TARGET :: P3D
TYPE(COLOR_POINT), TARGET :: CP
CLASS(POINT), POINTER :: P OR CP
P OR CP=> CP
SELECT TYPE ( AN => P OR CP )
CLASS IS ( POINT )
  ! "CLASS ( POINT ) :: AN" is implied here
  PRINT *, AN%X, AN%Y  ! This block gets executed
TYPE IS ( POINT_3D )
  ! "TYPE ( POINT_3D ) :: AN" is implied here
  PRINT *, AN%X, AN%Y, AN%Z
END SELECT
```

The following example uses declarations from the above example, but it omits the associate name AN:

```fortran
P OR CP => P3D
SELECT TYPE ( P OR CP )
CLASS IS ( POINT )
  ! "CLASS ( POINT ) :: P OR CP" is implied here
  PRINT *, P OR CP%X, P OR CP%Y
TYPE IS ( POINT_3D )
```

1873
! "TYPE ( POINT_3D ) :: P_OR_CP" is implied here
    PRINT *, P_OR_CP%X, P_OR_CP%Y, P_OR_CP%Z  ! This block gets executed
END SELECT

**SELECTED_CHAR_KIND**

*Transformational Intrinsic Function (Generic):*

*Returns the value of the kind type parameter of the character set named by the argument.***

**Syntax**

\[
\text{result} = \text{SELECTED_CHAR_KIND}(\text{name})
\]

\*name* 
(Input) Must be scalar and of type default character. Its value must be 'DEFAULT' or 'ASCII'.

**Results**

The result is a scalar of type default integer.

The result is a scalar of type default integer. The result value is 1 if NAME has the value 'DEFAULT' or 'ASCII'; otherwise, the result value is -1.

**SELECTED_INT_KIND**

*Transformational Intrinsic Function (Generic):*

*Returns the value of the kind parameter of an integer data type.***

**Syntax**

\[
\text{result} = \text{SELECTED_INT_KIND}(r)
\]

\*r* 
(Input) Must be scalar and of type integer.

**Results**

The result is a scalar of type default integer. The result has a value equal to the value of the kind parameter of the integer data type that represents all values \( n \) in the range of values \( n \) with \( -10^r < n < 10^r \).

If no such kind type parameter is available on the processor, the result is -1. If more than one kind type parameter meets the criteria, the value returned is the one with the smallest decimal exponent range. For more information, see Model for Integer Data.

**Example**

SELECTED_INT_KIND (6) = 4

The following shows another example:

\[
\begin{align*}
i & = \text{SELECTED_INT_KIND}(8) \quad ! \text{returns 4} \\
i & = \text{SELECTED_INT_KIND}(3) \quad ! \text{returns 2} \\
i & = \text{SELECTED_INT_KIND}(10) \quad ! \text{returns 8} \\
i & = \text{SELECTED_INT_KIND}(20) \quad ! \text{return -1 because 10^{**20} \\
& \quad \text{is bigger than 2^{**63}}
\end{align*}
\]

**See Also**

SELECTED_REAL_KIND
SELECTED_REAL_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of a real data type.

Syntax

\[
\text{result} = \text{SELECTED_REAL_KIND} ([\text{p}] [,\text{r}])
\]

\( p \)
(Input; optional) Must be scalar and of type integer.

\( r \)
(Input; optional) Must be scalar and of type integer.

At least one argument must be present.

Results

If \( p \) or \( r \) is absent, the result is as if the argument was present with the value zero.

The result is a scalar of type default integer. If both arguments are absent, the result is zero. Otherwise, the result has a value equal to a value of the kind parameter of a real data type with decimal precision, as returned by the function PRECISION, of at least \( p \) digits and a decimal exponent range, as returned by the function RANGE, of at least \( r \).

If no such kind type parameter is available on the processor, the result is as follows:

-1 if the precision is not available but the range is available
-2 if the exponent range is not available but the precision is available
-3 if neither is available
-4 if real types for the precision and the range are available separately but not together

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision. Intel® Fortran currently does not return -4 for any combination of \( p \) and \( r \). For more information, see Model for Real Data.

Example

SELECTED_REAL_KIND (6, 70) = 8

The following shows another example:

\[
\begin{align*}
\text{i} & = \text{SELECTED_REAL_KIND}(r=200) \quad ! \text{returns 8} \\
\text{i} & = \text{SELECTED_REAL_KIND}(13) \quad ! \text{returns 8} \\
\text{i} & = \text{SELECTED_REAL_KIND}(100, 200) \quad ! \text{returns -1} \\
\text{i} & = \text{SELECTED_REAL_KIND}(13, 5000) \quad ! \text{returns -2} \\
\text{i} & = \text{SELECTED_REAL_KIND}(100, 5000) \quad ! \text{returns -3}
\end{align*}
\]

The following example gives a compile-time error:

\[
\text{i} = \text{SELECTED_REAL_KIND} ()
\]

The following example returns a 0 at run-time to indicate that there was an error:

\[
\begin{verbatim}
PROGRAM TEST
CALL F ()
CONTAINS
  SUBROUTINE F (P, R)
    INTEGER, OPTIONAL :: P, R
    PRINT *, SELECTED_REAL_KIND (P=P, R=R) ! prints 0
  END SUBROUTINE F
END PROGRAM TEST
\end{verbatim}
\]

SELECTED_INT_KIND
SEQUENCE

Statement: Preserves the storage order of a derived-type definition.

Syntax
SEQUENCE

Description
The SEQUENCE statement allows derived types to be used in common blocks and to be equivalenced.

The SEQUENCE statement appears only as part of derived-type definitions. It causes the components of the derived type to be stored in the same sequence they are listed in the type definition. If you do not specify SEQUENCE, the physical storage order is not necessarily the same as the order of components in the type definition.

If a derived type is a sequence derived type, then any other derived type that includes it must also be a sequence type.

Example

```fortran
!DIR$ PACK:1
TYPE NUM1_SEQ
  SEQUENCE
  INTEGER(2)::int_val
  REAL(4)::real_val
  LOGICAL(2)::log_val
END TYPE NUM1_SEQ

TYPE num2_seq
  SEQUENCE
  LOGICAL(2)::log_val
  INTEGER(2)::int_val
  REAL(4)::real_val
end type num2_seq

type (num1_seq) num1
type (num2_seq) num2
character*8 t, t1
equivalence (num1,t)
equivalence (num2,t1)
num1%int_val=2
num1%real_val=3.5
num1%log_val=.TRUE.
t1(1:2)=t(7:8)
t1(3:4)=t(1:2)
t1(5:8)=t(3:6)
print *, num2%int_val, num2%real_val, num2%log_val
end
```

Data Types, Constants, and Variables Overview

SETACTIVEQQ (W*S)

QuickWin Function: Makes a child window active, but does not give it focus.

Module
USE IFQWIN
Syntax

result = SETACTIVEQQ (unit)

unit (Input) INTEGER(4). Unit number of the child window to be made active.

Results

The result type is INTEGER(4). The result is 1 if successful; otherwise, 0.

When a window is made active, it receives graphics output (from ARC, LINETO and OUTGTEXT, for example) but is not brought to the foreground and does not have the focus. If a window needs to be brought to the foreground, it must be given the focus. A window is given focus with FOCUSQQ, by clicking it with the mouse, or by performing I/O other than graphics on it, unless the window was opened with IOFOCUS='FALSE'. By default, IOFOCUS='TRUE.', except for child windows opened as unit '*'.

The window that has the focus is always on top, and all other windows have their title bars grayed out. A window can have the focus and yet not be active and not have graphics output directed to it. Graphical output is independent of focus.

If IOFOCUS='TRUE.', the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

SETBKCOLOR (W*S)

Graphics Function: Sets the current background color index for both text and graphics.

Module
USE IFQWIN

Syntax

result = SETBKCOLOR (color)

color (Input) INTEGER(4). Color index to set the background color to.

Results

The result type is INTEGER(4). The result is the previous background color index.

SETBKCOLOR changes the background color index for both text and graphics. The color index of text over the background color is set with SETTEXTCOLOR. The color index of graphics over the background color (used by drawing functions such as FLOODFILL and ELLIPSE) is set with SETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Changing the background color index does not change the screen immediately. The change becomes effective when CLEARSCREEN is executed or when doing text input or output, such as with READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background color index is 0, which is associated with black unless the user remaps the palette with REMAPPALLETTERGB.
NOTE
The SETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetBkColor.

Example
USE IFQWIN
INTEGER(4) i
i = SETBKCOLOR(14)

See Also
SETBKCOLORRGB (W*S)
GETBKCOLOR (W*S)
REMAPALLPALETTERGB, REMAPPALLETTERGB (W*S)
SETBKCOLOR (W*S)
SETTEXTCOLOR (W*S)

SETBKCOLORRGB (W*S)

**Graphics Function:** Sets the current background color to the given Red-Green-Blue (RGB) value.

Module
USE IFQWIN

Syntax
result = SETBKCOLORRGB (color)

color (Input) INTEGER(4). RGB color value to set the background color to. Range and result depend on the system's display adapter.

Results
The result type is INTEGER(4). The result is the previous background RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>G G G G G R</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FFFF00' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

The default background color is value 0, which is black. Changing the background color value does not change the screen immediately, but becomes effective when CLEARSCREEN is executed or when doing text input or output such as READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB.
SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETBKCOLORRGB(Z'FF0000') !blue
oldcolor = SETCOLORRGB(Z'FF') ! red
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

See Also
GETBKCOLORRGB (W*S)

SETTEXTCOLORRGB (W*S)
SETPIXELRGB, SETPIXELRGB_W (W*S)
SETPIXELSRGB (W*S)
SETBKCOLOR (W*S)

SETCLIPRGN (W*S)

Graphics Subroutine: Limits graphics output to part of the screen.

Module
USE IFQWIN

Syntax

CALL SETCLIPRGN (x1,y1,x2,y2)

x1, y1 (Input) INTEGER(2). Physical coordinates for upper-left corner of clipping region.

x2, y2 (Input) INTEGER(2). Physical coordinates for lower-right corner of clipping region.

The SETCLIPRGN function limits the display of subsequent graphics output and font text output to that which fits within a designated area of the screen (the "clipping region"). The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangle that defines the clipping region. The SETCLIPRGN function does not change the viewport-coordinate system; it merely masks graphics output to the screen.

SETCLIPRGN affects graphics and font text output only, such as OUTGTEXT. To mask the screen for text output using OUTTEXT, use SETTEXTWINDOW.
Example

This program draws an ellipse lying partly within a clipping region, as shown below.

```fortran
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2
INTEGER(4) oldcolor
x1 = 10;  y1 = 50
x2 = 170; y2 = 150
! Draw full ellipse in white
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
oldcolor = SETCOLORRGB(Z'FF0000') !blue
WRITE(*,*) "Hit enter"
READ(*,*)
CALL CLEARSCREEN($GCLEARSCREEN) ! clear screen
CALL SETCLIPRGN( INT2(0), INT2(0), &
                 INT2(150), INT2(125))
! only part of ellipse inside clip region drawn now
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

The following shows the output of this program.

Bounding rectangle

Clip region  Arc of clipped ellipse

SETCOLOR (W*S)

*Graphics Function: Sets the current graphics color index.*

Module
USE IFQWIN

Syntax
```
result = SETCOLOR (color)
```

```
color (Input) INTEGER(2). Color index to set the current graphics color to.
```
Results

The result type is INTEGER(2). The result is the previous color index if successful; otherwise, -1.

The SETCOLOR function sets the current graphics color index, which is used by graphics functions such as ELLIPSE. The background color index is set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

Example

USE IFQWIN
INTEGER(2) color, oldcolor
LOGICAL status
TYPE (windowconfig) wc

status = GETWINDOWCONFIG(wc)
color = wc%numcolors - 1
oldcolor = SETCOLOR(color)
END

SETPIXELS (W*S)

SETCOLORRGB (W*S)

Graphics Function: Sets the current graphics color to the specified Red-Green-Blue (RGB) value.

Module
USE IFQWIN

Syntax

result = SETCOLORRGB (color)

color (Input) INTEGER(4). RGB color value to set the current graphics color to. Range and result depend on the system's display adapter.

Results

The result type is INTEGER(4). The result is the previous RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B B B</td>
<td>G G G G G G G G</td>
<td>R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

**SETCOLORRGB** sets the RGB color value of graphics over the background color, used by the following graphics functions: ARC, ELLIPSE, FLOODFILL, LINETO, OUTGTEXT, PIE, POLYGON, RECTANGLE, and SETPIXEL. **SETBKCOLORRGB** sets the RGB color value of the current background for both text and graphics. **SETTEXTCOLORRGB** sets the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT).

**SETCOLORRGB** (and the other RGB color selection functions **SETBKCOLORRGB**, and **SETTEXTCOLORRGB**) sets the color to a value chosen from the entire available range. The non-RGB color functions (**SETCOLOR**, **SETBKCOLOR**, and **SETTEXTCOLOR**) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) oldcolor
TYPE (xycoord) xy
numfonts = INITIALIZEFONTS()
oldcolor = SETCOLORRGB(Z'0000FF')  ! red
oldcolor = SETBKCOLORRGB(Z'00FF00') ! green
CALL MOVETO(INT2(200), INT2(100), xy)
CALL OUTGTEXT("hello, world")
END
```

**SETCONTROLFPQQ**

*Portability Subroutine:* Sets the value of the floating-point processor control word.

**Module**

USE IFPORT
Syntax

CALL SETCONTROLFPQQ (controlword)

controlword    (Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math coprocessor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z’1000'</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z’1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z’0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z’0300'</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z’0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z’0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z’0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z’0C00'</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z’0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z’0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z’0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z’0000'</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z’003F'</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>Z’0001'</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>FPCW$DENORMAL</td>
<td>Z’0002'</td>
<td>Allow denormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZERODIVIDE</td>
<td>Z’0004'</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>Z’0008'</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>Z’0010'</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z’0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.

Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.
NOTE
The Intel® Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Intel Fortran with another compiler.

Example

USE IFPORT
INTEGER(2) status, control, controlo
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
! Save old control word
controlo = control
! Clear all flags
control = control .AND. Z'0000'
! Set new control to round up
control = control .OR. FPCW$UP
CALL SETCONTROLFPQQ(control)
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END

SETDAT
Portability Function: Sets the system date. This function is only available on Windows* and Linux* systems.

Module
USE IFPORT

Syntax
result = SETDAT (iyr, imon, iday)

iyr (Input) INTEGER(2) or INTEGER(4). Year ( xxxxAD).
imon (Input) INTEGER(2) or INTEGER(4). Month (1-12).
iday (Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

Results
The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.
Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.
All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.
Refer to your operating system documentation for the range of permitted dates.
NOTE
On Linux systems, you must have root privileges to execute this function.

Example

USE IFPORT
LOGICAL(4) success
success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))
END

GETDAT
GETTIM
SETTIM

SETENVQQ

Portability Function: Sets the value of an existing environment variable, or adds and sets a new environment variable.

Module
USE IFPORT

Syntax

result = SETENVQQ (varname=value)

varname=value (Input) Character*(*). String containing both the name and the value of the variable to be added or modified. Must be in the form: varname = value, where varname is the name of an environment variable and value is the value being assigned to it.

Results

The result is of type LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate value so that trailing blanks are preserved. For example, the string PATH= =sets value to ''. You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, LIB= removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.
SETENVQQ and GETENVQQ will not work properly with the Windows APIs SetEnvironmentVariable and GetEnvironmentVariable.

Example

USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END

See Also
GETENVQQ
RUNQQ

SETERRMODEQQ

Portability Subroutine: Sets the prompt mode for critical errors that by default generate system prompts.

Module
USE IFPORT

Syntax

CALL SETERRMODEQQ (pmode)

pmode (Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (pmode=.TRUE.). You can also enable system error prompts by calling SETERRMODEQQ with pmode set to ERR$HARDPROMPT (defined in IFPORT.F90).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting pmode to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).

Note that SETERRMODEQQ affects only errors that generate a system prompt. It does not affect other I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with STATUS='OLD'.

Example

! PROGRAM 1
!  DRIVE B door open
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
!  Generates a system prompt error here and waits for the user
!  to respond to the prompt before continuing
100 WRITE(*,*) ' Continuing'
END

! PROGRAM 2
!  DRIVE B door open
USE IFPORT
CALL SETERRORMODEQ(.FALSE.)
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
! Causes the statement at label 100 to execute
! without system prompt
100   WRITE(*,*) ' Drive B: not available, opening &
 &alternative drive.'
OPEN (10, FILE = 'C:\NOFILE.DAT')
END

SETEXITQQ

QuickWin Function: Sets a QuickWin application's exit behavior.

Module

USE IFQWIN

Syntax

result = SETEXITQQ (exitmode)

exitmode (Input) INTEGER(4). Determines the program exit behavior. The following exit parameters are defined in IFQWIN.F90:

- QWIN$EXITPROMPT - Displays the following message box:
  "Program exited with exit status X. Exit Window?"
  where X is the exit status from the program.
  If Yes is entered, the application closes the window and terminates. If No is entered, the dialog box disappears and you can manipulate the windows as usual. You must then close the window manually.
- QWIN$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN$EXITPERSIST - Leaves the application open without displaying a message box.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The default for both QuickWin and Standard Graphics applications is QWIN$EXITPROMPT.

Example

! Build as QuickWin Ap
USE IFQWIN
INTEGER(4) exmode, result

WRITE(*,'(1X,A,/)') 'Please enter the exit mode 1, 2 &
or 3'
READ(*,*) exmode
SELECT CASE (exmode)
CASE (1)
   result = SETEXITQQ(QWIN$EXITPROMPT)
CASE (2)
   result = SETEXITQQ(QWIN$EXITNOPERSIST)
CASE (3)
   result = SETEXITQQ(QWIN$EXITPERSIST)
CASE DEFAULT

```fortran
WRITE(*,*) 'Invalid option - checking for bad return'
IF(SETEXITQQ( exmode ) .NE. -1) THEN
  WRITE(*,*) 'Error not returned'
ELSE
  WRITE(*,*) 'Error code returned'
ENDIF
END SELECT
END
```

**See Also**

GETEXITQQ (W*S)

### SET_EXPONENT

**Elemental Intrinsic Function (Generic):** Returns the value of the exponent part (of the model for the argument) set to a specified value.

**Syntax**

```
result = SET_EXPONENT (x, i)
```

- `x` (Input) Must be of type real.
- `i` (Input) Must be of type integer.

**Results**

The result type and kind is the same as `x`. The result has the value $x \times b^{i/e}$. Parameters `b` and `e` are defined in Model for Real Data. If `x` has the value zero, the result is zero.

**Example**

If 3.0 is a REAL(4) value, SET_EXPONENT (3.0, 1) has the value 1.5.

**See Also**

EXPONENT

Data Representation Models

### SETFILEACCESSQQ

**Portability Function:** Sets the file access mode for a specified file.

**Module**

USE IFPORT

**Syntax**

```
result = SETFILEACCESSQQ (filename, access)
```

- `filename` (Input) Character*(*). Name of a file to set access for.
- `access` (Input) INTEGER(4). Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such as IOR or OR):
  - FILE$ARCHIVE - Marked as having been copied to a backup device.
  - FILE$HIDDEN - Hidden. The file does not appear in the directory list that you can request from the command console.
  - FILE$NORMAL - No special attributes (default).
• FILE$READONLY - Write-protected. You can read the file, but you cannot make changes to it.
• FILE$SYSTEM - Used by the operating system.

The flags are defined in module IFPORT.F90.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

To set the access value for a file, add the constants representing the appropriate access.

Example

```
USE IFPORT
INTEGER(4) permit
LOGICAL(4) result
permit = 0    ! clear permit
permit = IOR(FILE$READONLY, FILE$HIDDEN)
result = SETFILEACCESSQQ ('formula.f90', permit)
END
```

See Also
GETFILEINFOQQ

SETFILETIMEQQ

Portability Function: Sets the modification time for a specified file.

Module
USE IFPORT

Syntax

```
result = SETFILETIMEQQ (filename, timedate)
```

*timedate* (Input) INTEGER(4) . Time and date information, as packed by PACKTIMEQQ.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of different versions of the file. The process that calls SETFILETIMEQQ must have write access to the file; otherwise, the time cannot be changed. If you set *timedate* to FILE$CURTIME (defined in IFPORT.F90), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the following:

• ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
• ERR$INVAL - Invalid argument; the *timedate* argument is invalid.
• ERR$MFILE - Too many open files (the file must be opened to change its modification time).
• ERR$NOENT - File or path not found.
• ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

Example

USE IFPORT
INTEGER(2) day, month, year
INTEGER(2) hour, minute, second, hund
INTEGER(4) timedate
LOGICAL(4) result

CALL GETDAT(year, month, day)
CALL GETTIM(hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, &
                 hour, minute, second)
result = SETFILETIMEQQ('myfile.dat', timedate)
END

See Also

UNPACKTIMEQQ
GETLASTERRORQQ

SETFILLMASK (W*S)

*Graphics Subroutine:* Sets the current fill mask to a new pattern.

Module

USE IFQWIN

Syntax

CALL SETFILLMASK (mask)

mask (Input) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in mask, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of mask becomes the top 8 bits of the pattern, and the eighth element (byte) of mask becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of zero are set to the current background color. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

To change the current fill mask, determine the array of bytes that corresponds to the desired bit pattern and set the pattern with SETFILLMASK, as in the following example.
Example

This program draws six rectangles, each with a different fill mask, as shown below.

USE IFQWIN

INTEGER(1), TARGET :: style1(8) &
/ 'Z'18','Z'18','Z'18','Z'18','Z'18','Z'18','Z'18','Z'18' /
INTEGER(1), TARGET :: style2(8) &
/ 'Z'08','Z'08','Z'08','Z'08','Z'08','Z'08','Z'08','Z'08' /
INTEGER(1), TARGET :: style3(8) &
/ 'Z'00','Z'00','Z'18','Z'18','Z'18','Z'18','Z'18','Z'18' /
INTEGER(1), TARGET :: style4(8) &
/ 'Z'00','Z'08','Z'00','Z'08','Z'08','Z'08','Z'08','Z'08' /
INTEGER(1), TARGET :: style5(8) &
/ 'Z'00','Z'18','Z'00','Z'18','Z'18','Z'18','Z'18','Z'18' /
INTEGER(1), TARGET :: style6(8) &
/ 'Z'08','Z'00','Z'08','Z'00','Z'08','Z'08','Z'00','Z'00' /
INTEGER(1) oldstyle(8) ! Placeholder for old style
INTEGER loop
INTEGER(1), POINTER :: ptr(:)

CALL GETFILLMASK( oldstyle )
! Make 6 rectangles, each with a different fill
DO loop = 1, 6
    SELECT CASE ( loop )
        CASE ( 1 )
            ptr => style1
        CASE ( 2 )
            ptr => style2
        CASE ( 3 )
            ptr => style3
        CASE ( 4 )
            ptr => style4
        CASE ( 5 )
            ptr => style5
        CASE ( 6 )
            ptr => style6
        END SELECT
    CALL SETFILLMASK( ptr )
    status = RECTANGLE( $GFILLINTERIOR, INT2( loop*40+5 ), &
The following shows the output of this program.

![Typical fill masks for rectangle]

SETFONT (W*S)

**Graphics Function:** Finds a single font that matches a specified set of characteristics and makes it the current font used by the OUTGTEXT function.

**Module**
USE IFQWIN

**Syntax**

```fortran
result = SETFONT (options)
```

**options**

(Input) Character*(*) String describing font characteristics (see below for details).

**Results**

The result type is INTEGER(2). The result is the index number (x as used in the nx option) of the font if successful; otherwise, -1.

The SETFONT function searches the list of available fonts for a font matching the characteristics specified in options. If a font matching the characteristics is found, it becomes the current font. The current font is used in all subsequent calls to the OUTGTEXT function. There can be only one current font.

The options argument consists of letter codes, as follows, that describe the desired font. The argument is neither case sensitive nor position sensitive.

- **t** fontname
  Name of the desired typeface. It can be any installed font.

- **h** y
  Character height, where y is the number of pixels.

- **w** x
  Select character width, where x is the number of pixels.
Select only a fixed-space font (do not use with the \(p\) characteristic).

Select only a proportional-space font (do not use with the \(f\) characteristic).

Select only a vector-mapped font (do not use with the \(r\) characteristic). Roman, Modern, and Script are examples of vector-mapped fonts, also called plotter fonts. True Type fonts (for example, Arial, Symbol, and Times New Roman) are not vector-mapped.

Select only a raster-mapped (bitmapped) font (do not use with the \(v\) characteristic). Courier, Helvetica, and Palatino are examples of raster-mapped fonts, also called screen fonts. True Type fonts are not raster-mapped.

Select the bold text format. This parameter is ignored if the font does not allow the bold format.

Select the underline text format. This parameter is ignored if the font does not allow underlining.

Select the italic text format. This parameter is ignored if the font does not allow italics.

Select the font that best fits the other parameters specified.

Select font number \(x\), where \(x\) is less than or equal to the value returned by the INITIALIZEFONTS function.

You can specify as many options as you want, except with \(nx\), which should be used alone. If you specify options that are mutually exclusive (such as the pairs \(f/p\) or \(r/v\)), the SETFONT function ignores them.

There is no error detection for incompatible parameters used with \(nx\).

If the \(b\) option is specified and at least one font is initialized, SETFONT sets a font and returns 0 to indicate success.

In selecting a font, the SETFONT routine uses the following criteria, rated from highest precedence to lowest:

1. Pixel height
2. Typeface
3. Pixel width
4. Fixed or proportional font

You can also specify a pixel width and height for fonts. If you choose a nonexistent value for either and specify the \(b\) option, SETFONT chooses the closest match.

A smaller font size has precedence over a larger size. If you request Arial 12 with best fit, and only Arial 10 and Arial 14 are available, SETFONT selects Arial 10.

If you choose a nonexistent value for pixel height and width, the SETFONT function applies a magnification factor to a vector-mapped font to obtain a suitable font size. This automatic magnification does not apply if you specify the \(r\) option (raster-mapped font), or if you request a specific typeface and do not specify the \(b\) option (best-fit).

If you specify the \(nx\) parameter, SETFONT ignores any other specified options and supplies only the font number corresponding to \(x\).
If a height is given, but not a width, SETFONT computes the width to preserve the correct font proportions.

If a width is given, but not a height, SETFONT uses a default height, which may vary from font type to font type. This may lead to characters that appear distorted, particularly when a very wide width is specified. This behavior is the same as that of the Windows* API CreateFontIndirect. A sample program is provided below showing you how to calculate the correct height for a given width.

The font functions affect only OUTGTEXT and the current graphics position; no other Fortran Graphics Library output functions are affected by font usage.

For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
! Set typeface to Arial, character height to 18,
! character width to 10, and italic
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Demo text')
END

Another example follows:

! The following program shows you how to compute
! an appropriate font height for a given font width
!
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
TYPE (rccoord) rcc
TYPE (FONTINFO) info
CHARACTER*11 str, str1
CHARACTER*22 str2
real rh
integer h, inw
str = "t'Arial'bih"
str1= " 
numfonts = INITIALIZEFONTS ( )
! Default both height and width. This seems to work
! properly. From this setting get the ratio between
! height and width.
fontnum = SETFONT ("t'Arial'"
ireturn = GETFONTINFO(info)
rh = real(info%pixheight)/real(info%avgwidth)

! Now calculate the height for a width of 40
write(*,*) 'Input desired width:'
read(*,*) inw
h =int(inw*rh)
write(str1,'(I3.3)') h
str2 = str//str1
print *,str2
fontnum = SETFONT (str2)
CALL MOVETO (INT2(10), INT2(50), pos)
CALL OUTGTEXT('ABCDEFGabcdefg12345!@#$%')
CALL MOVETO (INT2(10), INT2(50+10+h), pos)
CALL OUTGTEXT('123456789012345678901234')
ireturn = GETFONTINFO(info)
call settextposition(4,1, rcc)
print *,  info%avgwidth, info%pixheight
END

See Also
GETFONTINFO (W*S)
GETGTEXTENTEXT (W*S)
GRSTATUS (W*S)
OUTGTEXT (W*S)
INITIALIZEFONTS (W*S)
SETGTEXTROTATION (W*S)

SETGTEXTROTATION (W*S)

Graphics Subroutine: Sets the orientation angle of the font text output in degrees. The current orientation is used in calls to OUTGTEXT.

Module
USE IFQWIN

Syntax
CALL SETGTEXTROTATION (degree-tenths)

degree-tenths (Input) INTEGER(4). Angle of orientation, in tenths of degrees, of the font text output.

The orientation of the font text output is set in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 (90°) is straight up, 1800 (180°) is upside down and left, 2700 (270°) is straight down, and so forth. If the user specifies a value greater than 3600 (360°), the subroutine takes a value equal to:

\[\text{MODULO (user-specified tenths of degrees, 3600)}\]

Although SETGTEXTROTATION accepts arguments in tenths of degrees, only increments of one full degree differ visually from each other on the screen.

Bitmap fonts cannot be rotated; TruType fonts should be used instead.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
INTEGER(4) oldcolor, deg
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Straight text')
deg = -1370
CALL SETGTEXTROTATION(deg)
oldcolor = SETCOLORRGB(Z'008080')
CALL OUTGTEXT('Slanted text')
END
SETLINESTYLE (W*S)

*Graphics Subroutine:* Sets the current line style to a new line style.

**Module**

USE IFQWIN

**Syntax**

CALL SETLINESTYLE (mask)

*mask*  (Input) INTEGER(2). Desired Quickwin line-style mask. (See the table below.)

The mask is mapped to the style that most closely equivalences the percentage of the bits in the mask that are set. The style produces lines that cover a certain percentage of the pixels in that line.

**SETLINESTYLE** sets the style used in drawing a line. You can choose from the following styles:

<table>
<thead>
<tr>
<th>QuickWin Mask</th>
<th>Internal Windows* Style</th>
<th>Selection Criteria</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFF</td>
<td>PS_SOLID</td>
<td>16 bits on</td>
<td></td>
</tr>
<tr>
<td>0xEEEE</td>
<td>PS_DASH</td>
<td>11 to 15 bits on</td>
<td></td>
</tr>
<tr>
<td>0xECEC</td>
<td>PS_DASHDOT</td>
<td>10 bits on</td>
<td></td>
</tr>
<tr>
<td>0xECCC</td>
<td>PS_DASHDOTDOT</td>
<td>9 bits on</td>
<td></td>
</tr>
<tr>
<td>0xAAAA</td>
<td>PS_DOT</td>
<td>1 to 8 bits on</td>
<td></td>
</tr>
<tr>
<td>0x0000</td>
<td>PS_NULL</td>
<td>0 bits on</td>
<td></td>
</tr>
</tbody>
</table>

SETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON, and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE, or PIE.

The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, style
TYPE (xycoord) xy

style = Z'FFFF'
CALL SETLINESTYLE(style)
CALL MOVETO(INT2(50), INT2(50), xy )
status = LINETO(INT2(300), INT2(300))
END
```

POLYGON, POLYGON_W (W*S)
**SETLINEWIDTHQQ (W*S)**

*Graphics Subroutine:* Sets the width of a solid line drawn using any of the supported graphics functions.

**Module**

USE IFQWIN

**Syntax**

CALL SETLINEWIDTHQQ (x)

x (Input) INTEGER(4). It can be any non-negative integer.

This subroutine sets the line width in pixels using the value that is passed as the argument.

**SETLINEWIDTHQQ** affects the drawing of straight lines using functions such as LINETO, POLYGON, LINETOAR, LINETOAREX, RECTANGLE, and it affects the drawing of curved lines using functions such as ARC, ELLIPSE, or PIE.

---

**NOTE**

The nWidth argument in the Windows* API CreatePen() is the width used to draw the lines or borders of a closed shape. A cosmetic pen can only have a width of 1 pixel. If you specify a higher width, it is ignored. A geometric pen can have a width of 1 or more pixels, but the line can only be solid or null. This means that if you specify the style as PS_DASH, PS_DOT, PS_DASHDOT, or PS_DASHDOTDOT, but set a width higher than 1 pixel, the line is drawn as PS_SOLID.

QWIN$MSG_FILEOPENDLG and QWIN$MSG_BMPSAVEDLG control the text in file choosing dialog boxes and have the following syntax:
"file description, file designation"

You can change any string produced by QuickWin by calling SETMESSAGEQQ with the appropriate id. This includes status messages displayed at the bottom of a QuickWin application, state messages (such as "Paused"), and dialog box messages. These messages can include multibyte characters. To change menu messages, use MODIFYMENUSTRINGQQ.

Example

USE IFQWIN
print*, "Hello"
CALL SETMESSAGEQQ('Changed exit text', QWIN$MSG_EXITQ)
SETMOUSECURSOR (W*S)

Quickwin Function: Sets the shape of the mouse cursor for the window in focus.

Module

USE IFQWIN
USE IFWIN

Syntax

oldcursor = SETMOUSECURSOR (newcursor)

oldcursor = (Input) INTEGER(4). A Windows HCURSOR value. For many predefined shapes, LoadCursor(0, shape) is a convenient way to get a legitimate value. See the list of predefined shapes below.

A value of zero prevents the cursor from being displayed.

Results

The result type is INTEGER(4). This is also an HCURSOR Value. The result is the previous cursor value.

The window in focus at the time SETMOUSECURSOR is called has its cursor changed to the specified value. Once changed, the cursor retains its shape until another call to SETMOUSECURSOR.

The following predefined values for cursor shapes are available:

<table>
<thead>
<tr>
<th>Predefined Value</th>
<th>Cursor Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDC_APPSTARTING</td>
<td>Standard arrow and small hourglass</td>
</tr>
<tr>
<td>IDC_ARROW</td>
<td>Standard arrow</td>
</tr>
<tr>
<td>IDC_CROSS</td>
<td>Crosshair</td>
</tr>
<tr>
<td>IDC_IBEAM</td>
<td>Text I-beam</td>
</tr>
<tr>
<td>IDC_ICON</td>
<td>Obsolete value</td>
</tr>
<tr>
<td>IDC_NO</td>
<td>Slashed circle</td>
</tr>
<tr>
<td>IDC_SIZE</td>
<td>Obsolete value; use IDC_SIZEALL</td>
</tr>
<tr>
<td>IDC_SIZEALL</td>
<td>Four-pointed arrow</td>
</tr>
<tr>
<td>IDC_SIZENESW</td>
<td>Double-pointed arrow pointing northeast and southwest</td>
</tr>
<tr>
<td>IDC_SIZENS</td>
<td>Double-pointed arrow pointing north and south</td>
</tr>
<tr>
<td>IDC_SIZENWSE</td>
<td>Double-pointed arrow pointing northwest and southeast</td>
</tr>
<tr>
<td>IDC_SIZEWE</td>
<td>Double-pointed arrow pointing west and east</td>
</tr>
<tr>
<td>IDC_UPARROW</td>
<td>Vertical arrow</td>
</tr>
</tbody>
</table>

MODIFYMENUSTRINGQQ (W*S)
A LoadCursor must be done on these values before they can be used by SETMOUSECURSOR.

**Example**

! Build as Standard Graphics or QuickWin
```
use ifqwin
use ifwin

integer*4 cursor, oldcursor
write(6,*) 'The cursor will now be changed to an hour glass shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_WAIT)
oldcursor = SetMouseCursor(cursor)
read(5,*)

write(6,*) 'The cursor will now be changed to a cross-hair shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_CROSS)
oldcursor = SetMouseCursor(cursor)
read(5,*)

write(6,*) 'The cursor will now be turned off'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(0)
read(5,*)

write(6,*) 'The cursor will now be turned on'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(oldcursor)
read(5,*)

stop
end```

**SETPIXEL, SETPIXEL_W (W*S)**

**Graphics Functions:** Set a pixel at a specified location to the current graphics color index.

**Module**

USE IFQWIN

**Syntax**

```
result = SETPIXEL (x, y)
result = SETPIXEL_W (wx, wy)
```

- **x, y** (Input) INTEGER(2). Viewport coordinates for target pixel.
- **wx, wy** (Input) REAL(8). Window coordinates for target pixel.

**Results**

The result type is INTEGER(2). The result is the previous color index of the target pixel if successful; otherwise, -1 (for example, if the pixel lies outside the clipping region).
SETPIXEL sets the specified pixel to the current graphics color index. The current graphics color index is set with SETCOLOR and retrieved with GETCOLOR. The non-RGB color functions (such as SETCOLOR and SETPIXELS) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function. SETPIXELRGB and SETPIXELRGB_W give access to the full color capacity of the system by using direct color values rather than indexes to a palette.

**NOTE**
The SETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft Platform SDK version of the SetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetPixel.

**Example**

```plaintext
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
status = SETCOLOR(INT2(2))
x = 10
! Draw pixels.
DO y = 50, 389, 3
   status = SETPIXEL( x, y )
x = x + 2
END DO
READ (*,*) ! Wait for ENTER to be pressed
END
```

**See Also**

SETPIXELRGB, SETPIXELRGB_W (W*S)
GETPIXEL, GETPIXEL_W (W*S)
SETPIXELS (W*S)
GETPIXELS (W*S)
GETCOLOR (W*S)
SETCOLOR (W*S)

**SETPIXELRGB, SETPIXELRGB_W (W*S)**

*Graphics Functions:* Set a pixel at a specified location to the specified Red-Green-Blue (RGB) color value.

**Module**

USE IFQWIN

**Syntax**

```plaintext
result = SETPIXELRGB (x,y,color)
result = SETPIXELRGB_W (x,y,color)
```

- **x, y** (Input) INTEGER(2). Viewport coordinates for target pixel.
- **wx, wy** (Input) REAL(8). Window coordinates for target pixel.
color  (Input) INTEGER(4). RGB color value to set the pixel to. Range and result depend on the system's display adapter.

Results
The result type is INTEGER(4). The result is the previous RGB color value of the pixel.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETPIXELRGB or SETPIXELRGB_W, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 B B B B B B G G G G G G G G R R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

If any of the pixels are outside the clipping region, those pixels are ignored.

SETPIXELRGB (and the other RGB color selection functions such as SETPIECREFLRGB, SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) x, y
INTEGER(4) color
DO i = 10, 30, 10
   SELECT CASE (i)
   CASE(10)
      color = Z'0000FF'
   CASE(20)
      color = Z'00FF00'
   CASE (30)
      color = Z'FF0000'
   END SELECT
   ! Draw pixels.
   DO y = 50, 180, 2
      status = SETPIXELRGB( x, y, color )
      x = x + 2
   END DO
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

See Also
GETPIXELRGB, GETPIXELRGB_W (W*S)
GETPIECREFLRGB (W*S)
SETCOLORRGB (W*S)
SETPIECREFLRGB (W*S)
SETPIXELS (W*S)

*Graphics Subroutine*: Sets the color indexes of multiple pixels.

**Module**

USE IFQWIN

**Syntax**

CALL SETPIXELS (n, x, y, color)

- **n** (Input) INTEGER(4). Number of pixels to set. Sets the number of elements in the other arguments.
- **x, y** (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to set.
- **color** (Input) INTEGER(2). Array containing color indexes to set the pixels to.

SETPIXELS sets the pixels specified in the arrays x and y to the color indexes in color. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELS with n less than 1 are also ignored. SETPIXELS is a much faster way to set multiple pixel color indexes than individual calls to SETPIXEL.

Unlike SETPIXELS, SETPIXELSRGB gives access to the full color capacity of the system by using direct color values rather than indexes to a palette. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) color(9)
INTEGER(2) x(9), y(9), i
DO i = 1, 9
  x(i) = 20 * i
  y(i) = 10 * i
  color(i) = INT2(i)
END DO
CALL SETPIXELS(9, x, y, color)
END
```

**See Also**

GETPIXELS (W*S)
SETPIXEL, SETPIXEL_W (W*S)
SETPIXELSRGB (W*S)

SETPIXELSRGB (W*S)

*Graphics Subroutine*: Sets multiple pixels to the given Red-Green-Blue (RGB) color.
Module
USE IFQWIN

Syntax
CALL SETPIXELSRGB (n, x, y, color)

\( n \) (Input) INTEGER(4). Number of pixels to be changed. Determines the number of elements in arrays \( x \) and \( y \).

\( x, y \) (Input) INTEGER(2). Parallel arrays containing viewport coordinates of the pixels to set.

\( \text{color} \) (Input) INTEGER(4). Array containing the RGB color values to set the pixels to. Range and result depend on the system's display adapter.

SETPIXELSRGB sets the pixels specified in the arrays \( x \) and \( y \) to the RGB color values in \( \text{color} \). These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three color values, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you set with SETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 B B B B B B G G G G G G G G G G R R R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex 'ZZ') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFF' full-intensity for all three, resulting in bright white.

A good use for SETPIXELSRGB is as a buffering form of SETPIXELRGB, which can improve performance substantially. The example code shows how to do this.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELSRGB with \( n \) less than 1 are also ignored.

SETPIXELSRGB (and the other RGB color selection functions such as SETPIXELRGB and SETCOLORRGB) sets colors to values chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Example

```fortran
! Buffering replacement for SetPixelRGB and
! SetPixelRGB_W. This can improve performance by
! doing batches of pixels together.

USE IFQWIN
PARAMETER (I$SIZE = 200)
INTEGER(4) bn, bc(I$SIZE), status
INTEGER(2) bx(I$SIZE), by(I$SIZE)

bn = 0
DO i = 1, I$SIZE
  bn = bn + 1
```
bx(bn) = i
by(bn) = i
bc(bn) = GETCOLORRGB()
status = SETCOLORRGB(bc(bn)+1)
END DO
CALL SETPIXELSRGB(bn,bx,by,bc)
END

See Also
GETPIXELSRGB (W*S)
SETPIXELRGB, SETPIXELRGB_W (W*S)
GETPIXELRGB, GETPIXELRGB_W (W*S)
SETPIXELS (W*S)

SETTEXTCOLOR (W*S)

*Graphics Function:* Sets the current text color index.

**Module**
USE IFQWIN

**Syntax**
result = SETTEXTCOLOR (index)

index
(Input) INTEGER(2). Color index to set the text color to.

**Results**
The result type is INTEGER(2). The result is the previous text color index.

SETTEXTCOLOR sets the current text color index. The default value is 15, which is associated with white unless the user remaps the palette. GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT.

The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

**NOTE**
The SETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetTextColor.

**Example**
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) oldtc
oldtc = SETTEXTCOLOR(INT2(2)) ! green
WRITE(*,*), "hello, world"
END

See Also
GETTEXTCOLOR (W*S)
REMAPALLPALETTERGB, REMAPPALETTERGB (W*S)
SETCOLOR (W*S)
SETTEXTCOLORRGB (W*S)

**Graphics Function:** Sets the current text color to the specified Red-Green-Blue (RGB) value.

**Module**
USE IFQWIN

**Syntax**
```
result = SETTEXTCOLORRGB (color)
```

**color** (Input) INTEGER(4). RGB color value to set the text color to. Range and result depend on the system's display adapter.

**Results**
The result type is INTEGER(4). The result is the previous text RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
       Bit  31 (MSB)  24  23  16  15  8  7  0
RGB   0 0 0 0 0 0 0 0 B B B B B B G G G G G G R R R R R R R R
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

SETTEXTCOLORRGB sets the current text RGB color. The default value is Z'00FFFFFF', which is full-intensity white. SETTEXTCOLORRGB sets the color used by OUTTEXT, WRITE, and PRINT. It does not affect the color of text output with the OUTGTEXT font routine. Use SETCOLORRGB to change the color of font output.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETCOLORRGB sets the RGB color value of graphics over the background color, used by the graphics functions such as ARC, FLOODFILLRGB, and OUTGTEXT.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVG and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Example**
```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(4) oldtc

oldtc = SETTEXTCOLORRGB(Z'000000FF')
WRITE(*,*) 'I am red'
oldtc = SETTEXTCOLORRGB(Z'0000FF00')
CALL OUTTEXT ('I am green'//CHAR(13)//CHAR(10))
```
oldtc = SETTEXTCOLORRGB(Z'00FF0000')
PRINT *, 'I am blue'
END

See Also
SETBKCOLORRGB (W*S)
SETCOLORRGB (W*S)
GETTEXTCOLORRGB (W*S)
GETWINDOWCONFIG (W*S)
OUTTEXT (W*S)

SETTEXTCURSOR (W*S)

**Graphics Function:** Sets the height and width of the
text cursor (the caret) for the window in focus.

Module
USE IFQWIN

Syntax
result = SETTEXTCURSOR (newcursor)

*newcursor*
(Input) INTEGER(2). The leftmost 8 bits specify the width of the cursor, and
the rightmost 8 bits specify the height of the cursor. These dimensions can
range from 1 to 8, and represent a fraction of the current character cell
size. For example:

- Z'0808' - Specifies the full character cell; this is the default size.
- Z'0108' - Specifies 1/8th of the character cell width, and 8/8th (or all) of
  the character cell height.

If either of these dimensions is outside the range 1 to 8, it is forced to 8.

Results
The result type is INTEGER(2); it is the previous text cursor value in the same format as *newcursor*.

**NOTE**
After calling SETTEXTCURSOR, you must call DISPLAYCURSOR($GCURSORON) to actually see the
cursor.

Example
use IFQWIN
integer(2) oldcur
integer(2) istat
type(rccoord) rc
open(10, file='user')
ista = displaycursor($GCURSORON)
write(10,*) 'Text cursor is now character cell size, the default.'
read(10,*)
write(10,*) 'Setting text cursor to wide and low.'
oldcur = settextcursor(Z'0801')
ista = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to high and narrow.'
oldcur = settextcursor(Z'0108')
ista = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to a dot.'
oldcur = settextcursor(Z'0101')
  istat  = displaycursor($GCURSORON)
read(10,*)
end

See Also
DISPLAYCURSOR (W*S)

SETTEXTPOSITION (W*S)
Graphics Subroutine: Sets the current text position to a specified position relative to the current text window.

Module
USE IFQWIN

Syntax
CALL SETTEXTPOSITION (row, column, t)

row (Input) INTEGER(2). New text row position.
column (Input) INTEGER(2). New text column position.
t (Output) Derived type rccoord. Previous text position. The derived type rcoords is defined in IFQWIN.F90 as follows:

TYPE rccoord
   INTEGER(2) row ! Row coordinate
   INTEGER(2) col ! Column coordinate
END TYPE rccoord

Subsequent text output with the OUTTEXT function (as well as standard console I/O statements, such as PRINT and WRITE) begins at the point (row, column).

Example
USE IFQWIN
  TYPE (rccoord) curpos
  WRITE(*,*) 'Original text position'
  CALL SETTEXTPOSITION (INT2(6), INT2(5), curpos)
  WRITE (*,*) 'New text position'
END

See Also
CLEARSCREEN (W*S)
GETTEXTPOSITION (W*S)
OUTTEXT (W*S)
SCROLLTEXTWINDOW (W*S)
SETTEXTWINDOW (W*S)
WRAPON (W*S)

SETTEXTWINDOW (W*S)
Graphics Subroutine: Sets the current text window.
**Module**

USE IFQWIN

**Syntax**

CALL SETTEXTWINDOW (r1,c1,r2,c2)

\( r1, c1 \) (Input) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

\( r2, c2 \) (Input) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

SETTEXTWINDOW specifies a window in row and column coordinates where text output to the screen using OUTTEXT, WRITE, or PRINT will be displayed. You set the text location within this window with SETTEXTPOSITION.

Text is output from the top of the window down. When the window is full, successive lines overwrite the last line.

SETTEXTWINDOW does not affect the output of the graphics text routine OUTGTEXT. Use the SETVIEWPORT function to control the display area for graphics output.

**Example**

USE IFQWIN

TYPE (rccoord) curpos

CALL SETTEXTWINDOW(INT2(5), INT2(1), INT2(7), INT2(40))

CALL SETTEXTPOSITION (INT2(5), INT2(5), curpos)

WRITE(*,*) "Only two lines in this text window"
WRITE(*,*) "so this line will be overwritten"
WRITE(*,*) "by this line"
END

**See Also**

**SETTIM**

*Portability Function:* Sets the system time in your programs. This function is only available on Windows* and Linux* systems.

**Module**

USE IFPORT

**Syntax**

result = SETTIM (ihr, imin, isec, i100th)
ihr  (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
imin  (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
ise  (Output) INTEGER(4) or INTEGER(2). Second (0-59).
i100th (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

Results
The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.

NOTE
On Linux systems, you must have root privileges to execute this function.

Example
USE IFPORT
LOGICAL(4) success
success = SETTIM(INT2(21),INT2(53+3),&
            INT2(14*2),INT2(88))
END

See Also
GETDAT
GETTIM
SETDAT

SETVIEWORG (W*S)
Graphics Subroutine: Moves the viewport-coordinate origin (0, 0) to the specified physical point.

Module
USE IFQWIN

Syntax
CALL SETVIEWORG (x, y, s)

x, y  (Input) INTEGER(2). Physical coordinates of new viewport origin.

s  (Output) Derived type xycoord. Physical coordinates of the previous viewport origin. The derived type xycoord is defined in IFQWIN.F90 as follows:

TYPE xycoord
    INTEGER(2) xcoord ! x-coordinate
    INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord

The xycoord type variable s, defined in IFQWIN.F90, returns the physical coordinates of the previous viewport origin.
Example

USE IFQWIN
TYPE ( xycoord ) xy

CALL SETVIEWORG(INT2(30), INT2(30), xy)

See Also

GETVIEWCOORD, GETVIEWCOORD_W (W*S)
GETWINDOWCOORD (W*S)
GRSTATUS (W*S)
SETCLIPRGN (W*S)
SETVIEWPORT (W*S)

SETVIEWPORT (W*S)

Graphics Subroutine: Redefines the graphics viewport by defining a clipping region in the same manner as SETCLIPRGN and then setting the viewport-coordinate origin to the upper-left corner of the region.

Module
USE IFQWIN

Syntax
CALL SETVIEWPORT (x1,y1,x2,y2)

x1, y1 (Input) INTEGER(2). Physical coordinates for upper-left corner of viewport.

x2, y2 (Input) INTEGER(2). Physical coordinates for lower-right corner of viewport.

The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangular clipping region. Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

Example

USE IFQWIN
INTEGER(2) upx, upy
INTEGER(2) downx, downy
upx = 0
upy = 30
downx= 250
downy = 100
CALL SETVIEWPORT(upx, upy, downx, downy)

See Also
GETVIEWCOORD, GETVIEWCOORD_W (W*S)
GETPHYSCOORD (W*S)
GRSTATUS (W*S)
SETCLIPRGN (W*S)
SETVIEWORG (W*S)
SETWINDOW (W*S)
SETWINDOW (W*S)

*Graphics Function:* Defines a window bound by the specified coordinates.

**Module**
USE IFQWIN

**Syntax**

result = SETWINDOW (finvert, wx1, wy1, wx2, wy2)

*finvert*  
(Input) LOGICAL(2). Direction of increase of the y-axis. If *finvert* is .TRUE., the y-axis increases from the window bottom to the window top (as Cartesian coordinates). If *finvert* is .FALSE., the y-axis increases from the window top to the window bottom (as pixel coordinates).

*wx1, wy1*  
(Input) REAL(8). Window coordinates for upper-left corner of window.

*wx2, wy2*  
(Input) REAL(8). Window coordinates for lower-right corner of window.

**Results**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0 (for example, if the program that calls SETWINDOW is not in a graphics mode).

The SETWINDOW function determines the coordinate system used by all window-relative graphics routines. Any graphics routines that end in _W (such as ARC_W, RECTANGLE_W, and LINETO_W) use the coordinate system set by SETWINDOW.

Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

An arc drawn using inverted window coordinates is not an upside-down version of an arc drawn with the same parameters in a noninverted window. The arc is still drawn counterclockwise, but the points that define where the arc begins and ends are inverted.

If *wx1* equals *wx2* or *wy1* equals *wy2*, SETWINDOW fails.

**Example**

```fortran
USE IFQWIN
INTEGER(2) status
LOGICAL(2) invert /.TRUE./
REAL(8) upx /0.0/, upy /0.0/
REAL(8) downx /1000.0/, downy /1000.0/
status = SETWINDOW(invert, upx, upy, downx, downy)
```

<tr>
<td></td>
<td>INTEGER(4) extendfontsize       ! Takes the same values as fontsize, when fontsize is set to QWIN$EXTENDFONT.</td>
</tr>
<tr>
<td></td>
<td>INTEGER(4) extendfontattributes ! Font attributes such as bold and italic.</td>
</tr>
</tbody>
</table>

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The following value can be used to configure a QuickWin window so that it will show the last line written and the text cursor (if it is on): 

wc%mode = QWIN$SCROLLDOWN

Note that if you scroll the window to another position, you will have to scroll back to the last line to see your input.

The following values can be used with SETWINDOWCONFIG extended fonts:
Style:

<table>
<thead>
<tr>
<th>Font Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_NORMAL</td>
<td>No underline, no italic, and a font weight of 400 out of 1000.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_UNDERLINE</td>
<td>Underlined characters.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_BOLD</td>
<td>A font weight of 700 out of 1000.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_ITALIC</td>
<td>Italic characters.</td>
</tr>
</tbody>
</table>

Pitch:

<table>
<thead>
<tr>
<th>Font Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FIXED_PITCH</td>
<td>QuickWin default. Equal character widths.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_VARIABLE_PITCH</td>
<td>Variable character widths.</td>
</tr>
</tbody>
</table>

Font Families:

<table>
<thead>
<tr>
<th>Font Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FF_ROMAN</td>
<td>Variable stroke width, serified. Times Roman, Century Schoolbook, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SWISS</td>
<td>Variable stroke width, sans-serifed. Helvetica, Swiss, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_MODERN</td>
<td>QuickWin default. Constant stroke width, serified or sans-serifed. Pica, Elite, Courier, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SCRIPT</td>
<td>Cursive, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_DECORATIVE</td>
<td>Old English, etc.</td>
</tr>
</tbody>
</table>

Character Sets:

<table>
<thead>
<tr>
<th>Font Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_ANSI_CHARSET</td>
<td>QuickWin default.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_OEM_CHARSET</td>
<td>Use this to get Microsoft* LineDraw.</td>
</tr>
</tbody>
</table>

Using QWIN$EXTENDFONT_OEM_CHARSET with the font name 'MS LineDraw'C will get the old DOS-style character set with symbols that can be used to draw lines and boxes. The pitch and font family items can be specified to help guide the font matching algorithms used by CreateFontIndirect, the Windows* API used by SETWINDOWCONFIG.

If you use SETWINDOWCONFIG to set the variables in windowconfig to -1, the function sets the highest resolution possible for your system, given the other fields you specify, if any. You can set the actual size of the window by specifying parameters that influence the window size: the number of x and y pixels, the number of rows and columns, and the font size. If you do not call SETWINDOWCONFIG, the window defaults to the best possible resolution and a font size of 8x16. The number of colors available depends on the video driver used.

If you use SETWINDOWCONFIG, you should specify a value for each field (-1 or your own value for the numeric fields and a C string for the title, for example, "words of text")C). Using SETWINDOWCONFIG with only some fields specified can result in useless values for the unspecified fields.

If you request a configuration that cannot be set, SETWINDOWCONFIG returns .FALSE. and calculates parameter values that will work and are as close as possible to the requested configuration. A second call to SETWINDOWCONFIG establishes the adjusted values; for example:

```fortran
status = SETWINDOWCONFIG(wc)
if (.NOT.status) status = SETWINDOWCONFIG(wc)
```

If you specify values for all four of the size parameters, `numxpixels`, `numypixels`, `numtextcols`, and `numtextrows`, the font size is calculated by dividing these values. The default font is Courier New and the default font size is 8x16. There is no restriction on font size, except that the window must be large enough to hold it.
Under Standard Graphics, the application attempts to start in Full Screen mode with no window decoration (window decoration includes scroll bars, menu bar, title bar, and message bar) so that the maximum resolution can be fully used. Otherwise, the application starts in a window. You can use ALT+ENTER at any time to toggle between the two modes.

If you are in Full Screen mode and the resolution of the window does not match the resolution of the video driver, graphics output will be slow compared to drawing in a window.

NOTE
You must call DISPLAYCURSOR($GCURSORON) to make the cursor visible after calling SETWINDOWCONFIG.

Example

USE IFQWIN
TYPE (windowconfig) wc
LOGICAL status /.FALSE./
! Set the x & y pixels to 800X600 and font size to 8x12
wc%numxpixels  = 800
wc%numypixels  = 600
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors   = -1
wc%title= "This is a test"C
wc%fontsize = Z'0008000C'
status = SETWINDOWCONFIG(wc)  ! attempt to set configuration with above values
! if attempt fails, set with system estimated values
if (.NOT.status) status = SETWINDOWCONFIG(wc)

See Also
DISPLAYCURSOR (W*S)
GETWINDOWCONFIG (W*S)

SETWINDOWMENUQQ (W*S)

QuickWin Function: Sets a top-level menu as the menu to which a list of current child window names is appended.

Module
USE IFQWIN

Syntax
result = SETWINDOWMENUQQ (menuID)

menuID (Input) INTEGER(4). Identifies the menu to hold the child window names, starting with 1 as the leftmost menu.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The list of current child window names can appear in only one menu at a time. If the list of windows is currently in a menu, it is removed from that menu. By default, the list of child windows appears at the end of the Window menu.
Example

USE IFQWIN
TYPE (windowconfig) wc
LOGICAL(4) result, status /.FALSE./
! Set title for child window
wc%numxpixels  = -1
wc%numypixels  = -1
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors   = -1
wc%fontsize    = -1
wc%title = "I am child window name"C
if (.NOT.status) status = SETWINDOWCONFIG(wc)
! put child window list under menu 3 (View)
result = SETWINDOWMENUQQ(3)
END

See Also
APPENDMENUQQ (W*S)

SETWRITEMODE (W*S)

Graphics Function: Sets the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions.

Module
USE IFQWIN

Syntax
result = SETWRITEMODE (wmode)

wmode
(Input) INTEGER(2). Write mode to be set. One of the following symbolic constants (defined in IFQWIN.F90):

- $GPSET - Causes lines to be drawn in the current graphics color. (Default)
- $GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- $GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- $GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- $GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

In addition, one of the following binary raster operation constants can be used (described in the online documentation for the Windows* API SetROP2):

- $GR2_BLACK
- $GR2_NOTMERGEPEN
- $GR2_MASKNOTPEN
- $GR2_NOTCOPYPEN (same as $GPRESET)
- $GR2_MASKPENNOT
• $GR2_NOT
• $GR2_XORPEN (same as $GXOR)
• $GR2_NOTMASKPEN
• $GR2_MASKPEN (same as $GAND)
• $GR2_NOTXORPEN
• $GR2_NOP
• $GR2_MERGENOTPEN
• $GR2_COPYPEN (same as $GPSET)
• $GR2_MERGEPENNOT
• $GR2_MERGEPEN (same as $GOR)
• $GR2_WHITE

Results

The result type is INTEGER(2). The result is the previous write mode if successful; otherwise, -1.

The current graphics color is set with SETCOLORRGB (or SETCOLOR) and the current background color is set with SETBKCOLORRGB (or SETBKCOLOR). As an example, suppose you set the background color to yellow (Z'00FFFF') and the graphics color to purple (Z'FF00FF') with the following commands:

```
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
```

If you then set the write mode with the $GAND option, lines are drawn in red (Z'0000FF'); with the $GOR option, lines are drawn in white (Z'FFFFFF'); with the $GXOR option, lines are drawn in turquoise (Z'FFFF00'); and with the $GPRESET option, lines are drawn in green (Z'00FF00'). Setting the write mode to $GPSET causes lines to be drawn in the graphics color.

Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) result, oldmode
INTEGER(4) oldcolor
TYPE (xycoord) xy

oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
CALL MOVETO(INT2(0), INT2(0), xy)
result = LINETO(INT2(200), INT2(200)) ! purple

oldmode = SETWRITEMODE( $GAND)
CALL MOVETO(INT2(50), INT2(0), xy)
result = LINETO(INT2(250), INT2(200)) ! red
END
```

**SETSIZESQQ (WS)***

*QuickWin Function:* Sets the size and position of a window.

**Module**

USE IFQWIN

**Syntax**

\[
\text{result} = \text{SETSIZESQQ} (\text{unit}, \text{winfo})
\]

*unit* (Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5, and 6 refer to the default startup window only if the program does not explicitly open them with the OPEN statement. To set the size of the frame window (as opposed to a child window), set *unit* to the symbolic constant QWIN$FRAMEWINDOW (defined in IFQWIN.F90).

When called from INITIALSETTINGS, SETWSIZEQQ behaves slightly differently than when called from a user routine after initialization. See below under **Results**.

*winfo* (Input) Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

```fortran
TYPE QWINFO
  INTEGER(2) TYPE  ! request type
  INTEGER(2) X     ! x coordinate for upper left
  INTEGER(2) Y     ! y coordinate for upper left
  INTEGER(2) H     ! window height
  INTEGER(2) W     ! window width
END TYPE QWINFO
```

This function's behavior depends on the value of QWINFO%TYPE, which can be any of the following:

- QWIN$MIN - Minimizes the window.
- QWIN$MAX - Maximizes the window.
- QWIN$RESTORE - Restores the minimized window to its previous size.
- QWIN$SET - Sets the window's position and size according to the other values in qwinfo.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero (unless called from INITIALSETTINGS). If called from INITIALSETTINGS, the following occurs:

- SETWSIZEQQ always returns -1.
- Only QWIN$SET will work.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width specified for a frame window reflects the actual size in pixels of the frame window including any borders, menus, and status bar at the bottom.
Example

USE IFQWIN
INTEGER(4)     result
INTEGER(2)     numfonts, fontnum
TYPE (qwinfo)  winfo
TYPE (xycoord) pos
! Maximize frame window
winfo%TYPE = QWIN$MAX
result =     SETWSIZEQQ(QWIN$FRAMEWINDOW, winfo)
! Maximize child window
result =   SETWSIZEQQ(0, winfo)
umfonts = INITIALIZEFONTS( )
fontnum =  SETFONT ('t''Arial''h50w34i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT("BIG Window")
END

See Also
GETWSIZEQQ (W*S)
INITIALSETTINGS (W*S)

SHAPE

Inquiry Intrinsic Function (Generic): Returns the shape of an array or scalar argument.

Syntax

result = SHAPE (source [, kind])

source        (Input) Is a scalar or array. It may be of any data type. It must not be an assumed-size array, a disassociated pointer, or an allocatable array that is not allocated. It cannot be an assumed-size array.

kind         (Input; optional) Must be a scalar integer initialization expression.

Results

The result is a rank-one integer array whose size is equal to the rank of source. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is the shape of source, unless source is assumed-rank and is associated with an assumed-size array. In that case, the last element of the value returned by SHAPE is -1.

The setting of compiler options specifying integer size can affect this function.

Example

SHAPE (2) has the value of a rank-one array of size zero.

If B is declared as B(2:4, -3:1), then SHAPE (B) has the value (3, 5).

The following shows another example:

INTEGER VEC(2)
REAL array(3:10, -1:3)
VEC = SHAPE(array)
WRITE(*,*) VEC ! prints   8       5
END

! Check if a mask is conformal with an array
REAL, ALLOCATABLE :: A(:,:,:)
LOGICAL, ALLOCATABLE :: MASK(:,:,:)
INTEGER B(3), C(3)
LOGICAL conform
ALLOCATE (A(5, 4, 3))
ALLOCATE (MASK(3, 4, 5))
! Check if MASK and A allocated. If they are, check
! that they have the same shape (conform).
IF(ALLOCATED(A) .AND. ALLOCATED(MASK)) THEN
  B = SHAPE(A); C = SHAPE(MASK)
  IF ((B(1) .EQ. C(1)) .AND. (B(2) .EQ. C(2)) .AND. (B(3) .EQ. C(3))) THEN
    conform = .TRUE.
  ELSE
    conform = .FALSE.
  END IF
END IF
WRITE(*,*) conform  ! prints F
END

See Also

SIZE Function

SHARED Clause

Parallel Directive Clause: Specifies variables that will be shared by all the threads in a team.

Syntax

SHARED (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

All threads within a team access the same storage area for SHARED data.

SHIFTA

Elemental Intrinsic Function (Specific): Performs a right shift with fill. This function cannot be passed as an actual argument.

Syntax

result = SHIFTA (i, shift)

i

(Input) Must be of type integer. This is the value to be shifted.

shift

(Input) Must be of type integer. It must be nonnegative and <= BIT_SIZE(i). This value is the number of positions to shift.

Results

The result type and kind are the same as i.

The result has the value obtained by shifting the bits of i to the right shift bits and replicating the leftmost bit of i in the left shift bits.

If shift is zero the result is i. Bits shifted off the right end are lost.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.
Example
SHIFTA (IBSET (0, BIT_SIZE (0) - 1), 2) is equal to SHIFTL (7, BIT_SIZE (0) - 3).

**SHIFTL**

*Elemental Intrinsic Function (Specific): Logically shifts an integer left by a specified number of bits. This function cannot be passed as an actual argument.*

**Syntax**

\[
\text{result} = \text{SHIFTL} (i, \text{shift})
\]

- \(i\) (Input) Must be of type integer. This is the value to be shifted.
- \(\text{shift}\) (Input) Must be of type integer. The value must be nonnegative and \(\leq \text{BIT\_SIZE}(i)\). This value is the number of positions to shift.

**Results**

The result type and kind is the same as \(i\). The result is the value of \(i\) shifted left by \(\text{shift}\) bit positions. Bits shifted off the left end are lost; zeros are shifted in from the opposite end.

SHIFTL \((i, j)\) is the same as ISHFT \((i, j)\).

**See Also**

ISHFT

**SHIFTR**

*Elemental Intrinsic Function (Specific): Logically shifts an integer right by a specified number of bits. This function cannot be passed as an actual argument.*

**Syntax**

\[
\text{result} = \text{SHIFTR} (i, \text{shift})
\]

- \(i\) (Input) Must be of type integer. This is the value to be shifted.
- \(\text{shift}\) (Input) Must be of type integer. The value must be nonnegative and \(\leq \text{BIT\_SIZE}(i)\). This value is the number of positions to shift.

**Results**

The result type and kind is the same as \(i\). The result is the value of \(i\) shifted right by \(\text{shift}\) bit positions. Bits shifted off the right end are lost; zeros are shifted in from the opposite end.

SHIFTR \((i, j)\) is the same as ISHFT \((i, -j)\).

**See Also**

ISHFT

**SHORT**

*Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.*

**Module**

USE IFPORT
Syntax

result = SHORT (int4)

int4     (Input) INTEGER(4). Value to be converted.

Results

The result type is INTEGER(2). The result is equal to the lower 16 bits of int4. If the int4 value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

Example

```
USE IFORT
INTEGER(4) this_one
INTEGER(2) that_one
READ(*,*) this_one
THAT_ONE = SHORT(THIS_ONE)
WRITE(*,10) THIS_ONE, THAT_ONE
END
```

See Also

INT
Type Declarations

SIGN

*Elemental Intrinsic Function (Generic): Returns the absolute value of the first argument times the sign of the second argument.*

Syntax

result = SIGN (a, b)

a     (Input) Must be of type integer or real.

b     (Input) Must have the same type and kind parameters as a.

Results

The result type and kind is the same as a. The value of the result is as follows:

- | a | if b > zero and -| a | if b < zero.
- | a | if b is of type integer and is zero.
- If b is of type real and zero and compiler option `assume minus0` is not specified, the value of the result is | a |.
- If b is of type real and zero and compiler option `assume minus0` is specified, the processor can distinguish between positive and negative real zero and the following occurs:
  - If b is positive real zero, the value of the result is | a |.
  - If b is negative real zero, the value of the result is -| a |.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSIGN</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IISIGN</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
</tbody>
</table>
Specific Name | Argument Type | Result Type
--- | --- | ---
ISIGN \(^2\) | INTEGER(4) | INTEGER(4)
KISIGN | INTEGER(8) | INTEGER(8)
SIGN \(^3\) | REAL(4) | REAL(4)
DSIGN \(^3,4\) | REAL(8) | REAL(8)
QSIGN | REAL(16) | REAL(16)

\(^1\) Or HSIGN.
\(^2\) Or JISIGN. For compatibility with older versions of Fortran, ISIGN is treated as a generic function.
\(^3\) The setting of compiler options specifying real size can affect SIGN and DSIGN.
\(^4\) The setting of compiler options specifying double size can affect DSIGN.

Example
SIGN (4.0, -6.0) has the value -4.0.
SIGN (-5.0, 2.0) has the value 5.0.
The following shows another example:
c = SIGN (5.2, -3.1)  ! returns -5.2
c = SIGN (-5.2, -3.1)  ! returns -5.2
c = SIGN (-5.2, 3.1)   ! returns 5.2

SIMD Directive (OpenMP* API)

OpenMP* Fortran Compiler Directive: Requires and controls SIMD vectorization of loops.

Syntax

\[
!$OMP SIMD [clause[, clause]]... ]
\]
do-loop
\[
!$OMP END SIMD
\]

clause

Is one of the following:

- ALIGNED (list [:n])
- COLLAPSE (n)
- LASTPRIVATE (list)
- LINEAR (var-list[: linear-step])
- PRIVATE (list)
- REDUCTION (operator : list)
- SAFELEN(m)

Limits the number of iterations in a SIMD chunk (set of concurrent iterations).

The \( m \) must be a constant positive integer expression; it indicates the number of iterations allowed in a SIMD chunk.
When this clause is used, no two iterations executed concurrently with SIMD instructions can have a greater distance in the logical iteration space than \( m \).

The number of iterations that are executed concurrently at any given time is defined by the implementation. Each concurrent iteration is executed by a different SIMD vector lane.

At most one SAFELEN clause can appear in a SIMD directive.

- **SIMDLEN \( (n) \)**
  
  Specifies the preferred number of iterations to be executed concurrently. \( n \) must be a positive scalar integer constant. The number of iterations that are executed concurrently at any given time is implementation defined. Each concurrent iteration will be executed by a different SIMD lane.
  
  If both SIMDLEN \( (n) \) and SAFELEN \( (m) \) are specified, the value of the \( n \) must be less than or equal to the value of \( m \).
  
  At most one SIMDLEN clause can appear in a SIMD directive.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a SIMD directive.

A SIMD construct binds to the current task region. The binding thread set of the simd region is the current team.

If used, the END SIMD directive must appear immediately after the end of the loop. If you do not specify an END SIMD directive, an END SIMD directive is assumed at the end of **do-loop**.

The SIMD construct enables the execution of multiple iterations of the associated loops concurrently by means of SIMD instructions. No other OpenMP* Fortran construct can appear in a SIMD directive.

A SIMD region binds to the current task region. The binding thread set of the SIMD region is the current team.

When any thread encounters a SIMD construct, the iterations of the loop associated with the construct may be executed concurrently using the SIMD lanes that are available to the thread.

If an ORDERED directive with the SIMD clause is specified inside the SIMD region, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

**See Also**

- OpenMP* Fortran Compiler Directives
- Syntax Rules for Compiler Directives
- Nested DO Constructs
- Parallel Processing Model for information about Binding Sets
**SIMD Loop Directive**

**General Compiler Directive:** Requires and controls SIMD vectorization of loops.

**Syntax**

```
!DIR$ SIMD [clause[, clause]...]
```

`clause` is an optional vectorization clause. It can be one or more of the following:

- **[NO]ASSERT**
  
  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.

- **FIRSTPRIVATE(list)**

  *list* is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, each variable has its initial value broadcast to all private instances for each iteration upon entering the SIMD loop.

  A variable in a FIRSTPRIVATE clause can appear in a LASTPRIVATE clause.

  A variable in a FIRSTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LASTPRIVATE(list)**

  *list* is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable).

  A variable in a LASTPRIVATE clause can appear in a FIRSTPRIVATE clause.

  A variable in a LASTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LINEAR(var1:step1 [, var2:step2]...)**

  *var* is a scalar variable.

  *step* is a positive, integer, scalar expression.

  For each iteration of a scalar loop, *var1* is incremented by *step1, var2* is incremented by *step2*, and so on. Therefore, every iteration of the vector loop increments the variables by VL (vector length)*step1,
VL*\text{step2}, \ldots, \text{to VL*stepN}, \text{respectively}. \text{If more than one step is specified for a var, a compile-time error occurs. Multiple LINEAR clauses are merged as a union.}

A variable in a LINEAR clause cannot appear in a REDUCTION, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

\begin{itemize}
\item \textbf{PRIVATE (list)}
\end{itemize}

\textit{list} \quad \text{Is a list of names of one or more variables or common blocks that are accessible to the scoping unit. A variable that is part of another variable (for example, subobjects such as an array or structure element) cannot appear. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).}

Causes each variable to be private to each iteration of a loop. Its initial and last values are undefined upon entering and exiting the SIMD loop. Multiple PRIVATE clauses are merged as a union.

A variable in a PRIVATE clause cannot appear in a LINEAR, REDUCTION, FIRSTPRIVATE, or LASTPRIVATE clause.

\begin{itemize}
\item \textbf{REDUCTION (oper:var1 [, var2]...)}
\end{itemize}

\textit{oper} \quad \text{Is a reduction operator ( +, *, - , .AND., .OR., .EQV., or .NEQV.).}

\textit{var} \quad \text{Is a scalar variable.}

Applies the vector reduction indicated by \textit{oper} to \textit{var1}, \textit{var2}, \ldots, \textit{varN}. A SIMD directive can have multiple reduction clauses using the same or different operators. \text{If more than one reduction operator is associated with a var, a compile-time error occurs.}

A variable in a REDUCTION clause cannot appear in a LINEAR, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

\begin{itemize}
\item \textbf{[NO]VECREMAINDER}
\end{itemize}

Directs the compiler to vectorize (or not to vectorize) the remainder loop when the original loop is vectorized.

If \texttt{!DIR$ VECTOR ALWAYS} is specified, the following occurs:

\begin{itemize}
\item \text{If neither the VECREMAINDER or NOVECREMAINDER clause is specified, the compiler overrides efficiency heuristics of the vectorizer and it determines whether the loop can be vectorized.}
\item \text{If VECREMAINDER is specified, the compiler vectorizes remainder loops when the original main loop is vectorized.}
\item \text{If NOVECREMAINDER is specified, the compiler does not vectorize the remainder loop when the original main loop is vectorized.}
\end{itemize}

\begin{itemize}
\item \textbf{VECTORLENGTH (n1 [, n2]...)}
\end{itemize}

\textit{n} \quad \text{Is a vector length (VL). \text{It must be an integer that is a power of 2; the value must be 2, 4, 8, 16, 32 or 64. If you specify more than one \textit{n}, the vectorizer will choose the VL from the values specified.}
Causes each iteration in the vector loop to execute the computation equivalent to $n$ iterations of scalar loop execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- VECTORLENGTHFOR (data-type)

  data-type  
  Is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
<tr>
<td>REAL</td>
<td>Default REAL</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>REAL (KIND=4)</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>REAL (KIND=8)</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Default COMPLEX</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>COMPLEX (KIND=4)</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>COMPLEX (KIND=8)</td>
</tr>
</tbody>
</table>

Causes each iteration in the vector loop to execute the computation equivalent to $n$ iterations of scalar loop execution where $n$ is computed from $\text{size_of_vector_register}/\text{sizeof(data_type)}$.

For example, VECTORLENGTHFOR (REAL (KIND=4)) results in $n=4$ for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and $n=8$ for AVX target (packed float operations available on 256-bit YMM registers). VECTORLENGTHFOR(INTEGER (KIND=4)) results in $n=4$ for SSE2 to AVX targets.

The VECTORLENGTHFOR and VECTORLENGTH clauses are mutually exclusive. You cannot use the VECTORLENGTHFOR clause with the VECTORLENGTH clause, and vice versa.

Multiple VECTORLENGTHFOR clauses cause a syntax error.

Without explicit VECTORLENGTH and VECTORLENGTHFOR clauses, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

If you specify the SIMD directive with no clause, default rules are in effect for variable attributes, vector length, and so forth.
If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

You can only specify a particular variable in at most one instance of a PRIVATE, LINEAR, or REDUCTION clause.

If the compiler is unable to vectorize a loop, a warning occurs by default. However, if ASSERT is specified, an error occurs instead.

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

A SIMD loop may contain one or more nested loops or be contained in a loop nest. Only the loop preceded by the SIMD directive is processed for SIMD vectorization.

The vectorization performed on this loop by the SIMD directive overrides any setting you may specify for options -fp-model (Linux* OS and OS X*) and /fp (Windows* OS) for this loop.

Note that the SIMD directive may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the SIMD directive:

- The countable loop for the SIMD directive has to conform to the DO-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating-point numbers, or single- or double-precision complex numbers.
- A SIMD directive loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable the SIMD transformations for vectorization, specify option -no-simd (Linux* OS and OS X*) or /Qsimd- (Windows* OS).

To disable transformations that enable more vectorization, specify options -no-vec-no-simd (Linux OS and OS X) or /Qvec-/Qsimd- (Windows OS).

**Example**

Consider the following:

```fortran
... subroutine add(A, N, X)
  integer N, X
  real    A(N)
cDIR$ SIMD
  DO I=X+1, N
    A(I) = A(I) + A(I-X)
  ENDDO
end
...```

When the program containing this subroutine is compiled, the DO loop will be vectorized.

Because no optional clause was specified for the directive, default rules will apply for variable attributes, vector length, and so forth.

**SIN**

*Elemental Intrinsic Function (Generic):* Produces the sine of an argument.

**Syntax**

\[
\text{result} = \text{SIN} (x)
\]

\(x\)  
(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*\(\pi\).

If \(x\) is of type complex, its real part is regarded as a value in radians.

**Results**

The result type and kind is the same as \(x\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>

<tr>
<td>CDSIN (^2)</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSIN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect CSIN.

\(^2\)This function can also be specified as ZSIN.

**Example**

SIN (2.0) has the value 0.9092974.

SIN (0.8) has the value 0.7173561.

**SIND**

*Elemental Intrinsic Function (Generic):* Produces the sine of an argument.

**Syntax**

\[
\text{result} = \text{SIND} (x)
\]

\(x\)  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind is the same as \(x\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIND</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSIND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>
### Example

SIND (2.0) has the value 3.4899496E-02.
SIND (0.8) has the value 1.3962180E-02.

### SINH

**Elemental Intrinsic Function (Generic):** Produces a hyperbolic sine.

**Syntax**

\[
\text{result} = \text{SINH} (x)
\]

\(x\)  
(Input) Must be of type real.

**Results**

The result type and kind is the same as \(x\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>DSINH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSINH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

SINH (2.0) has the value 3.626860.
SINH (0.8) has the value 0.8881060.

### SIGNAL

**Portability Function:** Controls interrupt signal handling and changes the action for a specified signal.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SIGNAL} (\text{signum}, \text{proc}, \text{flag})
\]

\(\text{signum}\)  
(Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names are listed in a table below.

\(\text{proc}\)  
(Input) Name of a signal-handler routine. It must be declared EXTERNAL and INTEGER(4). This routine is called only if \(\text{flag}\) is negative.

\(\text{flag}\)  
(Input) INTEGER(4). If negative, the user's \(\text{proc}\) routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.
Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the previous value of proc associated with the specified signal. For example, if the previous value of proc was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is invalid, if the flag value is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINVAL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns -(EINVAL) and a call to IERRNO returns EINVAL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C’s signal function, nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

The signal-handler argument proc accepts a single INTEGER(4) argument, which is the number of the signal to be handled. The function must use the compiler’s default calling conventions. If you have used compiler options, such as option iface, to change the default conventions, add the following directive to the signal handler function to reset the calling conventions:

!DIR$ ATTRIBUTES DEFAULT :: the-routine-specified-in-proc

The signal-handler function returns an INTEGER(4) value. If the function has handled the signal, the value returned is an integer, but the value is not used.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

- Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
- Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
- Functions that generate a system call (such as TIME).

The following table lists signals, their names and values:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABRT</td>
<td>6</td>
<td>Abnormal termination</td>
</tr>
<tr>
<td>SIGFPE</td>
<td>8</td>
<td>Floating-point error</td>
</tr>
<tr>
<td>SIGKILL¹</td>
<td>9</td>
<td>Kill process</td>
</tr>
<tr>
<td>SIGILL</td>
<td>4</td>
<td>Illegal instruction</td>
</tr>
<tr>
<td>SIGINT</td>
<td>2</td>
<td>CTRL+C signal</td>
</tr>
<tr>
<td>SIGSEGV</td>
<td>11</td>
<td>Illegal storage access</td>
</tr>
<tr>
<td>SIGTERM</td>
<td>15</td>
<td>Termination request</td>
</tr>
</tbody>
</table>

¹SIGKILL can be neither caught nor ignored.

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.
Example

```fortran
USE IFPORT
EXTERNAL h_abort
INTEGER(4) :: h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler #1. Return = ', iret1
procnum = getpid()
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END

! Signal-handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
!DIR$ ATTRIBUTES DEFAULT :: h_abort
WRITE(*,*) 'In signal handler function h_abort for SIG$ABORT'
WRITE(*,*) 'signum = ', sig_num
h_abort = 1
END
```

See Also

SIGNALQQ

**SIGNALQQ**

*Portability Function: Registers the function to be called if an interrupt signal occurs.*

Module

USE IFPORT

Syntax

```
result = SIGNALQQ (sig,func)
```

**sig**

(Input) INTEGER(2). Interrupt type. One of the following constants, defined in IFPORT.F90:

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+CSIGNAL
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

**func**

(Input) Function to be executed on interrupt. It must be declared EXTERNAL.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a positive integer if successful; otherwise, -1 (SIG$ERR).

SIGNALQQ installs the function *func* as the handler for a signal of the type specified by *sig*. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.
The argument *func* is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

**NOTE**
All signal-handler functions must be declared with the directive !DIR$ ATTRIBUTES C.

When an interrupt occurs, except a SIG$FPE interrupt, the *sig* argument SIG$INT is passed to *func*, and then *func* is executed.

When a SIG$FPE interrupt occurs, the function *func* is passed two arguments: SIG$FPE and the floating-point error code (for example, FPE$ZERODIVIDE or FPE$OVERFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPE$ and are defined in IFPORT.F90.

If *func* returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode.

Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).

To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.

The example below shows a signal handler for SIG$ABORT.

**Example**

```fortran
! This program shows a signal handler for
! SIG$ABORT
USE IFPORT
INTERFACE
  FUNCTION h_abort (signum)
    !DIR$ ATTRIBUTES C :: h_abort
    INTEGER(4) h_abort
    INTEGER(2) signum
  END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret

i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret

i2ret = RAISEQQ(SIG$ABORT)
WRITE(*,*) 'Raised signal. Return = ', i2ret
END
!
!      Signal handler routine
!
INTEGER(4) FUNCTION h_abort (signum)
  !DIR$ ATTRIBUTES C :: h_abort
  INTEGER(2) signum
  WRITE(*,*) 'In signal handler for SIG$ABORT'
```

1933
WRITE(*,*) 'signum = ', signum
h_abort = 1
END

RAISEQQ
SIGNAL
KILL
GETEXCEPTIONPTRSQQ (W*S)

SINGLE
OpenMP* Fortran Compiler Directive: Specifies that a block of code is to be executed by only one thread in the team at a time.

Syntax
!!OMP SINGLE [clause[,] clause] ... ]
  block
!!OMP END SINGLE [modifier]

clause
  Is one of the following:
  • FIRSTPRIVATE (list)
  • PRIVATE (list)

block
  Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

modifier
  Is one of the following:
  • COPYPRIVATE (list)
  • NOWAIT

The binding thread set for a SINGLE construct is the current team. A SINGLE region binds to the innermost enclosing parallel region.

Threads in the team that are not executing this directive wait at the END SINGLE directive unless NOWAIT is specified.

SINGLE directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example
In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

!!OMP PARALLEL DEFAULT(SHARED)
CALL WORK(X)
!!OMP BARRIER
!!OMP SINGLE
  CALL OUTPUT(X)
  CALL INPUT(Y)
!!OMP END SINGLE
  CALL WORK(Y)
!!OMP END PARALLEL

You should not make assumptions as to which thread executes the SINGLE section. All other threads skip the SINGLE section and stop at the barrier at the END SINGLE construct. If other threads can proceed without waiting for the thread executing the SINGLE section, you can specify NOWAIT in the END SINGLE directive.
SIZE Function

Inquiry Intrinsic Function (Generic): Returns the total number of elements in an array, or the extent of an array along a specified dimension.

Syntax

\[
\text{result} = \text{SIZE} (\text{array}[, \text{dim}][, \text{kind}])
\]

- \text{array} (Input) Must be an array; it can be assumed-rank. It can be of any data type. It must not be a disassociated pointer or an allocatable array that is not allocated. It can be an assumed-size array if \text{dim} is present with a value less than the rank of \text{array}.

- \text{dim} (Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \text{array}.

- \text{kind} (Input; optional) Must be a scalar integer initialization expression.

Results

The result is a scalar of type integer. If \text{kind} is present, the kind parameter of the result is that specified by \text{kind}; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

In general, if \text{dim} is present, the result is the extent of dimension \text{dim} in \text{array}; otherwise, the result is the total number of elements in \text{array}. However, the following exceptions apply:

- If \text{array} is assumed-rank and associated with an assumed-size array and \text{dim} is present with a value equal to the rank of \text{ARRAY}, the result has a value of -1.
- If \text{dim} is absent and \text{array} is assumed-rank, the result has a value equal to \text{PRODUCT(SHAPE(ARRAY, KIND))}.

The setting of compiler options specifying integer size can affect this function.

Example

If \text{B} is declared as \text{B(2:4, -3:1)}, then \text{SIZE (B, DIM=2)} has the value 5 and \text{SIZE (B)} has the value 15.

The following shows another example:

```
REAL(8) array (3:10, -1:3)
INTEGER i
i = SIZE(array, DIM = 2) ! returns 5
i = SIZE(array) ! returns 40
```

See Also

SHAPE
Character Count Specifier (SIZE=)

SIZEOF

Inquiry Intrinsic Function (Generic): Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.
**Syntax**

```fortran
result = SIZEOF (x)
```

x  
 (Input) Can be a scalar or array. It may be of any data type. It must not be an assumed-size array.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result value is the number of bytes of storage used by `x`. If `x` is of derived type, the result includes storage used by padding and descriptors for pointer or allocatable components, if any, but not the storage used for the data of pointer or allocatable components.

**Example**

```fortran
SIZEOF (3.44) ! has the value 4
SIZEOF ('SIZE') ! has the value 4
```

**See Also**

C_SIZEOF

**SLEEP**

*Portability Subroutine: Suspends the execution of a process for a specified interval.*

**Module**

USE IFPORT

**Syntax**

```fortran
CALL SLEEP (time)
```

time  
 (Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.

**Example**

```fortran
USE IFPORT
integer(4) hold_time
hold_time = 1 ! lets the loop execute
DO WHILE (hold_time .NE. 0)
    write(*,'(A)') "Enter the number of seconds to suspend"
    read(*,*) hold_time
    CALL SLEEP (hold_time)
END DO
END
```

**See Also**

SLEEPQQ

**SLEEPQQ**

*Portability Subroutine: Delays execution of the program for a specified duration.*

**Module**

USE IFPORT
Syntax

CALL SLEEPQQ (duration)

**duration** (Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).

Example

USE IFPORT
INTEGER(4) delay, freq, duration
delay = 2000
freq = 4000
duration = 1000
CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)
END

SNGL
Converts a REAL value to a default REAL result.

See Also
See REAL function.

SORTQQ
Portability Subroutine: Sorts a one-dimensional array. The array elements cannot be derived types or record structures.

Module
USE IFPORT

Syntax

CALL SORTQQ (adrarray, count, size)

**adrarray** (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

**count** (Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. On input, number of elements in the array to be sorted. On output, number of elements actually sorted.

To be certain that SORTQQ is successful, compare the value returned in **count** to the value you provided. If they are the same, then SORTQQ sorted the correct number of elements.

**size** (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>Constant</td>
<td>Type of array</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**CAUTION**
The location of the array must be passed by address using the LOC function. This defeats Fortran type-checking, so you must make certain that the `count` and `size` arguments are correct.

If you pass invalid arguments, SORTQQ attempts to sort random parts of memory. If the memory it attempts to sort is allocated to the current process, that memory is sorted; otherwise, the operating system intervenes, the program is halted, and you get a General Protection Violation message.

**Example**

```fortran
! Sort a 1-D array
! USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 2223, 67/

! Sort the array
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)

! Display the sorted array
DO i = 1, 10
   WRITE (*, 9000) i, array (i) 9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END
```

**See Also**
BSEARCHQQ
LOC

**SPACING**

*Elemental Intrinsic Function (Generic):* Returns the absolute spacing of model numbers near the argument value.

**Syntax**

```
result = SPACING (x)
```

`x`  (Input) Must be of type real.

**Results**
The result type and kind is the same as `x`. The result has the value $b^{e-p}$. Parameters $b$, $e$, and $p$ are defined in Model for Real Data. If the result value is outside of the real model range, the result is TINY( x).
Example

If 3.0 is a REAL(4) value, SPACING (3.0) has the value $2^{-22}$.

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = SPACING(3.0) ! returns 2.384186E-07
res4 = SPACING(-3.0) ! returns 2.384186E-07
r2 = 487923.3
res8 = SPACING(r2) ! returns 5.820766091346741E-011
```

SPLTPATHQQ

Portability Function: Breaks a file path or directory path into its components.

Module
USE IFPORT

Syntax

```fortran
result = SPLTPATHQQ (path, drive, dir, name, ext)
```

- **path**
  (Input) Character*(*). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in path.

- **drive**
  (Output) Character*(*). Drive letter followed by a colon.

- **dir**
  (Output) Character*(*). Path of directories, including the trailing slash.

- **name**
  (Output) Character*(*). Name of file or, if no file is specified in path, name of the lowest directory. A file name must not include an extension.

- **ext**
  (Output) Character*(*). File name extension, if any, including the leading period (\).

Results

The result type is INTEGER(4). The result is the length of dir.

The path parameter can be a complete or partial file specification.

$\texttt{MAXPATH}$ is a symbolic constant defined in module IFPORT.F90 as 260.

Example

```fortran
USE IFPORT
CHARACTER($\texttt{MAXPATH}$) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) length
```
buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
END

FULLPATHQQ

SPORT_CANCEL_IO (W*S)
Serial Port I/O Function: Cancels any I/O in progress to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_CANCEL_IO (port)

port (Input) Integer. The port number.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE
This call also kills the thread that keeps an outstanding read operation to the serial port. This call must be done before any of the port characteristics are modified.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CANCEL_IO( 2 )
END

See Also
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_CONNECT (W*S)
Serial Port I/O Function: Establishes the connection to a serial port and defines certain usage parameters.

Module
USE IFPORT

Syntax
result = SPORT_CONNECT (port [,options])
port

(Input) Integer. The port number of connection. The routine will open COM \( n \), where \( n \) is the port number specified.

options

(Input; optional) Integer. Defines the connection options. These options define how the \( nnn \) LINE routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>DL_TERM_LF</td>
<td>Causes SPORT_READ_LINE to terminate READ when a LF is encountered.</td>
</tr>
<tr>
<td>DL_TERM_CRLF</td>
<td>Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If \( \text{options} \) is not specified, the following occurs by default:

\[(DL\_OUT\_CR \text{ .OR. DL\_TERM\_CR .OR. DL\_TOSS\_CR .OR. DL\_TOSS\_LF})(\text{.OR.})\]

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT( 2 )
END
```

See Also

SPORT_RELEASE (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK
SPORT_CONNECT_EX (W*S)

Serial Port I/O Function: Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.

Module

USE IFPORT

Syntax

result = SPORT_CONNECT_EX (port [,options] [,BufferSize])

port

(Input) Integer. The port number of connection. The routine will open COM n, where n is the port number specified.

options

(Input; optional) Integer. Defines the connection options. These options define how the nnn_LINE routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>DL_TERM_LF</td>
<td>Causes SPORT_READ_LINE to terminate READ when a LF is encountered.</td>
</tr>
<tr>
<td>DL_TERM_CRLF</td>
<td>Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If options is not specified, the following occurs by default:

(DL_OUT_CR .OR. DL_TERM_CR .OR. DL_TOSS_CR .OR. DL_TOSS_LF)

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

BufferSize

(Input; optional) Integer. Size of the internal buffer for data reception. If BufferSize is not specified, the size of the buffer is 16384 bytes (the default).
The size of the buffer must be 4096 bytes or larger. If you try to specify a size smaller than 4096 bytes, your specification will be ignored and the buffer size will be set to 4096 bytes.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example

```
USE IFFORMT
INTEGER(4) iresult
iresult = SPORT_CONNECT_EX( 2, BufferSize = 8196 )
END
```

SPORT_GET_HANDLE (W*S)

Serial Port I/O Function: Returns the Windows* OS handle associated with the communications port. This is the handle that was returned by the Windows API CreateFile.

Module
USE IFFORMT

Syntax

```
result = SPORT_GET_HANDLE ( port, handle )
```

port  
(Input) Integer. The port number.

handle 
(Output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This is the Windows handle that was returned from CreatFile( ) on the serial port.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Example

```
USE IFFORMT
INTEGER(4) iresult
INTEGER(KIND=INT_PTR_KIND( )) handle
iresult = SPORT_GET_HANDLE( 2, handle )
END
```

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_GET_STATE (W*S)

Serial Port I/O Function: Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module
USE IFFORMT
Syntax

\[
\text{result} = \text{SPORT\_GET\_STATE}(\text{port} [,\text{baud}] [,\text{parity}] [,\text{dbits}] [,\text{sbits}])
\]

- **port** (Input) Integer. The port number.
- **baud** (Output; optional) Integer. The baud rate of the port.
- **parity** (Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
- **dbits** (Output; optional) Integer. The data bits for the port.
- **sbits** (Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Example

```fortran
USE IFPORT
INTEGER(4) iresult
INTEGER baud
INTEGER parity
INTEGER dbits
INTEGER sbits

iresult = SPORT\_GET\_STATE( 2, baud, parity, dbits, sbits )
END
```

See Also

SPORT\_SET\_STATE (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT\_GET\_STATE\_EX (W*S)

*Serial Port I/O Function:* Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.

Module

USE IFPORT

Syntax

\[
\text{result} = \text{SPORT\_GET\_STATE\_EX}(\text{port} [,\text{baud}] [,\text{parity}] [,\text{dbits}] [,\text{sbits}] [,\text{Binmode}] [,\text{DTRctrl}] [,\text{RTSctrl}] [,\text{OutCTSFlow}] [,\text{OutDSRFlow}] [,\text{DSRSense}] [,\text{OutXonOff}] [,\text{InXonOff}] [,\text{XonLim}] [,\text{XoffLim}] [,\text{TXContOnXoff}] [,\text{ErrAbort}] [,\text{ErrCharEnbl}] [,\text{NullStrip}] [,\text{XonChar}] [,\text{XoffChar}] [,\text{ErrChar}] [,\text{EofChar}] [,\text{EvtChar}])
\]

- **port** (Input) Integer. The port number.
- **baud** (Input; optional) Integer. The baud rate of the port.
parity (Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits (Output; optional) Integer. The data bits for the port.

sbits (Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Binmode (Output; optional) Integer. If binary mode is enabled; otherwise, 0. Currently, the value of this parameter is always 1.

DTRcntrl (Output; optional) Integer. 1 if DTR (data-terminal-ready) flow control is used; otherwise, 0.

RTScntrl (Output; optional) Integer. 1 if RTS (request-to-send) flow control is used; otherwise, 0.

OutCTSFlow (Output; optional) Integer. 1 if the CTS (clear-to-send) signal is monitored for output flow control; otherwise, 0.

OutDSRFlow (Output; optional) Integer. 1 if the DSR (data-set-ready) signal is monitored for output flow control; otherwise, 0.

DSRSense (Output; optional) Integer. 1 if the communications driver is sensitive to the state of the DSR signal; otherwise, 0.

OutXonOff (Output; optional) Integer. 1 if XON/XOFF flow control is used during transmission; otherwise, 0.

InXonOff (Output; optional) Integer. 1 if XON/XOFF flow control is used during reception; otherwise, 0.

XonLim (Output; optional) Integer. The minimum number of bytes accepted in the input buffer before the XON character is set.

XoffLim (Output; optional) Integer. The maximum number of bytes accepted in the input buffer before the XOFF character is set.

TXContOnXoff (Output; optional) Integer. 1 if transmission stops when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

ErrAbort (Output; optional) Integer. 1 if read and write operations are terminated when an error occurs; otherwise, 0.

ErrCharEnbl (Output; optional) Integer. 1 if bytes received with parity errors are replaced with the ErrChar character; otherwise, 0.

NullStrip (Output; optional) Integer. 1 if null bytes are discarded; otherwise, 0.

XonChar (Output; optional) Character. The value of the XON character that is used for both transmission and reception.

XoffChar (Output; optional) Character. The value of the XOFF character that is used for both transmission and reception.

ErrChar (Output; optional) Character. The value of the character that is used to replace bytes received with parity errors.
**EofChar**

(Output; optional) Character. The value of the character that is used to signal the end of data.

**EvtChar**

Output; optional) Character. The value of the character that is used to signal an event.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

**Example**

USE IFPORT
INTEGER(4) iresult
INTEGER(4) port, baud, parity, dbits, sbits
INTEGER(4) OutXonOff, InXonOff, OutDSRFlow
INTEGER(4) OutCTSFlow, DTRcntrl, RTScntl
INTEGER(4) DSRsense, XonLim, XoffLim
CHARACTER(1) XonChar, XoffChar
iresult = SPORT_GET_STATE_EX(port, baud, parity, dbits, sbits,               &
OutXonOff=OutXonOff, InXonOff=InXonOff, OutDSRFlow=OutDSRFlow, &
OutCTSFlow=OutCTSFlow, DTRcntrl=DTRcntrl, RTScntl=RTScntl, &
DSRSense = DSRsense, XonChar = XonChar, XoffChar = XoffChar, &
XonLim=XonLim, XoffLim=XoffLim)
END

Communications, Communications Functions, and SetCommState in the Microsoft* Platform SDK

**SPORT_GET_TIMEOUTS (W*S)**

*Serial Port I/O Function: Returns the user selectable timeouts for the serial port.*

**Module**

USE IFPORT

**Syntax**

result = SPORT_GET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])

**port**

(Input) Integer. The port number.

**rx_int**

(Output; optional) INTEGER(4). The receive interval timeout value.

**tx_tot_mult**

(Output; optional) INTEGER(4). The transmit multiplier part of the timeout value.

**tx_tot_const**

(Output; optional) INTEGER(4). The transmit constant part of the timeout value.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.
**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
INTEGER*4 rx_int
INTEGER*4 tx_tot_mult
INTEGER*4 tx_tot_const

iresult = SPORT_GET_TIMEOUTS( 2, rx_int, tx_tot_mult, tx_tot_const )
END
```

**See Also**

**SPORT_PEEK_DATA (W*S)**

*Serial Port I/O Function: Returns information about the availability of input data.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_PEEK_DATA (port [,present] [,count])
```

- **port** (Input) Integer. The port number.
- **present** (Output; optional) Integer. 1 if data is present, 0 if no data has been read.
- **count** (Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows*OS error value.

**NOTE**

CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
INTEGER    present
INTEGER    count

iresult =  SPORT_PEEK_DATA( 2, present, count )
END
```

**See Also**

SPORT_CONNECT (W*S)
SPORT_READ_DATA (W*S)
SPORT_PEEK_LINE (W*S)

SPORT_PEEK_LINE (W*S)

Serial Port I/O Function: Returns information about the availability of input records.

Module
USE IFPORT

Syntax
result = SPORT_PEEK_LINE (port [,present] [,count])

port (Input) Integer. The port number.

present (Output; optional) Integer. 1 if data is present, 0 if no data has been read.

count (Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.

NOTE
CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Example
USE IFPORT
INTEGER(4) iresult
INTEGER    present
INTEGER    count

iresult = SPORT_PEEK_LINE( 2, present, count )
END

SPORT_PURGE (W*S)

Serial Port I/O Function: Executes the Windows* API communications function PurgeComm on the specified port.

Module
USE IFPORT

Syntax
result = SPORT_PURGE (port, function)
**SPORT_PURGE**

**Input** Integer. The port number.

**Input** INTEGER(4). The function for PurgeComm (see the Windows* OS documentation).

**Results**
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows OS error value.

**Example**

```
USE IFWINTY
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_PURGE( 2, (PURGE_TXABORT .or. PURGE_RXABORT) )
END
```

**See Also**
Communications and Communications Functions in the Microsoft* Platform SDK

**SPORT_READ_DATA (W*S)**

**Serial Port I/O Function**: Reads available data from the specified port. This routine stalls until at least one character has been read.

**Module**
USE IFPORT

**Syntax**

```
result = SPORT_READ_DATA (port, buffer[,count])
```

**port**
(Input) Integer. The port number.

**buffer**
(Output) Character*(*). The data that was read.

**count**
(Output; optional) Integer. The count of bytes read.

**Results**
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows OS error value.

**NOTE**
CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

**Example**

```
USE IFPORT
INTEGER(4)      iresult
INTEGER         count
CHARACTER*1024  rbuff
iresult = SPORT_READ_DATA( 2, rbuff, count )
END
```

**See Also**
SPORT_CONNECT (W*S)
SPORT_PEEK_DATA (W*S)
SPORT_READ_LINE (W*S)
SPORT_WRITE_DATA (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_READ_LINE (W*S)

**Serial Port I/O Function:** Reads a record from the specified port. This routine stalls until at least one record has been read.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SPORT\_READ\_LINE}(\text{port}, \text{buffer}, \text{count})
\]

- **port** (Input) Integer. The port number.
- **buffer** (Output) Character*(*). The data that was read.
- **count** (Output; optional) Integer. The count of bytes read.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.

**NOTE**

CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

**Example**

USE IFPORT

```
INTEGER(4)      iresult
INTEGER         count
CHARACTER*1024  rbuff

iresult = SPORT_READ_LINE( 2, rbuff, count )
```

**See Also**

SPORT_PEEK_LINE (W*S)
SPORT_READ_DATA (W*S)
SPORT_WRITE_LINE (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_RELEASE (W*S)

**Serial Port I/O Function:** Releases a serial port that was previously connected when SPORT_CONNECT was specified.
Module
USE IFPORT

Syntax
result = SPORT_RELEASE (port)

port  (Input) Integer. The port number.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_RELEASE( 2 )
END

See Also
SPORT_CONNECT (W*S)
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_SET_STATE (W*S)
Serial Port I/O Function: Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module
USE IFPORT

Syntax
result = SPORT_SET_STATE (port [,baud] [,parity] [,dbits] [,sbits])

port  (Input) Integer. The port number.
baud  (Input; optional) Integer. The baud rate of the port.
parity  (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits  (Input; optional) Integer. The data bits for the port.
sbits  (Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

The following restrictions apply:
• The number of data bits must be 5 to 8 bits.
• The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.
NOTE
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_STATE( 2, 9600, 0, 7, 0 )
END

Module
USE IFPORT

Syntax
 [,XonLim]
 [,XoffChar]
 [,ErrChar] [,EofChar] [,EvtChar] [,fZeroDCB])

port (Input) Integer. The port number.

baud (Input; optional) Integer. The baud rate of the port.

parity (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits (Input; optional) Integer. The data bits for the port.

sbits (Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Binmode (Input; optional) Integer. 1 if binary mode should be enabled; otherwise, 0. Currently, if this parameter is used, the value must be 1.

DTRcntrl (Input; optional) Integer. 1 if DTR (data-terminal-ready) flow control should be used; otherwise, 0.

RTScntrl (Input; optional) Integer. 1 if RTS (request-to-send) flow control should be used; otherwise, 0.

USE IFPORT

**Syntax**

```fortran
result = SPORT_SET_TIMEOUTS (port [, rx_int] [, tx_tot_mult] [, tx_tot_const])
```

- **port** (Input) Integer. The port number.
- **rx_int** (Input; optional) INTEGER(4). The receive interval timeout value.
- **tx_tot_mult** (Input; optional) INTEGER(4). The transmit multiplier part of the timeout value.
- **tx_tot_const** (Input; optional) INTEGER(4). The transmit constant part of the timeout value.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

**NOTE**
This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.
Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_TIMEOUTS( 2, 100, 0, 1000 )
END

See Also
SPORT_CANCEL_IO (W*S)
SPORT_GET_TIMEOUTS (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_SHOW_STATE (W*S)

Serial Port I/O Function: Displays the state of a port to standard output.

Module

USE IFPORT

Syntax

result = SPORT_SHOW_STATE (port, level)

port (Input) Integer. The port number.
level (Input) Integer. Controls the level of detail displayed as follows:

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Basic one line display</td>
</tr>
<tr>
<td>1</td>
<td>Basic information</td>
</tr>
<tr>
<td>2</td>
<td>Add modem signal control flow information</td>
</tr>
<tr>
<td>3</td>
<td>Add XON/XOFF information</td>
</tr>
<tr>
<td>4</td>
<td>Add event character information</td>
</tr>
<tr>
<td>11</td>
<td>Add timeout information</td>
</tr>
<tr>
<td>901</td>
<td>Add debug information</td>
</tr>
</tbody>
</table>

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.

NOTE

This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SHOW_STATE( 2, 0 )
END
SPORT_SPECIAL_FUNC (W*S)

**Serial Port I/O Function:** Executes the Windows* API communications function EscapeCommFunction on the specified port.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_SPECIAL_FUNC (port, function)
```

- **port** (Input) Integer. The port number.
- **function** (Input) INTEGER(4). The function to perform.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, the result is a Windows* error value.

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SPECIAL_FUNC( 2, ? )
END
```

**See Also**

Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_WRITE_DATA (W*S)

**Serial Port I/O Function:** Outputs data to the specified port.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_WRITE_DATA (port, data[,count])
```

- **port** (Input) Integer. The port number.
- **data** (Input) Character*(*)(). The data to be output.
- **count** (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.
NOTE
When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions
SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs,
the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count
contains the number of bytes that were really written.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_DATA( 2, 'ATZ'//CHAR(13), 0 )
END

See Also
SPORT_WRITE_LINE (W*S)
SPORT_READ_DATA (W*S)
Communications and Communications Functions in the Microsoft* Platform SDK

SPORT_WRITE_LINE (W*S)
Serial Port I/O Function: Outputs data, followed by
a record terminator, to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_WRITE_LINE (port, data[, count])

port (Input) Integer. The port number.
data (Input) Character*(*). The data to be output.
count (Input; optional) Integer. The count of bytes to write. If the value is zero,
this number is computed by scanning the data backwards looking for a non-
blank character.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* OS error value.
After the data is output, a line terminator character is added based on the mode used during the
SPORT_CONNECT( ) call.

NOTE
When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions
SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs,
the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count
contains the number of bytes that were really written.

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_LINE( 2, 'ATZ', 0 )
END

- SPORT_READ_LINE (W*S)

Communications and Communications Functions in the Microsoft* Platform SDK

**SPREAD**

*Transformational Intrinsic Function (Generic):*

*Creates a replicated array with an added dimension by making copies of existing elements along a specified dimension.*

**Syntax**

```fortran
result = SPREAD (source, dim, ncopies)
```

- `source` *(Input)* Must be a scalar or array. It may be of any data type. The rank must be less than 31.
- `dim` *(Input)* Must be scalar and of type integer. It must have a value in the range 1 to n + 1 (inclusive), where n is the rank of `source`.
- `ncopies` Must be scalar and of type integer. It becomes the extent of the additional dimension in the result.

**Results**

The result is an array of the same type as `source` and of rank that is one greater than `source`. If `source` is an array, each array element in dimension `dim` of the result is equal to the corresponding array element in `source`.

If `source` is a scalar, the result is a rank-one array with `ncopies` elements, each with the value `source`.

If `ncopies` less than or equal to zero, the result is an array of size zero.

**Example**

SPREAD ("B", 1, 4) is the character array (/"B", "B", "B", "B").

B is the array [3, 4, 5] and NC has the value 4.

SPREAD (B, DIM=1, NCOPIES=NC) produces the array

```
[ 3  4  5 ]
[ 3  4  5 ]
[ 3  4  5 ]
[ 3  4  5 ].
```

SPREAD (B, DIM=2, NCOPIES=NC) produces the array

```
[ 3  3  3  3 ]
[ 4  4  4  4 ]
[ 5  5  5  5 ].
```

The following shows another example:

```fortran
INTEGER AR1(2, 3), AR2(3, 2)
AR1 = SPREAD((/1,2,3/),DIM= 1,NCOPIES= 2) ! returns
    ! 1 2 3
    ! 1 2 3
```
AR2 = SPREAD(/1,2,3/), 2, 2) ! returns 1 1
  !           2 2
  !           3 3

PACK Function
RESHAPE

SQRT

*Elemental Intrinsic Function (Generic): Produces the square root of its argument.*

Syntax

```
result = SQRT (x)
```

where

* x (Input) must be of type real or complex. If x is type real, its value must be greater than or equal to zero.

Results

The result type and kind is the same as x. The result has a value equal to the square root of x. A result of type complex is the principal value, with the real part greater than or equal to zero. When the real part of the result is zero, the imaginary part of the result has the same sign as the imaginary part of x, even if the imaginary part of x is a negative real zero.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQRT</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>

<tr>
<td>CDSQRT</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSQRT</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

1 The setting of compiler options specifying real size can affect CSQRT.
2 This function can also be specified as ZSQRT.

Example

SQRT (16.0) has the value 4.0.

SQRT (3.0) has the value 1.732051.

The following shows another example:

```
! Calculate the hypotenuse of a right triangle
! from the lengths of the other two sides.
REAL sidea, sideb, hyp
sidea = 3.0
sideb = 4.0
hyp = SQRT (sidea**2 + sideb**2)
WRITE (*, 100) hyp
100 FORMAT (/ ' The hypotenuse is ', F10.3)
END
```
SRAND

Portability Subroutine: Seeds the random number generator used with IRAND and RAND.

Module

USE IFPORT

Syntax

CALL SRAND (iseed)

iseed (Input) INTEGER(4). Any value. The default value is 1.

SRAND seeds the random number generator used with IRAND and RAND. Calling SRAND is equivalent to calling IRAND or RAND with a new seed.

The same value for iseed generates the same sequence of random numbers. To vary the sequence, call SRAND with a different iseed value each time the program is executed.

Example

! How many random numbers out of 100 will be between .5 and .6?
USE IFPORT
ICOUNT = 0
CALL SRAND(123)
DO I = 1, 100
   X = RAND(0)
   IF ((X>.5).AND.(x<.6)) ICOUNT = ICOUNT + 1
END DO
WRITE(*,*) ICOUNT, "numbers between .5 and .6!"
END

SSWRQQ

Portability Subroutine: Returns the floating-point processor status word.

Module

USE IFPORT

Syntax

CALL SSWRQQ (status)

status (Output) INTEGER(2). Floating-point processor status word.

SSWRQQ performs the same function as the run-time subroutine GETSTATUSFPQQ and is provided for compatibility.
Example

```
USE IFPORT
INTEGER(2) status
CALL SSWRQQ (status)
```

GETSTATUSFPQQ (W*S)

STAT

**Portability Function:** Returns detailed information about a file.

Module

USE IFPORT

Syntax

```
result = STAT (name, statb)
```

(name) Character*(*)). Name of the file to examine.

(statb) (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of `statb` contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
</table>
| `statb(1)` | Device the file resides on | W*S: Always 0  
L*X, M*X: System dependent |
| `statb(2)` | File inode number | W*S: Always 0  
L*X, M*X: System dependent |
| `statb(3)` | Access mode of the file | See the table in Results |
| `statb(4)` | Number of hard links to the file | W*S: Always 1  
L*X, M*X: System dependent |
| `statb(5)` | User ID of owner | W*S: Always 1  
L*X, M*X: System dependent |
| `statb(6)` | Group ID of owner | W*S: Always 1  
L*X, M*X: System dependent |
| `statb(7)` | Raw device the file resides on | W*S: Always 0  
L*X, M*X: System dependent |
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td></td>
</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed(^1)</td>
<td>W<em>S: Only available on non-FAT file systems; undefined on FAT systems L</em>X, M*X: System dependent</td>
</tr>
<tr>

</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W<em>S: Always 1 L</em>X, M*X: System dependent</td>
</tr>
</tbody>
</table>

\(^1\)Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

Results
The result type is INTEGER(4).

On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code ENOENT (the specified file could not be found). On Linux* and OS X* systems, the file inquired about must be currently connected to a logical unit and must already exist when STAT is called; if STAT fails, errno is set.

For a list of other error codes, see IERRNO.

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows* systems, LSTAT returns exactly the same information as STAT. On Linux and OS X systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

You can also use the INQUIRE statement to get information about file properties.

**Example**

```
USE IFFPORT
CHARACTER*12 file_name
INTEGER(4) info_array(12)
print *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
   print *, info_array else
```

Statement Function

**Statement**: Defines a function in a single statement in the same program unit in which the procedure is referenced.

**Syntax**

```
fun([d-arg [,d-arg]...]) = expr
```

- **fun** is the name of the statement function.
- **d-arg** is a dummy argument. A dummy argument can appear only once in any list of dummy arguments, and its scope is local to the statement function.
- **expr** is a scalar expression defining the computation to be performed.

Named constants and variables used in the expression must have been declared previously in the specification part of the scoping unit or made accessible by use or host association.

If the expression contains a function or statement function reference, that function must have been defined previously as a function or statement function in the same program unit.

A statement function reference takes the following form:

```
fun([ a-arg[, a-arg] ...])
```

- **fun** is the name of the statement function.
- **a-arg** is an actual argument.

**Description**

When a statement function reference appears in an expression, the values of the actual arguments are associated with the dummy arguments in the statement function definition. The expression in the definition is then evaluated. The resulting value is used to complete the evaluation of the expression containing the function reference.

The data type of a statement function can be explicitly defined in a type declaration statement. If no type is specified, the type is determined by implicit typing rules in effect for the program unit.

Actual arguments must agree in number, order, and data type with their corresponding dummy arguments.

Except for the data type, declarative information associated with an entity is not associated with dummy arguments in the statement function; for example, declaring an entity to be an array or to be in a common block does not affect a dummy argument with the same name.

The name of the statement function cannot be the same as the name of any other entity within the same program unit.

Any reference to a statement function must appear in the same program unit as the definition of that function.
A statement function reference must appear as (or be part of) an expression. The reference cannot appear on the left side of an assignment statement.

A statement function must not be provided as a procedure argument.

**Example**

The following are examples of statement functions:

```plaintext
REAL VOLUME, RADIUS
VOLUME(RADIUS) = 4.189*RADIUS**3

CHARACTER*10 CSF,A,B
CSF(A,B) = A(6:10)//B(1:5)
```

The following example shows a statement function and some references to it:

```plaintext
AVG(A,B,C) = (A+B+C)/3.
...
GRADE = AVG(TEST1,TEST2,XLAB)
IF (AVG(P,D,Q) .LT. AVG(X,Y,Z)) STOP
FINA1 = AVG(TEST3,TEST4,LAB2) ! Invalid reference; implicit
... ! type of third argument does not
... ! match implicit type of dummy argument
```

Implicit typing problems can be avoided if all arguments are explicitly typed.

The following statement function definition is invalid because it contains a constant, which cannot be used as a dummy argument:

```plaintext
REAL COMP, C, D, E
COMP(C,D,E,3.) = (C + D - E)/3.
```

The following shows another example:

```plaintext
Add (a, b) = a + b
REAL(4) y, x(6)
... DO n = 2, 6
  x(n) = Add (y, x(n-1))
END DO
```

FUNCTION

Argument Association in Procedures

Use and Host Association Overview

**STATIC**

**Statement and Attribute**: Controls the storage allocation of variables in subprograms (as does AUTOMATIC). Variables declared as STATIC and allocated in memory reside in the static storage area, rather than in the stack storage area.

**Syntax**

The STATIC attribute can be specified in a type declaration statement or a STATIC statement, and takes one of the following forms:

**Type Declaration Statement**:

type, [att-ls] STATIC [, att-ls] :: v[, v] ...

**Statement**:

STATIC[::] v[, v] ...
**type**

Is a data type specifier.

**att-ls**

Is an optional list of attribute specifiers.

**v**

Is the name of a variable or an array specification. It can be of any type.

STATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

By default, the compiler allocates local scalar variables of non-recursive subprograms in the static storage area. Local arrays, except for allocatable arrays, are in the static storage area by default.

The compiler may choose to allocate a variable in temporary (stack or register) storage if it notices that the variable is always defined before use. Appropriate use of the SAVE attribute can prevent compiler warnings if a variable is used before it is defined.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

To override any compiler option that may affect variables, explicitly specify the variables as STATIC.

**NOTE**

Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as STATIC more than once in the same scoping unit.

If the variable is a pointer, STATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as STATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>Yes</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

A variable can be specified with both the STATIC and SAVE attributes.

If a variable is in a module's outer scope, it can be specified as STATIC.

**Example**

The following example shows a type declaration statement specifying the STATIC attribute:

```fortran
INTEGER, STATIC :: ARRAY_A
```

The following example shows a STATIC statement:

```fortran
CONTAINS
  INTEGER FUNCTION REDO_FUNC
```
INTEGER I, J(10), K
REAL C, D, E(30)
AUTOMATIC I, J, K(20)
STATIC C, D, E

END FUNCTION

INTEGER N1, N2
N1 = -1
DO WHILE (N1)
   N2 = N1*2
   call sub1(N1, N2)
   read *, N1
END DO
CONTAINS
SUBROUTINE sub1 (iold, inew)
INTEGER, intent(INOUT):: iold
integer, STATIC ::N3
integer, intent(IN) :: inew
if (iold .eq. -1) then
   N3 = iold
end if
print *, 'New: ', inew, 'N3: ',N3
END subroutine

END

STOP and ERROR STOP

Statements: The STOP statement terminates program execution before the end of the program unit. The ERROR STOP statement initiates error termination of execution.

Syntax
STOP [stop-code]
ERROR STOP [stop-code]

stop-code
(Optional) A message. It can be any of the following:

- A scalar character constant expression of type default character
- A non-negative integer constant less than or equal to 2147483647; leading zeros are ignored.
- A scalar integer constant expression

If stop-code is specified, the STOP or ERROR STOP statement does the following:
• Writes the specified message to the standard error device.
• Writes one or more of the following messages to the standard error device indicating which IEEE floating-
  point exceptions are signaling:
  - IEEE_DIVIDE_BY_ZERO is signaling
  - IEEE_INVALID is signaling
  - IEEE_OVERFLOW is signaling
  - IEEE_UNDERFLOW is signaling
• Terminates program execution. If stop-code is a character constant, a status of zero is returned. If stop-code
  is an integer, a status equal to stop-code is returned.

If stop-code is not specified, the program is terminated, no message is printed, and a status of zero is
returned.

When a program is running on multiple images, a STOP statement on one image does not affect the other
images. An ERROR STOP initiates execution termination on all images, which may include flushing of I/O
buffers, closing of I/O files, and reporting error status on one or more images.

**Effect on Windows* Systems**

In QuickWin programs, the following is displayed in a message box:

Program terminated with Exit Code stop-code

If the application has no console window, the stop-code is displayed in a message box.

**Effect on Linux* and OS X* Systems**

Operating system shells (such as bash, sh, csh, etc.) work with one byte exit status. So, when stop-code is
an integer, only the lowest byte is significant. For example, consider the following statement:

STOP 99999

In this case, the program returns a status equal to 159 because integer 99999 = Z'1869F', and the lowest
byte is equal to Z'9F', which equals 159.

**Example**

The following examples show valid STOP statements:

STOP 98
STOP 'END OF RUN'

DO
  READ *, X, Y
  IF (X > Y) STOP 5555
END DO

The following shows another example:

OPEN(1,FILE='file1.dat', status='OLD', ERR=100)
  ...
100 STOP 'ERROR DETECTED!'
END

**See Also**

EXIT Statement

**STORAGE_SIZE**

*Inquiry Intrinsic Function (Generic)*: Returns the
storage size in bits.

**Syntax**

result = STORAGE_SIZE (a [, kind])
a  (Input) Must be a scalar or array. It can be of any type. If it has any
defered type parameters it must not be an unallocated allocatable variable,
or a disassociated, or undefined pointer.

kind  (Input; optional) Must be a scalar integer constant expression.

Results
The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by
kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent
the result value in the kind of the result, the result is undefined.

The result value is the size expressed in bits for an element of an array that has the dynamic type and kind
parameters of a.

If the type and kind parameters are such that storage association applies, the result is consistent with the
named constants defined in the intrinsic module ISO_FORTRAN_ENV.

An array element may take more bits to store than a scalar, since any hardware-imposed alignment
requirements for array elements may not apply to a scalar variable.

NOTE
The result is intended to be the size in memory that an object takes when it is stored. This may differ
from the size it takes during expression handling (which may be the native register size) or when
stored in a file. If an object is never stored in memory but only in a register, this function nonetheless
returns the size it would take if it were stored in memory.

Example
STORAGE_SIZE (1.0) has the same value as the named constant NUMERIC_STORAGE_SIZE in the intrinsic
module ISO_FORTRAN_ENV.

STRICT and NOSTRICT
General Compiler Directive: STRICT disables
language features not found in the language standard
specified on the command line (Fortran 2008, Fortran
2003, Fortran 95, or Fortran 90). NOSTRICT (the
default) enables these features.

Syntax
!DIR$ STRICT
!DIR$ NOSTRICT

If STRICT is specified and no language standard is specified on the command line, the default is to disable
features not found in Fortran 2003.

The STRICT and NOSTRICT directives can appear only appear at the top of a program unit. A program unit is
a main program, an external subroutine or function, a module, or a block data program unit. STRICT and
NOSTRICT cannot appear between program units, or at the beginning of internal subprograms. They do not
affect any modules invoked with the USE statement in the program unit that contains them.
Example

! NOSTRICT by default
TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff
TYPE (stuff) examp
DOUBLE COMPLEX cd  ! non-standard data type, no error
cd = (3.0D0, 4.0D0)
examp.k = 4        ! non-standard component designation, 
                  ! no error
END
SUBROUTINE STRICTDEMO( )
!DIR$ STRICT
TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff
TYPE (stuff) samp
DOUBLE COMPLEX cd   ! ERROR
cd = (3.0D0, 4.0D0)
samp.k = 4          ! ERROR
END SUBROUTINE

STRUCTURE and END STRUCTURE

Statement: Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.

Syntax

STRUCTURE [/structure-name/] [field-namelist]
  [field-declaration]
  [field-declaration]
  ...
  [field-declaration]
END STRUCTURE

structure-name

Is the name used to identify a structure, enclosed by slashes.
Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks.
Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

**field-namelist** is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.

**field-declaration** is also called the declaration body. A field-declaration consists of any combination of the following:

- **Type declarations**
  These are ordinary Fortran data type declarations.

- **Substructure declarations**
  A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.

- **Union declarations**
  A union declaration is composed of one or more mapped field declarations.

- **PARAMETER statements**
  PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

```
INTEGER*4 P
STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
END STRUCTURE
REAL*4 A(P)
```

The Standard Fortran derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.

In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.
A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).

**Example**

An item can be a RECORD statement that references a previously defined structure type:

```fortran
STRUCTURE /full_address/
   RECORD /full_name/ personsname
   RECORD /address/    ship_to
   INTEGER*1          age
   INTEGER*4          phone
END STRUCTURE
```

You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address` structure defined in the previous example:

```fortran
RECORD /full_address/ shippingaddress
```

In this case, the `age` item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.

In the following example, the declaration defines a structure named `APPOINTMENT`. `APPOINTMENT` contains the structure `DATE` (field `APP_DATE`) as a substructure. It also contains a substructure named `TIME` (field `APP_TIME`, an array), a `CHARACTER*20` array named `APP_MEMO`, and a `LOGICAL*1` field named `APP_FLAG`.

```fortran
STRUCTURE /DATE/
   INTEGER*1 DAY, MONTH
   INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/
   RECORD /DATE/     APP_DATE
   STRUCTURE /TIME/  APP_TIME (2)
      INTEGER*1 HOUR, MINUTE
END STRUCTURE
   CHARACTER*20      APP_MEMO (4)
   LOGICAL*1         APP_FLAG
END STRUCTURE
```

The length of any instance of structure `APPOINTMENT` is 89 bytes.
The following figure shows the memory mapping of any record or record array element with the structure APPOINTMENT.

**Memory Map of Structure APPOINTMENT**

<table>
<thead>
<tr>
<th>Byte offset</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>field DAY of field APP_DATE</td>
</tr>
<tr>
<td>1</td>
<td>field MONTH of field APP_DATE</td>
</tr>
<tr>
<td>2</td>
<td>field YEAR of field APP_DATE</td>
</tr>
<tr>
<td>4</td>
<td>field HOUR of field APP_TIME(1)</td>
</tr>
<tr>
<td>5</td>
<td>field MINUTE of field APP_TIME(1)</td>
</tr>
<tr>
<td>6</td>
<td>field HOUR of field APP_TIME(2)</td>
</tr>
<tr>
<td>7</td>
<td>field MINUTE of field APP_TIME(2)</td>
</tr>
<tr>

**SUBMODULE**

*Statement:* Marks the beginning of a submodule program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```
SUBMODULE (ancestor-module-name [:parent-submodule-name]) name
    [specification-part]
    [module-subprogram
    [module-subprogram]...]
END [SUBMODULE [name]]
```

- **ancestor-module-name** Must be the name of a nonintrinsic module. It is the name of the module at the root of the module or submodule tree.
- **parent-submodule-name** (Optional) Is the name of the parent submodule, if any. The parent submodule must be a descendant of *ancestor-module-name*.
- **name** Is the name of the submodule.
- **specification-part** Is one or more specification statements, except for the following:
  - ENTRY
  - FORMAT
  - AUTOMATIC (or its equivalent attribute)
  - INTENT (or its equivalent attribute)
  - OPTIONAL (or its equivalent attribute)
  - Statement functions
  An automatic object must not appear in a specification statement.
- **module-subprogram** Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.
  A module subprogram can contain internal procedures.

**Description**

If a name follows the END statement, it must be the same as the name specified in the SUBMODULE statement.

Each submodule has exactly one ancestor module and exactly one parent module or submodule. If the parent is a module then it must be the ancestor module. The relationship is tree-like, with the parent module or submodule at the root of the tree, and its descendant submodules as the branches of the tree.

A module or submodule may have one or more descendant submodules.

A submodule can access the entities from its parent module or submodule by host association. Unlike a module, a submodule cannot be referenced in other program units by use association. Entities declared in a submodule are only accessible from the submodule and its descendent submodules. Furthermore, a module procedure can have its interface declared in a module or submodule and its implementation contained in a descendent submodule in a separate file.

Submodules help the modularization of a large module in several ways:
Internal data can be shared among submodules without being exposed to users of the module. Without the submodule feature, when a large module is split into smaller modules, internal data may be forced to become public in order to be shared among the modules.

Even if a module procedure implementation in a submodule is changed, as long as the module procedure interface declared in the ancestor module remains the same, a recompilation would not be needed for the user of the module. This could reduce the rebuilding time for a complex system.

Separate concepts with circular dependencies can now be implemented in different submodules. It cannot be done with just modules.

A submodule is uniquely identified by a subroutine identifier which consists of its ancestor-module-name and the name of the submodule. The name of a submodule can therefore be the same as the name of another submodule so long as they do not have the same ancestor module.

The following rules also apply to submodules:

- The specification part of a subroutine must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
- A variable, common block, or procedure pointer declared in a subroutine implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the specification-part of a subroutine includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the subroutine subsequent to the specification or constant expression.

Unlike a module, the specification part of a subroutine must not contain PUBLIC and PRIVATE specifications. Any executable statements in a module or subroutine can only be specified in a module or subroutine subprogram.

A subroutine can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

Example

Consider the following example of a multilevel subroutine system:

```
Module M
  Submodule A
    Submodule X
    Submodule Y
  Submodule B
  Submodule C
    Submodule Z
END SUBMODULE

In the above example, module M is extended by submodules up to two levels. Module M is the ancestor module of all the submodules. Entities declared in module M can be shared among all the submodules. A is the parent submodule of X, Y, and Z. Entities declared in submodule A can be shared among submodules X, Y, and Z, but not by B or C.

Only public entities declared in M can be available to other program units by use association.

The SUBMODULE declarations for A and X are:

```
SUBMODULE (M) A
  ...
END SUBMODULE A

SUBMODULE (M : A) X
  ...
END SUBMODULE X
```

The following example shows modules and submodules, separate module procedures, and how circular dependency can be avoided with submodules. There are five parts in the example:

1. module color_points
2. level-1 submodule color_points_a
3. level-2 submodule color_points_b
4. module palette_stuff
5. program main

! part 1
module color_points ! This is the ancestor module
type color_point
  private
real :: x, y
integer :: color
end type color_point

! Below is the interface declaration of the separate module procedures.
! No IMPORT statement is used in the interface bodies.
! The separate module procedures are implemented in the two submodules.
Interface
module subroutine color_point_del ( p )
type(color_point), allocatable :: p
end subroutine color_point_del

  real module function color_point_dist ( a, b )
type(color_point), intent(in) :: a, b
end function color_point_dist

module subroutine color_point_draw ( p )
type(color_point), intent(in) :: p
end subroutine color_point_draw

module subroutine color_point_new ( p )
type(color_point), allocatable :: p
end subroutine color_point_new
end interface
end module color_points

! part 2
submodule ( color_points ) color_points_a ! submodule of color_points
  integer :: instance_count = 0

! Below is the interface declaration of the separate module procedure
! inquire_palette, which is implemented in the submodule color_points_b.
interface
module subroutine inquire_palette ( pt, pal )
use palette_stuff
! Later you will see that module palette_stuff uses color_points.
! This use of palette_stuff however does not cause a circular
! dependence because this use is not in the module.
type(color_point), intent(in) :: pt
  type(palette), intent(out) :: pal
end subroutine inquire_palette
end interface
contains
! Here are the implementations of three of the four separate module
! procedures declared in module color_point.
module subroutine color_point_del ( p )
type(color_point), allocatable :: p
instance_count = instance_count - 1
deallocate ( p )
end subroutine color_point_del
real module function color_point_dist ( a, b ) result ( dist )
type(color_point), intent(in) :: a, b
dist = sqrt( (b%x - a%x)**2 + (b%y - a%y)**2 )
end function color_point_dist

module subroutine color_point_new ( p )
type(color_point), allocatable :: p
instance_count = instance_count + 1
allocate ( p )
end subroutine color_point_new
end module color_points_a

! part 3
submodule ( color_points:color_points_a ) color_points_b
! submodule of color_point_a
contains
! Implementation of a module procedure declared in the ancestor module
module subroutine color_point_draw ( p )
use palette_stuff, only: palette
type(color_point), intent(in) :: p
type(palette) :: MyPalette
...; call inquire_palette ( p, MyPalette ); ... 
end subroutine color_point_draw

! Implementation of a module procedure declared in the parent submodule
module procedure inquire_palette
...
end procedure inquire_palette

! A procedure only accessible from color_points_b and its submodules
subroutine private_stuff
...
end subroutine private_stuff
end submodule color_points_b

! part 4
module palette_stuff
    type :: palette ; ... ; end type palette
contains
    subroutine test_palette ( p )
    use color_points
    ! This does not cause a circular dependency because the
    ! "use palette_stuff" that is logically within color_points
    ! is in the color_points_a submodule.
type(palette), intent(in) :: p
...
    end subroutine test_palette
end module palette_stuff

! part 5
program main
    use color_points
    ! Only public entities in color_points can be accessed here, not the
    ! entities from its submodules.
The separate module procedure color_point_draw can be a specific
procedure for a generic here. Recall that color_point_draw is
implemented in a submodule, but its interface is public in a module.

```fortran
interface draw
module procedure color_point_draw
end interface

type(color_point) :: C_1, C_2
real :: rc
...
call color_point_new (c_1)  ! body in color_points_a, interface in
!   color_points
...
call draw (c_1)             ! body in color_points_b, specific interface
!   in color_points, generic interface here
...
rc = color_point_dist (c_1, c_2)  ! body in color_points_a, interface in
!   color_points
...
call color_point_del (c_1)  ! body in color_points_a, interface in
!   color_points
...
end program main
```

MODULE
FUNCTION
SUBROUTINE

Resolving Procedure References

**SUBROUTINE**

**Statement:** The initial statement of a subroutine
subprogram. A subroutine subprogram is invoked in a
CALL statement or by a defined assignment
statement, and does not return a particular value.

**Syntax**

```
[prefix [prefix]] SUBROUTINE name [([d-arg-list]) [lang-binding]]
    [specification-part]
    [execution-part]
[CONTAINS
    [internal-subprogram-part] ]
END [SUBROUTINE [name]]
```

**prefix**

(Optional) Is any of the following:

- **ELEMENTAL**
  Acts on one array element at a time. This is a restricted form of pure
procedure.
- **IMPURE**
  Asserts that the procedure has side effects.
- **MODULE**
Indicates a separate module procedure. See separate module procedures.

- **PURE**
  
  Asserts that the procedure has no side effects.

- **RECURSIVE**
  
  Permits direct recursion to occur.

At most one of each of the above can be specified. You cannot specify both
ELEMENTAL and RECURSIVE. You cannot specify both PURE and IMPURE.
You cannot specify ELEMENTAL if lang-binding is specified.

**name**

Is the name of the subroutine.

**d-arg-list**

(Optional) Is a list of one or more dummy arguments or alternate return specifiers (*).

**lang-binding**

(Optional) Takes the following form:

\[
\text{BIND (C [, NAME=ext-name])}
\]

**ext-name**

Is a character scalar initialization expression that can be used to construct the external name.

**specification-part**

Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

**execution-part**

Is one or more executable constructs or statements, except for ENTRY or RETURN statements.

**internal-subprogram-part**

Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

A subroutine is invoked by a CALL statement or defined assignment. When a subroutine is invoked, dummy arguments (if present) become associated with the corresponding actual arguments specified in the call.

Execution begins with the first executable construct or statement following the SUBROUTINE statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

A subroutine subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A subroutine can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

You need an interface block for a subroutine when:

- Calling arguments use argument keywords.
- Some arguments are optional.
- A dummy argument is an assumed-shape array, a pointer, or a target.
- The subroutine extends intrinsic assignment.
- The subroutine can be referenced by a generic name.
• The subroutine is in a dynamic-link library.

If the subroutine is in a DLL and is called from your program, use the option DLLEXPORT or DLLIMPORT, which you can specify with the ATTRIBUTES directive.

Note that if you specify lang-binding, you have to use the parentheses even if there are no arguments. For example, without lang-binding you can specify SUBROUTINE F but with lang-binding you have to specify SUBROUTINE F( ) BIND (C).

Example

The following example shows a subroutine:

<table>
<thead>
<tr>
<th>Main Program Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL HELLO_WORLD</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>END</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

The following example uses alternate return specifiers to determine where control transfers on completion of the subroutine:

<table>
<thead>
<tr>
<th>Main Program Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL CHECK(A,B,*10,*20,C)</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>TYPE*, 'VALUE LESS THAN ZERO'</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>GO TO 30</td>
</tr>
<tr>
<td>TYPE*, 'VALUE EQUALS ZERO'</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>GO TO 30</td>
</tr>
<tr>
<td>TYPE*, 'VALUE MORE THAN ZERO'</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>GO TO 30</td>
</tr>
<tr>
<td>CONTINUE</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

The SUBROUTINE statement argument list contains two dummy alternate return arguments corresponding to the actual arguments *10 and *20 in the CALL statement argument list.

The value of Z determines the return, as follows:

- If Z < zero, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the main program.
- If Z = = zero, the return is to statement label 10 in the main program.
- If Z > zero, the return is to statement label 20 in the main program.

Note that an alternate return is an obsolescent feature in the Fortran Standard.

The following shows another example:

<table>
<thead>
<tr>
<th>SUBROUTINE GetNum (num, unit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER num, unit</td>
</tr>
<tr>
<td>10 READ (unit, '(I10)', ERR = 10) num</td>
</tr>
<tr>
<td>END</td>
</tr>
</tbody>
</table>

SUM

Transformational Intrinsic Function (Generic):
Returns the sum of all the elements in an entire array or in a specified dimension of an array.

Syntax

\[
\text{result} = \text{SUM}(\text{array}[, \text{dim}] [,\text{mask}])
\]

array
(Input) Must be an array of type integer, real, or complex.

dim
(Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \(\text{array}\).

mask
(Input; optional) Must be of type logical and conformable with \(\text{array}\).

Results

The result is an array or a scalar of the same data type as \(\text{array}\).

The result is a scalar if \(\text{dim}\) is omitted or \(\text{array}\) has rank one.

The following rules apply if \(\text{dim}\) is omitted:

- If \(\text{SUM}(\text{array})\) is specified, the result is the sum of all elements of \(\text{array}\). If \(\text{array}\) has size zero, the result is zero.
- If \(\text{SUM}(\text{array}, \text{MASK}=\text{mask})\) is specified, the result is the sum of all elements of \(\text{array}\) corresponding to true elements of \(\text{mask}\). If \(\text{array}\) has size zero, or every element of \(\text{mask}\) has the value .FALSE., the result is zero.

The following rules apply if \(\text{dim}\) is specified:

- If \(\text{array}\) has rank one, the value is the same as \(\text{SUM}(\text{array}[\text{MASK}=\text{mask}])\).
- An array result has a rank that is one less than \(\text{array}\), and shape \((d_1, d_2, ..., d_{\text{dim}+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of \(\text{array}\).
- The value of element \((s_1, s_2, ..., s_{\text{dim}-1}, s_{\text{dim}+1}, ..., s_n)\) of \(\text{SUM}(\text{array}, \text{dim}[\text{MASK}=\text{mask}])\) is equal to \(\text{SUM}(\text{array}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n) [,\text{MASK} = \text{mask}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)])\).

Example

\(\text{SUM}((/2, 3, 4/))\) returns the value 9 (sum of 2 + 3 + 4). \(\text{SUM}((/2, 3, 4/), \text{DIM}=1)\) returns the same result.

\(\text{SUM}(\text{B}, \text{MASK}=\text{B .LT. 0.0})\) returns the arithmetic sum of the negative elements of \(\text{B}\).

\(\text{C}\) is the array

\[
\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{array}
\]

\(\text{SUM}(\text{C}, \text{DIM}=1)\) returns the value \((5, 7, 9)\), which is the sum of all elements in each column. \(5\) is the sum of \(1 + 4\) in column 1. \(7\) is the sum of \(2 + 5\) in column 2, and so forth.

\(\text{SUM}(\text{C}, \text{DIM}=2)\) returns the value \((6, 15)\), which is the sum of all elements in each row. \(6\) is the sum of \(1 + 2 + 3\) in row 1. \(15\) is the sum of \(4 + 5 + 6\) in row 2.

The following shows another example:

```
INTEGER array (2, 3), i, j(3)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is 1 3 5
!   2 4 6
i = SUM((/ 1, 2, 3 /)) ! returns 6
```
\[ j = \text{SUM}(\text{array}, \text{DIM} = 1) \quad ! \text{returns } [3 \ 7 \ 11] \]
\[
\text{WRITE}(*,*) \ i, \ j \\
\text{END}
\]

PRODUCT

SYNC ALL

**Statement:** Performs a synchronization of all images.

*It takes the following form:*

**Syntax**

\[
\text{SYNC ALL}([\text{STAT} = \text{stat-var}], [\text{ERRMSG} = \text{err-var}])
\]

- **stat-var**: Is a scalar integer variable in which the status of the synchronization is stored.
- **err-var**: Is a scalar default character variable in which an error condition is stored if such a condition occurs.

**Description**

Execution on an image, for example, C, of the segment following the SYNC ALL statement is delayed until each other image has executed a SYNC ALL statement as many times as has image C.

The segments that executed before the SYNC ALL statement on an image, precede the segments that execute after the SYNC ALL statement on another image.

**Example**

In the following example, image 5 reads data and transmits the data to other images:

\[
\begin{align*}
\text{REAL :: W[*]} \\
\text{SYNC ALL} \\
\text{IF (THIS_IMAGE() == 5) THEN} \\
\quad \text{READ} (*,*) \ W \\
\quad \text{DO I = 6, NUM_IMAGES()} \\
\quad \quad \text{W[I] = W} \\
\quad \text{END DO} \\
\text{END IF} \\
\end{align*}
\]

**See Also**

Image Control Statements
Coarrays
Using Coarrays

SYNC IMAGES

**Statement:** Performs a synchronization of the image with each of the other images in the image set. It takes the following form:

**Syntax**

\[
\text{SYNC IMAGES} (\text{image-set}[, \text{STAT} = \text{stat-var}[[, \text{ERRMSG} = \text{err-var}])}
\]
**image-set**

Is an integer expression or *. If it is an integer expression, it must be scalar or of rank one. If it is an array expression, the value of each element must be positive and not greater than the number of images; there must be no repeated values.

If it is a scalar expression, the value must be positive and not greater than the number of images.

If * is specified, it indicates all images.

**stat-var**

Is a scalar integer variable in which the status of the synchronization is stored.

**err-var**

Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC IMAGES statement.

**Description**

When SYNC IMAGES statements are executed on images C and G, they correspond if the number of times image C has executed a SYNC IMAGES statement with G in its image set is the same as the number of times image G has executed a SYNC IMAGES statement with C in its image set. The segments that executed before the SYNC IMAGES statement on either image, precede the segments that execute after the corresponding SYNC IMAGES statement on the other image.

In a program that uses SYNC ALL as its only synchronization mechanism, every SYNC ALL statement can be replaced by a SYNC IMAGES (*) statement. However, SYNC ALL may provide better performance. SYNC IMAGES statements are not required to specify the entire image set, or even the same image set, on all images that participate in the synchronization.

**Example**

In the following example, image 5 waits for each of the other images to complete using the data. The other images wait for image 5 to set up the data, but do not wait for any other image:

```fortran
IF (THIS_IMAGE() == 5) then
    SYNC IMAGES(*)       ! Sets up coarray data for other images
ELSE
    SYNC IMAGES(5)       ! Other images use the data set up by image 5
END IF
```

In the following example, each image synchronizes with its neighbor:

```fortran
INTEGER :: THIS_STEP, TOTAL_STEPS, TOTAL_IMAGES, MY_IMAGE
MY_IMAGE = THIS_IMAGE ()
TOTAL_IMAGES = NUM_IMAGES ()
    ! Set up calculation
SYNC ALL
DO THIS_STEP = 1, TOTAL_STEPS
    IF (MY_IMAGE > 1) SYNC IMAGES (MY_IMAGE - 1)    ! Do the calculations
    IF (MY_IMAGE < TOTAL_IMAGES) SYNC IMAGES (MY_IMAGE + 1)
END DO
SYNC ALL
```

The calculation starts on image 1 since all the others will be waiting on SYNC IMAGES (TOTAL_IMAGES-1). When this is done, image 2 starts and image 1 performs its second calculation. This continues until they are all executing different steps at the same time. Eventually, image 1 finishes and then the others finish one by one.
SYNC MEMORY

Statement: Ends one image segment and begins another. Each segment can then be ordered in some way with respect to segments on other images. It takes the following form:

Syntax

SYNC MEMORY (((STAT=stat-var][, ERRMSG=err-var]))

stat-var Is a scalar integer variable in which the status of the synchronization is stored.

err-var Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC IMAGES statement.

Description

Unlike the other image control statements, this statement does not have any built-in synchronization effect.

The action regarding X on image Q precedes the action regarding Y on image Q if, by execution of statements on image P, the following is true:

- A variable X on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement
- That statement precedes a successful execution of a SYNC MEMORY statement
- A variable Y on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement that succeeds execution of that SYNC MEMORY statement,

User-defined ordering of segment Pi on image P to precede segment Qj on image Q occurs when the following happens:

- Image P executes an image control statement that ends segment Pi, and then executes statements that initiate a cooperative synchronization between images P and Q
- Image Q executes statements that complete the cooperative synchronization between images P and Q and then executes an image control statement that begins segment Qj

Execution of the cooperative synchronization between images P and Q must include a dependency that forces execution on image P of the statements that initiate the synchronization to precede the execution on image Q of the statements that complete the synchronization. The mechanisms available for creating such a dependency are processor dependent.

NOTE

SYNC MEMORY usually suppresses compiler optimizations that may reorder memory operations across the segment boundary defined by the SYNC MEMORY statement. It ensures that all memory operations initiated in the preceding segments in its image complete before any memory operations in the subsequent segment in its image are started.
Example
The following example should be run on two images:

```fortran
use, intrinsic :: iso_fortran_env
logical (atomic_logical_kind), save :: locked[*] = .true.
logical val
integer :: iam

iam = this_image()

if (iam == 1) then
  sync memory
  call atomic_define(locked[2], .false.)
else if (iam == 2) then
  val = .true.
  do while (val)
    call atomic_ref(val, locked)
  end do
  sync memory
end if

print *, 'success'
end
```

SYSTEM
*Portability Function*: Sends a command to the shell as if it had been typed at the command line.

Module
USE IFPORT

Syntax

```
result = SYSTEM (string)
```

string (Input) Character*(*). Operating system command.

Results
The result type is INTEGER(4). The result is the exit status of the shell command. If -1, use IERRNO to retrieve the error. Errors can be one of the following:

- E2BIG: The argument list is too long.
- ENOENT: The command interpreter cannot be found.
- ENOEXEC: The command interpreter file has an invalid format and is not executable.
- ENOMEM: Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.
The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Example

```
USE IFPORT
INTEGER(4) I, errnum
I = SYSTEM("dir > file.lst")
If (I .eq. -1) then
   errnum = ierrno()
   print *, 'Error ', errnum
end if
END
```

SYSTEMQQ

SYSTEM_CLOCK

*Intrinsic Subroutine:* Returns integer data from a real-time clock. SYSTEM_CLOCK returns the number of seconds from 00:00 Coordinated Universal Time (CUT) on 1 JAN 1970. The number is returned with no bias. To get the elapsed time, you must call SYSTEM_CLOCK twice, and subtract the starting time value from the ending time value.

Syntax

```
CALL SYSTEM_CLOCK ([count] [, count_rate] [, count_max])
```

- **count**
  (Output; optional) Must be scalar and of type integer. It is set to a value based on the current value of the processor clock. The value is increased by one for each clock count until the value `count_max` is reached, and is reset to zero at the next count. (`count` lies in the range 0 to `count_max`.)

- **count_rate**
  (Output; optional) Must be scalar and of type integer or real. It is set to the number of processor clock counts per second.
  - If the type is `INTEGER(2)`, `count_rate` is 1000. If the type is `INTEGER(4)`, `count_rate` is 10000. If the type is `INTEGER(8)`, `count_rate` is 1000000.

- **count_max**
  (Output; optional) Must be scalar and of type integer. It is set to the maximum value that `count` can have, HUGE(0).

All integer arguments used must have the same integer kind parameter. If the type is `INTEGER(1)`, `count`, `count_rate`, and `count_max` are all zero, indicating that there is no clock available to Intel® Fortran with an 8-bit range.

Example

Consider the following:

```
integer(2) :: ic2, crate2, cmax2
integer(4) :: ic4, crate4, cmax4
call system_clock(count=ic2, count_rate=crate2, count_max=cmax2)
call system_clock(count=ic4, count_rate=crate4, count_max=cmax4)
print *, ic2, crate2, cmax2
print *, ic4, crate4, cmax4
end
```
SYSTEMQQ

**Portability Function**: Executes a system command by passing a command string to the operating system's command interpreter.

**Module**

USE IFPORT

**Syntax**

\[
result = \text{SYSTEMQQ}(\text{commandline})
\]

**commandline** (Input) Character*. Command to be passed to the operating system.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- **ERR$2BIG** - The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
- **ERR$NOINT** - The command interpreter cannot be found.
- **ERR$NOEXEC** - The command interpreter file has an invalid format and is not executable.
- **ERR$NOMEM** - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

The command line character limit for the SYSTEMQQ function is the same limit that your operating system command interpreter accepts.

**Example**

USE IFPORT

LOGICAL(4) result
result = SYSTEMQQ('copy c:\bin\fmath.dat &
c:\dat\fmath2.dat')

SYSTEM
**TAN**

*Elemental Intrinsic Function (Generic):* Produces the tangent of an argument.

**Syntax**

```
result = TAN (x)
```

**x**

(Input) Must be of type real or complex. If x is of type real, it must be in radians and is treated as modulo 2 * pi.

If x is of type complex, its real part is regarded as a value in radians.

**Results**

The result type and kind is the same as x.

<table>
<thead>

<tr>
<td>CDTAN&lt;sup&gt;2&lt;/sup&gt;</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQTAN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

<sup>1</sup>The setting of compiler options specifying real size can affect CTAN.

<sup>2</sup>This function can also be specified as ZTAN.

**Example**

TAN (2.0) has the value -2.185040.
TAN (0.8) has the value 1.029639.

**TAND**

*Elemental Intrinsic Function (Generic):* Produces the tangent of an argument.

**Syntax**

```
result = TAND (x)
```

**x**

(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind is the same as x.
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<tr>
<td>DTAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QTAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

TAND (2.0) has the value 3.4920771E-02.
TAND (0.8) has the value 1.3963542E-02.

**TANH**

*Elemental Intrinsic Function (Generic):* Produces a hyperbolic tangent.

**Syntax**

```fortran
result = TANH (x)
```

- `x` (Input) Must be of type real.

**Results**

The result type and kind is the same as `x`.

<table>
<thead>
<tr>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

TANH (2.0) has the value 0.9640276.
TANH (0.8) has the value 0.6640368.

**TARGET DATA**

*OpenMP* Fortran Compiler Directive: Creates a device data environment for the extent of the region. This directive only applies to Intel® MIC Architecture.

**Syntax**

```fortran
!$OMP TARGET DATA [clause[, clause]...] 
  block
!$OMP END TARGET DATA 
```

- `clause` Is one or more of the following:
  - `DEVICE (integer-expression)`
  - `IF (expression)`
  - `MAP ([map-type: ] list)`
block

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding task region for a TARGET DATA construct is the encountering task. The target region binds to the enclosing parallel or task region.

When a TARGET DATA construct is encountered, a new device data environment is created, and the encountering task executes the target data region.

A program must not depend on any ordering of the evaluations of the clauses of the TARGET DATA directive, or on any side effects of the evaluations of the clauses.

TARGET Directive

OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. This directive only applies to Intel® MIC Architecture.

Syntax

```fortran
!$OMP TARGET [clause[,] clause]... 
  block
$OMP END TARGET
```

clause

Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF (expression)
- MAP ([map-type: ] list)
- NOWAIT

block

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding task for a TARGET construct is the encountering task. The target region binds to the enclosing parallel or task region.

This construct provides a superset of the functionality provided by the TARGET DATA construct.

The TARGET construct also specifies that the region is executed by a device. The encountering task waits for the device to complete the target region at the end of the construct.

If a TARGET, TARGET DATA, or TARGET UPDATE construct appears within a target region, the construct is ignored.

See Also
OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
TARGET DATA
TARGET UPDATE
TARGET Statement

Statement and Attribute: Specifies that an object can become the target of a pointer (it can be pointed to).

Syntax

The TARGET attribute can be specified in a type declaration statement or a TARGET statement, and takes one of the following forms:

Type Declaration Statement:

type, [att-ls,] TARGET [, att-ls] :: object [(a-spec)] [[coarray-spec]] [, object[(a-spec)] [[coarray-spec]]]...

Statement:

TARGET [:] object [(a-spec)] [[coarray-spec]] [, object[(a-spec)] [[coarray-spec]]]...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

object Is the name of the object. The object must not be declared with the PARAMETER attribute.

a-spec (Optional) Is an array specification or a coarray specification.

cooparray-spec (Optional) Is a deferred-coshape specification. The left bracket and right bracket are required.

Description

A pointer is associated with a target by pointer assignment or by an ALLOCATE statement.

If an object does not have the TARGET attribute or has not been allocated (using an ALLOCATE statement), no part of it can be accessed by a pointer.

Example

The following example shows type declaration statements specifying the TARGET attribute:

```fortran
TYPE(SYSTEM), TARGET :: FIRST
REAL, DIMENSION(20, 20), TARGET :: C, D
```

The following is an example of a TARGET statement:

```fortran
TARGET :: C(50, 50), D
```

The following fragment is from the program POINTER2.F90 in the <install-dir>/samples subdirectory:

```fortran
! An example of pointer assignment.
REAL, POINTER :: arrow1 (:)
REAL, POINTER :: arrow2 (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:)
ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye
```

TARGET ENTER DATA
OpenMP* Fortran Compiler Directive: Specifies that variables are mapped to a device data environment. This directive only applies to Intel® MIC Architecture.

Syntax
!$OMP TARGET ENTER DATA [clause[[], clause]... ]

clause Is one or more of the following:
• DEPEND (dependence-type : list)
• DEVICE (integer-expression)
• IF (expression)
• MAP ([map-type: ] list)
• NOWAIT

The binding task for the TARGET ENTER DATA construct is the encountering task. TARGET ENTER DATA is a stand-alone directive.

When a TARGET ENTER DATA construct is encountered, the list items in the MAP clauses are mapped to the device data environment according to map-type. A map-type must be specified in all MAP clauses and must be either TO or ALLOC.

The TARGET ENTER DATA construct executes as if it was enclosed in a TASK construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit TASK construct that encloses the TARGET ENTER DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause expression evaluates to .FALSE., the device is the host.

Syntax Rules for Compiler Directives
TARGET EXIT DATA
Parallel Processing Model for information about Binding Sets
**TARGET EXIT DATA**

*OpenMP* Fortran Compiler Directive: Specifies that variables are unmapped from a device data environment. This directive only applies to Intel® MIC Architecture.

**Syntax**

```
!$OMP TARGET EXIT DATA [clause[, clause]... ]
```

*clause* Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF (expression)
- MAP ([map-type: ] list)
- NOWAIT

The binding task for the TARGET EXIT DATA construct is the encountering task. TARGET EXIT DATA is a stand-alone directive.

When a TARGET EXIT DATA construct is encountered, the *list* items in the MAP clauses are unmapped from the device data environment according to *map-type*. A *map-type* must be specified in all MAP clauses and must be FROM.

The TARGET EXIT DATA construct executes as if it was enclosed in a task construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit task construct that encloses the TARGET EXIT DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause *expression* evaluates to .FALSE., the device is the host.
