*OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies to Intel® MIC Architecture.

**Syntax**

```
!$OMP TARGET TEAMS [clause[, clause]... ]
```

*block*

```
!$OMP END TARGET TEAMS
```

*clause* Can be any of the clauses accepted by the TARGET or TEAMS directives with identical meanings and restrictions.
block

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a TEAMS construct.

See Also
OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

TARGET TEAMS DISTRIBUTE

OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

Syntax

```fortran
!$OMP TARGET TEAMS DISTRIBUTE [clause[, clause]... ]
   do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE]
```

clause

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE construct.

If the END TARGET TEAMS DISTRIBUTE directive is not specified, an END TARGET TEAMS DISTRIBUTE directive is assumed at the end of do-loop.

See Also
OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

TARGET TEAMS DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that
are members of multiple teams created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.

Syntax

```fortran
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO [clause[, clause]... ]
    do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE PARALLEL DO]
```

**clause**

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE PARALLEL DO directives with identical meanings and restrictions.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE PARALLEL DO construct.

If the END TARGET TEAMS DISTRIBUTE PARALLEL DO directive is not specified, an END TARGET TEAMS DISTRIBUTE PARALLEL DO directive is assumed at the end of **do-loop**.

See Also

Syntax Rules for Compiler Directives

**TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD**

OpenMP* Fortran Compiler Directive: Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

Syntax

```fortran
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD [clause[, clause]... ]
    do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD]
```

**clause**

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE PARALLEL DO SIMD directives with identical meanings and restrictions.
do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE PARALLEL DO SIMD construct.

If the END TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of do-loop.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

TARGET TEAMS DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.

Syntax

!$OMP TARGET TEAMS DISTRIBUTE SIMD [clause[[,] clause]... ]

do-loop

[!$OMP END TARGET TEAMS DISTRIBUTE SIMD]

clause

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE SIMD directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct containing a TEAMS DISTRIBUTE SIMD construct.

If the END TARGET TEAMS DISTRIBUTE SIMD directive is not specified, an END TARGET TEAMS DISTRIBUTE SIMD directive is assumed at the end of do-loop.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

TARGET UPDATE

OpenMP* Fortran Compiler Directive: Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies to Intel® MIC Architecture.

Syntax

!$OMP TARGET UPDATE motion-clause [, clause[[], clause]...] 

motion-clause

Is one of the following:

• FROM (list)
• TO (list)

The list is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /).

For each list item in a TO or FROM clause, there is a corresponding list item and an original list item; for more information, see the MAP clause. Note that if the corresponding list item is not present in the device data environment, the behavior is unspecified.

For each list item in a TO clause, the value of the original list item is assigned to the corresponding list item.

For each list item in a FROM clause, the value of the corresponding list item is assigned to the original list item.

A list item may only appear in a TO or FROM clause, but not both.

clause

Is one of the following:

• DEPEND (dependence-type : list)
• DEVICE (integer-expression)
• IF (expression)
• NOWAIT

The binding task for a TARGET UPDATE construct is the encountering task. The TARGET UPDATE directive is a stand-alone directive.

A TARGET UPDATE construct must not appear inside of a target region.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
TARGET Directive
TARGET DATA
Parallel Processing Model for information about Binding Sets

TASK

OpenMP* Fortran Compiler Directive: Defines a task region.
Syntax

```
!$OMP TASK [clause[, clause] ... ]

block

!$OMP END TASK
```

clause

Is one of the following:

- **DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)**
- **DEPEND (dependence-type : list)**
- **FINAL (scalar-logical-expression)**

When the `scalar-logical-expression` evaluates to `.TRUE.`, it specifies that the generated task will be a final task. All task constructs encountered during execution of a final task will generate included tasks.

Note that if a variable is used in a final clause expression of a task construct, it causes an implicit reference to the variable in all enclosing constructs.

Only a single FINAL clause can appear in the directive.

- **FIRSTPRIVATE (list)**
- **IF (expression)**
- **MERGEABLE**

When the generated task is an undeferred task or an included task, it specifies that the implementation may generate a merged task instead.

- **PRIVATE (list)**
- **SHARED (list)**
- **UNTIED**

Specifies the task is never tied to the thread that started its execution. Any thread in the team can resume the task region after a suspension. For example, during runtime, the compiler can start the execution of a given task on thread A, break execution and later resume it on thread B.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The binding thread set of a TASK construct is the current team. A task region binds to the innermost enclosing parallel region.

The TASK and END TASK directive pair must appear in the same routine in the executable section of the code.

The END TASK directive denotes the end of the task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The encountering thread may immediately execute the task, or defer its execution. In the latter case, any thread in the team may be assigned the task.

A thread that encounters a task scheduling point within the task region may temporarily suspend the task region. By default, a task is then tied and its suspended task region can only be resumed by the thread that started its execution. However, if the untied clause is specified in a TASK construct, any thread in the team can resume the task region after a suspension. The untied clause is ignored in these cases:

- If a final clause has been specified in the same TASK construct and the final clause expression evaluates to `.TRUE.`.
- If a task is an included task.
A TASK construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

The TASK construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion. An implementation may add task scheduling points anywhere in untied task regions.

Note that when storage is shared by an explicit task region, you must add proper synchronization to ensure that the storage does not reach the end of its lifetime before the explicit task region completes its execution.

A program must not depend on any ordering of the evaluations of the clauses of the TASK directive and it must not depend on any side effects of the evaluations of the clauses. A program that branches into or out of a task region is non-conforming.

Unsynchronized use of Fortran I/O statements by multiple tasks on the same unit has unspecified behavior.

Example

The following example calculates a Fibonacci number. The Fibonacci sequence is 1,1,2,3,5,8,13, etc., where the current number is the sum of the previous two numbers. If a call to function fib is encountered by a single thread in a parallel region, a nested task region will be spawned to carry out the computation in parallel.

```fortran
RECURSIVE INTEGER FUNCTION fib(n)
INTEGER n, i, j
IF ( n .LT. 2) THEN
  fib = n
ELSE
  !$OMP TASK SHARED(i)
  i = fib( n-1 )
  !$OMP END TASK
  !$OMP TASK SHARED(j)
  j = fib( n-2 )
  !$OMP END TASK
  !$OMP TASKWAIT      ! wait for the sub-tasks to complete before summing
  fib = i+j
END IF
END FUNCTION
```

The following example generates a large number of tasks in one thread and executes them with the threads in the parallel team. While generating these tasks, if the implementation reaches the limit generating unassigned tasks, the generating loop may be suspended and the thread used to execute unassigned tasks. When the number of unassigned tasks is sufficiently low, the thread resumes execution of the task generating loop.

```fortran
real*8 item(10000000)
integer i
!$omp parallel
!$omp single     ! loop iteration variable i is private
  do i=1,10000000
    !$omp task
    ! i is firstprivate, item is shared
    call process(item(i))
    !$omp end task
    end do
!$omp end single
!$omp end parallel
end
```
The following example modifies the previous one to use an untied task to generate the unassigned tasks. If the implementation reaches the limit generating unassigned tasks and the generating loop is suspended, any other thread that becomes available can resume the task generation loop.

```fortran
real*8 item(10000000)
!$omp parallel
!$omp single!
$omp task untied
! loop iteration variable i is private
   do i=1,10000000
   !$omp task ! i is firstprivate, item is shared
      call process(item(i))
   !$omp end task
   end do
!$omp end task
!$omp end single
!$omp end parallel
```

The following example demonstrates four tasks with dependences:

```fortran
integer :: a

!$omp task depend(out:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(out:a)
!$omp end task
```

In the above example, the first task does not depend on any previous one. The second and third tasks depend on the first task but not on each other. The last task depends on the second and third tasks. The following shows the dependency graph:
The following example shows a set of sibling tasks that have dependences between them:

```fortran
INTEGER :: A(0:N*B-1)

DO I=0,N-1
   !$OMP TASK DEPEND(OUT:A(I*B:(I+1)*B-1))
   CALL FILL(A(I*B:(I+1)*B-1))
   !$OMP END TASK
END DO

DO I=1,N-1
   IB = (I-1)*B+1
   BB = I*B+1
   !$OMP TASK DEPEND(INOUT:A(I*B:(I+1)*B-1)) DEPEND(IN:A((I+1)*B:(I+2)*B-1))
   CALL PROCESS(A(I*B:(I+1)*B-1), A((I+1)*B:(I+2)*B-1))
   !$OMP END TASK
END DO

DO I=1,N
   IB = (I-1)*B+1
   !$OMP TASK DEPEND(IN:A(I*B:(I+1)*B-1))
   CALL OUTPUT(A(I*B:(I+1)*B-1))
   !$OMP END TASK
END DO
```

In the above example, the tasks of the first loop will be independent of any other tasks since there is no previous task that expresses a dependence on the same list items. Tasks of the second loop will depend on two tasks from the first loop. Also, because dependences are constructed in a sequential order, the IN
dependences force the tasks of the second loop to be dependent on the task from the previous iteration to be processed. Finally, tasks of the third loop can be executed when the corresponding Process task from the second loop has been executed. For example, if N was 4, the following shows the dependency graph:

- TASKYIELD
- SHARED Clause
- Parallel Processing Model for information about Binding Sets
TASKGROUP

OpenMP* Fortran Compiler Directive: Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

Syntax

```fortran
!$OMP TASKGROUP
   block
!$OMP END TASKGROUP
```

`block` is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

A TASKGROUP construct binds to the current task region. The binding thread set of the taskgroup region is the current team.

When a thread encounters a TASKGROUP construct, it starts executing the region. There is an implicit task scheduling point at the end of the TASKGROUP region. The current task is suspended at the task scheduling point until all child tasks that it generated in the TASKGROUP region and all of their descendant tasks complete execution.

Syntax Rules for Compiler Directives
TASK
TASKWAIT
TASKYIELD
Parallel Processing Model for information about Binding Sets

TASKWAIT

OpenMP* Fortran Compiler Directive: Specifies a wait on the completion of child tasks generated since the beginning of the current task.

Syntax

```fortran
!$OMP TASKWAIT
```

A TASKWAIT construct binds to the current task region. The binding thread set of the taskwait region is the current team.

The TASKWAIT region includes an implicit task scheduling point in the current task region. The current task region is suspended at the task scheduling point until execution of all its child tasks generated before the TASKWAIT region are completed.

See Also

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
TASK
TASKYIELD
Parallel Processing Model for information about Binding Sets
**TASKYIELD**

*OpenMP* Fortran Compiler Directive: Specifies that the current task can be suspended at this point in favor of execution of a different task.

**Syntax**

```
$OMP TASKYIELD
```

A taskyield region binds to the current task region. The binding thread set of the taskyield region is the current team.

Because the TASKYIELD construct is a stand-alone directive, there are some restrictions on its placement within a program:

- The TASKYIELD directive can only be placed at a point where a Fortran executable statement is allowed.
- The TASKYIELD directive cannot be used as the action statement in an IF statement or as the executable statement following a label if the label is referenced in the program.

The TASKYIELD construct includes an explicit task scheduling point in the current task region.

**Example**

The following example shows use of the TASKYIELD directive. It is non-conforming, because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are stand-alone directives and cannot be the action statement of an IF statement or a labeled branch target.

```fortran
SUBROUTINE NONCONFORMING_STANDALONE()
    INTEGER A
    A = 1
    ! the FLUSH directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP FLUSH(A)

    ! the BARRIER directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP BARRIER

    ! the TASKWAIT directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP TASKWAIT

    ! the TASKYIELD directive must not be the action statement in an IF statement
    !
    IF (A .NE. 0) !$OMP TASKYIELD

    GOTO 100

    ! the FLUSH directive must not be a labeled branch target statement
    !
    100 !$OMP FLUSH(A)
    GOTO 200

    ! the BARRIER directive must not be a labeled branch target statement
    !
    200 !$OMP BARRIER
    GOTO 300

    ! the TASKWAIT directive must not be a labeled branch target statement
    !
    300 !$OMP TASKWAIT
    GOTO 400
```

Intel® Fortran Compiler 16.0 User and Reference Guide

2004
! the TASKYIELD directive must not be a labeled branch target statement

END SUBROUTINE

The following version of the above example is conforming because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are enclosed in a compound statement.

SUBROUTINE CONFORMING_STANDALONE ()
  INTEGER N
  N = 1
  IF (N .NE. 0) THEN
    !$OMP FLUSH(N)
  ENDIF
  IF (N .NE. 0) THEN
    !$OMP BARRIER
  ENDIF
  IF (N .NE. 0) THEN
    !$OMP TASKWAIT
  ENDIF
  IF (N .NE. 0) THEN
    !$OMP TASKYIELD
  ENDIF
  GOTO 100
  100 CONTINUE
  !$OMP FLUSH(N)
  GOTO 200
  200 CONTINUE
  !$OMP BARRIER
  GOTO 300
  300 CONTINUE
  !$OMP TASKWAIT
  GOTO 400
  400 CONTINUE
  !$OMP TASKYIELD
END SUBROUTINE

TEAMS

OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team.

Syntax

!$OMP TEAMS [clause[, clause]... ]
  block
!$OMP END TEAMS

clause

Is one of the following:

- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
• **FIRSTPRIVATE (list)**

• **NUM_TEAMS** *(scalar-integer-expression)*

  Specifies the number of teams to be used in a parallel region. The *scalar-integer-expression* must evaluate to a positive scalar integer value.

  Only a single NUM_TEAMS clause can appear in the directive.

• **PRIVATE (list)**

• **REDUCTION** *(operator : list)*

• **SHARED (list)**

• **THREAD_LIMIT** *(scalar-integer-expression)*

  Specifies the maximum number of threads participating in the contention group that each team initiates. The *scalar-integer-expression* must evaluate to a positive scalar integer value.

  At most one THREAD_LIMIT clause can appear in the directive.

*block*  

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The binding thread set for a TEAMS construct is the encountering thread.

The TEAMS construct must appear within a TARGET construct. The enclosing TARGET construct must contain no other statements or directives outside of the TEAMS construct. The following are the only OpenMP* constructs that can be nested in the team's region:

- **DISTRIBUTE**
- **PARALLEL**
- **PARALLEL SECTIONS**
- **PARALLEL WORKSHARE**
- **PARALLEL DO**
- **PARALLEL DO SIMD**

The thread that encounters this directive constructs a league of thread teams that execute the *block* in the master thread of each team. After the teams are created, the number of teams remains constant for the duration of the team's parallel region.

The region following the TEAMS construct is executed by the master thread of each team. Other threads do not begin execution until the master thread encounters a parallel region. After the teams complete execution of the TEAMS construct region, the encountering thread resumes execution of the enclosing target region.

If NUM_TEAMS is not specified, the default number of teams is one. If THREAD_LIMIT is not specified, the default number of threads is *the-number-of-available-hardware-threads / NUM_TEAMS*.

A program must not depend on any side effects or any ordering of the evaluation of clauses in the TEAMS directive.

Each team has a unique team number. You can use the OpenMP* run-time library routine OMP_GET_TEAM_NUM to get the team number of the calling thread.

Each thread within the team has a unique thread identifier returned by the OpenMP run-time library routine OMP_GET_THREAD_NUM. As in any thread team, the thread identifier starts at zero for the master thread up to THREAD_LIMIT - 1 for the remaining threads.

Immediately after this directive, only the master threads in each team are executing, the other team members will only start to execute at the next (nested) parallel region. Therefore, there are only NUM_TEAMS threads executing, and each of them has OMP_GET_THREAD_NUM() == 0.

**See Also**

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

**TEAMS DISTRIBUTE**

*OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.

**Syntax**

```
!$OMP TEAMS DISTRIBUTE [clause[ [, clause] ... ]
   do-loop
   (!$OMP END TEAMS DISTRIBUTE]
```

*clause* Can be any of the clauses accepted by the TEAMS or DISTRIBUTE directives with identical meanings and restrictions.

*do-loop* Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct containing a DISTRIBUTE construct.

If the END TEAMS DISTRIBUTE directive is not specified, an END TEAMS DISTRIBUTE directive is assumed at the end of *do-loop*.

**See Also**

*OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

**TEAMS DISTRIBUTE PARALLEL DO**

*OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

**Syntax**

```
!$OMP TEAMS DISTRIBUTE PARALLEL DO [clause[ [, clause] ... ]
   do-loop
   (!$OMP END TEAMS DISTRIBUTE PARALLEL DO]
```

*clause* Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO directives with identical meanings and restrictions.
**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO construct. Some clauses are permitted on both constructs.

If the END TEAMS DISTRIBUTE PARALLEL DO directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO directive is assumed at the end of do-loop.

**See Also**
- OpenMP* Fortran Compiler Directives
- Syntax Rules for Compiler Directives

**TEAMS DISTRIBUTE PARALLEL DO SIMD**

*OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.

**Syntax**

```fortran
!$OMP TEAMS DISTRIBUTE PARALLEL DO SIMD [clause[,] clause]... ]
   do-loop
   [!$OMP END TEAMS DISTRIBUTE PARALLEL DO SIMD]
```

**clause**

Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO SIMD directives with identical meanings and restrictions.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO SIMD construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately.
If the END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of do-loop.

See Also

Syntax Rules for Compiler Directives

TEAMS DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams region. The loop will be executed concurrently using SIMD instructions.

Syntax

\[
!$\text{OMP TEAMS DISTRIBUTE SIMD [clause[, clause]... ]}
\]

\[
do-loop
\]

[$!$\text{OMP END TEAMS DISTRIBUTE SIMD}]

clause
Can be any of the clauses accepted by the TEAMS or DISTRIBUTE SIMD directives with identical meanings and restrictions.

do-loop
Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE SIMD construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately.

If the END TEAMS DISTRIBUTE SIMD directive is not specified, an END TEAMS DISTRIBUTE SIMD directive is assumed at the end of \textit{do-loop}.

OpenMP* Fortran Compiler Directives
Syntax Rules for Compiler Directives

THIS_IMAGE

Transformational Intrinsic Function (Generic):
Returns cosubscripts for the image.

Syntax

\[
\text{result} = \text{THIS_IMAGE ([coarray [, dim]])}
\]

coarray
(Input; optional) Must be a coarray; it can be of any type. If it is allocatable, it must be allocated.
(Input; optional) Must be a default integer scalar. Its value must be in the range \(1 \leq \text{dim} \leq n\), where \(n\) is the corank of \(\text{coarray}\). The corresponding actual argument must not be an optional dummy argument.

**Results**

The result type is default integer. It is scalar if \(\text{coarray}\) does not appear or \(\text{dim}\) is present; otherwise, the result has rank one and its size is equal to the corank of \(\text{coarray}\).

The result depends on which arguments are specified:

- If no argument is specified, as in \(\text{THIS\_IMAGE}()\), the result is a scalar with a value equal to the index of the invoking image.
- If only \(\text{coarray}\) is specified, the result is the sequence of cosubscript values for \(\text{coarray}\) that would specify the invoking image.
- If \(\text{coarray}\) and \(\text{dim}\) are specified, the result is the value of cosubscript \(\text{dim}\) in the sequence of cosubscript values for \(\text{coarray}\) that would specify the invoking image.

**Example**

Consider that \(\text{coarray} \ C\) is declared by the following statement:

```fortran
REAL C(5, 10) [10, 0:9, 0:*]
```

On image 5, \(\text{THIS\_IMAGE}()\) has the value 5 and \(\text{THIS\_IMAGE}(\ C)\) has the value [5, 0, 0]. For the same \(\text{coarray}\) on image 213, \(\text{THIS\_IMAGE}(\ C)\) has the value [3, 1, 2].

In the following example, image 1 is used to read data. The other images then copy the data:

```fortran
IF (\(\text{THIS\_IMAGE}()==1\)) READ (*,*) P
SYNC ALL
P = P[1]
```

**THREADPRIVATE**

*OpenMP* Fortran Compiler Directive: Specifies named common blocks to be private (local) to each thread; they are global within the thread.

**Syntax**

```fortran
!$OMP THREADPRIVATE (/ cb/ [/, cb/]...)
```

- **cb**
  - Is the name of the common block you want made private to a thread. Only named common blocks can be made thread private. Note that the slashes ( / ) are required.

Each thread gets its own copy of the common block, so data written to the common block by one thread is not directly visible to other threads.

During serial portions and MASTER sections of the program, accesses are to the master thread copy of the common block. On entry to the first parallel region, data in the THREADPRIVATE common blocks should be assumed to be undefined unless a COPYIN clause is specified in the PARALLEL directive.

When a common block (which is initialized using DATA statements) appears in a THREADPRIVATE directive, each thread copy is initialized once prior to its first use. For subsequent parallel regions, data in THREADPRIVATE common blocks are guaranteed to persist only if the dynamic threads mechanism has been disabled and if the number of threads are the same for all the parallel regions.

A THREADPRIVATE common block or its constituent variables can appear only in a COPYIN clause. They are not permitted in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, SHARED, or REDUCTION clause. They are not affected by the DEFAULT clause.
NOTE
On Windows* OS, if you specify option /Qopenmp-threadprivate:compat, the compiler does not generate threadsafe code for common blocks in an !$OMP THREADPRIVATE directive unless at least one element in the common block is explicitly initialized. For more information, see the article titled: /Qopenmp-threadprivate:compat doesn't work with uninitialized threadprivate common blocks, which is located in http://intel.ly/1aHhsjc

Example
In the following example, the common blocks BLK1 and FIELDS are specified as thread private:

```fortran
COMMON /BLK/ SCRATCH
COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
!$OMP THREADPRIVATE(/BLK/,/FIELDS/)
!$OMP PARALLEL DEFAULT(PRIVATE) COPYIN(/BLK1/,ZFIELD)
```

TIME Intrinsic Procedure

**Intrinsic Subroutine (Generic):** Returns the current time as set within the system. TIME can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL TIME (buf)
```

*buf* (Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least eight bytes of storage.

The date is returned as a 8-byte ASCII character string taking the form hh:mm:ss, where:

- **hh** is the 2-digit hour
- **mm** is the 2-digit minute
- **ss** is the 2-digit second

If *buf* is of numeric type and smaller than 8 bytes, data corruption can occur.

If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 8 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

**Example**

```fortran
CHARACTER*1 HOUR(8)
...
CALL TIME (HOUR)
```

The length of the first array element in CHARACTER array HOUR is passed to the TIME subroutine. The subroutine then truncates the time to fit into the 1-character element, producing an incorrect result.
TIME Portability Routine

Portability Function or Subroutine: The function returns the system time, in seconds, since 00:00:00 Greenwich mean time, January 1, 1970. TIME can be used as a portability function or subroutine, or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

Function Syntax:
result = TIME( )

Subroutine Syntax:
CALL TIME (timestr)

(timestr) Character(*)(4). Is the current time, based on a 24-hour clock, in the form hh:mm:ss, where hh, mm, and ss are two-digit representations of the current hour, minutes past the hour, and seconds past the minute, respectively.

Results

The result type is INTEGER(4). The result value is the number of seconds that have elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

The subroutine fills a parameter with the current time as a string in the format hh:mm:ss.

The value returned by this routine can be used as input to other portability date and time functions.

Example

USE IFPORT
INTEGER(4) int_time
character*8 char_time
int_time = TIME( )
call TIME(char_time)
print *, 'Integer: ', int_time, 'time: ', char_time
END

See Also

DATE_AND_TIME
TIME Portability Routine

TIMEF

Portability Function: Returns the number of seconds since the first time it is called, or zero.

Module

USE IFPORT
Syntax

\[
\text{result} = \text{TIMEF}( )
\]

Results

The result type is REAL(8). The result value is the number of seconds that have elapsed since the first time \( \text{TIMEF} \) was called.

The first time it is called, \( \text{TIMEF} \) returns 0.

Example

```
USE IFPORT
INTEGER i, j
REAL(8) elapsed_time
elapsed_time = TIMEF( )
DO i = 1, 100000
   j = j + 1
END DO
elapsed_time = TIMEF( )
PRINT *, elapsed_time
END
```

Date and Time Intrinsic Subroutines

TINY

\textit{Inquiry Intrinsic Function (Generic): Returns the smallest number in the model representing the same type and kind parameters as the argument.}

Syntax

\[
\text{result} = \text{TINY}(x)
\]

\( x \)  
(Input) Must be of type real; it can be scalar or array valued.

Results

The result is a scalar with the same type and kind parameters as \( x \). The result has the value \( b_{e_{\text{min}}} - 1 \). Parameters \( b \) and \( e_{\text{min}} \) are defined in \textit{Model for Real Data}.

Example

If \( X \) is of type REAL(4), \( \text{TINY}(X) \) has the value \( 2^{-126} \).

The following shows another example:

```
REAL(8) r, result
r = 487923.3D0
result = TINY(r)  ! returns 2.225073858507201E-308
```

HUGE

Data Representation Models
TRACEBACKQQ

**Run-Time Subroutine:** Provides traceback information. Uses the Intel® Fortran run-time library traceback facility to generate a stack trace showing the program call stack as it appeared at the time of the call to TRACEBACKQQ().

**Module**

USE IFCORE

**Syntax**

CALL TRACEBACKQQ ([string] [,user_exit_code] [,status] [,eptr])

- **string** (Input; optional) CHARACTER*(*) . A message string to precede the traceback output. It is recommended that the string be no more than 80 characters (one line) since that length appears better on output. However, this limit is not a restriction and it is not enforced. The string is output exactly as specified; no formatting or interpretation is done.

  If this argument is omitted, no header message string is produced.

- **user_exit_code** (Input; optional) INTEGER(4). An exit code. Two values are predefined:
  - A value of -1 causes the run-time system to return execution to the caller after producing traceback.
  - A value of zero (the default) causes the application to abort execution.

  Any other specified value causes the application to abort execution and return the specified value to the operating system.

- **status** (Input; optional) INTEGER(4). A status value. If specified, the run-time system returns the status value to the caller indicating that the traceback process was successful. The default is not to return status.

  Note that a returned status value is only an indication that the "attempt" to trace the call stack was completed successfully, not that it produced a useful result.

  You can include the file iosdef.for in your program to obtain symbolic definitions for the possible return values. A return value of FOR $IOS_SUCCESS (0) indicates success.

- **eptr** (Input; optional) Integer pointer. It is required if calling from a user-specified exception filter. If omitted, the default in null.

  To trace the stack after an exception has occurred, the runtime support needs access to the exception information supplied to the filter by the operating system.

  The eptr argument is a pointer to a T_EXCEPTION_POINTERS structure, which is defined in ifcore.f90. This argument is optional and is usually omitted. On Windows systems, T_EXCEPTION_POINTERS is returned by the Windows* API GetExceptionInformation( ), which is usually passed to a C try/except filter function.

The TRACEBACKQQ routine provides a standard way for an application to initiate a stack trace. It can be used to report application detected errors, debugging, and so forth. It uses the stack trace support in the Intel Fortran run-time library, and produces the same output that the run-time library produces for unhandled errors and exceptions.
The error message string normally included by the run-time system is replaced with the user-supplied message text, or omitted if no string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the run-time system.

Example

In the most simple case, you can generate a stack trace by coding the call to TRACEBACKQQ with no arguments:

```
CALL TRACEBACKQQ()
```

This call causes the run-time library to generate a traceback report with no leading header message, from wherever the call site is, and terminate execution.

The following example generates a traceback report with no leading header message, from wherever the call site is, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ()
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ("My application message string")
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution, returning a status code of 123 to the operating system:

```
USE IFCORE
CALL TRACEBACKQQ(STRING="Bad value for TEMP",USER_EXIT_CODE=123)
```

Consider the following:

```
... USE IFCORE INTEGER(4) RTN_STS INCLUDE 'IOSDEF.FOR'
... CALL TRACEBACKQQ(USER_EXIT_CODE=-1,STATUS=RTN_STS)
IF (RTN_STS .EQ. FOR$IOS_SUCCESS) THEN
   PRINT *,"TRACEBACK WAS SUCCESSFUL"
END IF
...
```

This example generates a traceback report with no header string, and returns to the caller to continue execution of the application. If the traceback process succeeds, a status will be returned in variable RTN_STS.

You can specify arguments that generate a stack trace with the user-supplied string as the header and instead of terminating execution, return control to the caller to continue execution of the application. For example:

```
CALL TRACEBACKQQ(STRING="Done with pass 1",USER_EXIT_CODE=-1)
```

By specifying a user exit code of -1, control returns to the calling program. Specifying a user exit code with a positive value requests that specified value be returned to the operating system. The default value is 0, which causes the application to abort execution.

Windows* OS Example:
The following example demonstrates the use of the EPTR argument when calling from a user-defined exception filter function. The premise of the example is a Fortran DLL containing entry points protected by a C try/except construct, such as:

```c
__declspec(dllexport) void FPE_TEST_WRAPPER ()
{
    __try {
        /*
        ** call the Fortran code...
        */
        FPE_TEST();
    }
    __except ( CHECK_EXCEPTION_INFO ( GetExceptionInformation() ) )
    {
        /*
        ** noncontinuable exception handling here, if any.
        */
    }
}
```

The C function shown above is guarding against a floating-point divide-by-zero exception. This function calls the user-supplied FPE_TEST (not shown). The Fortran function CHECK_EXCEPTION_INFO shown below (called in the __except filter expression above) can use TRACEBACKQQ to get a stack trace as follows:

```fortran
INTEGER*4 FUNCTION CHECK_EXCEPTION_INFO ( ExceptionInfo )
!DIR$ ATTRIBUTES DLLEXPORT::CHECK_EXCEPTION_INFO
USE IFWINTY
!DIR$ ATTRIBUTES REFERENCE :: ExceptionInfo
TYPE(T_EXCEPTION_POINTERS) eptr
TYPE(T_EXCEPTION_RECORD) erecptr
TYPE(T_CONTEXT) ctxptr
POINTER(eptr,erecptr)
POINTER(ctxp,ctxptr)
INTEGER(4) EXIT_CODE,STS
CHARACTER(LEN=70) MYSTR
! Init the arguments to TRACEBACKQQ appropriately for your needs...
EXIT_CODE=-1
eptr = ExceptionInfo.ExceptionRecord
cctxp = ExceptionInfo.ContextRecord
IF ( erecptr.ExceptionCode .EQ. STATUS_FLOAT_DIVIDE_BY_ZERO ) THEN
    PRINT *, 'Saw floating divide by zero.'
    PRINT '(',a,8.8)', 'ContextRecord.FloatSave.StatusWord = ', &
    ctxptr.FloatSave.StatusWord
    MYSTR = "FLTDIV EXCEPTION IN MY APPLICATION"
    CALL TRACEBACKQQ(MYSTR,EXIT_CODE,STS, %LOC(ExceptionInfo))
END IF
.
.
CHECK_EXCEPTION_INFO = 1
END
```

To return a pointer to C run-time exception information pointers within a user-defined handler that was established with SIGNALQQ (or directly with the C signal function), you can call the GETEXCEPTIONPTRSQQ routine.

**See Also**

GETEXCEPTIONPTRSQQ (W*S)

**TRAILZ**

*Elemental Intrinsic Function (Specific): Returns the number of trailing zero bits in an integer.*
Syntax

result = TRAILZ (i)

i (Input) Must be of type integer or logical.

Results

The result type is default integer. The result value is the number of trailing zeros in the binary representation of the integer i.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

Consider the following:

```
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J=-1, 40
   TYPE *, TRAILZ(TWO**J)  ! Prints 64, then 0 up to
   ENDDO                     !   40 (trailing zeros)
END
```

TRANSFER

Transformational Intrinsic Function (Generic):
Converts the bit pattern of the first argument
according to the type and kind parameters of the
second argument.

Syntax

result = TRANSFER (source, mold[, size])

source (Input) Must be a scalar or array (of any data type).

mold (Input) Must be a scalar or array (of any data type). It provides the type characteristics (not a value) for the result.

size (Input; optional) Must be scalar and of type integer. It provides the number of elements for the output result.

Results

The result has the same type and type parameters as mold.
If mold is a scalar and size is omitted, the result is a scalar.
If mold is an array and size is omitted, the result is a rank-one array. Its size is the smallest that is possible to hold all of source.
If size is present, the result is a rank-one array of size size.
If the physical representation of the result is larger than source, the result contains source's bit pattern in its right-most bits; the left-most bits of the result are undefined.
If the physical representation of the result is smaller than source, the result contains the right-most bits of source's bit pattern.

Example

TRANSFER (1082130432, 0.0) has the value 4.0 (on processors that represent the values 4.0 and 1082130432 as the string of binary digits 0100 0000 1000 0000 0000 0000 0000 0000).
TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0))) results in a scalar whose value is (2.2, 3.3).
TRANSFER ((/2.2, 3.3, 4.4/), (/(0.0, 0.0)/)) results in a complex rank-one array of length 2. Its first element is (2.2,3.3) and its second element has a real part with the value 4.4 and an undefined imaginary part.

TRANSFER ((/2.2, 3.3, 4.4/), (/(0.0, 0.0)/), 1) results in a complex rank-one array having one element with the value (2.2, 3.3).

The following shows another example:

```fortran
COMPLEX CVVECTOR(2), CX(1)
! The next statement sets CVVECTOR to
! [ 1.1 + 2.2i, 3.3 + 0.0i ]
CVVECTOR = TRANSFER((/1.1, 2.2, 3.3, 0.0/)), &
    (/(0.0, 0.0)/))
! The next statement sets CX to [ 1.1 + 2.2i ]
CX = TRANSFER((/1.1, 2.2, 3.3/), (/(0.0, 0.0)/), &
    SIZE= 1)
WRITE(*,*) CVVECTOR
WRITE(*,*) CX
END
```

**TRANSPOSE**

*Transformational Intrinsic Function (Generic):*

*Transposes an array of rank two.*

**Syntax**

```fortran
result = TRANSPOSE (matrix)
```

*matrix* (Input) Must be a rank-two array. It may be of any data type.

**Results**

The result is a rank-two array with the same type and kind parameters as *matrix*. Its shape is (n, m), where (m, n) is the shape of *matrix*. For example, if the shape of *matrix* is (4,6), the shape of the result is (6,4).

Element (i, j) of the result has the value *matrix*(j, i), where *i* is in the range 1 to *n*, and *j* is in the range 1 to *m*.

**Example**

B is the array

```
[ 2 3 4 ]
[ 5 6 7 ]
[ 8 9 1 ].
```

TRANSPOSE (B) has the value

```
[ 2 5 8 ]
[ 3 6 9 ]
[ 4 7 1 ].
```

The following shows another example:

```fortran
INTEGER array(2, 3), result(3, 2)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is 1 3 5
! 2 4 6
result = TRANSPOSE(array)
! result is 1 2
! 3 4
! 5 6
END
```
See Also
RESHAPE
PRODUCT

TRIM
Transformational Intrinsic Function (Generic):
Returns the argument with trailing blanks removed.

Syntax
result = TRIM (string)

string (Input) Must be a scalar of type character.

Results
The result is of type character with the same kind parameter as string. Its length is the length of string minus the number of trailing blanks in string.

The value of the result is the same as string, except any trailing blanks are removed. If string contains only blank characters, the result has zero length.

Example
TRIM (' NAME ') has the value ' NAME'.
TRIM (' C D ') has the value ' C D'.

The following shows another example:

```
! next line prints 30
WRITE(*, *) LEN("I have blanks behind me       ")
! the next line prints 23
WRITE(*,*) LEN(TRIM("I have blanks behind me       "))
END
```

See Also
LEN_TRIM

TTYNAM
Portability Subroutine: Specifies a terminal device name.

Module
USE IFPORT

Syntax
CALL TTYNAM (string, lunit)

string (Output) Character*(*). Name of the terminal device. If the Fortran logical unit is not connected to a terminal, it returns a string filled with blanks.

lunit (Input) INTEGER(4). A Fortran logical unit number.

Type Declarations
Statement: Explicitly specifies the properties of data objects or functions.
**Syntax**

A type declaration has the general form:

\[ \text{type-spec} \{[, \text{att}] \ldots :: \} \text{v[/c-list/]}\{[, \text{v[/c-list/]}\} \ldots \]

- **type-spec**
  
  Is one of the following:

  - **intrin-type**

    - **TYPE** (derived-type-name)
      
      For information about parameterized derived types, see Parameterized Derived-Type Declarations.

    - **TYPE (*)**
      
      This defines the entity as an assumed-type object.

    - **CLASS** (derived-type-name)

    - **CLASS (*)**

  - **intrin-type**

    Is one of the following data type specifiers:

    - **BYTE**
    - **INTEGER[((KIND=k))]**
    - **REAL[((KIND=k))]**
    - **DOUBLE PRECISION**
    - **COMPLEX[((KIND=k))]**
    - **DOUBLE COMPLEX**
    - **CHARACTER[((KIND=k))]**
    - **LOGICAL[((KIND=k))]**

    In the optional kind selector "([KIND=k])", k is the kind parameter. It must be an acceptable kind parameter for that data type. If the kind selector is not present, entities declared are of default type.

    Kind parameters for intrinsic numeric and logical data types can also be specified using the *n format, where n is the length (in bytes) of the entity; for example, INTEGER*4.

    See each data type for further information on that type.

- **att**

  Is one of the following attribute specifiers:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>External</th>
<th>Protected</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATABLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>INTENT</td>
<td>PUBLIC¹</td>
</tr>
<tr>
<td>AUTOMATIC</td>
<td>INTRINSIC</td>
<td>SAVE</td>
</tr>
<tr>
<td>BIND</td>
<td>OPTIONAL</td>
<td>STATIC</td>
</tr>
<tr>
<td>CODIMENSION</td>
<td>PARAMETER</td>
<td>TARGET</td>
</tr>
<tr>
<td>CONTIGUOUS</td>
<td>POINTER</td>
<td>VALUE</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>PRIVATE¹</td>
<td>VOLATILE</td>
</tr>
</tbody>
</table>

¹These are access specifiers.
You can also declare any attribute separately as a statement.

\( v \)  
Is the name of a data object or function. It can optionally be followed by:

- An array specification, if the object is an array.
  
  In a function declaration, an array must be a deferred-shape array if it has the POINTER or ALLOCATABLE attribute; otherwise, it must be an explicit-shape array.
- A coarray specification, if the object is a coarray
- A character length, if the object is of type character.
- An initialization expression preceded by an = or, for pointer objects, => NULL( ).
- A codimension

A function name must be the name of an intrinsic function, external function, function dummy procedure, or statement function.

\( c\)-list  
Is a list of constants, as in a DATA statement. If \( v \) has the PARAMETER attribute, the \( c\)-list cannot be present.

The \( c\)-list cannot specify more than one value unless it initializes an array. When initializing an array, the \( c\)-list must contain a value for every element in the array.

**Description**

Type declaration statements must precede all executable statements.

In most cases, a type declaration statement overrides (or confirms) the implicit type of an entity. However, a variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

The double colon separator (::) is required only if the declaration contains an attribute specifier or initialization; otherwise it is optional.

If \( att \) appears, \( c\)-list cannot be specified; for example:

| INTEGER I /2/ | ! Valid |
| INTEGER, SAVE :: I /2/ | ! Invalid |
| INTEGER, SAVE :: I = 2 | ! Valid |

The same attribute must not appear more than once in a given type declaration statement, and an entity cannot be given the same attribute more than once in a scoping unit.

If CLASS is specified, the entity must be a dummy argument or have the ALLOCATABLE or POINTER attribute.

If the PARAMETER attribute is specified, the declaration must contain an initialization expression. The PARAMETER attribute must not be specified for a dummy argument, a pointer, an allocatable entity, a function, or an object in a common block.

If => NULL( ) is specified for a pointer, its initial association status is disassociated.

A variable (or variable subobject) can only be initialized once in an executable program. If the variable is an array, it must have its shape specified in either the type declaration statement or a previous attribute specification statement in the same scoping unit.

The INTENT, VALUE, and OPTIONAL attributes can be specified only for dummy arguments.

The INTENT attribute must not be specified for a dummy procedure without the POINTER attribute.

If the VALUE attribute is specified, the length type parameter values must be omitted or specified by initialization expressions. The VALUE attribute must not be specified for a dummy procedure.
An entity must not have both the EXTERNAL attribute and the INTRINSIC attribute. It can only have one of these attributes if it is a function.

The BIND attribute and the PROTECTED attribute can appear only in the specification part of a module.
A function result can be declared to have the POINTER or ALLOCATABLE attribute.

An automatic object cannot appear in a SAVE or DATA statement and it cannot be declared with a SAVE attribute nor be initially defined by an initialization.

The SAVE attribute must not be specified for:

- An object that is in a common block
- A procedure
- A dummy argument
- An automatic data object
- A function result
- An object with the PARAMETER attribute

The PROTECTED attribute is only allowed for a procedure pointer or named variable that is not in a common block. A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as:

- A pointer object in a NULLIFY statement
- A data pointer object or procedure pointer object in a pointer assignment statement
- An allocate object in an ALLOCATE statement or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following objects cannot be initialized in a type declaration:

- A dummy argument
- A function result
- An object in a named common block (unless the type declaration is in a block data program unit)
- An object in blank common
- An allocatable variable
- An external name
- An intrinsic name
- An automatic object
- An object that has the AUTOMATIC attribute

If a declaration contains an initialization expression, but no PARAMETER attribute is specified, the object is a variable whose value is initially defined. The object becomes defined with the value determined from the initialization expression according to the rules of intrinsic assignment.

The presence of initialization implies that the name of the object is saved, except for objects in named common blocks or objects with the PARAMETER attribute.

When the entity is an assumed-type object, the following rules apply:

- The entity has no declared type and its dynamic type and type parameters are assumed from its effective argument. An assumed-type object is unlimited polymorphic.
- An assumed-type object must be a dummy variable that does not have the ALLOCATABLE, CODIMENSION, INTENT(OUT), POINTER, or VALUE attribute and is not an explicit-shape array.
- An assumed-type object that is not assumed-shape and not assumed-rank is intended to be passed as the C address of the object. A TYPE(*) explicit-shape array is not permitted because there is insufficient information passed for an assumed-type explicit-shape array that is an actual argument corresponding to an assumed-shape dummy argument to compute element offsets.
• An assumed-type variable name must not appear in a designator or expression except as an actual argument corresponding to a dummy argument that is assumed-type, or as the first argument to any of the following intrinsic or intrinsic module functions: IS_CONTIGUOUS, LBOUND, PRESENT, RANK, SHAPE, SIZE, UBOUND, and C_LOC.

• An assumed-type actual argument that corresponds to an assumed-rank dummy argument must be assumed-shape or assumed-rank.

An object can have more than one attribute. The following table lists the compatible attributes:

### Compatible Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Compatible with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATABLE</td>
<td>AUTOMATIC, ASYNCHRONOUS, CODIMENSION, DIMENSION ¹, PRIVATE, PROTECTED, PUBLIC,</td>

1With deferred shape

### Example

The following show valid type declaration statements:

```fortran
DOUBLE PRECISION B(6)
INTEGER(KIND=2) I
REAL(KIND=4) X, Y
REAL(4) X, Y
LOGICAL, DIMENSION(10,10) :: ARRAY_A, ARRAY_B
INTEGER, PARAMETER :: SMALLEST = SELECTED_REAL_KIND(6, 70)
REAL(KIND (0.0)) M
COMPLEX(KIND=8) :: D
TYPE(EMPLOYEE) :: MANAGER
REAL, INTRINSIC :: COS
CHARACTER(15) PROMPT
CHARACTER*12, SAVE :: HELLO_MSG
INTEGER COUNT, MATRIX(4,4), SUM
LOGICAL*2 SWITCH
```
REAL :: X = 2.0

TYPE (NUM), POINTER :: FIRST => NULL()

The following shows more examples:

REAL a (10)
LOGICAL, DIMENSION (5, 5) :: mask1, mask2
COMPLEX :: cube_root = (-0.5, 0.867)
INTEGER, PARAMETER :: short = SELECTED_INT_KIND (4)
REAL (KIND (0.0D0)) a1
REAL (KIND = 2) b
COMPLEX (KIND = KIND (0.0D0)) :: c
INTEGER (short) k ! Range at least -9999 to 9999
TYPE (member) :: george

TYPE Statement (Derived Types)

Statement: Declares a variable to be of derived type. It specifies the name of the user-defined type and the types of its components.

Syntax

TYPE [,[attr-list] :: ] name [(type-param-name-list)]

[type-param-def-stmts]

PRIVATE statement or SEQUENCE statement]. . .

[component-definition]. . .

[type-bound-procedure-part]

END TYPE [name]

attr-list

Is one of the following:

- access-spec
  - Is the PUBLIC or PRIVATE attribute. The attribute can only be specified if the derived-type definition is in the specification part of a module.
- BIND(C)
- EXTENDS (parent-type-name)
  - where parent-type-name is the name of a previously defined extensible type.
- ABSTRACT
The same `attr` must not appear more than once in any given derived-type statement.

If the type definition contains or inherits a deferred binding, `ABSTRACT` must appear.

The `EXTENDS` and `ABSTRACT` attributes apply to type extension and extended types. If `ABSTRACT` is specified, the type is an abstract type and it must be extensible.

A derived type that does not have the `SEQUENCE` or `BIND(C)` attribute is extensible. Conversely, a derived type that has the `SEQUENCE` or `BIND(C)` attribute is not extensible.

`name` is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.

`type-param-name-list` is a list of type parameter names separated by commas. For more information, see Parameterized Derived-Type Declarations.

`type-param-def-stmts` is one or more INTEGER declarations of the type parameters named in the `type-param-name-list`. For more information, see Parameterized Derived-Type Declarations.

`component-definition` is one or more type declaration statements or procedure pointer statements defining the component of derived type.

The first component definition can be preceded by an optional `PRIVATE` or `SEQUENCE` statement. (Only one `PRIVATE` or `SEQUENCE` statement can appear in a given derived-type definition.)

If `SEQUENCE` is present, all derived types specified in component definitions must be sequence types.

Procedure pointer component definitions are described in Procedure Pointers as Derived-Type Components.

The syntax for a type declaration component definition is described below.

`type-bound-procedure-part` is a `CONTAINS` statement, optionally followed by a `PRIVATE` statement, and one or more procedure binding statements (specific, generic, or final). For more information, see Type-Bound Procedures.

A type declaration component definition takes the following form:

```
  type[ [, attr] :: ] component[( a-spec)] [[ coarray-spec ]] [ *char-len] [ init-ex]
```

`type` is a type specifier. It can be an intrinsic type or a previously defined derived type.

If the `POINTER` attribute follows this specifier, the type can also be any accessible derived type, including the type being defined.

`attr` is at most one of the following:

- An optional `POINTER` attribute for a pointer component
- An optional `ALLOCATABLE` attribute for a scalar component
- An optional `DIMENSION` or `ALLOCATABLE` attribute for an array component

You cannot specify both the or `ALLOCATABLE` and `POINTER` attribute.
- An optional access specifier, PUBLIC or PRIVATE
- An optional CODIMENSION [coarray-spec] to specify a coarray
- An optional CONTIGUOUS attribute if the object is contiguous

Each attribute can only appear once in a given component definition.

If neither the POINTER nor the ALLOCATABLE attribute is specified, type must specify an intrinsic type or a previously defined derived type.

If the POINTER or ALLOCATABLE attribute is specified, each component array specification \( a\text{-spec} \) must be a deferred shape specification (d-spec).

If a coarray-spec appears, it must be a deferred specification list consisting of one or more colons (:), the component must have the ALLOCATABLE attribute, and the component must not be of type C_PTR or C_FUNPTR.

A data component whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar and must not be a coarray.

If neither the POINTER nor the ALLOCATABLE attribute is specified, each \( a\text{-spec} \) must be an explicit-shape specification.

If the CONTIGUOUS attribute is specified, the component must be an array with the POINTER attribute.

\textbf{component} \quad \text{Is the name of the component being defined.}

\textbf{a-spec} \quad \text{Is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression.}

If \textit{component} is an array and the array bounds are not specified here, they must be specified following the DIMENSION attribute.

\textbf{coarray-spec} \quad \text{Is a deferred-coshape specification. The left bracket and right bracket are required.}

\textbf{char-len} \quad \text{Is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.}

\textbf{init-ex} \quad \text{Is an initialization expression, or for pointer components, \( \Rightarrow \text{NULL( ).} \)}

If \textit{init-ex} is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components.

The initialization expression is evaluated in the scoping unit of the type definition.

\textbf{Description}

If a name is specified following the END TYPE statement, it must be the same name that follows TYPE in the derived type statement.

A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.
The default accessibility attribute for a module is PUBLIC unless it has been changed by a PRIVATE statement.

The PRIVATE keyword can only be specified if the derived-type definition is in the specification part of a module.

If a type definition is PRIVATE, the type name and the structure constructor for the type are accessible only within the module containing the definition.

Two data entities have the same type if they are both declared to be of the same derived type; the derived-type definition can be accessed from a module or a host scoping unit.

If EXTENDS appears and the type being defined has a coarray ultimate component, its parent type must have a coarray ultimate component.

Data entities in different scoping units also have the same type if the following is true:

- They are declared with reference to different derived-type definitions that specify the same type name.
- All have the SEQUENCE property.
- All have the BIND attribute.
- They have no components with PRIVATE accessibility.
- They have type parameters and components that agree in order, name, and attributes.

Otherwise, they are of different derived types.

A data component is a coarray if the component declaration contains a coarray specification. If the component declaration contains a coarray specification, it specifies the corank.

If BIND (C) is specified, the following rules apply:

- The derived type cannot be a SEQUENCE type.
- The derived type must not have type parameters.
- The derived type must not have the EXTENDS attribute.
- The derived type must not have a type-bound-procedure-part.
- Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.

Example

```fortran
! DERIVED.F90
! Define a derived-type structure, type variables, and assign values

TYPE member
  INTEGER age
  CHARACTER (LEN = 20) name
END TYPE member

TYPE (member) :: george
TYPE (member) :: ernie

george = member( 33, 'George Brown' )
ernie%age = 56
ernie%name = 'Ernie Brown'

WRITE (*,*) george
WRITE (*,*) ernie
END
```

The following shows another example of a derived type:

```fortran
TYPE mem_name
  SEQUENCE
  CHARACTER (LEN = 20) lastn
END TYPE
```
In the following example, \( a \) and \( b \) are both variable arrays of derived type \texttt{pair}:\
\begin{verbatim}
TYPE (pair)
  INTEGER i, j
END TYPE
TYPE (pair), DIMENSION (2, 2) :: a, b(3)
\end{verbatim}

The following example shows how you can use derived-type objects as components of other derived-type objects:

\begin{verbatim}
TYPE employee_name
  CHARACTER(25) last_name
  CHARACTER(15) first_name
END TYPE
TYPE employee_addr
  CHARACTER(20) street_name
  INTEGER(2) street_number
  INTEGER(2) apt_number
  CHARACTER(20) city
  CHARACTER(2) state
  INTEGER(4) zip
END TYPE
\end{verbatim}

Objects of these derived types can then be used within a third derived-type specification, such as:

\begin{verbatim}
TYPE employee_data
  TYPE (employee_name) :: name
  TYPE (employee_addr) :: addr
  INTEGER(4) telephone
  INTEGER(2) date_of_birth
  INTEGER(2) date_of_hire
  INTEGER(2) social_security(3)
  LOGICAL(2) married
  INTEGER(2) dependents
END TYPE
\end{verbatim}

Coarrays are a Fortran 2008 feature. The following example shows a derived-type definition with a coarray component:

\begin{verbatim}
TYPE NEW_TYPE
  REAL,ALLOCATABLE,CODIMENSION[:,:,::] :: NEW(:,,:,:)
END TYPE NEW_TYPE
\end{verbatim}

An object of type \texttt{NEW_TYPE} must be a scalar and it cannot be a pointer, allocatable, or a coarray.

The following example shows a derived-type definition containing a \texttt{coarray-spec}:

\begin{verbatim}
type t
  integer :: k
  real, allocatable :: x (::)[::]
end type t
\end{verbatim}

UBOUND

Inquiry Intrinsic Function (Generic): Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.

Syntax

\[
result = \text{UBOUND}(\text{array}[, \text{dim}] [, \text{kind}])
\]

array

(Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer. It can be an assumed-size array if \text{dim} is present with a value less than the rank of \text{array}.

dim

(Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \text{array}.

kind

(Input; optional) Must be a scalar integer initialization expression.

Results

The result type is integer. If \text{kind} is present, the kind parameter of the result is that specified by \text{kind}; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rule applies if \text{array} is not assumed-rank:

- If \text{dim} is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of \text{array}. Each element in the result corresponds to a dimension of \text{array}.

The following rules apply if \text{array} is assumed-rank:

- If \text{dim} is present and \text{array} is assumed-rank, the value of the result is as if \text{array} were a whole array, with the extent of the final dimension of \text{array} when \text{array} is associated with an assumed-size array being considered to be \(-1\) (that is, LBOUND (ARRAY, RANK (ARRAY), KIND) - 2).
- If UBOUND is invoked for an assumed-rank object that is associated with a scalar and \text{dim} is absent, the result is a zero-sized array. UBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if \text{dim} is present because the rank of a scalar is zero and \text{dim} must be \(>= 1\).

If \text{array} is an array section or an array expression that is not a whole array or array structure component, UBOUND\((array, dim)\) has a value equal to the number of elements in the given dimension.
If array is a whole array or array structure component, UBOUND(array, dim) has a value equal to the upper bound for subscript dim of array (if dim is nonzero). If dim has size zero, the corresponding element of the result has the value zero.

The setting of compiler options specifying integer size can affect this function.

Example

Consider the following:

```plaintext
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

UBOUND (ARRAY_A) is (3, 8). UBOUND (ARRAY_A, DIM=2) is 8.

UBOUND (ARRAY_B) is (8, 20). UBOUND (ARRAY_B (5:8, :)) is (4, 24) because the number of elements is significant for array section arguments.

The following shows another example:

```plaintext
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = UBOUND (ar1)          ! returns [3, 5, 14]
res2 = UBOUND (ar1, DIM= 3)  ! returns 14
res3 = UBOUND (vec1)         ! returns [35]
END
```

See Also

LBOUND

UCOBOUND

Inquiry Intrinsic Function (Generic): Returns the upper cobounds of a coarray.

Syntax

```plaintext
result = UCOBOUND (coarray [,dim [, kind]])
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coarray</td>
<td>(Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.</td>
</tr>
<tr>
<td>dim</td>
<td>(Input; optional) Must be an integer scalar with a value in the range 1 &lt;= dim &lt;= n, where n is the corank of coarray. The corresponding actual argument must not be an optional dummy argument.</td>
</tr>
<tr>
<td>kind</td>
<td>(Input; optional) Must be a scalar integer constant expression.</td>
</tr>
</tbody>
</table>

Results

The result type is integer. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default integer type. The result is scalar if dim is present; otherwise, the result is an array of rank one and size n, where n is the corank of coarray.

The result depends on whether dim is specified:

- If dim is specified, UCOBOUND (COARRAY, DIM) has a value equal to the upper cobound for cosubscript dim of coarray.
- If dim is not specified, UCOBOUND (COARRAY) has a value whose ith element is equal to UCOBOUND (COARRAY, i), for i = 1, 2, . . . , n, where n is the corank of coarray.

Example

If A is allocated by the statement ALLOCATE (A [2:3, 7:*]), then LCOBOUND (A) is [2, 7] and LCOBOUND (A, DIM=2) is 7.
If NUM_Images( ) has the value 30, and coarray B is allocated by the statement `ALLOCATE (B[2:3, 0:7, *])`, then `UCOBOUND (B)` is [3, 7, 2] and `UCOBOUND (B, DIM=2)` is 7. Note that the cosubscripts [3, 7, 2] do not correspond to an actual image.

**UNDEFINE**

*Statement:* Removes a defined symbol.

**See Also**

See DEFINE and UNDEFINE.

**UNION and END UNION**

*Statements:* Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.

**Syntax**

Each unique field or group of fields is defined by a separate map declaration.

**UNION**

```
UNION
    map-declaration
    map-declaration
    [map-declaration]
    ...
    [map-declaration]
END UNION
```

**map-declaration** Takes the following form:

```
MAP
    field-declaration
    [field-declaration]
    ...
    [field-declaration]
END MAP
```

**field-declaration** Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.

As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.
Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.

Example

In the following example, the structure WORDS_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER*2 variables (WORD_0, WORD_1, and WORD_2), and the second, an INTEGER*4 variable, LONG:

```
STRUCTURE /WORDS_LONG/
  UNION
    MAP
      INTEGER*2  WORD_0, WORD_1, WORD_2
    END MAP
    MAP
      INTEGER*4  LONG
    END MAP
  END UNION
END STRUCTURE
```

The length of any record with the structure WORDS_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS_LONG:

**Memory Map of Structure WORDS_LONG**

In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```
UNION
  MAP
    CHARACTER*20 string1, CHARACTER*10 string2(6)
  END MAP
  MAP
    INTEGER*2  number(10), INTEGER*4  var(10), INTEGER*2
    +      datum(10)
  END MAP
END UNION
```
See Also
STRUCTURE and END STRUCTURE
Record Structures

UNLINK

Portability Function: Deletes the file given by path.

Module
USE IFPORT

Syntax
result = UNLINK (name)

name (Input) Character*(*) Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

• ENOENT: The specified file could not be found.
• EACCES: The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.

Example
USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirName
READ *, dirName
ISTATUS = UNLINK (dirName)
IF (ISTATUS) then
   print *, 'Error ', ISTATUS
END IF
END

See Also
SYSTEM
DELDIRQQ

UNPACK

Transformational Intrinsic Function (Generic):
Takes elements from a rank-one array and unpacks them into another (possibly larger) array under the control of a mask.

Syntax
result = UNPACK (vector, mask, field)

vector (Input) Must be a rank-one array. It may be of any data type. Its size must be at least $t$, where $t$ is the number of true elements in mask.
mask (Input) Must be a logical array. It determines where elements of vector are placed when they are unpacked.

field (Input) Must be of the same type and type parameters as vector and conformable with mask. Elements in field are inserted into the result array when the corresponding mask element has the value false.

Results
The result is an array with the same shape as mask, and the same type and type parameters as vector.

Elements in the result array are filled in array element order. If element i of mask is true, the corresponding element of the result is filled by the next element in vector. Otherwise, it is filled by field (if field is scalar) or the ith element of field (if field is an array).

Example
N is the array

\[
\begin{bmatrix}
0 & 0 & 1 \\
1 & 0 & 1 \\
1 & 0 & 0 \\
\end{bmatrix}
\]

P is the array (2, 3, 4, 5), and Q is the array

\[
\begin{bmatrix}
T & F & F \\
F & T & F \\
T & T & F \\
\end{bmatrix}
\]

UNPACK (P, MASK=Q, FIELD=N) produces the result

\[
\begin{bmatrix}
2 & 0 & 1 \\
1 & 4 & 1 \\
3 & 5 & 0 \\
\end{bmatrix}
\]

UNPACK (P, MASK=Q, FIELD=1) produces the result

\[
\begin{bmatrix}
2 & 1 & 1 \\
1 & 4 & 1 \\
3 & 5 & 1 \\
\end{bmatrix}
\]

The following shows another example:

LOGICAL mask (2, 3)
INTEGER vector(3) /1, 2, 3/, AR1(2, 3)
mask = RESHAPE((/.TRUE.,.FALSE.,.FALSE.,.TRUE.,.FALSE.,.FALSE.,.TRUE.,.FALSE.,), (/2, 3/))
! vector = [1 2 3] and mask = T F T
! F T F
AR1 = UNPACK(vector, mask, 8) ! returns 1 8 3
! 8 2 8

See Also
PACK Function
RESHAPE
SHAPE

UNPACKTIMEQQ
Portability Subroutine: Unpacks a packed time and date value into its component parts.
Module
USE IFPORT

Syntax
CALL UNPACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

timedate (Input) INTEGER(4). Packed time and date information.
iyr (Output) INTEGER(2). Year (xxxxAD).
imon (Output) INTEGER(2). Month (1 - 12).
iday (Output) INTEGER(2). Day (1 - 31).
ihr (Output) INTEGER(2). Hour (0 - 23).
imin (Output) INTEGER(2). Minute (0 - 59).
isec (Output) INTEGER(2). Second (0 - 59).

GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values.
The output values reflect the time zone set on the local computer and the daylight savings rules for that time zone.
Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

Example
USE IFPORT
CHARACTER(80) file
TYPE (FILE$INFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec

file = 'd:\f90ps\bin\t???.*' handle = FILE$FIRST
result = GETFILEINFOQQ(file, info, handle)
CALL UNPACKTIMEQQ(info%lastwrite, iyr, imon, &
 iday, ihr, imin, isec)
WRITE(*,*) iyr, imon, iday
WRITE(*,*) ihr, imin, isec
END

See Also
PACKTIMEQQ
GETFILEINFOQQ

UNREGISTERMOUSEEVENT (W*S)
QuickWin Function: Removes the callback routine registered for a specified window by an earlier call to REGISTERMOUSEEVENT.

Module
USE IFQWIN
Syntax

result = UNREGISTERMOUSEEVENT (unit, mouseevents)

unit (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Unit number of the window whose callback routine on mouse events is to be unregistered.

mouseevents (Input) INTEGER(4). One or more mouse events handled by the callback routine to be unregistered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$LBUTTONUP - Left mouse button up
- MOUSE$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE$MOVE - Mouse moved

Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE$BADEVENT - The event specified is not supported.

Once you call UNREGISTERMOUSEEVENT, QuickWin no longer calls the callback routine specified earlier for the window when mouse events occur. Calling UNREGISTERMOUSEEVENT when no callback routine is registered for the window has no effect.

REGISTERMOUSEEVENT (W*S)
WAITONMOUSEEVENT (W*S)

UNROLL and NOUNROLL

General Compiler Directive: Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.

Syntax

!DIR$ UNROLL [(n)] -or- !DIR$ UNROLL [=n]

!DIR$ NOUNROLL

n Is an integer constant. The range of n is 0 through 255.

If n is specified, the optimizer unrolls the loop n times. If n is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or O3 must be set.
Example

```fortran
!DIR$ UNROLL
   do i =1, m
      b(i) = a(i) + 1
      d(i) = c(i) + 1
   enddo
```

The following shows another example:

```fortran
!DIR$ UNROLL= 4
   do i =1, m
      b(i) = a(c(i)) + 1
   enddo
```

See Also

General Compiler Directives
Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements

**UNROLL_AND_JAM and NOUNROLL_AND_JAM**

**General Compiler Directive:** Hints to the compiler to enable or disable loop unrolling and jamming. These directives can only be applied to iterative DO loops.

**Syntax**

```fortran
!DIR$ UNROLL_AND_JAM [(n)] -or- !DIR$ UNROLL_AND_JAM [=n]

!DIR$ NOUNROLL_AND_JAM
```

\( n \)

Is an integer constant. The range of \( n \) is 0 through 255.

The UNROLL_AND_JAM directive partially unrolls one or more loops higher in the nest than the innermost loop and fuses (jams) the resulting loops back together. This transformation allows more reuses in the loop.

This directive is not effective on innermost loops. You must ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this directive is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler will enable this transformation whenever possible.

The UNROLL_AND_JAM directive must precede the DO statement for each DO loop it affects. If \( n \) is specified, the optimizer unrolls the loop \( n \) times. If \( n \) is omitted or if it is outside the allowed range, the optimizer chooses the number of times to unroll the loop. The compiler generates correct code by comparing \( n \) and the loop count.

This directive is supported only when compiler option `O3` is set. The UNROLL_AND_JAM directive overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size, it may be necessary to prevent unrolling of a nested or imperfect nested loop. In such cases, use the NOUNROLL_AND_JAM directive, which hints to the compiler not to unroll a specified loop.

Example

```fortran
integer a(10,10), b(10,10), c(10,10), d(10,10)
integer i, j, k

!dir$ unroll_and_jam = 6
```
do i=1,10
   !dir$ unroll_and_jam (6)
   do j=1,10
      do k=1,10
         a (j, i) = a (j, i) + b (k, i) *c (k, j)
      end do  ! k
   end do  ! j
end do                  ! i
end

Rules for Loop Directives that Affect Array Assignment Statements

USE Statement: Gives a program unit accessibility to public entities in a module.

Syntax
USE [ [, mod-nature] :: ] name [ , rename-list ]
USE [ [, mod-nature] :: ] name, ONLY : [ only-list ]

mod-nature Is INTRINSIC or NON_INTRINSIC. If INTRINSIC is used, name must be the name of an intrinsic module. If NON_INTRINSIC is used, name must be the name of a nonintrinsic module. If mod-nature is not specified, name must be the name of an intrinsic or nonintrinsic module. If both are provided, the nonintrinsic module is used. It is an error to specify a user module and an intrinsic module of the same name in the same program unit (see Examples).

name Is the name of the module.

rename-list Is one or more items, separated by commas, having the following form:
local-name => mod-name

local-name Is the name of the entity in the program unit using the module or is "OPERATOR (op-name)", where op-name is the name of a defined operator in the program unit using the module.

mod-name Is the name of a public entity in the module or is "OPERATOR (op-name)", where op-name is the name of a public entity in the module.

only-list Is one or more items, separated by commas, where each item is the name of a public entity in the module or a generic identifier (a generic name, a defined operator specified as "OPERATOR (op-name)", or defined assignment).

An entity in the only-list can also take the form:
Description

If the USE statement is specified without the ONLY option, the program unit has access to all public entities in the named module.

If the USE statement is specified with the ONLY option, the program unit has access to only those entities following the option.

If more than one USE statement for a given module appears in a scoping unit, the following rules apply:

- If one USE statement does not have the ONLY option, all public entities in the module are accessible, and any rename-lists and only-lists are interpreted as a single, concatenated rename-list.
- If all the USE statements have ONLY options, all the only-lists are interpreted as a single, concatenated only-list. Only those entities named in one or more of the only-lists are accessible.

If two or more generic interfaces that are accessible in a scoping unit have the same name, the same operator, or are both assignments, they are interpreted as a single generic interface. Otherwise, multiple accessible entities can have the same name only if no reference to the name is made in the scoping unit.

The local names of entities made accessible by a USE statement must not be respecified with any attribute other than PUBLIC or PRIVATE. The local names can appear in namelist group lists, but not in a COMMON or EQUIVALENCE statement.

Example

The following shows examples of the USE statement:

```fortran
MODULE MOD_A
   INTEGER :: B, C
   REAL E(25,5), D(100)
END MODULE MOD_A
...
SUBROUTINE SUB_Y
   USE MOD_A, DX => D, EX => E   ! Array D has been renamed DX and array E
      ...                        ! has been renamed EX. Scalar variables B
   END SUBROUTINE SUB_Y         ! and C are also available to this
      ...                      ! subroutine (using their module names).
SUBROUTINE SUB_Z
   USE MOD_A, ONLY: B, C       ! Only scalar variables B and C are
      ...                     ! available to this subroutine
END SUBROUTINE SUB_Z
...
```

You must not specify a user module and an intrinsic module of the same name in the same program unit. For example, if you specify a user module named ISO_FORTRAN_ENV, then it is illegal to specify the following in the same program unit:

```fortran
USE :: ISO_FORTRAN_ENV
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

The following example shows a module containing common blocks:

```fortran
MODULE COLORS
   COMMON /BLOCKA/ C, D(15)
   COMMON /BLOCKB/ E, F
   ... 
END MODULE COLORS
...
FUNCTION HUE(A, B)
   USE COLORS
   ... 
END FUNCTION HUE
```
The USE statement makes all of the variables in the common blocks in module COLORS available to the function HUE.

To provide data abstraction, a user-defined data type and operations to be performed on values of this type can be packaged together in a module. The following example shows such a module:

```fortran
MODULE CALCULATION
  TYPE ITEM
    REAL :: X, Y
  END TYPE ITEM

  INTERFACE OPERATOR (+)
    MODULE PROCEDURE ITEM_CALC
  END INTERFACE

  CONTAINS
    FUNCTION ITEM_CALC (A1, A2)
      TYPE(ITEM) A1, A2, ITEM_CALC
      ...
    END FUNCTION ITEM_CALC
    ...
  END MODULE CALCULATION

PROGRAM TOTALS
USE CALCULATION
TYPE(ITEM) X, Y, Z
...
X = Y + Z
...
END
```

The USE statement allows program TOTALS access to both the type ITEM and the extended intrinsic operator + to perform calculations.

The following shows another example:

```fortran
! Module containing original type declarations
MODULE geometry
  type square
    real side
    integer border
  end type
  type circle
    real radius
    integer border
  end type
END MODULE

! Program renames module types for local use.
PROGRAM test
USE GEOMETRY, LSQUARE=>SQUARE, LCIRCLE=>CIRCLE
! Now use these types in declarations
type (LSQUARE) s1, s2
type (LCIRCLE) c1, c2, c3
```

The following shows a defined operator in a USE statement:

```fortran
USE mymod, OPERATOR(.localop.) => OPERATOR(.moduleop.)
```

Entities in modules can be accessed either through their given name, or through aliases declared in the USE statement of the main program unit. For example:

```fortran
USE MODULE_LIB, XTABS => CROSSTABS
```
This statement accesses the routine called CROSSTABS in MODULE_LIB by the name XTABS. This way, if two modules have routines called CROSSTABS, one program can use them both simultaneously by assigning a local name in its USE statement.

When a program or subprogram renames a module entity, the local name (XTABS, in the preceding example) is accessible throughout the scope of the program unit that names it.

The ONLY option also allows public variables to be renamed. Consider the following:

```
USE MODULE_A, ONLY: VARIABLE_A => VAR_A
```

In this case, the host program accesses only VAR_A from module A, and refers to it by the name VARIABLE_A.

Consider the following example:

```fortran
MODULE FOO
  integer foos_integer
PRIVATE
  integer foos_my_integer
END MODULE FOO
```

PRIVATE, in this case, makes the PRIVATE attribute the default for the entire module FOO. To make foos_integer accessible to other program units, add the line:

```
PUBLIC :: foos_integer
```

Alternatively, to make only foos_my_integer inaccessible outside the module, rewrite the module as follows:

```fortran
MODULE FOO
  integer foos_integer
  integer, private::foos_my_integer
END MODULE FOO
```

Program Units and Procedures Overview

**%VAL**

**Built-in Function:** Changes the form of an actual argument. Passes the argument as an immediate value.

#### Syntax

```
%VAL (a)
```

- **a** (Input) An expression, record name, procedure name, array, character array section, or array element.

#### Description

The argument is passed as follows:

- On IA-32 architecture, as a 32-bit immediate value. If the argument is integer (or logical) and shorter than 32 bits, it is sign-extended to a 32-bit value. For complex data types, %VAL passes two 32-bit arguments.
- On Intel® 64 architecture, as a 64-bit immediate value. If the argument is integer (or logical) and shorter than 64 bits, it is sign-extended to a 64-bit value. For complex data types, %VAL passes two 64-bit arguments.

You must specify %VAL in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following tables list the Intel® Fortran defaults for argument passing, and the allowed uses of %VAL:
Expressions

</tbody>
</table>

¹ If a logical or integer value occupies less than 64 bits of storage on Intel® 64 architecture, or 32 bits of storage on IA-32 architecture, it is converted to the correct size by sign extension. Use the ZEXT intrinsic function if zero extension is desired.

² A character argument is passed by address and hidden length.

³ In Intel® Fortran record structures

The %VAL and %REF functions override related !DIR$ ATTRIBUTE settings.

Example

```fortran
CALL SUB(2, %VAL(2))
```

Constant 2 is passed by reference. The second constant 2 is passed by immediate value.

CALL
CALL

VALUE
Statement and Attribute: Specifies a type of argument association for a dummy argument.

Syntax
The VALUE attribute can be specified in a type declaration statement or a VALUE statement, and takes one of the following forms:

Type Declaration Statement:

```
type, [att-ls, ] VALUE [, att-ls] :: arg [, arg] ...
```

Statement:

```
VALUE [::] arg [, arg]...
```

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

arg Is the name of a dummy argument.

Description
The VALUE attribute can be used in INTERFACE body or in a procedure. It can only be specified for dummy arguments. It cannot be specified for a dummy procedure.

An entity with the VALUE attribute must be a dummy data object that is not an assumed-size array or a coarray, and does not have a coarray ultimate component.

When this attribute is specified for a present dummy argument, the dummy argument becomes associated with a temporary, definable data object whose initial value is that of the corresponding actual argument. The actual mechanism by which this happens is determined by the compiler. If the procedure also has the BIND(C) attribute, the dummy argument is interoperable with the corresponding formal parameter of the C language prototype, causing the argument to be passed or received by value if C would do so.

When the VALUE attribute is used in a type declaration statement, any length type parameter values must be omitted or they must be specified by initialization expressions.

If the VALUE attribute is specified, you cannot specify a PARAMETER, EXTERNAL, POINTER, ALLOCATABLE, VOLATILE, or INTENT (INOUT or OUT) attribute in the same scoping unit.

You can use option assume nostd_value to tell the compiler to use non-standard semantics for VALUE so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.

Example
The following example shows how the VALUE attribute can be applied in a type declaration statement.

```
j = 3
call sub (j)
write (*,*) j ! Writes 3
contains
subroutine sub (i)
integer, value :: I
i = 4
write (*,*) i ! Writes 4
end subroutine sub
end
```

assume compiler option

VECTOR and NOVECTOR

General Compiler Directive: Overrides default heuristics for vectorization of DO loops. It can also affect certain optimizations.

Syntax

!DIR$ VECTOR [clause[,] clause]...

!DIR$ NOVECTOR

clause

Is an optional vectorization or optimizer clause. It can be one or more of the following:

- **ALWAYS [ASSERT]**
  Enables or disables vectorization of a DO loop. The ALWAYS clause overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized. You should use the IVDEP directive to ignore assumed dependences.

- **ALIGNED | UNALIGNED**
  Specifies that all data is aligned or no data is aligned in a DO loop. These clauses override efficiency heuristics in the optimizer. The clause ALIGNED instructs the compiler to use aligned data movement instructions for all array references. The clause UNALIGNED instructs the compiler to avoid dynamic or static loop peeling transformation as an alignment optimization; the compiler can still use available alignment information. These clauses disable all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

  Be careful when using the ALIGNED clause. Instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

- **TEMPORAL | NONTEMPORAL [(var1 [, var2]...)]**
  var
  Is an optional memory reference in the form of a variable name.

  Controls how the "stores" of register contents to storage are performed (streaming versus non-streaming).

  The TEMPORAL clause directs the compiler to use temporal (that is, non-streaming) stores.

  The NONTEMPORAL clause directs the compiler to use non-temporal (that is, streaming) stores. On Intel® MIC Architecture, the compiler generates clevict (cache-line-evict) instructions after the stores based on the non-temporal directive when the compiler knows that the store addresses are aligned.

  By default, the compiler automatically determines whether a streaming store should be used for each variable.
Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

- VECREMAINDER | NOVECREMAINDER

Directs the compiler to vectorize (or not to vectorize) the remainder loop when the original loop is vectorized.

If !DIR$ VECTOR ALWAYS is specified, the following occurs:

- If neither the VECREMAINDER or NOVECREMAINDER clause is specified, the compiler overrides efficiency heuristics of the vectorizer and it determines whether the loop can be vectorized.
- If VECREMAINDER is specified, the compiler vectorizes remainder loops when the original main loop is vectorized.
- If NOVECREMAINDER is specified, the compiler does not vectorize the remainder loop when the original main loop is vectorized.

The VECREMAINDER and NOVECREMAINDER directives control vectorization of the DO loop that directly follows the directive.

**CAUTION**
The VECREMAINDER directive should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

**Example**
The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).

In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```fortran
!DIR$ VECTOR ALWAYS
  do i = 1, 100, 2
    ! two references with stride 2 follow
    a(i) = b(i)
  enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the NOVECTOR directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```fortran
!DIR$ NOVECTOR
  do i = 1, 100
    a(i) = b(i) + c(i)
  enddo
```

General Compiler Directives
Syntax Rules for Compiler Directives
IVDEP
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements
**VERIFY**

**Elemental Intrinsic Function (Generic):** Verifies that a set of characters contains all the characters in a string by identifying the first character in the string that is not in the set.

**Syntax**

\[ \text{result} = \text{VERIFY}(\text{string}, \text{set} [, \text{back}] [, \text{kind}]) \]

- **string** (Input) Must be of type character.
- **set** (Input) Must be of type character with the same kind parameter as string.
- **back** (Input; optional) Must be of type logical.
- **kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If back is omitted (or is present with the value false) and string has at least one character that is not in set, the value of the result is the position of the leftmost character of string that is not in set.

If back is present with the value true and string has at least one character that is not in set, the value of the result is the position of the rightmost character of string that is not in set.

If each character of string is in set or the length of string is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

VERIFY ('CDDDC', 'C') has the value 2.
VERIFY ('CDDDC', 'C', BACK=.TRUE.) has the value 4.
VERIFY ('CDDDC', 'CD') has the value zero.

The following shows another example:

```fortran
INTEGER(4) position

position = VERIFY ('banana', 'nbc')  ! returns 2
position = VERIFY ('banana', 'nbc', BACK=.TRUE.)
    ! returns 6
position = VERIFY ('banana', 'nbca') ! returns 0
```

**See Also**

SCAN

**VIRTUAL**

**Statement:** Has the same form and effect as the DIMENSION statement. It is included for compatibility with PDP-11 FORTRAN.

**See Also**

DIMENSION
VOLATILE

Statement and Attribute: Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. It prevents objects from being optimized during compilation.

Syntax

The VOLATILE attribute can be specified in a type declaration statement or a VOLATILE statement, and takes one of the following forms:

Type Declaration Statement:

type, [att-ls, ] VOLATILE [, att-ls] :: object[, object] ...

Statement:

VOLATILE [::] object[, object] ...

type
Is a data type specifier.

att-ls
Is an optional list of attribute specifiers.

object
Is the name of an object, or the name of a common block enclosed in slashes.

A variable or COMMON block must be declared VOLATILE if it can be read or written in a way that is not visible to the compiler. For example:

• If an operating system feature is used to place a variable in shared memory (so that it can be accessed by other programs), the variable must be declared VOLATILE.
• If a variable is accessed or modified by a routine called by the operating system when an asynchronous event occurs, the variable must be declared VOLATILE.

If an array is declared VOLATILE, each element in the array becomes volatile. If a common block is declared VOLATILE, each variable in the common block becomes volatile.

If an object of derived type is declared VOLATILE, its components become volatile.

If a pointer is declared VOLATILE, the pointer itself becomes volatile.

A VOLATILE statement cannot specify the following:

• A procedure
• A namelist group

The VOLATILE attribute must not be specified for a coarray that is accessed by use or host association. A noncoarray object that has the VOLATILE attribute can be associated with an object that does not have the VOLATILE attribute, including by use or host association.

Example

The following example shows a type declaration statement specifying the VOLATILE attribute:

```
INTEGER, VOLATILE :: D, E
```

The following example shows a VOLATILE statement:

```
PROGRAM TEST
LOGICAL(KIND=1) IPI(4)
INTEGER(KIND=4) A, B, C, D, E, ILOOK
INTEGER(KIND=4) P1, P2, P3, P4
COMMON /BLK1/A, B, C
VOLATILE /BLK1/, D, E
```
EQUIVALENCE (ILOOK, IPI)
EQUIVALENCE (A, P1)
EQUIVALENCE (P1, P4)

The named common block, BLK1, and the variables D and E are volatile. Variables P1 and P4 become volatile because of the direct equivalence of P1 and the indirect equivalence of P4.

Type Declarations
Type Declarations

WAIT

**Statement:** Performs a wait operation for a specified pending asynchronous data transfer operation. It takes one of the following forms:

**Syntax**

```
```

WAIT io-unit

io-unit

(Input) Is an external unit specifier.

label

(Input) Is the label of the branch target statement that receives control if an error occurs.

id-var

(Input) Is a scalar integer variable that is the identifier of a pending data transfer operation for the specified unit. If it is specified, a wait operation is performed for that pending operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

msg-var

(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var

(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

A wait operation completes the processing of a pending data transfer operation. Each wait operation completes only a single data transfer operation, although a single statement may perform multiple wait operations.

The WAIT statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The EOR= specifier only has effect if the pending data transfer operation is a nonadvancing read. The END= specifier only has effect if the pending data transfer operation is a READ.

Example

The following example shows how the WAIT statement can be applied.

```fortran
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1, file='asynch.dat', asynchronous='YES', form='unformatted')
  write (1) (i, i=1, 100)
  rewind (1)
  read (1, asynchronous='YES') array
```

39

| 2049 |
WAIT(1)
write (*,*) array(1:10)
end

WAITONMOUSEEVENT (W*S)

QuickWin Function: Waits for the specified mouse input from the user.

Module
USE IFQWIN

Syntax
result = WAITONMOUSEEVENT (mouseevents, keystate, x, y)

mouseevents (Input) INTEGER(4). One or more mouse events that must occur before the function returns. Symbolic constants for the possible mouse events are:
- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$LBUTTONUP - Left mouse button up
- MOUSE$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE$MOVE - Mouse moved

keystate (Output) INTEGER(4). Bitwise inclusive OR of the state of the mouse during the event. The value returned in keystate can be any or all of the following symbolic constants:
- MOUSE$KS_LBUTTON - Left mouse button down during event
- MOUSE$KS_RBUTTON - Right mouse button down during event
- MOUSE$KS_SHIFT - SHIFTkey held down during event
- MOUSE$KS_CONTROL - CTRLkey held down during event

x (Output) INTEGER(4). X position of the mouse when the event occurred.

y (Output) INTEGER(4). Y position of the mouse when the event occurred.

Results
The result type is INTEGER(4). The result is the symbolic constant associated with the mouse event that occurred if successful. If the function fails, it returns the constant MOUSE$BADEVENT, meaning the event specified is not supported.

WAITONMOUSEEVENT does not return until the specified mouse input is received from the user. While waiting for a mouse event to occur, the status bar changes to read "Mouse input pending in XXX", where XXX is the name of the window. When a mouse event occurs, the status bar returns to its previous value.

A mouse event must happen in the window that had focus when WAITONMOUSEEVENT was initially called. Mouse events in other windows will not end the wait. Mouse events in other windows cause callbacks to be called for the other windows, if callbacks were previously registered for those windows.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system’s CONTROL PANEL/MOUSE.
Example

```fortran
USE IFQWIN
INTEGER(4) mouseevent, keystate, x, y, result
... mouseevent = IOR(MOUSE$RBUTTONDOWN, MOUSE$LBUTTONDOWN)
result = WAITONMOUSEEVENT (mouseevent, keystate, x, y)
!
! Wait until right or left mouse button is clicked, then check the keystate
! with the following:
!
if (IAND(MOUSE$KS_SHIFT, keystate) == MOUSE$KS_SHIFT) &
  & write (*,*) 'Shift key was down'
if (IAND(MOUSE$KS_CONTROL, keystate) == MOUSE$KS_CONTROL) &
  & write (*,*) 'Ctrl key was down'
```

REGISTERMOUSEEVENT
UNREGISTERMOUSEEVENT

WHERE

**Statement and Construct:** Lets you use masked array assignment, which performs an array operation on selected elements. This kind of assignment applies a logical test to an array on an element-by-element basis.

**Syntax**

**Statement:**

```fortran
WHERE (mask-exp1) assign-stmt
```

**Construct:**

```fortran
[name:]WHERE (mask-exp1)

  [where-body-stmt] ...

[ELSE WHERE(mask-exp2) [name]

  [where-body-stmt] ...

[ELSE WHERE[name]

  [where-body-stmt] ...

END WHERE [name]
```

**mask-exp1, mask-exp2**

Are logical array expressions (called mask expressions).

**assign-stmt**

Is an assignment statement of the form: array variable = array expression.

**name**

Is the name of the WHERE construct.

**where-body-stmt**

Is one of the following:

- An **assign-stmt**
  
The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
- A WHERE statement or construct
**Description**

If a construct name is specified in a WHERE statement, the same name must appear in the corresponding END WHERE statement. The same construct name can optionally appear in any ELSE WHERE statement in the construct. (ELSE WHERE cannot specify a different name.)

In each assignment statement, the mask expression, the variable being assigned to, and the expression on the right side, must all be conformable. Also, the assignment statement cannot be a defined assignment.

Only the WHERE statement (or the first line of the WHERE construct) can be labeled as a branch target statement.

The following shows an example using a WHERE statement:

```fortran
INTEGER A, B, C
DIMENSION A(5), B(5), C(5)
DATA A /0,1,1,1,0/
DATA B /10,11,12,13,14/
C = -1
WHERE(A .NE. 0) C = B / A
```

The resulting array C contains: -1,11,12,13, and -1.

The assignment statement is only executed for those elements where the mask is true. Think of the mask expression as being evaluated first into a logical array that has the value true for those elements where A is positive. This array of trues and falses is applied to the arrays A, B and C in the assignment statement. The right side is only evaluated for elements for which the mask is true; assignment on the left side is only performed for those elements for which the mask is true. The elements for which the mask is false do not get assigned a value.

In a WHERE construct, the mask expression is evaluated first and only once. Every assignment statement following the WHERE is executed as if it were a WHERE statement with "mask-expr1" and every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(.NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

You should be careful if the statements have side effects, or modify each other or the mask expression.

The following is an example of the WHERE construct:

```fortran
DIMENSION PRESSURE(1000), TEMP(1000), PRECIPITATION(1000)
WHERE(PRESSURE .GE. 1.0)
  PRESSURE = PRESSURE + 1.0
  TEMP = TEMP - 10.0
ELSEWHERE
  PRECIPITATION = .TRUE.
ENDWHERE
```

The mask is applied to the arguments of functions on the right side of the assignment if they are considered to be elemental functions. Only elemental intrinsics are considered elemental functions. Transformational intrinsics, inquiry intrinsics, and functions or operations defined in the subprogram are considered to be nonelemental functions.

Consider the following example using LOG, an elemental function:

```fortran
WHERE(A .GT. 0)  B = LOG(A)
```

The mask is applied to A, and LOG is executed only for the positive values of A. The result of the LOG is assigned to those elements of B where the mask is true.

Consider the following example using SUM, a nonelemental function:

```fortran
REAL A, B
DIMENSION A(10,10), B(10)
WHERE(B .GT. 0.0)  B = SUM(A, DIM=1)
```
Since SUM is nonelemental, it is evaluated fully for all of A. Then, the assignment only happens for those elements for which the mask evaluated to true.

Consider the following example:

```fortran
REAL A, B, C
DIMENSION A(10,10), B(10), C(10)
WHERE(C .GT. 0.0)  B = SUM(LOG(A), DIM=1)/C
```

Because SUM is nonelemental, all of its arguments are evaluated fully regardless of whether they are elemental or not. In this example, LOG(A) is fully evaluated for all elements in A even though LOG is elemental. Notice that the mask is applied to the result of the SUM and to C to determine the right side. One way of thinking about this is that everything inside the argument list of a nonelemental function does not use the mask, everything outside does.

Example

```fortran
REAL(4) a(20)
. . .
WHERE (a > 0.0)
a = LOG (a)
!LOG is invoked only for positive elements
END WHERE
```

FORALL
Arrays

WORKSHARE

OpenMP* Fortran Compiler Directive: Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

Syntax

```fortran
!$OMP WORKSHARE
  block
!$OMP END WORKSHARE [NOWAIT]
```

block

Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed.

The block is executed so that each statement is completed before the next statement is started and the evaluation of the right hand side of an assignment is completed before the effects of assigning to the left hand side occur.

The following are additional rules for block:

- It may contain statements which bind to lexically enclosed PARALLEL constructs. Statements in these PARALLEL constructs are not restricted.
- It may contain ATOMIC directives and CRITICAL constructs.
- It must only contain array assignment statements, scalar assignment statements, FORALL statements, FORALL constructs, WHERE statements, or WHERE constructs.
- It must not contain any user defined function calls unless the function is ELEMENTAL.
The binding thread set for a WORKSHARE construct is the current team. A workshare region binds to the innermost enclosing parallel region.

If you do not specify the NOWAIT keyword, synchronization is implied following the code.

Multithreaded code is not always generated for the statements inside the block of an OMP WORKSHARE construct. Some statements parallelize; others do not parallelize and instead execute sequentially inside an OMP SINGLE construct to preserve the correct semantics of WORKSHARE. Some specific details follow:

- Simple array assignments such as \( A = B + C \) parallelize.
- Simple array assignments with overlap such as \( A = A + B + C \) parallelize.
- Array assignments with user-defined function calls parallelize such as \( A = A + F(B) \). \( F \) must be ELEMENTAL.
- Array assignments with array slices on the right hand side of the assignment such as \( A = A + B(1:4) + C(1:4) \) parallelize. If the lower bound of the left hand side or the array slice lower bound or the array slice stride on the right hand side is not 1, then the statement does not parallelize.
- Assigning into array slices does not parallelize.
- Scalar assignments do not parallelize – there is no work that needs to be done in parallel.
- FORALL and WHERE constructs do not parallelize.

**WRAPON (W*S)**
*Graphics Function: Controls whether text output is wrapped.*

**Module**
USE IFQWIN

**Syntax**
result = WRAPON (option)

Option: INTEGER(2). Wrap mode. One of the following symbolic constants:
- $GWRAPOFF - Truncates lines at right edge of window border.
- $GWRAPON - Wraps lines at window border, scrolling if necessary.

**Results**
The result type is INTEGER(2). The result is the previous value of option.

WRAPON controls whether text output with the OUTTEXT function wraps to a new line or is truncated when the text output reaches the edge of the defined text window.

WRAPON does not affect font routines such as OUTGTEXT.

**Example**
USE IFQWIN
INTEGER(2) row, status2
INTEGER(4) status4
TYPE ( rcoord ) curpos
TYPE ( windowconfig ) wc
LOGICAL status
status = GETWINDOWCONFIG( wc )
w%numtextcols = 80
w%numxpixels  = -1
w%numypixels  = -1
w%numtextrows = -1
w%numcolors   = -1
w%fontsize    = -1
w%title = "This is a test"
w%bitsperpixel = -1
status = SETWINDOWCONFIG( wc )
status4= SETBKCOLORRGB(#FF0000 )
CALL CLEARSCREEN( $GCLEARSCREEN )

! Display wrapped and unwrapped text in text windows.
CALL SETTEXTWINDOW( INT2(1),INT2(1),INT2(5),INT2(25))
CALL SETTEXTPOSITION( INT2(1),INT2(1), curpos )
status2 = WRAPON( $GWRAPON )
status4 = SETTEXTCOLORRGB(#00FF00)
DO i = 1, 5
   CALL OUTTEXT( 'Here text does wrap. ')
END DO
CALL SETTEXTWINDOW(INT2(7),INT2(10),INT2(11),INT2(40))
CALL SETTEXTPOSITION(INT2(1),INT2(1),curpos)
status2 = WRAPOFF( $GWRAPOFF )
status4 = SETTEXTCOLORRGB(#008080)
DO row = 1, 5
   CALL SETTEXTPOSITION(INT2(row), INT2(1), curpos )
   CALL OUTTEXT('Here text does not wrap. ')
   CALL OUTTEXT('Here text does not wrap.')
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

SETTEXTWINDOW (W*S)

WRITE Statement
Statement: Transfers output data to external sequential, direct-access, or internal records.

Syntax
Sequential
Formatted:

Formatted - List-Directed:

Formatted - Namelist:
Unformatted:

Direct-Access

Formatted:

Unformatted:

Internal

WRITE (iunit, format [, nml-group] [, iostat] [, err] [, iomsg])[io-list]

Internal Namelist

WRITE (iunit, nml-group [, iostat] [, err] [, iomsg])[io-list]

eunit

Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if eunit is not the first specifier in the list.

format

Is a format specifier. It is optionally prefaced by FMT= if format is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

advance

Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous

Is an asynchronous specifier (ASYNCRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

decimal

Is a decimal mode specifier (DECIMAL=dmode) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.

delim

Is a delimiter specifier (DELIM=del). If the value of del is 'APOSTROPHE', apostrophes delimit character constants. If the value is 'QUOTE', quotes delimit character constants. If the value of del is 'NONE', character constants have no delimiters.

id

Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

pos

Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

round

Is a rounding specifier (ROUND=rmode) that determines the I/O rounding mode for this WRITE statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.
sign  Is a plus sign specifier (SIGN=sn). This controls whether optional plus characters appear in formatted numeric output.

iostat  Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

err  Are branch specifiers if an error (ERR=label) condition occurs.

iomsg  Is an I/O message specifier (IOMSG=msg-var).

io-list  Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

form  Is the nonkeyword form of a format specifier (no FMT=).

*  Is the format specifier indicating list-directed formatting. (It can also be specified as FMT= *.)

nml-group  Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if nml-group is not the second I/O specifier. For more information, see Namelist Specifier.

rec  Is the cell number of a record to be accessed directly. It must be prefaced by REC=.

iunit  Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if iunit is not the first specifier in the list.

It must be a character variable. It must not be an array section with a vector subscript.

If an item in io-list is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as eunit.

If you specify DECIMAL=, ROUND=, or SIGN= you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Example

```fortran
! write to file
open(1,FILE='test.dat')
write (1, '(A20)') namedef
! write with FORMAT statement
WRITE (*, 10) (n, SQRT(FLOAT(n)), FLOAT(n)**(1.0/3.0), n = 1, 100)
10 FORMAT (i5, f8.4, f8.5)
```

The following shows another example:

```fortran
WRITE(6,'("Expected ",F12.6")') 2.0
```

XOR

_Elemental Intrinsic Function (Generic):_ An alternative name for intrinsic function IEOR.

See Also
See IEOR.

ZEXT

_Elemental Intrinsic Function (Generic):_ Extends an argument with zeros. This function is used primarily for bit-oriented operations. It cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{ZEXT} \left( x \left[, kind \right] \right)
\]

\( x \) (Input) Must be of type logical or integer.

\( \text{kind} \) (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is \( x \) extended with zeros and treated as an unsigned value.

The storage requirements for integer constants are never less than two bytes. Integer constants within the range of constants that can be represented by a single byte still require two bytes of storage.

The setting of compiler options specifying integer size can affect this function.

</tbody>
</table>

These specific functions cannot be passed as actual arguments.

Example

Consider the following example:

```fortran
INTEGER(2) W_VAR  /'FFFF'X/
INTEGER(4) L_VAR
L_VAR = ZEXT( W_VAR )
```

This example stores an INTEGER(2) quantity in the low-order 16 bits of an INTEGER(4) quantity, with the resulting value of L_VAR being '0000FFFF'X. If the ZEXT function had not been used, the resulting value would have been 'FFFFFFFF'X, because W_VAR would have been converted to the left-hand operand’s data type by sign extension.
Glossary A

absolute pathname
A directory path specified in fixed relationship to the root directory. On Windows* systems, the first character is a backslash (\). On Linux* and OS X* systems, the first character is a slash (/).

abstract interface
A named set of procedure characteristics that can be referenced in PROCEDURE declarations.

abstract type
A derived type, declared with the ABSTRACT keyword, which can be extended to declare an object. An abstract type cannot be used directly to declare an object.

active screen buffer
The screen buffer that is currently displayed in a console's window.

active window
A top-level window of the application with which the user is working. The Windows system identifies the active window by highlighting its title bar and border.

actual argument
A value (a variable, expression, or procedure) passed from a calling program unit to a subprogram (function or subroutine). See also dummy argument.

adjustable array
An explicit-shape array that is a dummy argument to a subprogram. The term is from FORTRAN 77. See also explicit-shape array.

aggregate reference
A reference to a record structure field.

allocatable array
A named array that has the ALLOCATABLE attribute. The array's rank is specified at compile time, but its bounds are determined at run time. Once space has been allocated for this type of array, the array has a shape and can be defined (and redefined) or referenced. It is an error to allocate an allocatable array that is currently allocated.

allocation status
Indicates whether an allocatable array or pointer is allocated. An allocation status is one of: allocated, deallocated, or undefined. An undefined allocation status means an array can no longer be referenced, defined, allocated, or deallocated. See also association status.

alphanumeric
Pertaining to letters and digits.

alternate return
A subroutine argument that permits control to branch immediately to some position other than the statement following the call. The actual argument in an alternate return is the statement label to which control should be transferred. (An alternate return is an obsolescent feature in Standard Fortran.)

ANSI
The American National Standards Institute. An organization through which accredited organizations create and maintain voluntary industry standards.

<thead>
<tr>
<th>ASCII</th>
<th>The American Standard Code for Information Interchange. A 7-bit character encoding scheme associating an integer from 0 through 127 with 128 characters.</th>
</tr>
</thead>
</table>

| Assignment Statement      | Usually, a statement that assigns (stores) the value of an expression on the right of an equal sign to the storage location of the variable to the left of the equal sign. In the case of Fortran pointers, the storage location is assigned, not the pointer itself. |
associate name
The name of a construct entity associated with a selector of an ASSOCIATE or SELECT TYPE construct.

association
The relationship that allows an entity to be referenced by different names in one scoping unit or by the same or different names in more than one scoping unit. The principal kinds of association are argument, host, pointer, storage, and use association. See also argument association, host association, pointer association, storage association, and use association.

association status
Indicates whether or not a pointer is associated with a target. An association status is one of: undefined, associated, or disassociated. An undefined association status means a pointer can no longer be referenced, defined, or deallocated. An undefined pointer can, however, be allocated, nullified, or pointer assigned to a new target. See also allocation status.

assumed-length character argument
A dummy argument that assumes the length attribute of the corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

assumed-shape array
A dummy argument array that assumes the shape of its associated actual argument array. The rank of the array is the number of colons (:) specified in parentheses.

assumed-size array
A dummy array whose size (only) is assumed from its associated actual argument. The upper bound of its last dimension is specified by an asterisk (*). All other extents (if any) must be specified.

atomic subroutine
An intrinsic subroutine that performs an action on a variable (its ATOM argument) indivisibly.

attribute
A property of a data object that can be specified in a type declaration statement. These properties determine how the data object can be used in a program.

Most attributes can be alternatively specified in statements. For example, the DIMENSION statement has the same meaning as the DIMENSION attribute appearing in a type declaration statement.

automatic array
An explicit-shape array that is a local variable in a subprogram. It is not a dummy argument, and has bounds that are nonconstant specification expressions. The bounds (and shape) are determined at entry to the procedure by evaluating the bounds expressions. See also automatic object.

automatic object
A local data object that is created upon entry to a subprogram and disappears when the execution of the subprogram is completed. There are two kinds of automatic objects: arrays (of any data type) and objects of type CHARACTER. Automatic objects cannot be saved or initialized.

An automatic object is not a dummy argument, but is declared with a specification expression that is not a constant expression. The specification expression can be the bounds of the array or the length of the character object.
**Glossary B**

**background process**  
On Linux* systems, a process for which the command interpreter is not waiting. Its process group differs from that of its controlling terminal, so it is blocked from most terminal access. Contrast with foreground process.

**background window**  
Any window created by a thread other than the foreground thread.

**big endian**  
A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the highest addressed byte. Contrast with little endian.

**binary constant**  
A constant that is a string of binary (base 2) digits (0 or 1) enclosed by apostrophes or quotation marks and preceded by the letter B.

**binary operator**  
An operator that acts on a pair of operands. The exponentiation, multiplication, division, and concatenation operators are binary operators.

**bit constant**  
A constant that is a binary, octal, or hexadecimal number.

**bit field**  
A contiguous group of bits within a binary pattern; they are specified by a starting bit position and length. Some intrinsic functions (for example, IBSET and BTEST) and the intrinsic subroutine MVBITS operate on bit fields.

**bitmap**  
An array of bits that contains data that describes the colors found in a rectangular region on the screen (or the rectangular region found on a page of printer paper).

**blank common**  
A common block (one or more contiguous areas of storage) without a name. Common blocks are defined by a COMMON statement.

**block**  
In general, a group of related items treated as a physical unit. For example, a block can be a group of constructs or statements that perform a task; the task can be executed once, repeatedly, or not at all.

**block data program unit**  
A program unit, containing a BLOCK DATA statement and its associated specification statements, that establishes common blocks and assigns initial values to the variables in named common blocks. In FORTRAN 77, this was called a block data subprogram.

**bounds**  
The range of subscript values for elements of an array. The lower bound is the smallest subscript value in a dimension, and the upper bound is the largest subscript value in that dimension. Array bounds can be positive, zero, or negative. These bounds are specified in an array specification. See also array specification.

**breakpoint**  
A critical point in a program, at which execution is stopped so that you can see if the program variables contain the correct values. Breakpoints are often used to debug programs.

**brush**  
A bitmap that is used to fill the interior of closed shapes, polygons, ellipses, and paths.
brush origin A coordinate that specifies the location of one of the pixels in a brush's bitmap. The Windows system maps this pixel to the upper left corner of the window that contains the object to be painted. See also bitmap.

built-in procedure See intrinsic procedure.

byte A group of 8 contiguous bits (binary digits) starting on an addressable boundary.

byte-order mark A special Unicode character (0xFEFF) that is placed at the beginning of Unicode text files to indicate that the text is in Unicode format.

Glossary C
carriage-control character A character in the first position of a printed record that determines the vertical spacing of the output line.

character constant A constant that is a string of printable ASCII characters enclosed by apostrophes (’) or quotation marks (").

character expression A character constant, variable, function value, or another constant expression, separated by a concatenation operator (//); for example, DAY// 'FIRST'.

character storage unit The unit of storage for holding a scalar value of default character type (and character length one) that is not a pointer. One character storage unit corresponds to one byte of memory.

character string A sequence of contiguous characters; a character data value. See also character constant.

character substring One or more contiguous characters in a character string.

child process A process initiated by another process (the parent). The child process can operate independently from the parent process. Also, the parent process can suspend or terminate without affecting the child process. See also parent process.

child window A window that has the WS_CHILD style. A child window always appears within the client area of its parent window. See also parent window.

column-major order See order of subscript progression.

coarray A data entity that has nonzero corank. A Fortran program containing coarrays is interpreted as if it were replicated a fixed number of times and all copies were executed asynchronously. Its corank, cobounds, and coextents are given by the data in square brackets in its declaration or allocation.

cobound A bound (limit) of a codimension. The values of each lower cobound and upper cobound determine the cobounds of the coarray along a particular codimension.

codimension A dimension of the pattern formed by a set of corresponding coarrays.
comment

Text that documents or explains a program. In free source form, a comment begins with an exclamation point (!), unless it appears in a Hollerith or character constant.

In fixed and tab source form, a comment begins with a letter C or an asterisk (*) in column 1. A comment can also begin with an exclamation point anywhere in a source line (except in a Hollerith or character constant) or in column 6 of a fixed-format line. The comment extends from the exclamation point to the end of the line.

The compiler does not process comments, but shows them in program listings. See also compiler directive.

common block

A physical storage area shared by one or more program units. This storage area is defined by a COMMON statement. If the common block is given a name, it is a named common block; if it is not given a name, it is a blank common. See also blank common and named common block.

compilation unit

The source or files that are compiled together to form a single object file, possibly using interprocedural optimization across source files.

compiler directive

A structured comment that tells the compiler to perform certain tasks when it compiles a source program unit. Compiler directives are usually compiler-specific. (Some Fortran compilers call these directives "metacommands".)

compiler option

An option (or flag) that can be used on the compiler command line to override the default behavior of the Intel® Fortran compiler.

complex constant

A constant that is a pair of real or integer constants representing a complex number; the pair is separated by a comma and enclosed in parentheses. The first constant represents the real part of the number; the second constant represents the imaginary part. The following types of complex constants are available on all systems: COMPLEX(KIND=4), COMPLEX(KIND=8), and COMPLEX(KIND=16).

complex type

A data type that represents the values of complex numbers. The value is expressed as a complex constant. See also data type.

component

Part of a derived-type definition. There must be at least one component (intrinsic or derived type) in every derived-type definition.

component order

The ordering of the components of a derived type that is used for intrinsic formatted input/output and for structure constructors.

concatenate

The combination of two items into one by placing one of the items after the other. In Standard Fortran, the concatenation operator (///) is used to combine character items. See also character expression.

conformable

Pertains to dimensionality. Two arrays are conformable if they have the same shape. A scalar is conformable with any array.

conformance

See shape conformance.

conservative automatic inlining

The inline expansion of small procedures, with conservative heuristics to limit extra code.

console

An interface that provides input and output to character-mode applications.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>A data object whose value does not change during the execution of a program; the value is defined at the time of compilation. A constant can be named (using the PARAMETER attribute or statement) or unnamed. An unnamed constant is called a literal constant. The value of a constant can be numeric or logical, or it can be a character string. Contrast with variable.</td>
</tr>
<tr>
<td>constant expression</td>
<td>An expression whose value does not change during program execution.</td>
</tr>
<tr>
<td>construct</td>
<td>A series of statements starting with a statement denoting the kind of construct, such as DO, SELECT CASE, IF, FORALL, or WHERE, and ending with the appropriate termination statement.</td>
</tr>
<tr>
<td>construct association</td>
<td>The association between a selector and an associate name in an ASSOCIATE or SELECT TYPE construct.</td>
</tr>
<tr>
<td>contiguous</td>
<td>Pertaining to entities that are adjacent (next to one another) without intervening blanks (spaces); for example, contiguous characters or contiguous areas of storage.</td>
</tr>
<tr>
<td>control edit descriptor</td>
<td>A format descriptor that directly displays text or affects the conversions performed by subsequent data edit descriptors. Except for the slash descriptor, control edit descriptors are nonrepeatable.</td>
</tr>
<tr>
<td>control statement</td>
<td>A statement that alters the normal order of execution by transferring control to another part of a program unit or a subprogram. A control statement can be conditional (such as the IF construct or computed GO TO statement) or unconditional (such as the STOP or GO TO statement).</td>
</tr>
<tr>
<td>corank</td>
<td>The number of codimensions of a coarray.</td>
</tr>
<tr>
<td>critical section</td>
<td>An object used to synchronize the threads of a single process. Only one thread at a time can own a critical-section object.</td>
</tr>
</tbody>
</table>

**Glossary D**

<table>
<thead>
<tr>

<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>data abstraction</td>
<td>A style of programming in which you define types to represent objects in your program, define a set of operations for objects of each type, and restrict the operations to only this set, making the types abstract. The Standard Fortran modules, derived types, and defined operators, support this programming paradigm.</td>
</tr>
<tr>
<td>data edit descriptor</td>
<td>A repeatable format descriptor that causes the transfer or conversion of data to or from its internal representation. In FORTRAN 77, this term was called a field descriptor.</td>
</tr>
<tr>
<td>data entity</td>
<td>A data object that has a data type. It is the result of the evaluation of an expression, or the result of the execution of a function reference (the function result).</td>
</tr>
<tr>
<td>data item</td>
<td>A unit of data (or value) to be processed. Includes constants, variables, arrays, character substrings, or records.</td>
</tr>
<tr>
<td>data object</td>
<td>A constant, variable, or subobject (part) of a constant or variable. Its type may be specified implicitly or explicitly.</td>
</tr>
</tbody>
</table>
data type

The properties and internal representation that characterize data and functions. Each intrinsic and user-defined data type has a name, a set of operators, a set of values, and a way to show these values in a program. The basic intrinsic data types are integer, real, complex, logical, and character. The data value of an intrinsic data type depends on the value of the type parameter. See also type parameter.

data type declaration

See type declaration statement.

data type length specifier

The form *n appended to Intel® Fortran-specific data type names. For example, in REAL*4, the *4 is the data type length specifier.

deadlock

A bug where the execution of thread A is blocked indefinitely waiting for thread B to perform some action, while thread B is blocked waiting for thread A. For example, two threads on opposite ends of a named pipe can become deadlocked if each thread waits to read data written by the other thread. A single thread can also deadlock itself. See also thread.

declaration

See specification statement.

declared type

The type that a data entity is declared to have. For polymorphic data entities, it may differ from the type during execution (the dynamic type).

decorated name

An internal representation of a procedure name or variable name that contains information about where it is declared; for procedures, the information includes how it is called. Decorated names are mainly of interest in mixed-language programming, when calling Fortran routines from other languages.

default character

The kind for character constants if no kind type parameter is specified. Currently, the only kind type parameter for character constants is CHARACTER(1), the default character kind.

default complex

The kind for complex constants if no kind type parameter is specified.
The default complex kind is affected by compiler options specifying double size. If no compiler option is specified, default complex is COMPLEX(4) (COMPLEX*8). See also default real.

default integer

The kind for integer constants if no kind type parameter is specified.
The default integer kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default integer is INTEGER(4) (INTEGER*4).

If a command line option affecting integer size has been specified, the integer has the kind specified, unless it is outside the range of the kind specified by the option. In this case, the kind type of the integer is the smallest integer kind which can hold the integer.

default logical

The kind for logical constants if no kind type parameter is specified.
The default logical kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default logical is LOGICAL(4) (LOGICAL*4). See also default integer.

default real

The kind for real constants if no kind type parameter is specified. The default real kind is affected by compiler options specifying real size and by the REAL directive. If neither of these is specified, default real is REAL(4) (REAL*4).
If a real constant is encountered that is outside the range for the default, an error occurs.

**deferred-shape array**
An array pointer (an array with the `POINTER` attribute) or an allocatable array (an array with the `ALLOCATABLE` attribute). The size in each dimension is determined by pointer assignment or when the array is allocated.

The array specification contains a colon (:) for each dimension of the array. No bounds are specified.

**definable**
A property of variables. A variable is definable if its value can be changed by the appearance of its name or designator on the left of an assignment statement. An example of a variable that is not definable is an allocatable array that has not been allocated.

**defined**
For a data object, the property of having or being given a valid value.

**defined assignment**
An assignment statement that is not intrinsic, but is defined by a subroutine and an `ASSIGNMENT(=)` interface block. See also derived type and interface block.

**defined operation**
An operation that is not intrinsic, but is defined by a function subprogram containing a generic interface block with the specifier `OPERATOR`. See also derived type and interface block.

**denormalized number**
A computational floating-point result smaller than the lowest value in the normal range of a data type (the smallest representable normalized number). You cannot write a constant for a denormalized number.

**derived type**
A data type that is user-defined and not intrinsic. It requires a type definition to name the type and specify its components (which can be intrinsic or user-defined types). A structure constructor can be used to specify a value of derived type. A component of a structure is referenced using a percent sign (%).

Operations on objects of derived types (structures) must be defined by a function with an `OPERATOR` interface. Assignment for derived types can be defined intrinsically, or be redefined by a subroutine with an `ASSIGNMENT(=)` interface. Structures can be used as procedure arguments and function results, and can appear in input and output lists. Also called a user-defined type. See also record, the first definition.

**designator**
A name that references a subobject (part of a data object) that can be defined and referenced separately from other parts of the data object. A designator is the name of the object followed by a selector that selects the subobject. For example, B(3) is a designator for an array element. Also called a subobject designator. See also selector and subobject.

**dimension**
A range of values for one subscript or index of an array. An array can have from 1 to 7 dimensions. The number of dimensions is the rank of the array.

**dimension bounds**
See bounds.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>direct access</td>
<td>A method for retrieving or storing data in which the data (record) is identified by the record number, or the position of the record in the file. The record is accessed directly (nonsequentially); therefore, all information is equally accessible. Also called random access. Contrast with sequential access.</td>
</tr>
<tr>
<td>DLL</td>
<td>See Dynamic Link Library.</td>
</tr>
<tr>
<td>double-byte character set (DBCS)</td>
<td>A mapping of characters to their identifying numeric values, in which each value is 2 bytes wide. Double-byte character sets are sometimes used for languages that have more than 256 characters.</td>
</tr>
<tr>
<td>double-precision constant</td>
<td>A processor approximation to the value of a real number that occupies 8 bytes of memory and can assume a positive, negative, or zero value. The precision is greater than a constant of real (single-precision) type. For the precise ranges of the double-precision constants, see Data Representation Overview in the Compiler Reference. See also denormalized number.</td>
</tr>
<tr>
<td>driver program</td>
<td>A program that is the user interface to the language compiler. It accepts command line options and file names and causes one or more language utilities or system programs to process each file.</td>
</tr>
<tr>
<td>dummy aliasing</td>
<td>The sharing of memory locations between dummy (formal) arguments and other dummy arguments or COMMON variables that are assigned.</td>
</tr>
<tr>
<td>dummy argument</td>
<td>A variable whose name appears in the parenthesized list following the procedure name in a FUNCTION statement, a SUBROUTINE statement, an ENTRY statement, or a statement function statement. A dummy argument takes the value of the corresponding actual argument in the calling program unit (through argument association). Also called a formal argument.</td>
</tr>
<tr>
<td>dummy array</td>
<td>A dummy argument that is an array.</td>
</tr>
<tr>
<td>dummy pointer</td>
<td>A dummy argument that is a pointer.</td>
</tr>
<tr>
<td>dummy procedure</td>
<td>A dummy argument that is specified as a procedure or appears in a procedure reference. The corresponding actual argument must be a procedure.</td>
</tr>
<tr>
<td>Dynamic Link Library (DLL)</td>
<td>A separate source module compiled and linked independently of the applications that use it. Applications access the DLL through procedure calls. The code for a DLL is not included in the user’s executable image, but the compiler automatically modifies the executable image to point to DLL procedures at run time.</td>
</tr>
<tr>
<td>dynamic type</td>
<td>The type of a data entity during execution of a program. The dynamic type of a data entity that is not polymorphic is the same as its declared type.</td>
</tr>
</tbody>
</table>

</tbody>
</table>
| elemental             | Pertains to an intrinsic operation, intrinsic procedure, or assignment statement that is independently applied to either of the following:  
  - The elements of an array  
  - Corresponding elements of a set of conformable arrays and scalars |
| end-of-file           | The condition that exists when all records in a file open for sequential access have been read. |
| entity                | A general term referring to any Standard Fortran concept; for example, a constant, a variable, a program unit, a statement label, a common block, a construct, an I/O unit and so forth. |
| environment variable  | A symbolic variable that represents some element of the operating system, such as a path, a filename, or other literal data. |
| error number          | An integer value denoting an I/O error condition, obtained by using the IOSTAT keyword in an I/O statement. |
| exceptional values    | For floating-point numbers, values outside the range of normalized numbers, including denormal (subnormal) numbers, infinity, Not-a-Number (NaN) values, zero, and other architecture-defined numbers. |
| executable construct  | A CASE, DO, IF, WHERE, or FORALL construct. |
| executable program    | A set of program units that include only one main program. |
| executable statement  | A statement that specifies an action to be performed or controls one or more computational instructions. |
| explicit interface    | A procedure interface whose properties are known within the scope of the calling program, and do not have to be assumed. These properties are the names of the procedure and its dummy arguments, the attributes of a procedure (if it is a function), and the attributes and order of the dummy arguments.  
  The following have explicit interfaces:  
  - Internal and module procedures (explicit by definition)  
  - Intrinsic procedures  
  - External procedures that have an interface block  
  - External procedures that are defined by the scoping unit and are recursive  
  - Dummy procedures that have an interface block |
| explicit-shape array  | An array whose rank and bounds are specified when the array is declared. |
| expression            | A data reference or a computation formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values. |
| extended type         | An extensible type that is an extension of another type. A type that is declared with the EXTENDS attribute. |
| extensible type       | A type from which new types may be derived using the EXTENDS attribute. A nonsequence type that does not have the BIND attribute. |
| extent                | The size of (number of elements in) one dimension of an array. |
external file  A sequence of records that exists in a medium external to the executing program.

external procedure  A procedure that is contained in an external subprogram. External procedures can be used to share information (such as source files, common blocks, and public data in modules) and can be used independently of other procedures and program units. Also called an external routine.

external subprogram  A subroutine or function that is not contained in a main program, module, or another subprogram. A module is not a subprogram.

**Glossary F**

field  Can be either of the following:
- A set of contiguous characters, considered as a single item, in a record or line.
- A substructure of a STRUCTURE declaration.

field descriptor  See data edit descriptor.

field separator  The comma (,) or slash (/) that separates edit descriptors in a format specification.

field width  The total number of characters in the field. See also field, the first definition.

file  A collection of logically related records. If the file is in internal storage, it is an internal file; if the file is on an input/output device, it is an external file.

file access  The way records are accessed (and stored) in a file. The standard Fortran file access modes are sequential and direct.

file handle  A unique identifier that the system assigns to a file when the file is opened or created. A file handle is valid until the file is closed.

file organization  The way records in a file are physically arranged on a storage device. Standard Fortran files can have sequential or relative organization.

final subroutine  A subroutine whose name appears in a FINAL statement in a type definition. It can be automatically invoked by the processor when an object of that type is finalized.

final task  A task that forces all of its descendant tasks to become included tasks.

fixed-length record type  A file format in which all the records are the same length.

floating-point environment  A collection of registers that control the behavior of floating-point (FP) machine instructions and indicate the current FP status. The floating-point environment may include rounding mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

focus window  The window to which keyboard input is directed.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground process</td>
<td>On Linux* systems, a process for which the command interpreter is waiting. Its process group is the same as that of its controlling terminal, so the process is allowed to read from or write to the terminal. Contrast with background process.</td>
</tr>
<tr>
<td>foreground window</td>
<td>The window the user is currently working with. The system assigns a slightly higher priority to the thread that created the foreground window than it does to other threads.</td>
</tr>
<tr>
<td>foreign file</td>
<td>An unformatted file that contains data from a foreign platform, such as data from a CRAY*, IBM*, or big endian IEEE* machine.</td>
</tr>
<tr>
<td>format</td>
<td>A specific arrangement of data. A FORMAT statement specifies how data is to be read or written.</td>
</tr>
<tr>
<td>format specification</td>
<td>The part of a FORMAT statement that specifies explicit data arrangement. It is a list within parentheses that can include edit descriptors and field separators. A character expression can also specify format; the expression must evaluate to a valid format specification.</td>
</tr>
<tr>
<td>formatted data</td>
<td>Data written to a file by using formatted I/O statements. Such data contains ASCII representations of binary values.</td>
</tr>
<tr>
<td>formatted I/O statement</td>
<td>An I/O statement specifying a format for data transfer. The format specified can be explicit (specified in a format specification) or implicit (specified using list-directed or namelist formatting). Contrast with unformatted I/O statement. See also list-directed I/O statement and namelist I/O statement.</td>
</tr>
<tr>
<td>frame window</td>
<td>The outermost parent window in QuickWin.</td>
</tr>
<tr>
<td>function</td>
<td>A series of statements that perform some operation and return a single value (through the function or result name) to the calling program unit. A function is invoked by a function reference in a main program unit or a subprogram unit. In Standard Fortran, a function can be used to define a new operator or extend the meaning of an intrinsic operator symbol. The function is invoked by the appearance of the new or extended operator in the expression (along with the appropriate operands). For example, the symbol * can be defined for logical operands, extending its intrinsic definition for numeric operands. See also function subprogram, statement function, and subroutine.</td>
</tr>
<tr>
<td>function reference</td>
<td>Used in an expression to invoke a function, it consists of the function name and its actual arguments. A function reference returns a value (through the function or result name) that is used to evaluate the calling expression.</td>
</tr>
<tr>
<td>function result</td>
<td>The result value associated with a particular execution or call to a function. This result can be of any data type (including derived type) and can be array-valued. In a FUNCTION statement, the RESULT option can be used to give the result a name different from the function name. This option is required for a recursive function that directly calls itself.</td>
</tr>
<tr>
<td>function subprogram</td>
<td>A sequence of statements beginning with a FUNCTION (or optional OPTIONS) statement that is not in an interface block and ending with the corresponding END statement. See also function.</td>
</tr>
</tbody>
</table>
Glossary G

generic identifier
A generic name, operator, or assignment specified in an INTERFACE statement that is associated with all of the procedures within the interface block. Also called a generic specification.

global entity
An entity (a program unit, common block, or external procedure) that can be used with the same meaning throughout the executable program. A global entity has global scope; it is accessible throughout an executable program. See also local entity.

global section
A data structure (for example, global COMMON) or shareable image section potentially available to all processes in the system.

Glossary H

handle
A value (often, but not always, a 32-bit integer) that identifies some operating system resource, for example, a window or a process. The handle value is returned from an operating system call when the resource is created; your program then passes that value as an argument to subsequent operating system routines to identify which resource is being accessed.

Your program should consider the handle value a "private" type and not try to interpret it as having any specific meaning (for example, an address).

hexadecimal constant
A constant that is a string of hexadecimal (base 16) digits (range 0 to 9, or an uppercase or lowercase letter in the range A to F) enclosed by apostrophes or quotation marks and preceded by the letter Z.

Hollerith constant
A constant that is a string of printable ASCII characters preceded by nH, where n is the number of characters in the string (including blanks and tabs).

host
Either the main program or subprogram that contains an internal procedure, or the module that contains a module procedure. The data environment of the host is available to the (internal or module) procedure.

host association
The process by which a module procedure, internal procedure, or derived-type definition accesses the entities of its host.

Glossary I

image
An instance of a Fortran program.

image index
An integer value that identifies an image.

image control statement
A statement that affects the execution ordering between images.

implicit interface
A procedure interface whose properties (the collection of names, attributes, and arguments of the procedure) are not known within the scope of the calling program, and have to be assumed. The information is assumed by the calling program from the properties of the procedure name and actual arguments in the procedure call.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>implicit typing</td>
<td>The mechanism by which the data type for a variable is determined by the beginning letter of the variable name.</td>
</tr>
<tr>
<td>import library</td>
<td>A .LIB file that contains information about one or more dynamic-link libraries (DLLs), but does not contain the DLL’s executable code. To provide the information needed to resolve the external references to DLL functions, the linker uses an import library when building an executable module of a process.</td>
</tr>
<tr>
<td>included task</td>
<td>A task for which execution is sequentially included in the generating task region; that is, the task is undeferrred and executed immediately by the encountering thread.</td>
</tr>
<tr>
<td>index</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>• The variable used as a loop counter in a DO statement.</td>
</tr>
<tr>
<td></td>
<td>• An intrinsic function specifying the starting position of a substring inside a string.</td>
</tr>
<tr>
<td>inheritance association</td>
<td>The relationship between the inherited components and the parent component in an extended type.</td>
</tr>
<tr>
<td>initialize</td>
<td>The assignment of an initial value to a variable.</td>
</tr>
<tr>
<td>initialization expression</td>
<td>A form of constant expression that is used to specify an initial value for an entity.</td>
</tr>
<tr>
<td>inlining</td>
<td>An optimization that replaces a subprogram reference (CALL statement or function invocation) with the replicated code of the subprogram.</td>
</tr>
<tr>
<td>input/output (I/O)</td>
<td>The data that a program reads or writes. Also, devices to read and write data.</td>
</tr>
<tr>
<td>inquiry function</td>
<td>An intrinsic function whose result depends on properties of the principal argument, not the value of the argument.</td>
</tr>
<tr>
<td>integer constant</td>
<td>A constant that is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.</td>
</tr>
<tr>
<td>intent</td>
<td>An attribute of a dummy argument that is not a procedure or a pointer. It indicates whether the argument is used to transfer data into the procedure, out of the procedure, or both.</td>
</tr>
<tr>
<td>interactive process</td>
<td>A process that must periodically get user input to do its work. Contrast with background process.</td>
</tr>
<tr>
<td>interface</td>
<td>See procedure interface.</td>
</tr>
<tr>
<td>interface block</td>
<td>The sequence of statements starting with an INTERFACE statement and ending with the corresponding END INTERFACE statement.</td>
</tr>
<tr>
<td>interface body</td>
<td>The sequence of statements in an interface block starting with a FUNCTION or SUBROUTINE statement and ending with the corresponding END statement. Also called a procedure interface body.</td>
</tr>
<tr>
<td>internal file</td>
<td>The designated internal storage space (or variable buffer) that is manipulated during input and output. An internal file can be a character variable, character array, character array element, or</td>
</tr>
</tbody>
</table>
character substring. In general, an internal file contains one record. However, an internal file that is a character array has one record for each array element.

internal procedure
A procedure (other than a statement function) that is contained within an internal subprogram. The program unit containing an internal procedure is called the host of the internal procedure. The internal procedure (which appears between a CONTAINS and END statement) is local to its host and inherits the host's environment through host association.

internal subprogram
A subprogram contained in a main program or another subprogram.

intrinsic
Describes entities defined by the Fortran 2003 language (such as data types and procedures). Intrinsic entities can be used freely in any scoping unit.

intrinsic procedure
A subprogram supplied as part of the Fortran library that performs array, mathematical, numeric, character, bit manipulation, and other miscellaneous functions. Intrinsic procedures are automatically available to any Fortran program unit (unless specifically overridden by an EXTERNAL statement or a procedure interface block). Also called a built-in or library procedure.

invoke
To call upon; used especially with reference to subprograms. For example, to invoke a function is to execute the function.

iteration count
The number of executions of the DO range, which is determined as follows:

\[((terminal value - initial value + increment value) / increment value)\]

Glossary K
keyword
See argument keyword and statement keyword.

kind type parameter
Indicates the range of an intrinsic data type; for example: INTEGER(KIND=2). For real and complex types, it also indicates precision. If a specific kind parameter is not specified, the kind is the default for that type (for example, default integer). See also default character, default complex, default integer, default logical, and default real.

Glossary L
label
An integer, from 1 to 5 digits long, that precedes a statement and identifies it. For example, labels can be used to refer to a FORMAT statement or branch target statement.

language extension
An Intel® Fortran language element or interpretation that is not part of the Fortran 2003 standard.

lexical token
A sequence of one or more characters that have an indivisible interpretation. A lexical token is the smallest meaningful unit (a basic language element) of a Fortran statement; for example, constants, and statement keywords.
| **library routines** | Files that contain functions, subroutines, and data that can be used by Fortran programs. For example: one library contains routines that handle the various differences between Fortran and C in argument passing and data types; another contains run-time functions and subroutines for Windows* graphics and QuickWin* applications. Some library routines are intrinsic (automatically available) to Fortran; others may require a specific USE statement to access the module defining the routines. See also intrinsic procedure. |
| **line** | A source form record consisting of 0 or more characters. A standard Fortran line is limited to a maximum of 132 characters. |
| **linker** | A system program that creates an executable program from one or more object files produced by a language compiler or assembler. The linker resolves external references, acquires referenced library routines, and performs other processing required to create Linux* and Windows* executable files. |
| **list-directed I/O statement** | An implicit, formatted I/O statement that uses an asterisk (*) specifier rather than an explicit format specification. See also formatted I/O statement and namelist I/O statement. |
| **listing** | A printed copy of a program. |
| **literal constant** | A constant without a name; its value is directly specified in a program. See also named constant. |
| **little endian** | A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the lowest addressed byte. This is the method used on Intel® systems. Contrast with big endian. |
| **local entity** | An entity that can be used only within the context of a subprogram (its scoping unit); for example, a statement label. A local entity has local scope. See also global entity. |
| **local optimization** | A level of optimization enabling optimizations within the source program unit and recognition of common expressions. See also optimization. |
| **local symbol** | A name defined in a program unit that is not accessible outside of that program unit. |
| **logical constant** | A constant that specifies the value .TRUE. or .FALSE.. |
| **logical expression** | An integer or logical constant, variable, function value, or another constant expression, joined by a relational or logical operator. The logical expression is evaluated to a value of either true or false. For example, .NOT. 6.5 + (B .GT. D). |
| **logical operator** | A symbol that represents an operation on logical expressions. The logical operators are .AND., .OR., .NEQV., .XOR., .EQV., and .NOT.. |
| **logical unit** | A channel in memory through which data transfer occurs between the program and the device or file. See also unit identifier. |
| **longword** | Four contiguous bytes (32 bits) starting on any addressable byte boundary. Bits are numbered 0 to 31. The address of the longword is the address of the byte containing bit 0. When the longword is
interpreted as a signed integer, bit 31 is the sign bit. The value of signed integers is in the range -2**31 to 2**31-1. The value of unsigned integers is in the range 0 to 2**32-1.

loop A group of statements that are executed repeatedly until an ending condition is reached.

lower bounds See bounds.

**Glossary M**

main program The first program unit to receive control when a program is run; it exercises control over subprograms. The main program usually contains a PROGRAM statement (or does not contain a SUBROUTINE, FUNCTION, or BLOCK DATA statement). Contrast with subprogram.

makefile On Linux* and OS X* systems, an argument to the make command containing a sequence of entries that specify dependencies. On Windows* systems, a file passed to the NMAKE utility containing a sequence of entries that specify dependencies. The contents of a makefile override the system built-in rules for maintaining, updating, and regenerating groups of programs.

For more information on makefiles on Linux* and OS X* systems, see make(1). For more information on using makefiles, see Using Makefiles to Compile Your Application in Getting Started.

many-one array section An array section with a vector subscript having two or more elements with the same value.

master thread In an OpenMP* Fortran program, the thread that creates a team of threads when a parallel region (PARALLEL directive construct) is encountered. The statements in the parallel region are then executed in parallel by each thread in the team. At the end of the parallel region, the team threads synchronize and only the master thread continues execution. See also thread.

merged task A task whose data environment, inclusive of internal control variables, is the same as that of its generating task region. Internal control variables (ICVs) are discussed in the latest OpenMP* specifications.

message file A Linux* and OS X* catalog that contains the diagnostic message text of errors that can occur during program execution (run time).

metacommand See compiler directive.

misaligned data Data not aligned on a natural boundary. See also natural boundary.

module A program unit that contains specifications and definitions that other program units can access (unless the module entities are declared PRIVATE). Modules are referenced in USE statements.

module procedure A subroutine or function that is not an internal procedure and is contained in a module. The module procedure appears between a CONTAINS and END statement in its host module, and inherits the host module's environment through host association. A module procedure can be declared PRIVATE to the module; it is public by default.

<tr>
<td>name</td>
<td>Identifies an entity within a Fortran program unit (such as a variable, function result, common block, named constant, procedure, program unit, namelist group, or dummy argument). A name can contain letters, digits, underscores (_), and the dollar sign ($) special character. The first character must be a letter or a dollar sign. In earlier versions of Fortran, this term was called a symbolic name.</td>
</tr>
<tr>
<td>name association</td>
<td>Pertains to argument, host, or use association. See also argument association, host association, and use association.</td>
</tr>
<tr>
<td>named common block</td>
<td>A common block (one or more contiguous areas of storage) with a name. Common blocks are defined by a COMMON statement.</td>
</tr>
<tr>
<td>named constant</td>
<td>A constant that has a name. In earlier versions of Fortran, this term was called a symbolic constant.</td>
</tr>
<tr>
<td>namelist I/O statement</td>
<td>An implicit, formatted I/O statement that uses a namelist group specifier rather than an explicit format specifier. See also formatted I/O statement and list-directed I/O statement.</td>
</tr>
<tr>
<td>NaN</td>
<td>Not-a-Number. The condition that results from a floating-point operation that has no mathematical meaning; for example, zero divided by zero.</td>
</tr>
<tr>
<td>natural boundary</td>
<td>The virtual address of a data item that is the multiple of the size of its data type. For example, a REAL(8) (REAL*8) data item aligned on natural boundaries has an address that is a multiple of eight.</td>
</tr>
<tr>
<td>naturally aligned record</td>
<td>A record that is aligned on a hardware-specific natural boundary; each field is naturally aligned. Contrast with packed record.</td>
</tr>
<tr>
<td>nesting</td>
<td>The placing of one entity (such as a construct, subprogram, format specification, or loop) inside another entity of the same kind. For example, nesting a loop within another loop (a nested loop), or nesting a subroutine within another subroutine (a nested subroutine).</td>
</tr>
<tr>
<td>nonexecutable statement</td>
<td>A Fortran statement that describes program attributes, but does not cause any action to be taken when the program is executed.</td>
</tr>
<tr>
<td>nonsignaled</td>
<td>The state of an object used for synchronization in one of the wait functions is either signaled or nonsignaled. A nonsignaled state can prevent the wait function from returning. See also wait function.</td>
</tr>
</tbody>
</table>
numeric expression
A numeric constant, variable, or function value, or combination of these, joined by numeric operators and parentheses, so that the entire expression can be evaluated to produce a single numeric value. For example, \(-L\) or \(X+(Y-4.5*Z)\).

numeric operator
A symbol designating an arithmetic operation. In Standard Fortran, the symbols \(+, -, *, /, \text{ and } **\) are used to designate addition, subtraction, multiplication, division, and exponentiation, respectively.

numeric storage unit
The unit of storage for holding a non-pointer scalar value of type default real, default integer, or default logical. One numeric storage unit corresponds to 4 bytes of memory.

numeric type
Integer, real, or complex type.

Glossary O

object
See data object.

object file
The binary output of a language processor (such as an assembler or compiler), which can either be executed or used as input to the linker.

obsolescent feature
A feature of earlier versions of Fortran that is considered to be redundant in Fortran 2003. These features are still in frequent use.

octal constant
A constant that is a string of octal (base 8) digits (range of 0 to 7) enclosed by apostrophes or quotation marks and preceded by the letter \(O\).

operand
The passive element in an expression on which an operation is performed. Every expression must have at least one operand. For example, in \(I \neq J\), \(I\) and \(J\) are operands. Contrast with operator.

operation
A computation involving one or two operands.

operator
The active element in an expression that performs an operation. An expression can have zero or more operators. Intrinsic operators are arithmetic \((+, -, *, /, \text{ and } **)\) or logical \((., .\text{AND.}, .\text{NOT.}, \text{and so on})\). For example, in \(I \neq J\), \(.\neq\) is the operator.

Executable programs can define operators which are not intrinsic.

optimization
The process of producing efficient object or executing code that takes advantage of the hardware architecture to produce more efficient execution.

optional argument
A dummy argument that has the \texttt{OPTIONAL} attribute (or is included in an \texttt{OPTIONAL} statement in the procedure definition). This kind of argument does not have to be associated with an actual argument when its procedure is invoked.

order of subscript progression
A characteristic of a multidimensional array in which the leftmost subscripts vary most rapidly. Also called column-major order.

overflow
An error condition occurring when an arithmetic operation yields a result that is larger than the maximum value in the range of a data type.

</tbody>
</table>
If a data pointer is an array, the rank is declared, but the extents are determined when the pointer is associated with a target.

A data pointer is one of the following:

- **A Fortran pointer**
  A data object that has the POINTER attribute. To be referenced or defined, it must be "pointer-associated" with a target (have storage space associated with it). If the pointer is an array, it must be pointer-associated to have a shape. See also pointer association.

- **An integer pointer**
  A data object that contains the address of its paired variable. This is also called a Cray* pointer.

**pointer assignment**
The association of a pointer with a target by the execution of a pointer assignment statement or the execution of an assignment statement for a data object of derived type having the pointer as a subobject.

**pointer association**
The association of storage space to a Fortran pointer by means of a target. A pointer is associated with a target after pointer assignment or the valid execution of an ALLOCATE statement.

**polymorphic object**
An object that can have different types during program execution. An object declared with the CLASS keyword is polymorphic.

**precision**
The number of significant digits in a real number. See also double-precision constant, kind type parameter, and single-precision constant.

**primary**
The simplest form of an expression. A primary can be any of the following data objects:

- A constant
- A constant subobject (parent is a constant)
- A variable (scalar, structure, array, or pointer; an array cannot be assumed size)
- An array constructor
- A structure constructor
- A function reference
- An expression in parentheses

**primary thread**
The initial thread of a process. Also called the main thread or thread 1. See also thread.

**procedure**
A computation that can be invoked during program execution. It can be a subroutine or function, an internal, external, dummy or module procedure, or a statement function. A subprogram can define more than one procedure if it contains an ENTRY statement. See also subprogram.

**procedure interface**
The statements that specify the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.

If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration).
process object  A virtual address space, security profile, a set of threads that execute in the address space of the process, and a set of resources visible to all threads executing in the process. Several thread objects can be associated with a single process.

program  A set of instructions that can be compiled and executed by itself. Program blocks contain a declaration and an executable section.

program section  A particular common block or local data area for a particular routine containing equivalence groups.

program unit  The fundamental component of an executable program. A sequence of statements and comment lines. It can be a main program, a module, an external subprogram, or a block data program unit.

**Glossary Q**

quadword  Four contiguous words (64 bits) starting on any addressable byte boundary. Bits are numbered 0 to 63. (Bit 63 is used as the sign bit.) A quadword is identified by the address of the word containing the low-order bit (bit 0). The value of a signed quadword integer is in the range \(-2^{63}\) to \(2^{63}-1\).

**Glossary R**

random access  See direct access.

rank  The number of dimensions of an array. A scalar has a rank of zero.

rank-one object  A data structure comprising scalar elements with the same data type and organized as a simple linear sequence. See also scalar.

real constant  A constant that is a number written with a decimal point, exponent, or both. It can have single precision (REAL(KIND=4)), double precision (REAL(KIND=8)), or quad precision (REAL(KIND=16)).

record  Can be either of the following:
- A set of logically related data items (in a file) that is treated as a unit; such a record contains one or more fields. This definition applies to I/O records and items that are declared in a record structure.
- One or more data items that are grouped in a structure declaration and specified in a RECORD statement.

record access  The method used to store and retrieve records in a file.

record structure declaration  A block of statements that define the fields in a record. The block begins with a STRUCTURE statement and ends with END STRUCTURE. The name of the structure must be specified in a RECORD statement.

record type  The property that determines whether records in a file are all the same length, of varying length, or use other conventions to define where one record ends and another begins.

recursion  Pertains to a subroutine or function that directly or indirectly references itself.
reference Can be any of the following:
- For a data object, the appearance of its name, designator, or associated pointer where the value of the object is required. When an object is referenced, it must be defined.
- For a procedure, the appearance of its name, operator symbol, or assignment symbol that causes the procedure to be executed. Procedure reference is also called "calling" or "invoking" a procedure.
- For a module, the appearance of its name in a USE statement.

relational expression An expression containing one relational operator and two operands of numeric or character type. The result is a value that is true or false. For example, A-C .GE. B+2 or DAY .EQ. 'MONDAY'.

relational operator The symbols used to express a relational condition or expression. The relational operators are (.EQ., .NE., .LT., .LE., .GT., and .GE.).

relative file organization A file organization that consists of a series of component positions, called cells, numbered consecutively from 1 to \( n \). Intel Fortran uses these numbered, fixed-length cells to calculate the component's physical position in the file.

relative pathname A directory path expressed in relation to any directory other than the root directory. Contrast with absolute pathname.

root On Windows* systems, the top-level directory on a disk drive; it is represented by a backslash (\). For example, C:\ is the root directory for drive C.

On Linux* systems, the top-level directory in the file system; it is represented by a slash (/).

routine A subprogram; a function or procedure. See also function, subroutine, and procedure.

run time The time during which a computer executes the statements of a program.

**Glossary S**

saved object A variable that retains its association status, allocation status, definition status, and value after execution of a RETURN or END statement in the scoping unit containing the declaration.

scalar Pertaining to data items with a rank of zero. A single data object of any intrinsic or derived data type. Contrast with array. See also rank-one object.

scalar memory reference A reference to a scalar variable, scalar record field, or array element that resolves into a single data item (having a data type) and can be assigned a value with an assignment statement. It is similar to a scalar reference, but it excludes constants, character substrings, and expressions.

scalar reference A reference to a scalar variable, scalar record field, derived-type component, array element, constant, character substring, or expression that resolves into a single data item having a data type.
scalar variable A variable name specifying one storage location.

scale factor A number indicating the location of the decimal point in a real number and, if there is no exponent, the size of the number on input.

scope The portion of a program in which a declaration or a particular name has meaning. Scope can be global (throughout an executable program), scoping unit (local to the scoping unit), or statement (within a statement, or part of a statement).

scoping unit The part of the program in which a name has meaning. It is one of the following:

- A program unit or subprogram
- A derived-type definition
- A procedure interface body

Scoping units cannot overlap, though one scoping unit can contain another scoping unit. The outer scoping unit is called the host scoping unit.

screen coordinates Coordinates relative to the upper left corner of the screen.

section subscript A subscript list (enclosed in parentheses and appended to the array name) indicating a portion (section) of an array. At least one of the subscripts in the list must be a subscript triplet or vector subscript. The number of section subscripts is the rank of the array. See also array section, subscript, subscript triplet, and vector subscript.

seed A value (which can be assigned to a variable) that is required in order to properly determine the result of a calculation; for example, the argument k in the random number generator (RAN) function syntax: $y = \text{RAN} \ (k)$

selector A mechanism for designating the following:

- Part of a data object (an array element or section, a substring, a derived type, or a structure component)
- The set of values for which a CASE block is executed

sequence A set ordered by a one-to-one correspondence with the numbers 1 through n, where n is the total number of elements in the sequence. A sequence can be empty (contain no elements).

sequential access A method for retrieving or storing data in which the data (record) is read from, written to, or removed from a file based on the logical order (sequence) of the record in the file. (The record cannot be accessed directly.) Contrast with direct access.

sequential file organization A file organization in which records are stored one after the other, in the order in which they were written to the file.

shape The rank and extents of an array. Shape can be represented by a rank-one array (vector) whose elements are the extents in each dimension.

shape conformance Pertains to the rule concerning operands of binary intrinsic operations in expressions: to be in shape conformance, the two operands must both be arrays of the same shape, or one or both of the operands must be scalars.
short field termination  The use of a comma (,) to terminate the field of a numeric data edit descriptor. This technique overrides the field width (w) specification in the data edit descriptor and therefore avoids padding of the input field. The comma can only terminate fields less than w characters long. See also data edit descriptor.

signal  The software mechanism used to indicate that an exception condition (abnormal event) has been detected. For example, a signal can be generated by a program or hardware error, or by request of another program.

global single-precision constant  A processor approximation of the value of a real number that occupies 4 bytes of memory and can assume a positive, negative, or zero value. The precision is less than a constant of double-precision type. For the precise ranges of the single-precision constants, see Data Representation Overview in the Compiler Reference. See also denormalized number.

size  The total number of elements in an array (the product of the extents).

source file  A program or portion of a program library, such as an object file, or image file.

specification expression  A restricted expression that is of type integer and has a scalar value. This type of expression appears only in the declaration of array bounds and character lengths.

specification statement  A nonexecutable statement that provides information about the data used in the source program. Such a statement can be used to allocate and initialize variables, arrays, records, and structures, and define other characteristics of names used in a program.

statement  An instruction in a programming language that represents a step in a sequence of actions or a set of declarations. In Standard Fortran, an ampersand can be used to continue a statement from one line to another, and a semicolon can be used to separate several statements on one line.

There are two main classes of statements: executable and nonexecutable.

statement function  A computing procedure defined by a single statement in the same program unit in which the procedure is referenced.

statement function definition  A statement that defines a statement function. Its form is the statement function name (followed by its optional dummy arguments in parentheses), followed by an equal sign (=), followed by a numeric, logical, or character expression.

A statement function definition must precede all executable statements and follow all specification statements.

statement keyword  A word that begins the syntax of a statement. All program statements (except assignment statements and statement function definitions) begin with a statement keyword. Examples are INTEGER, DO, IF, and WRITE.

statement label  See label.

static variable  A variable whose storage is allocated for the entire execution of a program.
storage association
The relationship between two storage sequences when the storage unit of one is the same as the storage unit of the other. Storage association is provided by the COMMON and EQUIVALENCE statements. For modules, pointers, allocatable arrays, and automatic data objects, the SEQUENCE statement defines a storage order for structures.

storage location
An addressable unit of main memory.

storage sequence
A sequence of any number of consecutive storage units. The size of a storage sequence is the number of storage units in the storage sequence. A sequence of storage sequences forms a composite storage sequence. See also storage association and storage unit.

storage unit
In a storage sequence, the number of storage units needed to represent one real, integer, logical, or character value. See also character storage unit, numeric storage unit, and storage sequence.

stride
The increment between subscript values that can optionally be specified in a subscript triplet. If it is omitted, it is assumed to be one.

string edit descriptor
A format descriptor that transfers characters to an output record.

structure
Can be either of the following:
- A scalar data object of derived (user-defined) type.
- An aggregate entity containing one or more fields or components.

structure component
Can be either of the following:
- One of the components of a structure.
- An array whose elements are components of the elements of an array of derived type.

structure constructor
A mechanism that is used to specify a scalar value of a derived type. A structure constructor is the name of the type followed by a parenthesized list of values for the components of the type.

subobject
Part of a data object (parent object) that can be referenced and defined separately from other parts of the data object. A subobject can be an array element, an array section, a substring, a derived type, or a structure component. Subobjects are referenced by designators and can be considered to be data objects themselves. See also designator.

subobject designator
See designator.

subprogram
A function or subroutine subprogram that can be invoked from another program unit to perform a specific task. A subprogram can define more than one procedure if it contains an ENTRY statement. Contrast with main program. See also procedure.

subroutine
A procedure that can return many values, a single value, or no value to the calling program unit (through arguments). A subroutine is invoked by a CALL statement in another program unit.

In recent versions of Fortran, a subroutine can also be used to specify a defined assignment. Such assignments are invoked with an ASSIGNMENT(=) interface block rather than the CALL statement. See also function, statement function, and subroutine subprogram.
<table>
<thead>
<tr>
<th><strong>subroutine subprogram</strong></th>
<th>A sequence of statements starting with a <code>SUBROUTINE</code> (or optional <code>OPTIONS</code>) statement and ending with the corresponding <code>END</code> statement. See also <code>subroutine</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>subscript</strong></td>
<td>A scalar integer expression (enclosed in parentheses and appended to the array name) indicating the position of an array element. The number of subscripts is the rank of the array. See also <code>array element</code>.</td>
</tr>
<tr>
<td><strong>subscript triplet</strong></td>
<td>An item in a section subscript list specifying a range of values for the array section. A subscript triplet contains at least one colon and has three optional parts: a lower bound, an upper bound, and a stride. Contrast with <code>vector subscript</code>. See also <code>array section</code> and <code>section subscript</code>.</td>
</tr>
<tr>
<td><strong>substring</strong></td>
<td>A contiguous portion of a scalar character string. Do not confuse this with the substring selector in an array section, where the result is another array section, not a substring.</td>
</tr>
<tr>
<td><strong>symbolic name</strong></td>
<td>See <code>name</code>.</td>
</tr>
<tr>
<td><strong>syntax</strong></td>
<td>The formal structure of a statement or command string.</td>
</tr>
</tbody>
</table>

**Glossary T**

<table>
<thead>
<tr>
<th><strong>target</strong></th>
<th>The named data object associated with a pointer (in the form <code>pointer-object =&gt; target</code>). A target is declared in a type declaration statement that contains the <code>TARGET</code> attribute. See also <code>pointer</code> and <code>pointer association</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>thread</strong></td>
<td>Part of a program that can run at the same time as other parts, usually with some form of communication and/or synchronization among the threads. See also <code>multithreading</code>.</td>
</tr>
<tr>
<td><strong>transformational function</strong></td>
<td>An intrinsic function that is not an elemental or inquiry function. A transformational function usually changes an array actual argument into a scalar result or another array, rather than applying the argument element by element.</td>
</tr>
<tr>
<td><strong>truncation</strong></td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- A technique that approximates a numeric value by dropping its fractional value and using only the integer portion.</td>
</tr>
<tr>
<td></td>
<td>- The process of removing one or more characters from the left or right of a number or string.</td>
</tr>
<tr>
<td><strong>type declaration statement</strong></td>
<td>A nonexecutable statement specifying the data type of one or more variables: an <code>INTEGER</code>, <code>REAL</code>, <code>DOUBLE PRECISION</code>, <code>COMPLEX</code>, <code>DOUBLE COMPLEX</code>, <code>CHARACTER</code>, <code>LOGICAL</code>, or <code>TYPE</code> statement. A type declaration statement may also specify attributes for the variables. Also called a type declaration or type specification.</td>
</tr>
<tr>
<td><strong>type parameter</strong></td>
<td>Defines an intrinsic data type. The type parameters are kind and length. The kind type parameter (KIND=) specifies the range for the integer data type, the precision and range for real and complex data types, and the machine representation method for the character and logical data types. The length type parameter (LEN=) specifies the length of a character string. See also <code>kind type parameter</code>.</td>
</tr>
<tr>

</table>
Glossary V

variable
A data object (stored in a memory location) whose value can change during program execution. A variable can be a named data object, an array element, an array section, a structure component, or a substring. In FORTRAN 77, a variable was always scalar and named. Contrast with constant.

variable format expression
A numeric expression enclosed in angle brackets (<>) that can be used in a FORMAT statement. If necessary, it is converted to integer type before use.

variable-length record type
A file format in which records may be of different lengths.

vector subscript
A rank-one array of integer values used as a section subscript to select elements from a parent array. Unlike a subscript triplet, a vector subscript specifies values (within the declared bounds for the dimension) in an arbitrary order. Contrast with subscript triplet. See also array section and section subscript.

Glossary W

wait function
A function that blocks the execution of a calling thread until a specified set of conditions has been satisfied.

whole array
An array reference (for example, in a type declaration statement) that consists of the array name alone, without subscript notation. Whole array operations affect every element in the array. See also array.

Glossary Z

zero-sized array
An array with at least one dimension that has at least one extent of zero. A zero-sized array has a size of zero and contains no elements. See also array.
Part V

Compilation

Topics:

- Supported Environment Variables
- Using Other Methods to Set Environment Variables
- Understanding Files Associated with Intel® Fortran Applications (Windows*)
- Compiling and Linking Multithreaded Programs
- Linking Tools and Options
- Using Configuration Files
- Using Response Files
- Creating Fortran Executables
- Linking Debug Information
- Debugging
Supported Environment Variables

You can customize your system environment by specifying paths where the compiler searches for certain files such as libraries, include files, configuration files, and certain settings.

Compiler Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the compiler:

<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFORTCFG</td>
<td>Specifies a configuration file that the compiler should use instead of the default configuration file. By default, the compiler uses the default configuration file (ifort.cfg) from the same directory where the compiler executable resides.</td>
</tr>
</tbody>
</table>

**NOTE**
On Windows* operating systems, this environment variable cannot be set from Visual Studio.

| INTEL_LICENSE_FILE               | Specifies the location for the Intel license file. |

**NOTE**
On Windows* operating systems, this environment variable cannot be set from Visual Studio.

| __INTEL_PRE_FFLAGS               | Specifies a set of compiler options to add to the compile line. This is an extension to the facility already provided in the compiler configuration file ifort.cfg. |

**NOTE**
By default, a configuration file named ifort.cfg is used. This file is in the same directory as the compiler executable. To use another configuration file in another location, you can use the IFORTCFG environment variable to assign the directory and file name for the configuration file.

You can insert command line options in the prefix position using __INTEL_PRE_FFLAGS, or in the suffix position using __INTEL_POST_FFLAGS. The command line is built as follows:

**Syntax:**
ifort <PRE flags> <flags from configuration file> <flags from the compiler invocation> <POST flags>
NOTE
The driver issues a warning that the compiler is overriding an option because of an environment variable, but only when you include the option /W5 (Windows*) or -w3 (Linux* and OS X*).

<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>
<th>Description</th>

<tbody>
<tr>
<td>PATH</td>
<td>Specifies the directories the system searches for binary executable files.</td>
</tr>
<tr>
<td>TMP</td>
<td>Specifies the location for temporary files. If none of these are specified, or writeable, or found, the compiler stores temporary files in /tmp (Linux, OS X) or the current directory (Windows).</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>On Windows* and OS X*, The compiler searches for these variables in the following order: TMP, TMPDIR, and TEMP.</td>
</tr>
<tr>
<td>TEMP</td>
<td>On Linux*, The compiler searches for these variables in the following order: TMPDIR, TMP, and TEMP.</td>
</tr>
</tbody>
</table>

NOTE
On Windows* operating systems, these environment variables cannot be set from Visual Studio.

LD_LIBRARY_PATH
(Windows*)

Specifies the path for dynamic libraries.

DYLD_LIBRARY_PATH
(Windows*)

Specifies the location for shared objects (.so files).

INCLUDE
Specifies the directory path for the include files (files included by INCLUDE statements, #include files, RC INCLUDE files, and module files referenced by USE statements).

LIB
Specifies the directories for all libraries used by the compiler and linker.

Intel® MIC Architecture Environment Variables

MIC_LIBRARY_PATH
(Windows*)

Specifies the location on the host for target-specific static libraries. LIBRARY_PATH specifies the location on the host for host-specific static libraries.

NOTE
On Windows* operating systems, this environment variable cannot be set from Visual Studio.

GNU Environment Variables and Extensions

CPATH
(Windows*)

Specifies the path for include and module files.

GCCROOT
(Windows*)

Specifies the location of the gcc* binaries.

Set this variable only when the compiler cannot locate the gcc binaries when using the -gcc-name option.
<table>
<thead>
<tr>
<th>Compile-Time Environment Variable</th>

Compiler Run-Time Environment Variables

The Intel® Fortran Compiler run-time system recognizes a number of environment variables. These variables can be used to customize run-time diagnostic error reporting, allow program continuation under certain conditions, disable the display of certain dialog boxes under certain conditions, and allow just-in-time debugging.

Environment variables relating to file I/O are interpreted when the file is opened. Other variables are read when the program starts.

The order of precedence for run-time environment variables is:

1. OPEN keyword
2. Environment variable(s)
3. Command line option

For Fortran runtime environment variables that are boolean (either enabled or disabled), the following tables describe values you can use to enable or disable them. These rules do not apply to environment variables for OpenMP* (OMP_) and their extensions (KMP_), PGO, or Intel® MIC Architecture.

<table>

Setting a Run-Time Environment Variable to ON or OFF

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>decfort_dump_flag</code></td>
<td>Boolean. When set to TRUE, a core dump will be taken when any severe Intel® Fortran run-time error occurs. <strong>Default</strong>: FALSE</td>
</tr>
<tr>
<td><code>F_UFMTENDIAN</code></td>
<td>This variable specifies the numbers of the units to be used for little-endian-to-big-endian conversion purposes. See Environment Variable <strong>F_UFMTENDIAN Method</strong>. The variable is retrieved once when the first unit is opened, and then checked for every open.</td>
</tr>
<tr>
<td><code>FOR_COARRAY_CONFIG_FILE</code></td>
<td>(Windows* and Linux*) This variable specifies the coarray configuration file and path to be used at execution time. The variable overrides the value specified by the [Q]coarray-config-file=value qualifier at runtime.</td>
</tr>
<tr>
<td><code>FOR_COARRAY_NUM_IMAGES</code></td>
<td>(Windows* and Linux*) This variable specifies the number of images created for coarrays. The value overrides the value specified by the [Q]coarray-num-images=value qualifier at runtime.</td>
</tr>
<tr>
<td><code>FOR_FMT_TERMINATOR</code></td>
<td>This variable specifies the numbers of the units to have a specific record terminator. See <strong>Record Types</strong>. The variable is retrieved once when the first unit is opened, and then checked for every open.</td>
</tr>
<tr>
<td><code>FORT_FMT_NO_WRAP_MARGIN</code></td>
<td>Boolean. When set to TRUE, disables column wrapping in Fortran list-directed output when the record being written is longer than 80 characters. <strong>NOTE</strong> There is no mechanism to set a value for the right margin, this only disables wrapping. <strong>Default</strong>: FALSE (Wrap margin)</td>
</tr>
</tbody>
</table>

Anything that doesn't enable the environment variable disables it.

Examples

- 0
- -1
- +1
- <no value set>

The following table summarizes compiler environment variables that are recognized at run time.
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR_ACCEPT</td>
<td>The <code>ACCEPT</code> statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the <code>FOR_ACCEPT</code> environment variable. If <code>FOR_ACCEPT</code> is not defined, the code <code>ACCEPT f,iolist</code> reads from <code>CONIN$</code> (standard input). If <code>FOR_ACCEPT</code> is defined (as a file name optionally containing a path), the specified file would be read.</td>
</tr>
<tr>
<td>FOR_DEBUGGER_IS_PRESENT</td>
<td>Boolean. When set to TRUE, this variable tells the Fortran run-time library that your program is executing under a debugger, and generates debug exceptions whenever severe or continuable errors are detected. Under normal conditions, this variable can be extracted from the operating system for Windows*. On Linux* and OS X*, this variable must be set for debug exceptions. Setting this variable to TRUE when a program is not executing under a debugger causes unpredictable behavior. <strong>Default</strong>: FALSE</td>
</tr>
<tr>
<td>FOR_DEFAULT_PRINTDEVICE</td>
<td>(Windows*) This variable lets you specify the print device other than the default print device PRN (LPT1) for files closed (<code>CLOSE</code> statement) with the <code>DISPOSE='PRINT'</code> specifier. To specify a different print device for the file associated with the <code>CLOSE</code> statement <code>DISPOSE='PRINT'</code> specifier, set <code>FOR_DEFAULT_PRINTDEVICE</code> to any legal DOS print device before executing the program.</td>
</tr>
<tr>
<td>FOR_DIAGNOSTIC_LOG_FILE</td>
<td>If this variable is set to the name of a file, diagnostic output is written to the specified file. The Fortran run-time system attempts to open that file (append output) and write the error information (ASCII text) to the file. Because the setting of <code>FOR_DIAGNOSTIC_LOG_FILE</code> is independent of <code>FOR_DISABLE_DIAGNOSTIC_DISPLAY</code>, you can disable the screen display of information but still capture the error information in a file. Because the text string you assign for the file name is used literally, you must specify the full name. If the file open fails, no error is reported and the run-time system continues diagnostic processing. See also Locating Run-Time Errors and Using Traceback Information Overview.</td>
</tr>
<tr>
<td>FOR_DISABLE_DIAGNOSTIC_DISPLAY</td>
<td>Boolean.</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>FOR_DISABLE_STACK_TRACE</td>
<td>When set to TRUE, this variable disables the display of all error information. This variable is helpful if you just want to test the error status of your program and do not want the Fortran run-time system to display any information about an abnormal program termination. See also Using Traceback Information Overview.</td>
</tr>
<tr>
<td>FOR_FORCE_STACK_TRACE</td>
<td>When set to TRUE, this variable forces a traceback to follow any run-time diagnostic message. If FOR_DISABLE_STACK_TRACE is also set, FOR_FORCE_STACK_TRACE takes precedence over FOR_DISABLE_STACK_TRACE. Default: FALSE</td>
</tr>
<tr>
<td>FOR_IGNORE_EXCEPTIONS</td>
<td>When set to TRUE, this variable disables default run-time exception handling to allow, for example, just-in-time debugging. The run-time system exception handler returns EXCEPTION_CONTINUE_SEARCH to the operating system, which looks for other handlers to service the exception. Default: FALSE</td>
</tr>
<tr>
<td>FOR_NOERROR_DIALOGS</td>
<td>When set to TRUE, this variable disables the display of dialog boxes when certain exceptions or errors occur. This is useful when running many test programs in batch mode to prevent a failure from stopping execution of the entire test stream. Default: FALSE</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>FOR_PRINT</td>
<td>Neither the PRINT statement nor a WRITE statement with an asterisk (<em>) in place of a unit number includes an explicit logical unit number. Instead, both use an implicit internal logical unit number and the FOR_PRINT environment variable. If FOR_PRINT is not defined, the code PRINT f,iolist or WRITE (</em>,f) iolist writes to CONOUT$ (standard output). If FOR_PRINT is defined (as a file name optionally containing a path), the specified file would be written to.</td>
</tr>
<tr>
<td>FOR_READ</td>
<td>A READ statement that uses an asterisk (<em>) in place of a unit number does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_READ environment variable. If FOR_READ is not defined, the code READ (</em>,f) iolist or READ f,iolist reads from CONIN$ (standard input). If FOR_READ is defined (as a file name optionally containing a path), the specified file would be read.</td>
</tr>
<tr>
<td>FOR_TYPE</td>
<td>The TYPE statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_TYPE environment variable. If FOR_TYPE is not defined, the code TYPE f,iolist writes to CONOUT$ (standard output). If FOR_TYPE is defined (as a file name optionally containing a path), the specified file would be written to.</td>
</tr>
<tr>
<td>FORT_BLOCKSIZE</td>
<td>Specifies the default BLOCKSIZE value to be used when BLOCKSIZE= is omitted on the OPEN statement. Valid values are 0 to 2147467264. Sizes are rounded up to the next 512-byte boundary. This variable applies to all Fortran I/O units except stderr, which is never buffered. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_BUFFERCOUNT</td>
<td>Specifies the default BUFFERCOUNT value to be used when BUFFERCOUNT= is omitted on the OPEN statement. Valid values are 0 to 127. If set to 0, the default value of 1 is used. This variable applies to all Fortran I/O units except stdout (units * and 6) and stderr. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_BUFFERED</td>
<td>Boolean.</td>
</tr>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>FORT_BUFFERING_THRESHOLD=n</td>
<td>When set to TRUE, this variable specifies that buffered I/O should be used at run time for input and output on all Fortran I/O units, except stdout (units * and 6). Output to stderr is never buffered.</td>
</tr>
<tr>
<td><strong>Default:</strong> FALSE</td>
<td></td>
</tr>
<tr>
<td>FORT_CONVERTn</td>
<td>Specifies the data format for an unformatted file associated with a particular unit number (n), as described in Methods of Specifying the Data Format.</td>
</tr>
<tr>
<td>FORT_CONVERT_.ext and FORT_CONVERT_ext</td>
<td>Specifies the data format for unformatted files with a particular file extension suffix (.ext), as described in Methods of Specifying the Data Format.</td>
</tr>
<tr>
<td>FORT_FMT_RECL</td>
<td>Specifies the default record length (normally 132 bytes) for formatted files. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORT_UFMT_RECL</td>
<td>Specifies the default record length (normally 2040 bytes) for unformatted files. The variable is retrieved once at program initialization, and checked for each unit open.</td>
</tr>
<tr>
<td>FORTn</td>
<td>Specifies the file name for a particular unit number n, when a file name is not specified in the OPEN statement or an implicit OPEN is used, and the compiler option fpscomp with option keyword filesfromcmd was not specified. Preconnected files attached to units 0, 5, and 6 are associated with system standard I/O files by default.</td>
</tr>
<tr>
<td>NLSPATH (Linux* and OS X*)</td>
<td>Specifies the path for the Intel® Fortran run-time error message catalog.</td>
</tr>
<tr>
<td>TBK_ENABLE_VERBOSE_STACK_TRACE</td>
<td>Boolean. When set to TRUE, traceback output displays more detailed call stack information in the event of an error.</td>
</tr>
</tbody>
</table>
### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run-Time Environment Variable</td>
<td>Description</td>
</tr>
</tbody>
</table>
| The default brief output is usually sufficient to determine where an error occurred. Brief output includes up to twenty stack frames, reported one line per stack frame. For each frame, the image name containing the PC, routine name, line number, and source file are given. The verbose output, if selected, will provide the exception context record (in addition to the information in brief output) if the error was a machine exception (machine register dump), and for each frame, the return address, frame pointer and stack pointer and possible parameters to the routine. This output can be quite long (limited to 16K bytes) and use of the environment variable FOR_DIAGNOSTIC_LOG_FILE is recommended if you want to capture the output accurately. Most situations should not require the use of verbose output. **Default**: FALSE  
See also Locating Run-Time Errors and Using Traceback Information Overview. |

**TBK_FULL_SRC_FILE_SPEC**  
Boolean.  
When set to TRUE, traceback output displays complete file name information including the path. By default, the traceback output displays only the file name and extension in the source file field. **Default**: FALSE  
See also Locating Run-Time Errors and Using Traceback Information Overview.  

**FORT_TMPDIR**  
**TMP**  
**TMPDIR**  
**TEMP**  

**GNU extensions (recognized by the Intel® OpenMP compatibility library)**  
**GOMP_CPU_AFFINITY (Linux*)**  
GNU extension recognized by the Intel® OpenMP compatibility library. Specifies a list of OS processor IDs. You must set this environment variable before the first parallel region or before certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls. For detailed information on this environment variable, see Thread Affinity Interface. **Default**: Affinity is disabled.
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **GOMP_STACKSIZE** (Linux*)   | GNU extension recognized by the Intel® OpenMP compatibility library. Same as `OMP_STACKSIZE,KMP_STACKSIZE` overrides `GOMP_STACKSIZE`, which overrides `OMP_STACKSIZE`.  
**Default:** See the description for `OMP_STACKSIZE`. |

**OpenMP® Environment Variables (OMP_) and Extensions (KMP_)**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **OMP_CANCELLATION**          | Activates cancellation of the innermost enclosing region of the type specified. If set to true, the effects of the cancel construct and of cancellation points are enabled and cancellation is activated. If set to false, cancellation is disabled and the cancel construct and cancellation points are effectively ignored.  
**NOTE**  
Internal barrier code will work differently depending on whether the cancellation is enabled. Barrier code should repeatedly check the global flag to figure out if the cancellation had been triggered. If a thread observes the cancellation it should leave the barrier prematurely with the return value 1 (may wake up other threads). Otherwise, it should leave the barrier with the return value 0. |
|                              | Enables (true) or disables (false) cancellation of the innermost enclosing region of the type specified.  
**Default:** FALSE  
**Example:** `OMP_CANCELLATION=true` |
| **OMP_DYNAMIC**               | Enables (true) or disables (false) the dynamic adjustment of the number of threads.  
**Default:** FALSE  
**Example:** `OMP_DYNAMIC=true` |
| **OMP_MAX_ACTIVE_LEVELS**     | The maximum number of levels of parallel nesting for the program.  
**Default:** 1  
**Syntax:** `OMP_MAX_ACTIVE_LEVELS=true` |
| **OMP_NESTED**                | Enables (true) or disables (false) nested parallelism.  
**Default:** FALSE  
**Example:** `OMP_NESTED=true` |
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_NUM_THREADS</td>
<td>Sets the maximum number of threads to use for OpenMP* parallel regions if no other value is specified in the application. The value can be a single integer, in which case it specifies the number of threads for all parallel regions. The value can also be a comma-separated list of integers, in which case each integer specifies the number of threads for a parallel region at a nesting level. The first position in the list represents the outer-most parallel nesting level, the second position represents the next-inner parallel nesting level, and so on. At any level, the integer can be left out of the list. If the first integer in a list is left out, it implies the normal default value for threads is used at the outer-most level. If the integer is left out of any other level, the number of threads for that level is inherited from the previous level. This environment variable applies to the options Qopenmp (Windows) or qopenmp (Linux and OS X), or Qparallel (Windows) or qparallel (Linux and OS X). <strong>Default:</strong> The number of processors visible to the operating system. <strong>Syntax:</strong> OMP_NUM_THREADS=value[,value]*</td>
</tr>
</tbody>
</table>
| OMP_PLACES                   | Specifies an explicit ordered list of places, either as an abstract name describing a set of places or as an explicit list of places described by nonnegative numbers. An exclusion operator "!" can also be used to exclude the number or place immediately following the operator. For **explicit lists**, the meaning of the numbers and how the numbering is done for a list of nonnegative numbers are implementation defined. Generally, the numbers represent the smallest unit of execution exposed by the execution environment, typically a hardware thread. **Intervals can be specified using the** `<lower-bound>:<length>:<stride>` **notation to represent the following list of numbers:**

"<lower-bound>, <lower-bound> + <stride>, ..., <lower-bound> + (<length>-1)*<stride>."
Run-Time Environment Variable | Description
--- | ---
When `<stride>` is omitted, a unit stride is assumed. Intervals can specify numbers within a place as well as sequences of places.

```
setenv OMP_PLACES "{0,1,2,3},{4,5,6,7},
{8,9,10,11},{12,13,14,15}"
setenv OMP_PLACES "{0:4},{4:4},{8:4},{12:4}"
setenv OMP_PLACES "{0:4}:4:4"
```

The **abstract names** listed below should be understood by the execution and runtime environment:

- **threads**: Each place corresponds to a single hardware thread on the target machine.
- **cores**: Each place corresponds to a single core (having one or more hardware threads) on the target machine.
- **sockets**: Each place corresponds to a single socket (consisting of one or more cores) on the target machine.

When requesting fewer places or more resources than available on the system, the determination of which resources of type `abstract_name` are to be included in the place list is implementation-defined. The precise definitions of the abstract names are implementation defined. An implementation may also add abstract names as appropriate for the target platform. The abstract name may be appended by a positive number in parentheses to denote the length of the place list to be created, that is `abstract_name(num-places)`.

```
setenv OMP_PLACES threads
setenv OMP_PLACES threads(4)
```

**NOTE**

If any numerical values cannot be mapped to a processor on the target platform the behavior is implementation-defined. The behavior is also implementation-defined when the `OMP_PLACES` environment variable is defined using an abstract name.

```
setenv OMP_PLACES threads
setenv OMP_PLACES threads(4)
```

**OMP_PROC_BIND** *(Windows, Linux)*

Sets the thread affinity policy to be used for parallel regions at the corresponding nested level. Enables (true) or disables (false) the binding of threads to processor contexts. If enabled, this is the same as specifying `KMP_AFFINITY=scatter`. If disabled, this is the same as specifying `KMP_AFFINITY=none`.

</table>
| **KMP_CPUINFO_FILE** | Specifies an alternate file name for a file containing the machine topology description. The file must be in the same format as /proc/cpuinfo.  
**Default**: None |
| **KMP_DETERMINISTIC_REDUCTION** | Enables (true) or disables (false) the use of a specific ordering of the reduction operations for implementing the reduction clause for an OpenMP* parallel region. This has the effect that, for a given number of threads, in a given parallel region, for a given data set and reduction operation, a floating point reduction done for an OpenMP* reduction clause has a consistent floating point result from run to run, since round-off errors are identical.  
**Default**: false |
| **KMP_DYNAMIC_MODE** | Selects the method used to determine the number of threads to use for a parallel region when OMP_DYNAMIC=true. Possible values: (asat | load_balance | thread_limit), where,  
• asat: estimates number of threads based on parallel start time;  
**NOTE**  
Support for asat (automatic self-allocating threads) is now deprecated and will be removed in a future release.  
• load_balance: tries to avoid using more threads than available execution units on the machine;  
• thread_limit: tries to avoid using more threads than total execution units on the machine.  
**Default (IA-32 architecture)**: load_balance (on all supported OSes)  
**Default (Intel® 64 architecture)**: load_balance (on all supported OSes) |
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>KMP_HOT_TEAMS_MAX_LEVEL</strong></td>
<td>Default (Intel® MIC architecture): thread_limit (on supported OSes) Sets the maximum nested level to which teams of threads will be hot. <strong>NOTE</strong> A hot team is a team of threads optimized for faster reuse by subsequent parallel regions. In a hot team, threads are kept ready for execution of the next parallel region, in contrast to the cold team, which is freed after each parallel region, with its threads going into a common pool of threads. For values of 2 and above, nested parallelism should be enabled. <strong>Default:</strong> 1</td>
</tr>
<tr>
<td><strong>KMP_HOT_TEAMS_MODE</strong></td>
<td>Specifies the run-time behavior when the number of threads in a hot team is reduced. Possible values:  • 0: Extra threads are freed and put into a common pool of threads.  • 1: Extra threads are kept in the team in reserve, for faster reuse in subsequent parallel regions. <strong>Default:</strong> 0</td>
</tr>
<tr>
<td><strong>KMP_INHERIT_FP_CONTROL</strong></td>
<td>Enables (true) or disables (false) the copying of the floating-point control settings of the master thread to the floating-point control settings of the OpenMP® worker threads at the start of each parallel region. <strong>Default:</strong> true</td>
</tr>
<tr>
<td><strong>KMP_LIBRARY</strong></td>
<td>Selects the OpenMP® run-time library execution mode. The values for this variable are serial, turnaround, or throughput. <strong>Default:</strong> throughput</td>
</tr>
<tr>
<td><strong>KMP_MONITOR_STACKSIZE</strong></td>
<td>Sets the number of bytes to allocate for the monitor thread, which is used for book-keeping during program execution. Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes).</td>
</tr>
</tbody>
</table>
Run-Time Environment Variable | Description
--- | ---
KMP_PLACE_THREADS | **Default:** max (32k, system minimum thread stack size)

Specifies the number of sockets, cores per socket, and the number of threads per core, to use with an OpenMP* application, as an alternative to writing explicit affinity settings or a process affinity mask. You can also specify an offset value to set which sockets and cores to use.

**Syntax:**
socketsS[@offset], coresC[@offset], threads T

S, C and T are not case-sensitive.

- **sockets** The number of sockets to use.
- **cores** The number of cores to use per socket.
- **threads** The number of threads to use per core.
- **offset** (Optional) The number of sockets or cores to skip.

**NOTE**
If you don’t specify one or more types of resource, sockets, cores or threads, all available resources of that type are used.

**NOTE**
This variable does not work if the OpenMP* affinity is set to none, the default on Intel® Xeon® processors, or disabled. Set the affinity type by setting the environment variable OMP_PROC_BIND to a value other than false, or by setting the environment variable KMP_AFFINITY to a value other than none or disabled.

On Intel® Xeon® Phi™ coprocessors, the default affinity type is scatter, so KMP_PLACE_THREADS works by default on this platform.

**Default:** If omitted, the default value is the available number of sockets, cores, or threads.

**Examples:**

- 2s, 4c, 2t: Use the first 2 sockets (s0 and s1), the first 4 cores on each socket (c0 - c3), and 2 threads per core.
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Run-Time Environment Variable</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>2s@2,4c@8,2t:</td>
<td>Skip the first 2 sockets (s0 and s1) and use 2 sockets (s2-s3), skip the first 8 cores (c0-c7) and use 4 cores on each socket (c8-c11), and use 2 threads per core.</td>
</tr>
<tr>
<td>5c@1,3T:</td>
<td>Use all available sockets, skip the first core and use 5 cores, and use 3 threads per core.</td>
</tr>
<tr>
<td>2T:</td>
<td>Use all cores on all sockets, 2 threads per core.</td>
</tr>
<tr>
<td>4c@12:</td>
<td>Use 4 cores with offset 12, all available threads per core.</td>
</tr>
</tbody>
</table>

**KMP_SETTINGS**

Enables (true) or disables (false) the printing of OpenMP* run-time library environment variables during program execution. Two lists of variables are printed: user-defined environment variables settings and effective values of variables used by OpenMP* run-time library.

**Default:** false

**KMP_STACKSIZE**

Sets the number of bytes to allocate for each OpenMP* thread to use as its private stack.

Recommended size is 16m.

Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes).

This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP* program or parallel programs created using the option Qparallel (Windows) or qparallel (Linux and OS X).

**Default (IA-32 architecture):** 2m

**Default (Intel® 64 architecture):** 4m

**Default (Intel® MIC architecture):** 4M (on supported OSes)

**KMP_VERSION**

Enables (true) or disables (false) the printing of OpenMP* run-time library version information during program execution.

**Default:** false

**KMP_WARNINGS**

Enables (true) or disables (false) displaying warnings from the OpenMP* run-time library during program execution.

**Default:** true
### Intel® Many Integrated Core (Intel® MIC) Environment Variables

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| MIC_ENV_PREFIX                | Controls environment variables passed to the target.  
                                 By default, all environment variables set on the host are passed to the target. Setting MIC_ENV_PREFIX passes only environment variables that have a prefix of the value of this variable. For example, setting MIC_ENV_PREFIX=ABC passes only environment variables that have a prefix of ABC. |
| MIC_LD_LIBRARY_PATH           | Specifies the location on the host for target-specific shared objects that may be loaded to the target. The value is not passed to the target. See MIC_ENV_PREFIX for special handling of the value on the target. |
| MIC_PROXY_IO                  | Enables (1) or disables (0) the proxy of stderr and stdout, and specifies whether the process wants I/O proxy support between the host and target.  
                                 **Default:** 1  
                                 **Example:** MIC_PROXY_IO=0 |
Run-Time Environment Variable | Description
--- | ---
MIC_SEP_MONITOR | Enables (1) or disabled (0) SEP at offload regions.  
**Default:** 0  
**Example:** MIC_SEP_MONITOR=1

MIC_STACKSIZE | Specifies the stack size of the main thread for the offload. This value is typically much larger than the stack size for individual threads. It corresponds to what you would set with `ulimit-s` (BASH shell) or `limit stacksize` (C shell) if you were running natively on either the target or the host.  
Set this variable to `integerB|K|M|G|T`, where:  
- `B` = bytes  
- `K` = kilobytes  
- `M` = megabytes  
- `G` = gigabytes  
- `T` = terabytes  
**Default:** 12M  
**Example:** MIC_STACKSIZE=16M

MIC_USE_2MB_BUFFERS | Use 2M pages for (size > MIC_USE_2MB_BUFFERS). Variables with the ALLOCATABLE or POINTER attribute whose runtime length exceeds the value of this environment variable are allocated in large pages.  
Set this variable to `integerB|K|M|G|T`, where:  
- `B` = Bytes  
- `K` = Kilobytes  
- `M` = Megabytes  
- `G` = Gigabytes  
- `T` = Terabytes  
**Example:** MIC_USE_2MB_BUFFERS=64K

OFFLOAD_DEVICES | Restricts the offload process to use only the coprocessors specified as the value of the variable.  
Set this variable to a comma-separated list of target device numbers in the range 0 to \((number\_of\_devices\_in\_the\_system - 1)\), where 0 is the first coprocessor in the system, and \((number\_of\_devices\_in\_the\_system - 1)\) is the last coprocessor in the system.  
Coprocessors available for offloading are numbered logically. The function \(OFFLOAD\_NUMBER\_OF\_DEVICES\) returns the number of available coprocessors. Coprocessor indices that you use in the `target` specifier of the offload directives are in the range 0 to \(number\_of\_devices\_in\_the\_system - 1\).
Run-Time Environment Variable  | Description
---|---
**Default:** The offload process uses all devices.  
**Example:** OFFLOAD_DEVICES = 1,2

On a system with more than two coprocessors installed, this setting enables the application to use only coprocessors 1 and 2. Offloads to coprocessors 0 or 1 are performed on the second and third physical coprocessors. Offloads to target numbers higher than 1 wrap around, and all offloads remain within coprocessors 0 and 1. The function OFFLOAD_NUMBER_OF_DEVICES, executed on a coprocessor, returns 0 or 1 when the offload is running on the first or second coprocessor.

Setting this variable to an empty value on Linux (export OFFLOAD_DEVICES=) or the value none on Windows (set OFFLOAD_DEVICES=none) impacts the execution of offloaded code within your program as follows:

- When you use optional offloading, the code executes on the host CPU.
- When you use mandatory offloading, the program terminates with an offload error, reporting that a device is not available, when it reaches a point in the execution where the coprocessor requires initialization for offloading.

You can specify optional and mandatory offloading using the optional and mandatory clauses in either of the following:

- The compiler option qoffload (Linux) or Qoffload (Windows)
- The OFFLOAD directive

**OFFLOAD_INIT**

Specifies a hint to the offload runtime indicating when to initialize targets.

Possible values:

- **on_start:** All available coprocessors are initialized before entering the main program.
- **on_offload:** The target is initialized immediately before the first offload to it. Initialization is done only on the target that handles the offload.
- **on_offload_all:** All available targets are initialized immediately before the first offload in an application.

**Default:** on_offload_all  
**Example:** OFFLOAD_INIT=on_start
<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| OFFLOAD_REPORT                    | Controls printing offload execution time, in seconds, and the amount of data transferred, in bytes. This environment variable is equivalent to using the _Offload_report API. Possible values:  
  - 1: Prints the offload computation time, in seconds.  
  - 2: In addition to the information produced at value 1, adds the amount of data transferred between the CPU and the target, in bytes.  
  - 3: In addition to the information produced at value 2, gives additional details on offload activity, including device initialization, and individual variable transfers.  
  **Default:** None  
  **Example:** OFFLOAD_REPORT=1  
  See also _Offload_report. |

### Profile Guided Optimization (PGO_) Environment Variables

<table>
<thead>
<tr>
<th>INTEL_PROF_DUMP_CUMULATIVE</th>
<th>When using interval profile dumping (initiated by INTEL_PROF_DUMP_INTERVAL or the function _PGOPTI_Set_Interval_Prof_Dump) during the execution of an instrumented user application, allows creation of a single .dyn file to contain profiling information instead of multiple .dyn files. If not set, executing an instrumented user application creates a new .dyn file for each interval. Setting this environment variable is useful for applications that do not terminate or those that terminate abnormally (bypass the normal exit code).</th>
</tr>
</thead>
</table>
| INTEL_PROF_DUMP_INTERVAL        | Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application.  
  **See** Interval Profile Dumping for more information |
| INTEL_PROF_DYN_PREFIX           | Specifies the prefix to be used for the .dyn filename to distinguish it from the other .dyn files dumped by other PGO runs. Executing the instrumented application generates a .dyn filename as follows: <prefix>_<timestamp>_<pid>.dyn, where <prefix> is the identifier that you have specified. |
### Run-Time Environment Variable

<table>
<thead>
<tr>
<th>Run-Time Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PROF_DIR</strong></td>
<td>Specifies the directory where profiling files (files with extensions <code>.dyn</code>, <code>.dpi</code>, <code>.spi</code> and so on) are stored. The default is to store the <code>.dyn</code> files in the source directory of the file containing the first executed instrumented routine in the binary compiled with <code>\[Q\]prof-gen</code> option. This variable applies to all three phases of the profiling process: • Instrumentation compilation and linking • Instrumented execution • Feedback compilation</td>
</tr>
<tr>
<td><strong>PROF_DPI</strong></td>
<td>Name for the <code>.dpi</code> file. <strong>Default:</strong> <code>pgopti.dpi</code></td>
</tr>
<tr>
<td><strong>PROF_DUMP_INTERVAL</strong></td>
<td>Deprecated; use <code>INTEL_PROF_DUMP_INTERVAL</code> instead.</td>
</tr>
<tr>
<td><strong>PROF_NO_CLOBBER</strong></td>
<td>Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new <code>pgopti.dpi</code> file if the <code>.dyn</code> files are newer than an existing <code>pgopti.dpi</code> file. When this variable is set, the compiler does not overwrite the existing <code>pgopti.dpi</code> file. Instead, the compiler issues a warning. You must remove the <code>pgopti.dpi</code> file if you want to use additional dynamic information files.</td>
</tr>
</tbody>
</table>

**NOTE**
The value specified in this environment variable must not contain `< > :" / | ? * characters. The default naming scheme is used if an invalid prefix is specified.
Using Other Methods to Set Environment Variables

All Operating Systems

- From the command line: You can use the `SET` command at the command prompt to set environment variables.
- From within a program: Call the `SETENVQQ` routine to set environment variables. For example:

```fortran
USE IFORT
  LOGICAL(4) success
  success = SETENVQQ("PATH=c:\mydir\tmp")
  success = success .and. SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
```

Depending on your operating system, there are additional ways to set environment variables.

Linux* and OS X*

Within the Bourne*/Bourne* Again shell (`sh/bash`), or the Korn shell (`ksh`), use the `export` command and assignment command to set an environment variable:

```bash
export FORT9
FORT9=/usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the Bourne*, Korn shell, or bash shells, use the `unset` command:

```bash
unset FORT9
```

Within the C shell (`csh`), use the `setenv` command to set an environment variable:

```bash
setenv FORT9 /usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the C shell, use the `unsetenv` command.

```bash
unsetenv FORT9
```

Windows*

Environment variables specifying path, library, and include directories can be defined in Visual Studio* on a per user basis using `Tools > Options` ... from the menu bar. For more information, see Specifying Path Library and Include Directories.

NOTE
If you specify `devenv` or `useenv` options on the command line to start the IDE, the IDE uses the `PATH`, `INCLUDE`, and `LIB` environment variables defined for that command line when performing a build. It uses these values instead of the values defined using `Tool > Options`.

For more information on the `devenv` command, see the Visual Studio* documentation.

During installation, the Intel® Fortran compiler may modify certain system-wide environment variables, depending on your installation choices. For more information, see the `install.htm` file.

To view or change these environment variable settings, do the following:
1. Using an account with Administrator privilege, open the **Control Panel**.
2. Select **System**.
3. Select **Advanced System Settings**, then click the **Environment Variables** button from the **Advanced** tab.
4. View or change the displayed environment variables.
5. To have any environment variable changes take effect immediately, click **Apply**.
6. Click **OK**.

**NOTE**
Changing system-wide environment variables affects command line builds (those done without IDE involvement), but not builds done through the IDE. IDE builds are managed by the environment variables set in the IDE using **Tools > Options**. An exception to this is an IDE build (**devenv**) done from the command line that specifies the **useenv** option. In this case, the IDE uses the **PATH**, **INCLUDE**, and **LIB** environment variables defined for that command line.
## Understanding Files Associated with Intel® Fortran Applications (Windows*)

There are a number of files associated with Intel® Fortran Compiler applications. The following table shows common files used by the Intel® Fortran Compiler and lists their contents.

<table>
<thead>
<tr>
<th>File Extension</th>
<th>Type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>.asm</td>
<td>Intermediate</td>
<td>Assembly file, passed to the assembler</td>
</tr>
<tr>
<td>.exe</td>
<td>Output</td>
<td>Executable, dynamic- link library, or library files</td>
</tr>
<tr>
<td>.dll</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.lib</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.fi</td>
<td>Source</td>
<td>Header files</td>
</tr>
<tr>
<td>.fd</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.for</td>
<td>Source</td>
<td>Fortran source files (fixed format)</td>
</tr>
<tr>
<td>.f</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.fpp</td>
<td>Source</td>
<td>Fortran source file (free format)</td>
</tr>
<tr>
<td>.f90</td>
<td>Source</td>
<td>Linker</td>
</tr>
<tr>
<td>.def</td>
<td>Source</td>
<td>Microsoft IDL (non-Fortran)</td>
</tr>
<tr>
<td>.idl</td>
<td>Source</td>
<td>Incremental link file</td>
</tr>
<tr>
<td>.ilk</td>
<td>Source</td>
<td>Incremental link file</td>
</tr>
<tr>
<td>.map</td>
<td>Output</td>
<td>Map file; output from the linker</td>
</tr>
<tr>
<td>.mod</td>
<td>Output</td>
<td>Module file; created if a source file defines a Fortran module</td>
</tr>
<tr>
<td>.obj</td>
<td>Intermediate</td>
<td>Object file; passed to the linker</td>
</tr>
<tr>
<td>.pdb</td>
<td>Output (Debug)</td>
<td>Program debug database file</td>
</tr>
<tr>
<td>.tbl</td>
<td>Output (MIDL)</td>
<td>Type library; passed to Resource</td>
</tr>
<tr>
<td>.rc</td>
<td>Resource</td>
<td>Resource file (non-Fortran)</td>
</tr>
<tr>
<td>.res</td>
<td>Intermediate</td>
<td>Resource file; passed to the linker</td>
</tr>
<tr>
<td>.sln</td>
<td>Solution</td>
<td>Visual Studio* solution file and solution options file</td>
</tr>
<tr>
<td>.suo</td>
<td>Project</td>
<td>Intel® Fortran, Intel® C++, and Microsoft Visual C++* project files</td>
</tr>
<tr>
<td>.vfproj</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.vcproj</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.icproj</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
You can specify additional Fortran file extensions to be recognized by Visual Studio*. For more information, see Specifying Fortran File Extensions.
Compiling and Linking
Multithreaded Programs

To build a multithreaded application that uses the Fortran run-time libraries, specify the *threads* compiler option from the command line. The Visual Studio* integrated development environment (IDE), described later in this topic, can also be used on Windows*.

You must also link with the correct library files. Some libraries, such as those for OpenMP* or coarrays, are always linked dynamically.

**Linux* and OS X***

To create statically-linked, multithreaded programs, link with the static library named *libifcoremt.a*.

To use shared libraries, link your application with *libifcoremd.so* (Linux*) or *libifcoremd.dylib* (OS X*).

**To compile and link your multithreaded program from the command line:**

1. Make sure the *IA32ROOT* environment variable points to the directory containing your library files.
2. Compile and link the program with the *-threads* option. For example:

   ```fortran
   ifort -threads mythread.f90
   ```

   **NOTE**
   To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option *threads* should also be used for the link step and for the compilation of the main routine.

**Windows***

To create statically linked multithreaded programs, link with the re-entrant support library *LIBIFCOREMT.LIB*.

To use shared libraries, use the shared *LIBIFCOREMD.DLL* library, which is also re-entrant, and is referenced by linking your application with the *LIBIFCOREMD.LIB* import library.

Programs built with *LIBIFCOREMT.LIB* do not share Fortran run-time library code or data with any dynamic-link libraries they call. You must link with *LIBIFCOREMD.LIB* if you plan to call a DLL.

**Additional Notes:**

- The */threads* option is automatically set when a multithreaded application is specified in the IDE.
- Specify the compiler options */libs=dll* and */threads* if you are using both multithreaded code and DLLs.
- You can use the */libs=dll* and */threads* options only with Fortran Console projects, not QuickWin applications.

**To compile and link your multithreaded program using Visual Studio***

1. Create a new project by clicking **File > New > Project**.
2. Select the Intel® Visual Fortran project type from **Intel® Visual Fortran Projects** in the left pane.
3. Add the file containing the source code to the project.

   From the **Project** menu, select **Properties**. The **Property Pages** dialog box appears.
4. Choose the Fortran folder, Libraries category, and set the Runtime Library to Multithreaded or Multithread DLL (or their debug equivalents).

5. Create the executable file by choosing Build Solution from the Build menu.

To compile and link your multithreaded program from the command line:

1. Make sure your LIB environment variable points to the directory containing your library files.
2. Compile and link the program with the /threads option. For example:

   ifort /threads mythread.f90

**NOTE**
To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option threads should also be used for the link step and for the compilation of the main routine.
This topic describes how to use the Intel® linking tools, xild (Linux* and OS X*) and xilink (Windows*). The Intel® linking tools behave differently on different platforms. The following sections summarize the primary differences between linking behavior.

### Linux* and OS X* Linking Behavior Summary

The linking tool invokes the Intel® Fortran Compiler to perform IPO if objects containing IR (intermediate representation) are found. These are mock objects. The tool invokes GNU ld to link the application.

The command-line syntax for xild is the same as that of the GNU linker:

```
xild [options] <normal command-line>
```

where:

- `[options]`: One or more options supported only by xild (optional).
- `<normal command-line>`: Linker command line containing a set of valid arguments for ld.

To create the file app using IPO, use the option `o[filename]` as shown in the following example:

```
xild -qipo-fas-oapp a.o b.o c.o
```

The linking tool calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker then calls ld to link the object files that are specified in the new list and produce the application with the name specified by the `o` option. The linker supports the `ipo[n]` and `ipo-separate` options.

To display a list of the supported link options from xild, use the following command:

```
$ xild -qhelp
```

### Windows* Linking Behavior Summary

The linking tool invokes the Intel® Fortran Compiler to perform multi-file IPO if objects containing IR (intermediate representation) is found. These are mock objects. It invokes the Microsoft linker link.exe to link the application.

The command-line syntax for the Intel® linker is the same as that of the Microsoft linker:

```
xilink [options] <normal command-line>
```

where:

- `[options]`: One or more options supported only by xilink (optional).
- `<normal command-line>`: Linker command line containing a set of valid arguments for the Microsoft linker.

To place the multifile IPO executable in ipo_file.exe, use the linker option `out:[filename]`, for example:

```
xilink -qipo-fas/out:ipo_file.exe a.obj b.obj c.obj
```
Windows* Linking Behavior Summary

The linker calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker calls Microsoft link.exe to link the object files that are specified in the new list and produce the application with the name specified by the out:[filename] linker option.

To display a list of support link options from xilink, use the following command:

```
>> xilink /qhelp
```

xilink.exe accepts all the options of link.exe and will pass them on to link.exe at the final linking stage.

Using the Linking Tools

You must use the Intel® linking tools to link your application if the following conditions apply:

- Your source files were compiled with multi-file IPO enabled. Multi-file IPO is enabled by specifying compiler option [Q]ipo.
- You would normally invoke the GNU linker (ld) to link your application.
- You would normally invoke the Microsoft linker (link.exe) to link your application.

Linker Options

The following table provides information on linking options.

<table>
<thead>
<tr>
<th>Linking Tools Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>qdiag- [type]=[diag-list]</td>
<td>Controls the display of diagnostic information. The type is an action to perform on diagnostics. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>• Enable: Enables a diagnostic message or a group of messages.</td>
</tr>
<tr>
<td></td>
<td>• Disable: Disables a diagnostic message or a group of messages.</td>
</tr>
<tr>
<td></td>
<td>The diag-list is a diagnostic group or ID value. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>• thread: Specifies diagnostic messages that help in thread-enabling a program.</td>
</tr>
<tr>
<td></td>
<td>• vec: Specifies diagnostic messages issued by the vectorizer.</td>
</tr>
<tr>
<td></td>
<td>• par: Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).</td>
</tr>
<tr>
<td></td>
<td>• openmp: Specifies diagnostic messages issued by the OpenMP* parallelizer.</td>
</tr>
<tr>
<td></td>
<td>• warn: Specifies diagnostic messages that have a &quot;warning&quot; severity level.</td>
</tr>
<tr>
<td></td>
<td>• error: Specifies diagnostic messages that have an &quot;error&quot; severity level.</td>
</tr>
<tr>
<td></td>
<td>• remark: Specifies diagnostic messages that are remarks or comments.</td>
</tr>
<tr>
<td></td>
<td>• cpu-dispatch: Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.</td>
</tr>
<tr>
<td></td>
<td>• id[,id,...]: Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each &quot;id&quot;.</td>
</tr>
<tr>
<td></td>
<td>• tag[,tag,...]: Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each &quot;tag&quot;.</td>
</tr>
<tr>
<td>Linking Tools Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>Diagnostic messages generated by this option can be affected by other options, such as <code>/arch</code> (Windows*), <code>-m</code> (Linux* and OS X*), or <code>[Q]x</code>.</td>
</tr>
</tbody>
</table>

qm32, qm64

- **qm32** generates code for IA-32 architecture.
- **qm64** generates code for Intel® 64 architecture.

For example, when your compilation environment is configured for Intel® 64 architecture, and you use `qm32` with the compiler, you also need to use `qm32` on the linker command line to make sure the proper compilation target is set up for any IPO compilations or the final link.
You can decrease the time you spend entering command-line options by using the configuration file to automate command-line entries. Configuration files are automatically processed every time you run the Intel® Fortran Compiler. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the specified command-line options when the compiler is invoked.

**NOTE**
Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use Using Response Files.

**Sample Configuration Files**
The default configuration file `ifort.cfg` is located in the same directory as the compiler executable file. If you want to use a different configuration file than the default, you can use the `IFORTCFG` environment variable to specify the location of another configuration file.

**NOTE**
Anytime you instruct the compiler to use a different configuration file, the system configuration file(s) are ignored.

The following examples illustrate basic configuration files. The pound (#) character indicates that the rest of the line is a comment.

In the Windows® examples, the compiler reads the configuration file and invokes the `i` option every time you run the compiler, along with any options specified on the command line.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| ```
## Sample ifort.cfg file
## Define preprocessor macro MY_PROJECT.
-DMY_PROJECT

## Set extended-length source lines.
-extend_source

## Set maximum floating-point significand precision.
-pc80

## Sample ifort.cfg file
## Define preprocessor macro MY_PROJECT
/DMY_PROJECT

## Set extended-length source lines.
/extend_source

## Set maximum floating-point significand precision.
``` |
### Example

```
/Qpc80

## Additional directories to be searched for include files, before the default.
/Ic:\project\include

## Use the static, multithreaded run-time library.
/MT
```

### NOTE

64-bit decimal transcendental functions rely on binary double-extended precision arithmetic. To obtain accurate results, user applications that call 64-bit decimal transcendental functions should ensure that the x87 unit is operating in 80-bit precision (64-bit binary significands). In an environment where the default x87 precision is not 80 bits, such as Windows®, it can be set to 80 bits by compiling the application source files with the `/Qpc80` option.
You can use response files to:

- Specify options used during particular compilations or projects.
- Save this information in individual files.

Response files are invoked as options on the command line. Options in response files are inserted in the command line at the point where the response file is invoked. Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file without specifying it on the command line, it will not be invoked.

Use response files to decrease the time spent entering command-line options and to ensure consistency by automating command-line entries. Use individual response files to maintain options for specific projects.

Any number of options or file names can be placed on a line in a response file. Several response files can be referenced in the same command line. The following example shows how to specify a response file on the command line:

```
ifort @responsefile1 [@responsefile2 ... ]
```

**NOTE**

An "at" sign (@) must precede the name of the response file on the command line.
The simplest way to build an application is to compile all of your Fortran source files, then link the resulting object files into a single executable. You can build single-file executables using the `ifort` command. You can also use the Visual Studio* IDE on Windows*.

The executable file you build with this method contains all of the code needed to execute the program, including the run-time library. Because the program resides in a single file, it is easy to copy or install. The project contains all of the source and object files for the routines used to build the application. To use these routines in other projects, all source and object files must be relinked.

Exceptions to this are as follows:

- If you are using shared libraries, all code will not be contained in the executable file.
- On OS X*, the object files contain debug information and would need to be copied along with the executable.
**Linking Debug Information**

**Windows**
Use option `Z7` at compile time or option `debug` at link time to tell the compiler to generate symbolic debugging information in the object file. Alternately, use option `Zi` at link time to generate executables with debug information in the `.pdb` file.

**Linux**
Use option `g` at compile time to tell the compiler to generate symbolic debugging information in the object file.

Use option `gsplit-dwarf` to create a separate object file containing DWARF debug information. Because the DWARF object file is not used by the linker, this reduces the amount of debug information the linker must process and it results in a smaller executable file. See `gsplit-dwarf` for detailed information.

**OS X**
You can link the DWARF debug information from the object files for an executable using `dsymutil`, a utility included with Xcode. By linking the debug information in an executable, you eliminate the need to retain object files specifically for debugging purposes.

The utility runs automatically in the following cases:

- When you use the Intel® Fortran Compiler to compile directly from source to executable using the command line with option `g`. For example:

  ```
  ifort -g myprogram.f90
  ```

- When you compile using Xcode.

In other cases, you must explicitly run `dsymutil`, such as when you compile using a make file that builds `.o` files and subsequently links the program.
**Debugging**

**Debugging Fortran Programs**
Depending on your operating system and architecture platform, several debuggers may be available to you. You can use the debugger provided by your operating system:

- On Linux* OS and OS X*, this debugger is `gdb`.
- On Windows* OS, the debugger is the Microsoft integrated debugger.

On Windows* systems, you can use your local (host) system to debug an application running on a remote system. For more information, see Using Remote Debugging.

**See Also**
Using Remote Debugging

**Preparing Your Program for Debugging**
This section describes preparing your program for debugging.

**Preparing for Debugging using the Command Line**
To prepare your program for debugging when using the command line (ifort command):

1. Correct any compilation and linker errors.
2. In a command window, such as the Fortran command window available from the Intel® Fortran program folder, compile and link the program with full debug information and no optimization:

   ```plaintext
   // (Linux* OS and OS X*)
   ifort -g file.f90
   // (Windows* OS)
   ifort /debug:full file.f90
   ```

   On Linux* OS and on OS X*, specify the `g` compiler option to create unoptimized code and provide the symbol table and traceback information needed for symbolic debugging. The `notraceback` option cancels the traceback information.

   On Windows* OS, specify the `debug` compiler option with keyword `full` to produce full debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking.

**Preparing for Debugging using Visual Studio***
The following applies to Windows* operating systems only.

To prepare your program for debugging when using the integrated development environment (IDE):

1. Start the IDE (select the appropriate version of Visual Studio* in the program folder).
2. Open the appropriate solution (using the Solution menu, either Open Solution or Recent Projects).
3. Open the Solution Explorer View.
4. To view the source file to be debugged, double-click on the file name. The screen resembles the following:
5. In the Build menu, select Configuration Manager and select the Debug configuration.
6. To check your project settings for compiling and linking, select the project name in Solution Explorer. Now, in the Project menu, select Properties, then click the Fortran folder in the left pane. Similarly, to check the debug options set for your project (such as command arguments or working directory), click the Debugging folder in the Property Pages dialog box.
7. To build your application, select Build > Build Solution.
8. Eliminate any compiler diagnostic messages using the text editor to resolve problems detected in the source code and recompile if needed.
9. Set breakpoints in the source file and debug the program. For more information, see Debugging the Squares Example Program.

Debugging the Squares Example Program
Using Breakpoints in the Debugger

This topic applies to Fortran applications for Windows* only.

This topic describes how to use the Microsoft Visual Studio* debugger to set file and data breakpoints. Information is organized as follows:

- Viewing All Current Breakpoints
- Working with File Breakpoints
- Adding Conditions to File Breakpoints
- Working with Data Breakpoints

In addition to file and data breakpoints, the Visual Studio* debugger supports the following:

- Address breakpoints
- Function breakpoints
- Tracepoints

For information on these additional features, see the Microsoft documentation for your version of Visual Studio*.

Viewing All Current Breakpoints

You can view all currently set breakpoints in the Breakpoints window. To view all set breakpoints using the Breakpoints window:

1. In the Debug menu, select Windows > Breakpoints.
2. Scroll up or down in the Breakpoints list to view the breakpoints. Enabled breakpoints have a check mark in the check box and disabled breakpoints have an empty check box. The window displays all types of breakpoints.

Working with File Breakpoints

Use a file breakpoint to interrupt program execution when the program reaches a specified location within a file. Several symbols are used to show the status of file breakpoints; these appear in the left margin of the Source window:

- **Enabled** file breakpoints are identified as a red circle.
- **Disabled** file breakpoints are identified as a hollow circle in the left margin.

During debugging, a currently active breakpoint appears as a red circle containing a yellow arrow in the left margin of the Source window.

For a walk-through of a sample debugging session using file breakpoints, see Debugging the Squares Example Program.

To set (enable) a file breakpoint:

1. Open the desired source file in the solution.
2. In the Source window, click the line at which you want to enable a file breakpoint.
3. Do one of the following:
   - Click in the left margin of the line or press the F9 key. When you set a breakpoint, it is enabled by default.
   - Right click on the desired line and select Insert Breakpoint from the pop-up menu.

To disable a file breakpoint:
1. In the **Source** window, click the line containing the file breakpoint you want to disable.
2. Do one of the following:
   - Right click on that line, and select **Disable Breakpoint** from the pop-up menu.
   - In the **Debug** menu, select **Windows > Breakpoints**, which opens the **Breakpoints** window. Select the check box for that breakpoint so it is unchecked (disabled).

**To remove a file breakpoint:**
1. In the **Source** window, click the line containing the file breakpoint you want to remove.
2. Do one of the following:
   - Click in the left margin of the line or press the F9 key. If the breakpoint was originally disabled, press F9 again to remove it.
   - Right click on that line, and select **Delete Breakpoint** from the pop-up menu.
   - In the **Debug** menu, select **Windows > Breakpoints**. In the **Breakpoints** window, select the breakpoint in the Name column and click the **Delete** button (which looks like an "X").

**To view the source code where a file breakpoint is set:**
1. In the **Debug** menu, select **Windows > Breakpoints**.
2. In the Breakpoints window, click a file breakpoint.
3. Click the **Go To Source Code** button.
   This action takes you to the source code for a breakpoint set at a line number or function (or subroutine) name. In the case of function (or subroutine) names, the debugger must be running for this to work.

**To remove all breakpoints (including data breakpoints):**
In the **Debug** menu, select **Delete All Breakpoints**.

**Adding Conditions to File Breakpoints**
When you associate a condition with a file breakpoint, the program executes until that location is reached and the specified condition is met, such as when the value of an array element is greater than 1.

To add a condition to a breakpoint:
1. Set a file breakpoint.
2. Right-click in the associated line and select **Breakpoint > Condition...**

   The **Breakpoint Condition** dialog box appears.

The condition that you specify in the **Breakpoint Condition** dialog box must relate to a local variable within the breakpoint’s scoping unit, or to a global variable. You must apply proper Fortran syntax in the **Condition** field in order for the specified condition to be properly detected. Consider the following examples:

To break when the local variable **RecNum** reaches a value of 7520, enter the following condition:

```
RecNum == 7520
```

You can also specify joint conditions. To break when **RecNum** reaches at least 7520 and the variable **Var2** is equal to 90, enter the following condition:

```
RecNum >= 7520 .and. Var2 == 90
```

You can also specify an or condition. For example:

```
Var1 == 3.14 .or. Var2 < 500.0
```
If the condition that you specify occurs at the chosen location when the program is run, a message box appears. If the breakpoint is set in part of a loop, continuing execution proceeds until the debugger detects another specified condition. If no such condition is detected, the debugger continues to the next breakpoint or, if no more breakpoints are set, until the end of the loop.

To disable, enable, or remove a file breakpoint with a defined condition, follow the general procedures for a file breakpoint. Use the checkbox for the **Condition** field to enable or disable the condition setting.

**Working with Data Breakpoints**

Use a data breakpoint to interrupt program execution when the value of a certain variable changes. A data breakpoint displays a message box when the value of a variable changes, or, if a condition has been defined, when a condition is met. Unlike a file breakpoint, data breakpoints are not associated with a specific source location.

**Using Visual C++ Data Breakpoint Support**

The Visual Studio IDE does not provide data breakpoint support specifically for Fortran, but you can still use data breakpoints in a Fortran program; they are handled using the existing mechanism provided by Microsoft Visual C++. This means that you must use Visual C++ syntax; you cannot enter the variable name or condition using Fortran syntax. The following guidelines apply:

- For scalar variables, enter the variable name in upper case. This allows Visual C++ to find the variable in the debug information and apply the correct breakpoint.
- For arrays and types, use the Fortran LOC intrinsic function in a **Watch** window or the Immediate window to obtain the address of the variable. Use this address in the variable name edit box.

For example, to prepare to set a data breakpoint at an array element a(5), do the following:

1. Select **Debug > Windows > Immediate**.
2. Enter `loc(a(5))` in the immediate window and press Enter.

The result displayed is the address of the array element. The address may be displayed as a decimal number or a hexadecimal number, depending upon your current display mode. For a decimal number, you will enter it in the **Address**: field. For a hexadecimal number, you will use the Visual C++ hexadecimal syntax (`0xnnnnnnnn`) rather than the Fortran syntax (`#nnnnnnnn`) in the fields.

The following procedure applies to debugging the current routine (current scope).

**To set a data breakpoint:**

1. Start debugging.
2. In the **Debug** menu, select **New Breakpoint > New Data Breakpoint...**
3. Enter the desired address. Also enter the Byte Count and Language (specify C++).

If you want to associate a condition with this breakpoint, right-click on the breakpoint in the **Breakpoints** window and choose **Condition...**

**To disable, enable, or remove a data breakpoint:**

1. In the **Debug** menu, select **Windows > Breakpoints**.
2. To disable or enable the data breakpoint, use the check box to the left of the data breakpoint (check indicates enabled).
3. To remove a data breakpoint, select the data breakpoint and click the **Delete** button.

Under certain conditions, the debugger may disable a data breakpoint. In this case, you should either try to enable it or remove and set it again.

**To remove all breakpoints (including file breakpoints):**

In the **Debug** menu, select **Delete All Breakpoints**.
Debugging the Squares Example Program

This topic applies to Fortran applications for Windows* only.

The example below shows a program called SQUARES that requires debugging. The program was compiled and linked without diagnostic messages from either the compiler or the linker, however, this program contains a logic error in an arithmetic expression.

Program SQUARES

```fortran
PROGRAM SQUARES
    INTEGER INARR(10), OUTARR(10), I, K
! Read the input array from the data file.
    OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')
    READ(8,*,END=5) N, (INARR(I), I=1,N)
5   CLOSE (UNIT=8)

! Square all nonzero elements and store in OUTARR.
    K  = 0
    DO I = 1, N
        IF (INARR(I) .NE. 0) THEN
            OUTARR(K) = INARR(I)**2
        ENDIF
    END DO

! Print the squared output values. Then stop.
    PRINT 20, N
20  FORMAT (' Total number of elements read is',I4)
    PRINT 30, K
30  FORMAT (' Number of nonzero elements is',I4)
    DO I=1,K
        PRINT 40, I, OUTARR(K)
    END DO
40    FORMAT(' Element', I4, 'Has value',I6)
END PROGRAM SQUARES
```

The program SQUARES performs the following functions:

- Reads a sequence of integer numbers from a data file and saves these numbers in the array INARR. The file datafile.dat contains one record with the integer values 4, 3, 2, 5, and 2. The first number indicates the number of data items that follow.
- Enters a loop in which it copies the square of each nonzero integer into another array OUTARR.
- Prints the number of nonzero elements in the original sequence and the square of each such element.

In the program, the logic error occurs because variable K, which keeps track of the current index into OUTARR, is not incremented in the loop on lines 9 through 13. The statement K = K + 1 should be inserted just before line 11.

This example assumes that the program was executed without array bounds checking (set by specifying nobounds for the check command-line option). When executed with array bounds checking, a run-time error message appears.

**Debugging Example:** The following shows how to debug a Windows* OS based program using the Microsoft integrated debugger within the integrated development environment (see Preparing Your Program for Debugging and Using Breakpoints in the Debugger). This example assumes a solution already exists.

**To debug this program:**

1. Start Visual Studio*.
2. In the File menu, select Open Solution. Open the solution containing the file.
3. Edit the file squares.f90: double-click the file name in the Solution Explorer View. The screen appears as follows:
The following toolbars are shown: Build toolbar, Standard toolbar.

4. To change the displayed toolbars, select View > Toolbars. To display the debug toolbar, select Debug.

5. Click the first executable line to set the cursor position. In this case, click the beginning of the OPEN statement line:

   \[ \text{OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')} \]

6. Click in the left margin of the first executable line to set a breakpoint. The red circle in the left margin of the text editor/debugger window shows where a breakpoint is set:
7. This example assumes you have previously built your application (see Preparing Your Program for Debugging).

In the Debug menu, select Start Debugging.

The debugger is now active. The current position is marked by a yellow arrow at the first executable line (the initial breakpoint).

8. If needed, you can set another breakpoint. Position the cursor at the line where you want to add a breakpoint, right click, and select Breakpoint > Insert Breakpoint.

9. Step through the lines of source code. You can do this with Debug > Step Over or with the Step Over button on the Debug toolbar.

10. Repeat the Step Over action and follow program execution into the DO loop and unto the end of the program. Position the cursor over the variable \( K \) to view its value in a Data Tip box:
The error seems related to the value of variable $K$.

11. In the Text Editor, add the line $K = K + 1$ as follows:

```fortran
K = 0
DO I = 1, N
  IF (INARR(I) .NE. 0) THEN
    K = K + 1  ! add this line
    OUTARR(K) = INARR(I)**2
  ENDIF
END DO
```

12. Since you have modified the source, you need to rebuild the application:

- In the Debug menu, select Stop Debugging
- In the Build menu, select Build debugtest.
- In the Debug menu, select Start Debugging.

The output screen appears as follows:

```
Total number of elements read is  4
Number of nonzero elements is  4
Element 1 has value  9
Element 2 has value  4
Element 3 has value  25
Element 4 has value  4
```

13. The program now generates better results. You can examine the values of both the input array INARR (read from the file) and the output array OUTARR that the program calculates. In the Text Editor window, the previously set breakpoint remains set.
In the **Debug** menu, select **Start Debugging**.

14. To view the values of certain variables as the program executes, display the Locals window. In the **Debug** menu, select **Windows > Locals**.

15. You can view the values of the local variables in the Locals window. Click the plus sign to view array values.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>1</td>
</tr>
<tr>
<td>OUTARR</td>
<td>{...}</td>
</tr>
<tr>
<td>INARR</td>
<td>{...}</td>
</tr>
</tbody>
</table>

The **Locals** window does not let you display module variables or other non-local variables. To display non-local variables, display one of the **Watch** windows.

16. Although this example does not use module variables or non-local variables, you can drag a variable name into the **Watch** window so the variable can be displayed. The **Watch** window allows you to display expressions.

In the **Text Editor** window, select the variable name **INARR** (without its subscript syntax), drag it, and drop it into the **Watch** window, Name column:

17. Also drag the **OUTARR** array name to the **Watch** window. Click the Plus sign (+) to the left of the **OUTARR** variable’s name to display the values of its array elements.

18. Execute lines of the program by using the **Step Over** button on the **Debug** toolbar. As the program executes, you can view the values of scalar variables with the data tips feature and view the values of arrays (or other variables) in the **Watch** window.

If a **Disassembly** window (shows disassembled code with source-code symbols) unintentionally appears, click the **Step Out** button on the debugger toolbar (or select **Step Out** in the **Debug** menu) as needed to dismiss the **Disassembly** window.

### Preparing Your Program for Debugging

#### Using Breakpoints in the Debugger

#### Viewing Fortran Data Types in the Microsoft Debugger

This topic applies to Fortran applications for Windows* only.

The following general suggestions apply to different types of Fortran data:

- For scalar (nonarray) data, use the data tips (leave pointer on a variable name) feature or use the **Locals** window or a **Watch** window. Intel® Fortran does not support the **Autos** window.
- For single-dimension array data, derived-type data, record structure data, and COMPLEX data, use the **Locals** window or a **Watch** window.
- For common blocks exported from a DLL, enter the name of the common block in a **Watch** window. You will be able to view the common block variables like any other structure.

For information on using Data Tips, the **Locals** window, or a **Watch** window, see **Debugging the Squares Example Program**.

The following sections apply to using a **Watch** window:

- **Specifying Array Sections**
- **Specifying Module Variables**
- **Specifying Format Specifiers**

To display a **Watch** window:

1. In the **Debug** menu, select **Windows > Watch**.
2. In the submenu, click Watch 1, 2, 3, or 4.
Specifying Array Sections

You can specify array sections in a Watch window. For example, consider an array declared as:

```plaintext
integer foo(10)
```

You can specify the following statement in a Watch window to see the 2nd, 5th, and 8th elements:

```plaintext
foo(2:10:3)
```

When working with character arrays, this syntax may be combined with a substring specification. Consider the following array declaration:

```plaintext
character*8 chr_arr(10)
```

You can specify the following statement in a Watch window to display the substring made up of character 3 through 8 of array elements 2 through 5:

```plaintext
chr_arr(2:5)(3:8)
```

This support is available for arrays of any type, including array pointers, assumed-shape, allocatable, and assumed-size arrays.

Any valid integer expression can be used when specifying lower bound, upper bound, or stride. If the lower bound is omitted, the array lower bound is used. If the upper bound is omitted, the array upper bound is used. For example, consider the following declaration:

```plaintext
integer foo(10)
```

To display:

- Elements 1 through 8, specify `foo(:8)`
- Elements 5 through 10, specify `foo(5:)`
- All 10 elements, specify `foo(:)`

Specifying Module Variables

To view a module variable in a Watch window, specify the module name, followed by `::`, followed by the variable name.

For example, to watch variable "bar" of module "foo", specify the following expression:

```
foo::bar
```

Specifying Format Specifiers

You can use format specifiers in Watch windows to display variables in different data formats.

For example, given a REAL variable 'foo' in a program, it is now possible to see 'foo' in different floating point notation (by typing "foo,f" "foo,g" or "foo,e" in a Watch window) or as an integer ("foo,i" or "foo,d"), a hexadecimal value ("foo,x"), an an octal value ("foo,o"), and so on.

You can change the display format of variables in a Watch window using the formatting symbols in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Format</th>
<th>Value</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>d,i</td>
<td>signed decimal integer</td>
<td>0xF000F065</td>
<td>-268373915</td>
</tr>
<tr>
<td>o</td>
<td>unsigned</td>
<td>0xF065</td>
<td>0170145</td>
</tr>
<tr>
<td>x,X</td>
<td>Hexadec</td>
<td>61541</td>
<td>#0000F065</td>
</tr>
<tr>
<td>f</td>
<td>signed</td>
<td>3./2.</td>
<td>1.5000000</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Format</th>
<th>Value</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>d,i</td>
<td>signed decimal integer</td>
<td>0xF000F065</td>
<td>-268373915</td>
</tr>
<tr>
<td>o</td>
<td>unsigned</td>
<td>0xF065</td>
<td>0170145</td>
</tr>
<tr>
<td>x,X</td>
<td>Hexadec</td>
<td>61541</td>
<td>#0000F065</td>
</tr>
<tr>
<td>f</td>
<td>signed</td>
<td>3./2.</td>
<td>1.5000000</td>
</tr>
</tbody>
</table>
You can use the formatting symbols shown in the following table to format the contents of memory locations:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Format</th>
<th>Displays</th>
</tr>
</thead>
</table>
| ma     | 64 ASCII characters | 0x0012ffac .4...0...".0W&.......1W&.0:.W..1...."..
|        |        | 1.JO&.1.2.."..1...0y....1                   |
| m      | 16 bytes in hexadecimal, followed by 16 ASCII characters | 0x0012ffac B3 34 CB 00 84 30 94 80 FF 22 8A 30
|        |        | 57 26 00 00 .4...0..."."0W&.                  |
| mb     | 16 bytes in hexadecimal, followed by 16 ASCII characters | 0x0012ffac B3 34 CB 00 84 30 94 80 FF 22 8A 30
|        |        | 57 26 00 00 .4...0..."."0W&.                  |
| mw     | 8 words | 0x0012ffac 34B3 00CB 3084 8094 22FF 308A 2657
|        |        | 0000                                             |
| md     | 4 doublewords | 0x0012ffac 00CB34B3 80943084 308A22FF
|        |        | 00002657                                           |

With the memory location formatting symbols, you can type any value or expression that evaluates to a location.

A formatting character can also follow an expression:

```
rep+1,x
xloc,g
count,d
```

**NOTE**

You can apply formatting symbols to structures, arrays, pointers, and objects as unexpanded variables only. If you expand the variable, the specified formatting affects all members. You cannot apply formatting symbols to individual members.

**See Also**

Debugging the Squares Example Program

Viewing the Call Stack in the Microsoft Debugger

In most cases, your program will automatically stop at the point where the exception occurs, allowing you to view the source code and values of variables. If the error is related to an I/O statement, you may want to view the call stack.
If you want to view where your program is currently executing in the hierarchy of routines, you can display the Call Stack window in the debugger. For example, you may want to display this window to determine where in your program an exception occurs.

To view the call stack:

1. Start the debugger and stop at a breakpoint.
2. Select Debug > Windows > Call Stack.

A severe unhandled I/O programming error (such as an End-of-File condition) can occur while the program is executing in the debugger. When this occurs, the Fortran run-time system will raise a debug event automatically to stop program execution, allowing display of the Call Stack.

When the severe unhandled I/O error occurs in the debugger:

- An information box is displayed that contains:
  ```
  User breakpoint called from code at 0xnnnnnnn
  ```
- A window appears with your cursor in NTDLL disassembly code

Click OK to dismiss the information box.

Scanning down the Call Stack display, there will be a few frames from NTDLL and the Fortran run-time system displayed, then the actual Fortran routine with the I/O statement that caused the error. In the call stack, select the Fortran routine to display the Fortran code and the variables using the Locals window. The green arrow points to the I/O statement that caused the error.

This action all occurs after the error message and traceback information has been displayed. The error message and traceback information is available in the program output window. To view the program output window, either iconize (minimize) the integrated development environment (IDE) or click the icon for the output window in the task bar. You should not need the stack dump because you have the Call Stack window in the IDE, but the error message with the file name might be useful to see.

Locating Run-Time Errors
Using Traceback Information Overview

Locating Unaligned Data
Unaligned data can slow program execution. You should determine the cause of the unaligned data, fix the source code (if necessary), and recompile and relink the program.

If your program encounters unaligned data at run time, to make it easier to debug the program, you should recompile and relink with the `-g` (Linux* OS and OS X*) or `/debug:full` (Windows* OS) option to generate sufficient table information and debug unoptimized code.

Debugging a Program that Encounters a Signal or Exception
If your program encounters a signal (exception) at run time, you may want to recompile and relink with certain command-line options before debugging the cause. The following will make it easier to debug the program:

- Use the `fpe[:n]` option to control the handling of floating point exceptions.
- To generate sufficient symbol table information and debug unoptimized code, as with other debugging tasks, use the `-g` (Linux* OS and OS X*) or `/debug:full` (Windows* OS) compiler option.

Debugging an Exception in the Microsoft Debugger (Windows* OS)
You can request that the program always stop when a certain type of exception occurs. Because certain exceptions are caught by default by the Intel® Fortran run-time library, your program stops in the run-time library code. In most cases, you want the program to stop in your program's source code instead.

To change how an exception is handled in the Microsoft debugger:
1. In the **Debug** menu, select **Exceptions**.
2. View the displayed exceptions.
3. Select **Windows Exceptions**. Select each type of exception to be changed and change its handling using the radio buttons.
4. Start program execution using **Start** in the **Debug** menu.
5. When the exception occurs, you can now view the source line being executed, examine current variable values, execute the next instruction, and so on, to help you better understand that part of your program.
6. After you locate the error and correct the program, consider whether you want to reset the appropriate type of exception to "**Use Parent Setting**" before you debug the program again.

For machine exceptions, you can use the just-in-time debugging feature to debug your programs as they run outside of the visual development environment. To do this, set the following items:

- In **Tools > Options**, select **Native** in the **Debugging Just-In Time** category.
- Set the **FOR_IGNORE_EXCEPTIONS**, as listed in **Supported Environment Variables**, to **TRUE**.

**See Also**

**Supported Environment Variables**

### Debugging and Optimizations

This topic describes the relationship between various command-line options that control debugging and optimizing.

Whenever you enable debugging with the **-g** option (Linux* OS and OS X*) or **/debug:full** option (Windows* OS), you disable optimizations. You can override this behavior by explicitly specifying compiler options for optimizations on the command line.

The following summarizes commonly used options for debugging and for optimization.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-O0</code> (Linux* OS and OS X*)</td>
<td>Disables optimizations so you can debug your program before any optimization is attempted. This is the default behavior when debugging.</td>
</tr>
<tr>
<td><code>/Od</code> (Windows* OS)</td>
<td>Notes: On Linux* OS and OS X*, <code>-fno-omit-frame-pointer</code> is set if either option <code>-O0</code> or <code>-g</code> is specified.</td>
</tr>
<tr>
<td><strong>01, 02, or 03</strong> (Linux* OS and OS X*)</td>
<td>Specifies the code optimization level for applications. If you use any of these options, it is recommended that you use <strong>-debug extended</strong> when debugging.</td>
</tr>
<tr>
<td><code>/O</code> (Windows* OS)</td>
<td>For more information, see the following topics:</td>
</tr>
<tr>
<td><code>–g</code> (Linux* OS and OS X*)</td>
<td>Generates symbolic debugging information and line numbers in the object code for use by the source-level debuggers. Turns off <em><em>02 and makes -O0 (Linux</em> OS and OS X</em>)** or <code>/Od</code> (Windows* OS) the default. The exception to this is if options <strong>01, 02, or 03</strong> are explicitly specified in the command line.</td>
</tr>
</tbody>
</table>

For more information, see the following topics:

- `-O0` (Linux* OS and OS X*) compiler option
- `/Od` (Windows* OS) compiler option
- `–O1, –O2, –O3` (Linux* OS and OS X*) compiler options
- `/O` (Windows* OS) compiler option
- `–g` (Linux* OS and OS X*)
• /debug:full (Windows* OS) compiler option

-debug extended (Linux* OS and OS X*)

Specifies settings that enhance debugging.
For more information, see the following topic:
• -debug extended (Linux* OS and OS X*)

-fp (Linux* OS and OS X*)
Disables the ebp register in optimizations and sets the ebp register to be used as the frame pointer.
For more information, see the following compiler option topics:
• -fp (Linux* OS and OS X*)
• /Oy (Windows* OS)
(IA-32 architecture only)

Traceback
Causes the compiler to generate extra information in the object file, which allows a symbolic stack traceback.
For more information, see the following topic:
• Traceback compiler option

Combining Optimization and Debugging
The compiler lets you generate code to support symbolic debugging when 01, 02, or 03 optimization options are specified on the command line along with -g (Linux* OS and OS X*) or /debug:full (Windows* OS); this produces symbolic debug information in the object file.

NOTE
Note that if you specify an 01, 02, or 03 option with the -g (Linux* OS and OS X*) or /debug:full (Windows* OS) option, some of the debugging information returned may be inaccurate as a side-effect of optimization.
To counter this on Linux* OS and OS X*, you should also specify the -debug extended option.

It is best to make your optimization and/or debugging choices explicit:
• If you need to debug your program excluding any optimization effect, use the -O0 (Linux* OS and OS X*) or /Od (Windows* OS) option, which turns off all the optimizations.
• If you need to debug your program with optimizations enabled, then you can specify the 01, 02, or 03 option on the command line along with debug extended.

NOTE
When no optimization level is specified, the -g or /debug:full option slows program execution; this is because this option turns on -O0 or /Od, which causes the slowdown. However, if both 02 and -g (Linux* OS and OS X*) or /debug:full (Windows* OS) are specified, for example, the code should not experience much of a slowdown.

Refer to the table below for the summary of the effects of using the -g or /debug:full option with the optimization options.

<table>
<thead>
<tr>
<th>These options</th>
<th>Produce these results</th>
</tr>
</thead>
<tbody>
<tr>
<td>-g (Linux* OS and OS X*)</td>
<td>Debugging information produced, -O0 (Linux* OS and OS X*) or /Od (Windows* OS) enabled (meaning optimizations are disabled).</td>
</tr>
</tbody>
</table>
These options | Produce these results
---|---
-`g-01` (Linux* OS and OS X*) /debug:full /O1 (Windows* OS) | Debugging information produced, O1 optimizations enabled.
-`g-02` (Linux* OS and OS X*) /debug:full /O2 (Windows* OS) | Debugging information produced, O2 optimizations enabled.
-`g-02` (Linux* OS and OS X*) /debug:full /O2 /Oy- (Windows* OS) | Debugging information produced, O2 optimizations enabled. For Windows* OS using IA-32 architecture, /Oy disabled.
-`g` -fp (Linux* OS and OS X*) /debug:full /O3 (Windows* OS) | Debugging information produced, O3 optimizations enabled. For Linux* OS, -fp enabled for compilations targeted for IA32 architecture.

**NOTE**
Even the use of option `debug extended` with optimized programs may not allow you to examine all variables or to set breaks at all lines, due to code movement or removal during the optimization process.

### Debugging Mixed-Language Programs

The Visual Studio* debugger let you debug mixed-language programs. Program flow of control across subprograms written in different languages is transparent.

The debugger uses debug information associated with the program to automatically identify the language of the current subprogram or code segment.

For example, if program execution is suspended in a subprogram in Fortran, the current language is seen as Fortran. If the debugger stops the program in a C function, the current language becomes C.

### Debugging Multithreaded Programs

The debugging of multithreaded programs discussed in this topic applies to both the OpenMP* Fortran API and the Intel® Fortran parallel compiler directives. When a program uses parallel decomposition directives, you must take into consideration that the bug might be caused either by an incorrect program statement or it might be caused by an incorrect parallel decomposition directive. In either case, the program to be debugged can be executed by multiple threads simultaneously.

To determine the correctness of and debug multithreaded programs, you can use the following:

- Linux* and OS X* systems: `gdb`.
- Windows* operating systems: Microsoft Visual Studio* Debugger.
- Intel® Fortran Compiler debugging options and methods; in particular, `debug` and `traceback` options.

### Using Remote Debugging

#### Using Remote Debugging

The following applies to Microsoft Visual Studio* 2012 and 2010.
Remote debugging lets you use your local (host) system to debug an application running on a remote system.

**Remote Debugging using Visual Studio**

There are two remote connection types available: DCOM ("Remote with Windows authentication") and TCP/IP ("Remote with no authentication"). For more information on initial setup for remote debugging, refer to the Visual Studio* remote debugging setup topics in the Microsoft* MSDN documentation.

Remote debugging typically requires use of the debugging monitor (`msvsmon.exe`). Run the monitor in the correct mode for the remote system’s architecture. To do this, on the remote system, select the program group **Microsoft Visual Studio 2010** (or applicable version year), then choose **Visual Studio Tools** and select the correct **Remote Debugger Folder**.

Remote debugging also requires proper set up of the IDE Debugging property page on the host machine.

To set up remote debugging using the IDE property pages:

1. On the host machine, choose **Project > Properties > Configuration Properties > Debugging**. Your screen should resemble the following:

   ![Remote_2010_Property_Pages](image)

2. Specify the following:

   **Connection**: Use the drop-down box to select the type of connection.

   **Remote Server Name**: Use the drop-down box to select the name of the remote system.

   **Remote Command**: Type the command you want to issue on the remote machine. Typically, this is a pathname to an executable file (.exe) on the remote machine; for example: `d:\remote\myapp.exe`
3. Optionally, set **Attach** to "**Yes**" to attach to an application that is already running on the remote machine.

To start remote debugging:

1. **Make sure you have the necessary remote debugging permissions on the remote machine.** For example, you need Administrator privileges if you want to debug a process running on a remote machine under another account name.
2. Run the Remote Debugging Monitor on the remote machine.
3. Launch Visual Studio on the host machine and use it to attach to a program you want to debug on the remote machine, or launch a program you want to debug on the remote machine.

**Remote Debugging Scenario**

This topic applies to Fortran applications for Windows only.

The remote debugging scenario described here includes the cross-platform and cross-compilation remote debugging features. The following parameters apply:

| Host platform: | IA-32 |
| Remote platform: | Intel® 64 |
| Name of host machine: | HOST_MACHINE (domain name of host machine) |
| Name of remote machine: | REMOTE_SERVER (domain name of remote machine) |
| Host OS: | Windows* 7 |
| Remote OS: | Windows* Server 2008* Enterprise x64 Edition |
| Executable for debugging: | Win64 (x64) |
| Type of executable: | Console application |
| Visual Studio*: | Microsoft Visual Studio* 2010 |
| Connection types: | Remote with/without Windows authentication |
| Sessions: | Remote debugging, remote execution, attach to process on a remote machine |

1. **HOST_MACHINE**
   Start Visual Studio 2010 on the host machine (**HOST_MACHINE**).
2. Create a new console application; for this example, use remote_2010.
3. Add the following lines to the remote_2010.f90 file:
   ```fortran
   REAL, DIMENSION(1) :: xxx = 0
   PRINT *, 'Type one number: '  
   READ (*,'(F10.3)') xxx
   ```
4. Open **Project > Properties** and create a new platform configuration for x64 using the **Configuration Manager**.

5. Make sure, that current (target) configuration is **Debug|x64** and build the solution (**Build > Build Solution**). This invokes the cross-compiler and causes the 64-bit executable file `remote_2010.exe` to be built.

6. Run the `remote_2010.exe` application to make sure that it is 64-bit code. An error should result, explaining that it is not a valid Win32 application.

7. Run the Remote Desktop Connection program (`%SystemRoot%\System32\mstsc.exe`) and connect to the remote machine (**REMOTE_SERVER**).

8. Create `C:\remote_dir` on **REMOTE_SERVER** and copy `remote_2010.exe` from **HOST_MACHINE** to **REMOTE_SERVER**.

10. Set a breakpoint at line 27.
Open Project > Properties for remote debugging and set the following properties:

Connection: Remote with Windows authentication
Remote Machine: REMOTE_SERVER
Remote Command: C:\remote_dir\remote_2010.exe

Press F5 to start debugging.

If there is a firewall you will get an Unable to start debugging error message. In this case go to REMOTE_SERVER and run Remote Debugging Monitor (64-bit mode). Go back to LOCAL_SERVER and press F5 to start debugging.

Go to REMOTE_SERVER and make sure that the remote_2010 application is started.
Type 5 and press Enter. Go back to HOST_MACHINE.
Verify that the Debugger reaches the breakpoint at the line 27.
Open the Locals window and make sure that value xxx is 64-bit.
Press Shift+F5 to stop debugging and terminate the application on the remote server.
Open the project properties again and set Attach to Yes.
Press Ctrl+F5 (remote execution).
Press F5 for attaching to a process.
Repeat steps 12-17 to check that the attach to process works correctly.
Open Project > Properties and set Attach to No.
Open Project > Properties and set Connection to Remote with no authentication (Native only).
Go to REMOTE_SERVER and switch debugging monitor to No Authentication mode using the Tools > Options menu.
Repeat steps 12-22 to check that Remote with no authentication (Native only) mode works correctly.
Results of Remote Debugging Exercise

The results of this remote debugging exercise for Visual Studio* 2010 are summarized in the table below.

<table>
<thead>
<tr>
<th>Connection Type</th>
<th>Session</th>
<th>Result</th>
<th>Debugging Monitor status</th>

VI

Program Structure

Topics:

- Using Module (.mod) Files
- Using Include Files
- Advantages of Internal Procedures
- Implications for Array Copies
One way to reduce potential confusion when you use the same source code in several projects is to organize the routines into modules. A module (.mod file) is a type of program unit that contains specifications of such entities as data objects, parameters, structures, procedures, and operators. These precompiled specifications and definitions can be used by one or more program units. Partial or complete access to the module entities is provided by the program’s USE statement. Typical applications of modules are the specification of global data or the specification of a derived type and its associated operations.

Modules are excellent ways to organize programs. You can set up separate modules for:

- Commonly used routines.
- Data definitions specific to certain operating systems.
- System-dependent language extensions.

Some programs require modules located in multiple directories. You can use the -I compiler option when you compile the program to specify the location of the .mod files that should be included in the program.

You can use the modulepath compiler option to specify the directory in which to create the module files. If you do not use this option, module files are created in the current directory.

Directories are searched for .mod files in this order:

1. Directory of the source file that contains the USE statement.
2. Directories specified by the modulepath compiler option.
3. Current working directory.
4. Directories specified by the -Idir (Linux* and OS X*) or /include (Windows*) option.
5. Directories specified with the CPATH or INCLUDE environment variable.

You need to make sure that the module files are created before they are referenced by another program or subprogram.

**Compiling Programs with Modules**

If a file being compiled has one or more modules defined in it, the compiler generates one or more .mod files.

For example, a file a.f90 contains modules defined as follows:

```
module test
  integer:: a
  contains
  subroutine f()
  end subroutine
dend module test
module payroll
...  
dend module payroll
```

This compiler command:

```
ifort -c a.f90
```

generates the following files:
The .mod files contain the necessary information regarding the modules that have been defined in the program a.f90.

The following example uses the program mod_def.f90 which contains a module defined as follows:

```fortran
mod_def.f90 Module
file: mod_def.f90
module definedmod
...
end module
```

Compile the program as follows:

```fortran
ifort -c mod_def.f90
```

This produces the object files mod_def.o (Linux* and OS X*) or mod_def.obj (Windows*) and also the .mod file definedmod.mod, all in the current directory.

```fortran
Using .mod files from another directory
file: use_mod_def.f90
program usemod
use definedmod
...
end program
```

To compile the above program, use the -i compiler option to specify the path to search and locate the definedmod.mod file.
Include files are brought into a program with the `#include` preprocessor directive or a Fortran `INCLUDE` statement.

Directories are searched for include files in this order:

1. Directory of the source file that contains the include.
2. Current working directory.
3. Directories specified by the `I` option.
4. Directory specified by the `-isystem` option (Linux* and OS X* systems only).
5. Directories specified with the `CPATH` (Linux* and OS X*) or `INCLUDE` (Windows*) environment variable.

The locations of directories to be searched are known as the include file path. More than one directory can be specified in the include file path.

**Specifying and Removing an Include File Path**

You can use the `I` compiler option to indicate the location of include files (and also module files).

To prevent the compiler from searching the default path specified by the `CPATH` or the `INCLUDE` environment variable, use the `-X` or `/noinclude` option.

You can specify these options in the configuration file, `ifort.cfg`, or on the command line.

For example, to direct the compiler to search a specified path instead of the default path, use the following command line:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| // Linux* and OS X*  
  `ifort -I/alt/include` `newmain.f` |
| // Windows*  
  `ifort /noinclude` `/IC:/Project2/include` `newmain.f` |
Advantages of Internal Procedures

Functions or subroutines that are used in only one program can be organized as internal procedures, following the CONTAINS statement of a program or module.

Internal procedures have the advantage of host association, that is, variables declared and used in the main program are also available to any internal procedure it may contain. For more information on procedures and host association, see Program Units and Procedures Overview.

Internal procedures, like modules, provide a means of encapsulation. Where modules can be used to store routines commonly used by many programs, internal procedures separate functions and subroutines whose use is limited or temporary.
Implications for Array Copies

Fortran language semantics sometimes require the compiler to make a temporary copy of an array or array slice. Situations where this can occur include:

- Passing a non-contiguous array to a procedure that does not declare it as assumed-shape.
- Array expressions, especially those involving `RESHAPE`, `PACK`, and `MERGE`.
- Assignments of arrays where the array appears on both the left and right-hand sides of the assignment.
- Assignments of `POINTER` arrays.

By default, these temporary values are created on the stack and, if large, may result in a stack overflow error at runtime. The size of the stack can be increased, but with limitations dependent on the operating system. Use of the `heap-arrays` compiler option tells the compiler to use heap allocation, rather than the stack, for such temporary copies. Heap allocation adds a small amount of overhead when creating and removing the temporary values, but this is usually inconsequential in comparison to the rest of the code.

Performance can be further improved by eliminating the need for a temporary copy entirely. For the first case above, passing a non-contiguous array to a procedure expecting a contiguous array, enabling the `check: arg_temp_created` compiler option will produce a run-time informational message when the compiler determines that the argument being passed is not contiguous. A run-time test is made and if the argument is contiguous, no copy is made. However, this option will not issue a diagnostic for other uses of temporary copies.

One way to avoid temporary copies for array arguments is to change the called procedure to declare the array as assumed-shape, with the `DIMENSION(:)` attribute. Such procedures require an explicit interface to be visible to the caller. This is best provided by placing the called procedure in a module or a `CONTAINS` section. As an alternative, an `INTERFACE` block can be declared.

Use of `POINTER` arrays makes it difficult for the compiler to know if a temporary value can be avoided. Where possible, replace `POINTER` with `ALLOCATABLE`, especially as components of derived types. The language definition allows the compiler to assume that `ALLOCATABLE` arrays are contiguous and that they do not overlap other variables, unlike `POINTERs`.

Another situation where the temporary values can be created is for automatic arrays, where an array’s bounds are dependent on a routine argument, use or host associated variable, or `COMMON` variable, and the array is a local variable in the procedure. As above, these automatic arrays are created on the stack by default; the `heap-arrays` compiler option will create them on the heap. Consider making such arrays `ALLOCATABLE` instead; local `ALLOCATABLE` variables that do not have the `SAVE` attribute are automatically deallocated when the routine exits. For example, replace:

```fortran
SUBROUTINE SUB (N)
  INTEGER, INTENT(IN) :: N
  REAL :: A(N)
END SUBROUTINE
```

with:

```fortran
SUBROUTINE SUB (N)
  INTEGER, INTENT(IN) :: N
  REAL, ALLOCATABLE :: A(:)
  ALLOCATE (A(N))
END SUBROUTINE
```

OpenMP* Support Overview

The Intel® compiler supports most of OpenMP* Version 4.0. For the complete OpenMP specification, see the OpenMP* Application Program Interface Version 4.0 specification, which is available from the OpenMP* web site (http://www.openmp.org, see OpenMP Specifications). The descriptions of OpenMP* language characteristics in this documentation often use terms defined in the specification.

The OpenMP* API provides symmetric multiprocessing (SMP) with the following major features:

- Relieves you from implementing the low-level details of iteration space partitioning, data sharing, thread creation, scheduling, or synchronization.
- Provides the benefit of performance available from shared memory multiprocessor and multi-core processor systems on all supported Intel architectures, including those processors with Intel® Hyper-Threading Technology (Intel® HT Technology).
- Provides support for the Intel® Xeon Phi™ coprocessor.

The compiler performs transformations to generate multithreaded code based on your placement of OpenMP* directives in the source program, making it simple to add threading to existing software. The Intel compiler compiles parallel programs and supports the industry-standard OpenMP* directives.

The compiler provides Intel-specific extensions to the OpenMP* specification including run-time library routines and environment variables. A summary of the compiler options appear in the OpenMP* Options Quick Reference.

Parallel Processing with OpenMP*

To compile with the OpenMP* API, add the directives in the form of the Fortran program comments to your code. The compiler processes the code and internally produces a multithreaded version which is then compiled into an executable with the parallelism implemented by threads that execute parallel regions or constructs.

Using Other Compilers

The OpenMP* specification does not define interoperability of multiple implementations, so the OpenMP* implementation supported by other compilers and OpenMP* support in the Intel compiler might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP* source compatibility that enable you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

The Intel compiler includes two sets of OpenMP* libraries, as described in OpenMP* Source Compatibility and Interoperability with Other Compilers.

OpenMP* Source Compatibility and Interoperability with Other Compilers

The Intel® Fortran Compiler includes OpenMP* libraries that are object-level compatible with OpenMP* support provided by certain versions of the following compilers:

- Microsoft® Visual C++® compiler on Windows®
- Intel® Fortran Compiler version 10.x (and later)
The term "object-level interoperability" refers to the ability to link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, such that the resulting executable runs successfully. In contrast, "source compatibility" means that the entire application is compiled and linked by one compiler, and you do not need to modify the sources to get the resulting executable to run successfully.

Different compilers support different versions of the OpenMP specification. Based on the OpenMP features your application uses, determine what version of the OpenMP specification your application requires. If your application uses an OpenMP specification level equal or less than the OpenMP specification level supported by all the compilers, your application should have source compatibility with all compilers, but you need to link all object files and libraries with the same compiler's OpenMP libraries.

The Intel OpenMP run-time libraries provide source compatibility and object-level interoperability with the OpenMP support provided by:

- Certain versions of Microsoft Visual C++ libraries that support OpenMP, starting with Microsoft Visual C++ 2010.
- The Intel® Fortran Compiler versions 10.0 and later and their supplied OpenMP compatibility libraries.

For Fortran applications on Linux systems, it is not possible to link objects compiled by the Intel® Fortran Compiler (ifort) with objects compiled by the GNU* Fortran compiler (gfortran*). Thus, for mixed-language C++ and Fortran applications, you can do one of the following:

- Combine objects created by gfortran* and Intel® C++ objects.
- Combine objects created by the Intel® C++ Compiler and the Intel® Fortran Compiler.

**Guidelines for Using Different Intel® Compiler Versions**

To avoid possible linking or run-time problems, follow these guidelines:

- Object modules produced by current Intel compilers are not compatible with object modules compiled by the Intel® Fortran Compiler prior to version 10.0.
- Object modules produced by current versions of the Intel® Fortran Compiler are compatible with object modules produced by the compatibility libraries, for the Intel® Fortran Compiler versions 10.0 and later.
- Use dynamic instead of static OpenMP libraries to avoid linking multiple copies of the libraries into a single program.

**Guidelines for Using the Intel® Fortran Compiler with non-Intel Compilers**

To avoid possible linking or run-time problems, follow these guidelines:

- Always link using the Intel® Fortran Compiler OpenMP libraries. This avoids linking multiple copies of the OpenMP runtime libraries from different compilers. It is easiest if you use the Intel compiler command (driver) to link the application, but it is possible to link with the Intel® Fortran Compiler OpenMP libraries when linking the application using GCC or the Visual C++ compiler (or linker) commands.
- If possible, compile all the OpenMP sources with the same compiler. If you compile (not link) using multiple compilers such as the Microsoft* Visual C++* or GNU* compilers that provide object-level interoperability with the libraries, see the instructions in Using the OpenMP Libraries.
- Use dynamic instead of static OpenMP libraries to avoid linking multiple copies of the libraries into a single program.

**Limitations When Using OpenMP Libraries with Other Compilers**

Limitations of threadprivate objects on object-level interoperability:

- On Windows* systems, the Intel® Fortran Compiler by default (/Qopenmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than does the Microsoft* Visual C++* compiler. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® Fortran Compiler and the Visual C++* Compiler, the code compiled by the Intel® Fortran Compiler and the code compiled by the Visual C++* compiler reference different locations for the variable even when referenced by the same thread. Use the /Qopenmp-threadprivate:compat compiler option when compiling with the Intel® Fortran Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by Microsoft* Visual C++*.
- On Linux* systems, the Intel® Fortran Compiler by default (-openmp-threadprivate:legacy) use a different mechanism to reference threadprivate data than GCC*. If you declare a variable as threadprivate in your code and you compile the code with both the Intel® Fortran Compiler and GCC* compiler, the code compiled by the Intel® Fortran Compiler and the code compiled by the gcc reference
different locations for the variable even when referenced by the same thread. Use the –openmp-threadprivate:compat compiler option when compiling with the Intel® Fortran Compiler to enable the code that they compile to reference the same threadprivate locations as code compiled by GCC.

OpenMP* Options and Parallel Processing Options
OpenMP* Support Libraries
qopenmp-threadprivate, Qopenmp-threadprivate compiler option
Using the OpenMP* Libraries

Adding OpenMP* Support to your Application
To add OpenMP* support to your application, do the following:

1. Add the appropriate OpenMP* directives to your source code.
2. Compile the application with [Q]openmp option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at run-time. In addition, you may need to increase the stack allocated to individual threads by using the KMP_STACKSIZE environment variable or by setting the corresponding library routines.

You can set other environment variables to control multi-threaded code execution.

OpenMP Directive Syntax
To add OpenMP* support to your application, first add appropriate OpenMP* directives to your source code.

OpenMP* directives use a specific format and syntax. Intel Extension Routines to OpenMP* describes the OpenMP* extensions to the specification that have been added to the Intel® Fortran Compiler.

The following syntax illustrates using the directives in your source.

Example

```plaintext
<prefix> <directive> [<clause>[[,]<clause>...]]
```

where:

- `<prefix>` - Required for all OpenMP* directives. For free form source input, the prefix is !$OMP only; for fixed form source input, the prefix is !$OMP or C$OMP.
- `<directive>` - A valid OpenMP* directive. Must immediately follow the prefix; for example: !$OMP PARALLEL.
- `[<clause>]` - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
- `[<newline>]` - A required component of directive syntax. It precedes the structured block which is enclosed by this directive.
- `[,]`: Optional. Commas between more than one `<clause>` are optional.

The directives are interpreted as comments if you omit the [Q]openmp option.

The OpenMP* constructs defining a parallel region have one of the following syntax forms:

Example

```plaintext
!$OMP <directive>
   <structured block of code>
!$OMP END <directive>
```

# OR

```plaintext
!$OMP <directive>
```
The following example demonstrates one way of using an OpenMP* directive to parallelize a loop.

```fortran
Example

subroutine simple_omp(a, N)
  use omp_lib
  integer :: N, a(N)
  !$OMP PARALLEL DO
  do i = 1, N
    a(i) = i*2
  end do
end subroutine simple_omp
```

**Compile the Application**

The `[Q]openmp` option enables the parallelizer to generate multi-threaded code based on the OpenMP* directives in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

The `[Q]openmp` option works with both `-O0` (Linux* and OS X*) and `/Od` (Windows*) and with any optimization level of `O1`, `O2` and `O3`.

Specifying `-O0` (Linux* and OS X*) or `/Od` (Windows*) with the OpenMP* option helps to debug OpenMP* applications.

Compile your application using commands similar to those shown below:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -openmp source_file</td>
</tr>
<tr>
<td>OS X*</td>
<td>ifort -openmp source_file</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort /Qopenmp source_file</td>
</tr>
</tbody>
</table>

Assume that you compile the sample above, using commands similar to the following, where the `-c` option instructs the compiler to compile the code without generating an executable:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Extended Syntax Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -openmp -c parallel.f90</td>
</tr>
<tr>
<td>OS X*</td>
<td>ifort -openmp -c parallel.f90</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort /Qopenmp /c parallel.f90</td>
</tr>
</tbody>
</table>

The compiler might return a message similar to the following:

```fortran
Example

parallel.f90(20) : (col. 6) remark: OpenMP DEFINED LOOP WAS PARALLELIZED.
```

**Configure the OpenMP* Environment**
Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP* environment variable, OMP_NUM_THREADS.

Parallel Processing Model

A program containing OpenMP* API compiler directives begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

In the OpenMP* API, the PARALLEL and END PARALLEL directives define the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the master of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the master thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP* constructs. The comments in the code explain the structure of each construct or section.

```
Example

PROGRAM MAIN           ! Begin serial execution.
    ...                  ! Only the initial thread executes.
    !$OMP PARALLEL        ! Begin a Parallel construct, form a team.
        ...             ! This code is executed by each team member.
    !$OMP SECTIONS       ! Begin a worksharing construct.
        !$OMP SECTION    ! One unit of work.
            ...         !
        !$OMP SECTION    ! Another unit of work.
            ...         !
    !$OMP END SECTIONS  ! Wait until both units of work complete.
        ...             ! More Replicated Code.
    !$OMP DO             ! Begin a worksharing construct,
        DO              ! each iteration is a unit of work.
            ...         ! Work is distributed among the team.
        END DO           !
    !$OMP END DO NOWAIT  ! End of worksharing construct, NOWAIT
        ! is specified (threads need not wait).
        ! This code is executed by each team member.
    !$OMP CRITICAL       ! Begin critical construct.
        ...             ! One thread executes at a time.
    !$OMP END CRITICAL   ! End the critical construct.
        ...             ! This code is executed by each team member.
    !$OMP BARRIER        ! Wait for all team members to arrive.
        ...             ! This code is executed by each team member.
    !$OMP END PARALLEL    ! End of parallel onstruct, disband team.
```
Using Orphaned Directives

In routines called from within parallel constructs, you can also use directives. Directives that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned directives. Orphaned directives allow you to execute portions of your program in parallel with only minimal changes to the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:

```
Example
subroutine F
...
!$OMP PARALLEL...
call G
...
subroutine G
!$OMP DO... ! This is an orphaned directive.
...
```

This is an orphaned DO loop directive since the parallel region is not lexically present in subroutine G.

Data Environment Controls

You can control the data environment within parallel and worksharing constructs. Using directives and data environment clauses on directives, you can privatize named global-lifetime objects by using THREADPRIVATE directive, or control data scope attributes by using the data environment clauses for directives that support them.

The data scope attribute clauses are:
- DEFAULT
- PRIVATE
- FIRSTPRIVATE
- LASTPRIVATE
- REDUCTION
- SHARED

The data copying clauses are:
- COPYIN
- COPYPRIVATE

You can use several directive clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a directive, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP* API specification, for the variables affected by the directive.

Determining How Many Threads to Use

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/
video size and resolution, depth/breadth/bushiness of tree-based structures, and size of list based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer the number of threads to employ until application run-time when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex threads on the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has higher-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the 

```
NUM_THREADS
```

clause on parallel regions to control the number of threads employed and use the 

```
if
```

clause on parallel regions to decide whether to employ multiple threads at all. The 

```
OMP_SET_NUM_THREADS
```

routine can also be used, but it also affects parallel regions created by the calling thread. The 

```
NUM_THREADS
```

clause is local in its effect, so it does not impact other parallel regions. The disadvantages of explicitly setting a number of threads are:

1. In a system with a large number of processors, your application will use some but not all of the processors.
2. In a system with a small number of processors, your application may force over subscription that results in poor performance.

The Intel OpenMP runtime will create the same number of threads as the available number of logical processors unless you use 

```
OMP_SET_NUM_THREADS
```

routine. To determine the actual limits, use 

```
OMP_GET_THREAD_LIMIT() and OMP_GET_MAX_ACTIVE_LEVELS()
```

. Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The 

```
OMP_THREAD_LIMIT
```

environment variable limits the number of OpenMP* threads to use for the whole OpenMP* program. The 

```
OMP_MAX_ACTIVE_LEVELS
```

environment variable limits the number of active nested parallel regions.

### Binding Sets

The various binding sets describe which OpenMP constructs can be nested in which other OpenMP constructs and what effect that nesting has.

The binding region for an OpenMP construct is the enclosing region that determines the execution context and the scope of the effects of the directive:

- The binding region for an ORDERED construct is the innermost enclosing DO loop region.
- The binding region for a TASKWAIT construct is the innermost enclosing TASK region.
- For all other constructs for which the binding thread set is the current team or the binding task set is the current team tasks, the binding region is the innermost enclosing PARALLEL region.
- For constructs for which the binding task set is the generating task, the binding region is the region of the generating task.
- A PARALLEL construct need not be active nor explicit to be a binding region.
- A TASK construct need not be explicit to be a binding region.
- A region never binds to any region outside of the innermost enclosing parallel region.

The binding task set for an OpenMP construct is the set of tasks that are affected by, or provide the context for, the execution of a region. The binding task set for a given construct can be all tasks, the current team tasks, or the generating task.

The binding thread set for an OpenMP construct is the set of threads that are affected by, or provide the context for, the execution of a region. The binding thread set for a given construct can be all threads on a device, all threads in a contention group, the current team, or the encountering thread.
Controlling Thread Allocation

The `KMP_PLACE_THREADS` and `KMP_AFFINITY` environment variables allow you to control how the OpenMP* runtime uses the hardware threads on the processors. These environment variables allow you to try different thread distributions on the cores of the processors and determine how these threads are bound to the cores. You can use the environment variables to work out what is optimal for your application.

The `KMP_PLACE_THREADS` variable controls the allocation of hardware resources and the `KMP_AFFINITY` variable controls how the OpenMP* threads are bound to those resources.

Controlling Thread Distribution

The `KMP_PLACE_THREADS` variable controls the hardware resource that will be used by the program. This variable specifies the number of sockets to use, how many cores to use per socket and how many threads to assign per core. For example, on Intel® Xeon Phi™ coprocessors, while each coprocessor can take up to four threads, specifying fewer than four threads per core may result in a better performance. While specifying two threads per core often yields better performance than one thread per core, specifying three or four threads per core may or may not improve the performance. This variable enables you to conveniently measure the performance of up to four threads per core.

For example, you can determine the effects of assigning 24, 48, 72, or the maximum 96 OpenMP* threads in a system with 24 cores by specifying the following variable settings:

<table>
<thead>
<tr>
<th>To Assign This Number of Threads ...</th>
<th>... Use This Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td><code>KMP_PLACE_THREADS=24c,1t</code></td>
</tr>
<tr>
<td>48</td>
<td><code>KMP_PLACE_THREADS=24c,2t</code></td>
</tr>
<tr>
<td>72</td>
<td><code>KMP_PLACE_THREADS=24c,3t</code></td>
</tr>
<tr>
<td>96</td>
<td><code>KMP_PLACE_THREADS=24c,4t</code></td>
</tr>
</tbody>
</table>

**NOTE**

Take care when using the `OMP_NUM_THREADS` variable along with this variable. Using the `OMP_NUM_THREADS` variable can result in over or under subscription.

Controlling Thread Bindings

The `KMP_AFFINITY` variable controls how the OpenMP* threads are bound to the hardware resources allocated by the `KMP_PLACE_THREADS` variable. While this variable can be set to several binding or affinity types, the following are the recommended affinity types to use to run your OpenMP* threads on the processor:

- **compact**: sequentially distribute the threads among the cores that share the same cache.
- **scatter**: distribute the threads among the cores without regard to the cache.

The following table shows how the threads are bound to the cores when you want to use three threads per core on two cores by specifying `KMP_PLACE_THREADS=2c,3t`:

<table>
<thead>
<tr>
<th>Affinity</th>
<th>OpenMP* Threads on Core 0</th>
<th>OpenMP* Threads on Core 1</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>KMP_AFFINITY=compact</code></td>
<td>0, 1, 2</td>
<td>3, 4, 5</td>
</tr>
<tr>
<td><code>KMP_AFFINITY=scatter</code></td>
<td>0, 2, 4</td>
<td>1, 3, 5</td>
</tr>
</tbody>
</table>
**Determining the Best Setting**

To determine the best thread distribution and bindings using these variables, use the following:

1. Ensure that your OpenMP* code is working properly before using these environment variables.
2. Establish a baseline with your current OpenMP* code to compare to the performance when you allocate the threads to a processor.
3. Measure the performance of distributing one, two, three, or four threads per core by using the `KMP_PLACE_THREADS` variable.
4. Measure the performance of binding the threads to the cores by using the `KMP_AFFINITY` variable.

Supported Environment Variables

**OpenMP* Directives Summary**

This is a summary of the OpenMP* directives and clauses supported in the Intel® Fortran Compiler. For detailed information about the OpenMP* API, see the OpenMP Application Program Interface Versions 4.0 and 4.1 specifications, which are available from the OpenMP* web site.

In the directive lists below, an OpenMP directive is qualified with the word **Directive** when the name of the directive is also used for one or more elements besides the directive. For example: FLUSH refers to a directive, a statement, and a subroutine.

**PARALLEL Directive**

Use this directive to form a team of threads and execute those threads in parallel.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARALLEL Directive (OpenMP*)</td>
<td>Defines a parallel region.</td>
</tr>
</tbody>
</table>

**TASKING Directive**

Use this directive for deferring execution.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TASK</td>
<td>Defines a task region.</td>
</tr>
</tbody>
</table>

**WORKSHARING Directives**

Use these directives to share work among a team of threads.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO Directive</td>
<td>Identifies an iterative worksharing construct in which the iterations of the associated loop should be divided among threads in a team.</td>
</tr>
<tr>
<td>SECTIONS</td>
<td>Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>Specifies that a block of code is to be executed by only one thread in the team at a time.</td>
</tr>
</tbody>
</table>
Directive | Description
--- | ---
WORKSHARE | Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

**SYNCHRONIZATION Directives**
Use these directives to synchronize between threads.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC</td>
<td>Ensures that a specific memory location is updated atomically; this prevents the possibility of multiple, simultaneous reading and writing of threads.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.</td>
</tr>
<tr>
<td>CRITICAL Directive</td>
<td>Restricts access to a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>FLUSH Directive</td>
<td>Identifies synchronization points at which the threads in a team must provide a consistent view of memory.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.</td>
</tr>
<tr>
<td>TASKGROUP</td>
<td>Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.</td>
</tr>
<tr>
<td>TASKWAIT</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>TASKYIELD</td>
<td>Specifies that the current task can be suspended at this point in favor of execution of a different task.</td>
</tr>
</tbody>
</table>

**Data Environment Directive**
Use this directive to give threads global private data.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THREADPRIVATE</td>
<td>Specifies named common blocks to be private (local) to each thread; they are global within the thread.</td>
</tr>
</tbody>
</table>

**Coprocessor Control Directives**
Use these directives to control execution on one or more coprocessors.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECLARE TARGET</td>
<td>Causes the creation of a device-specific version of a named routine that can be called from a target region. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>Directive</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DISTRIBUTE</td>
<td>Specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a teams construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET Directive</td>
<td>Creates a device data environment and executes the construct on the same device. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET DATA</td>
<td>Creates a device data environment for the extent of the region. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET ENTER DATA</td>
<td>Specifies that variables are mapped to a device data environment. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET EXIT DATA</td>
<td>Specifies that variables are unmapped from a device data environment. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET UPDATE</td>
<td>Makes the list items in the device data environment consistent with their corresponding original list items. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TEAMS</td>
<td>Creates a league of thread teams inside a target region to execute a structured block in the master thread of each team. This directive only applies to Intel® MIC Architecture.</td>
</tr>
</tbody>
</table>

**Vectorization Directives**

Use these directives to control execution on vector hardware.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMD Directive (OpenMP*)</td>
<td>Requires and controls SIMD vectorization of loops.</td>
</tr>
<tr>
<td>DECLARE SIMD</td>
<td>Generates a SIMD procedure.</td>
</tr>
</tbody>
</table>

**Cancellation Constructs**

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CANCEL</td>
<td>Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering implicit or explicit task to proceed to the end of the cancelled construct.</td>
</tr>
<tr>
<td>CANCELLATION POINT</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.</td>
</tr>
</tbody>
</table>

**Combined Directives**

Use these directives as shortcuts for multiple directives in sequence.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISTRIBUTE PARALLEL DO</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>Directive</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO SIMD</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DISTRIBUTE SIMD</td>
<td>Specifies a loop that will be distributed across the master threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Provides an abbreviated way to specify a parallel region containing a single DO directive.</td>
</tr>
<tr>
<td>PARALLEL DO SIMD</td>
<td>Specifies a parallel region that contains a loop to execute with Single Instruction Multiple Data (SIMD) instructions.</td>
</tr>
<tr>
<td></td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.</td>
</tr>
<tr>
<td>PARALLEL SECTIONS</td>
<td>Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.</td>
</tr>
<tr>
<td>PARALLEL WORKSHARE</td>
<td>Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.</td>
</tr>
<tr>
<td>TARGET TEAMS</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the master thread in each team executing the structured block. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>Directive</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE SIMD</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions. This directive only applies to Intel® MIC Architecture.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a league of thread teams to execute a structured block in the master thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the master threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE SIMD</td>
<td>Creates a league of thread teams to execute the structured block in the master thread of each team. It also specifies a loop that will be distributed across the master threads of the teams.</td>
</tr>
</tbody>
</table>

OpenMP* Library Support

OpenMP* Run-time Library Routines
OpenMP* provides run-time library routines to help you manage your program in parallel mode. Many of these run-time library routines have corresponding environment variables that can be set as defaults. The run-time library routines let you dynamically change these factors to assist in controlling your program. In all cases, a call to a run-time library routine overrides any corresponding environment variable. These routines are all external procedures.

CAUTION
Running OpenMP runtime library routines may initialize the OpenMP runtime environment, which might cause a situation where subsequent programmatic setting of OpenMP environment variables has no effect. To avoid this situation, you can use the Intel extension routine kmp_set_defaults() to set OpenMP environment variables.

The compiler supports all the OpenMP* run-time library routines. Refer to the OpenMP* API Version 4.0 specification for detailed information about using these routines.

Include the appropriate declarations of the routines by adding a statement similar to the following in the program unit containing the routine:

Example
The module files are provided in the ..\include (Linux* and OS X*) or ..\include (Windows*) directory of your compiler installation.

The following tables specify the interfaces to these routines. (The names for the routines are in user name space.)

---

## Execution Environment Routines

Use these routines to monitor and influence threads and the parallel environment.

<table>
<thead>
<tr>
<th>Routine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL FUNCTION OMP_IN_FINAL()</td>
<td>Returns .TRUE. if called within a final task region; otherwise returns .FALSE..</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_NUM_THREADS(num_threads)</td>
<td></td>
</tr>
<tr>
<td>INTEGER num_threads</td>
<td>Sets the number of threads to use for subsequent parallel regions created by the calling thread.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_NUM_THREADS()</td>
<td>Returns the number of threads that are being used in the current parallel region. This function does not necessarily return the value inherited by the calling thread from the OMP_SET_NUM_THREADS() function.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_MAX_THREADS()</td>
<td>Returns the number of threads available to subsequent parallel regions created by the calling thread.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_THREAD_NUM()</td>
<td>Returns the thread number of the calling thread, within the context of the current parallel region.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_NUM_PROCS()</td>
<td>Returns the number of processors available to the program.</td>
</tr>
<tr>
<td>LOGICAL FUNCTION OMP_IN_PARALLEL()</td>
<td>Returns .TRUE. if called within the dynamic extent of a parallel region executing in parallel; otherwise returns .FALSE..</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_DYNAMIC(dynamic_threads)</td>
<td></td>
</tr>
<tr>
<td>LOGICAL dynamic_threads</td>
<td>Enables or disables dynamic adjustment of the number of threads used to execute a parallel region. If dynamic_threads is .TRUE., dynamic threads are enabled. If dynamic_threads is .FALSE., dynamic threads are disabled. Dynamic threads are disabled by default.</td>
</tr>
<tr>
<td>LOGICAL FUNCTION OMP_GET_DYNAMIC()</td>
<td>Returns .TRUE. if dynamic thread adjustment is enabled, otherwise returns .FALSE..</td>
</tr>
<tr>
<td>Routine</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_NESTED(nested) LOGICAL nested</td>
<td>Enables or disables nested parallelism. If <em>nested</em> is <code>.TRUE.</code>, nested parallelism is enabled. If <em>nested</em> is <code>.FALSE.</code>, nested parallelism is disabled. Nested parallelism is disabled by default.</td>
</tr>
<tr>
<td>LOGICAL FUNCTION OMP_GET_NESTED()</td>
<td>Returns <code>.TRUE.</code> if nested parallelism is enabled, otherwise returns <code>.FALSE.</code>.</td>

</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_DEFAULT_DEVICE()</td>
<td>Returns the default device number.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_NUM_DEVICES()</td>
<td>Gets the number of target devices.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_NUM_TEAMS()</td>
<td>Gets the number of teams in the current teams region.</td>
</tr>
<tr>
<td>INTEGER FUNCTION OMP_GET_TEAM_NUM()</td>
<td>Gets the team number of the calling thread.</td>
</tr>
<tr>
<td>SUBROUTINE OMP_SET_DEFAULT_DEVICE(device_number)</td>
<td>Sets the default device number.</td>
</tr>
</tbody>
</table>
**Routine** | **Description**
---|---
INTEGER device_number | Returns .TRUE. if cancellation is enabled; otherwise, .FALSE..

LOGICAL FUNCTION OMP_GET_CANCELLATION() | This routine can be affected by the setting for environment variable OMP_CANCELLATION.

INTEGER(KIND=OMP_PROC BIND) OMP_GET_PROC BIND() | Returns the currently active thread affinity policy, which is set by environment variable OMP_PROC BIND.

LOGICAL FUNCTION OMP_IS_INITIAL_DEVICE() | Returns .TRUE. if the current task is running on the host device; otherwise, .FALSE..

**Lock Routines**

Use these routines to affect OpenMP* locks.

**Function** | **Description**
---|---
SUBROUTINE OMP_INIT_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock | Initializes the lock associated with lock for use in subsequent calls.

SUBROUTINE OMP_DESTROY_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock | Causes the lock specified by lock to become undefined or uninitialized. The lock must be initialized and not locked.

SUBROUTINE OMP_SET_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock | Forces the executing thread to wait until the lock associated with lock is available. The thread is granted ownership of the lock when it becomes available. The lock must be initialized.

SUBROUTINE OMP_UNSET_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock | Releases the executing thread from ownership of the lock associated with lock. The behavior is undefined if the executing thread does not own the lock associated with lock.

LOGICAL OMP_TEST_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock | Attempts to set the lock associated with lock. If successful, returns .TRUE., otherwise returns .FALSE.. The lock must be initialized.

SUBROUTINE OMP_INIT_NEST LOCK(lock) INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock | Initializes the nested lock associated with lock for use in the subsequent calls.

SUBROUTINE OMP_DESTROY_NEST_LOCK(lock) INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock | Causes the nested lock associated with lock to become undefined or uninitialized. The lock must be initialized and not locked.
### Function Description

**Intel® Compiler Extension Routines to OpenMP**

The Intel compiler implements the following group of routines as extensions to the OpenMP run-time library:

- Get and set the execution environment
- Get and set the stack size for parallel threads
- Memory allocation
- Get and set the thread sleep time for the throughput execution mode

The Intel extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in the other compiler. To execute these OpenMP routines, use the `[Q]openmp-stubs` option.

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the `OMP_STACKSIZE` environment variable rather than the `KMP_SET_STACKSIZE_S()` library routine.

**NOTE**

A run-time call to an Intel extension routine takes precedence over the corresponding environment variable setting.
## Execution Environment

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBROUTINE KMP_SET_DEFAULTS(STRING) CHARACTER*(*) STRING</td>
<td>Sets OpenMP* environment variables defined as a list of variables separated by &quot;</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_THROUGHPUT()</td>
<td>Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_TURNAROUND()</td>
<td>Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_LIBRARY_SERIAL()</td>
<td>Sets execution mode to serial.</td>
</tr>
</tbody>
</table>
| SUBROUTINE KMP_SET_LIBRARY(LIBNUM) INTEGER (KIND=OMP_INTEGER_KIND) LIBNUM | Sets execution mode indicated by the value passed to the function. Valid values are:  
- 1 - serial mode  
- 2 - turnaround mode  
- 3 - throughput mode  
Call this routine before the first parallel region is executed. |
| FUNCTION KMP_GET_LIBRARY() INTEGER (KIND=OMP_INTEGER_KIND) KMP_GET_LIBRARY | Returns a value corresponding to the current execution mode:  
- 1 - serial  
- 2 - turnaround  
- 3 - throughput |

## Stack Size

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION KMP_GET_STACKSIZE_S() INTEGER(KIND=KMP_SIZE_T_KIND) &amp; KMP_GET_STACKSIZE_S</td>
<td>Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with KMP_SET_STACKSIZE_S() routine, prior to the first parallel region or via the KMP_STACKSIZE environment variable.</td>
</tr>
<tr>
<td>FUNCTION KMP_GET_STACKSIZE() INTEGER KMP_GET_STACKSIZE</td>
<td>Provided for backwards compatibility only. Use KMP_GET_STACKSIZE_S() routine for compatibility across different families of Intel processors.</td>
</tr>
<tr>
<td>SUBROUTINE KMP_SET_STACKSIZE_S(size) INTEGER (KIND=KMP_SIZE_T_KIND)size</td>
<td>Sets to size the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can also be set via the KMP_STACKSIZE environment variable. In order for KMP_SET_STACKSIZE_S() to have an effect, it must be called before the beginning of the first (dynamically executed) parallel region in the program.</td>
</tr>
</tbody>
</table>
SUBROUTINE KMP_SET_STACKSIZE_S(size)
    INTEGER size

Provided for backward compatibility only. Use KMP_SET_STACKSIZE_S(size) for compatibility across different families of Intel® processors.

Memory Allocation

The Intel compiler implements a group of memory allocation routines as an extension to the OpenMP* runtime library to enable threads to allocate memory from a heap local to each thread. These routines are: KMP_MALLOC(), KMP_CALLOC(), and KMP_REALLOC().

The memory allocated by these routines must also be freed by the KMP_FREE() routine. While you can allocate memory in one thread and then free that memory in a different thread, this mode of operation incurs a slight performance penalty.

Working with the local heap might lead to improved application performance because synchronization is not required.

SUBROUTINE KMP_FREE(ptr)
    INTEGER (KIND=KMP_POINTER_KIND) ptr

Free memory block at address ptr from thread-local heap.

Memory must have been previously allocated with KMP_MALLOC(), KMP_CALLOC(), or KMP_REALLOC().

Thread Sleep Time

In the throughput OpenMP* Support Libraries, threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the KMP_BLOCKTIME environment variable or by the KMP_SET_BLOCKTIME() function.

FUNCTION KMP_GET_BLOCKTIME()
    INTEGER KMP_GET_BLOCKTIME

Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the KMP_BLOCKTIME environment variable or by KMP_SET_BLOCKTIME().
FUNCTION KMP_SET_BLOCKTIME(msec)
INTEGER msec

Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP* team threads formed by the calling thread. The routine does not affect the block time for any other threads.

OpenMP* Support Libraries

OpenMP* Support Libraries
The Intel® Compiler provides support libraries for OpenMP*. There are several kinds of libraries:

- **Performance**: supports parallel OpenMP* execution.
- **Stubs**: supports serial execution of OpenMP* applications.

Each kind of library is available for both dynamic and static linking on Linux* and OS X* operating systems. Only dynamic linking is supported on Windows* operating systems.

Performance Libraries
To use these libraries, specify the [Q]openmp compiler option.

Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Dynamic Link</th>
<th>Static Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>libiomp5.so</td>
<td>libiomp5.a</td>
</tr>
<tr>
<td>OS X*</td>
<td>libiomp5.dylib</td>
<td>libiomp5.a</td>
</tr>
<tr>
<td>Windows*</td>
<td>libiomp5md.lib</td>
<td>libiomp5md.dll</td>
</tr>
</tbody>
</table>

Many routines in the OpenMP* support libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Stubs Libraries
To use these libraries, specify -[Q]openmp-stubs compiler option. These allow you to compile OpenMP* applications in serial mode and provide stubs for OpenMP* routines and extended Intel-specific routines.

</tbody>
</table>

### Execution modes

The Intel® Compiler enables you to run an application under different execution modes specified at run time; the libraries support the turnaround, throughput, and serial modes. Use the `KMP_LIBRARY` environment variable to select the modes at run time.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| **throughput** (default) | The throughput mode allows the program to yield to other running programs and adjust resource usage to produce efficient execution in a dynamic environment.  

In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work.  

After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications.  

The amount of time to wait before sleeping is set either by the `KMP_BLOCKTIME` environment variable or by the `KMP_SET_BLOCKTIME()` function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP* execution, but may penalize other concurrently-running OpenMP* or threaded applications.  

The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads (although they are still subject to `KMP_BLOCKTIME` control). In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time.  

**NOTE**  
Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at run time. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.  

| serial | The serial mode forces parallel applications to run as a single thread. |

qopenmp, Qopenmp compiler option
Using the OpenMP* Libraries

This section describes the steps needed to set up and use the OpenMP* Libraries from the command line. On Windows* systems, you can also build applications compiled with the OpenMP libraries in the Microsoft Visual Studio* development environment.

For a summary of the support provided by the libraries provided with Intel compilers, see OpenMP* Source Compatibility and Interoperability with Other Compilers.

For a list of the options and libraries used by the OpenMP* libraries, see OpenMP* Support Libraries.

Set up your environment for access to the Intel® Fortran Compiler to ensure that the appropriate OpenMP* library is available during linking. On Windows* systems, you can either execute the appropriate batch (.bat) file or use the command-line window supplied in the compiler program folder that already has the environment set up. On Linux* and OS X* systems, you can source the appropriate script file (ifortvars file).

To use the gfortran compiler with the Intel OpenMP library along with the OpenMP* API functions, do the following:

1. Use the use omp_lib statement to compile the omp_lib.f90 source file, which is in the Intel® Fortran Compiler include directory.
2. Add the -I option to the compile command line with appropriate path to the directory containing the resulting module file.

During compilation, ensure that the version of omp_lib.h or omp_lib.mod used when compiling is the version provided by that compiler.

**CAUTION**
Be aware that when using the gcc* or Microsoft* compiler, you may inadvertently use inappropriate header/module files. To avoid this, copy the header/module file(s) to a separate directory and put it in the appropriate include path using the -I option.

If a program uses data structures or classes that contain members with data types defined in omp_lib.h file, then source files that use those data structures should all be compiled with the same omp_lib.h file.

The command for the Intel® Fortran Compiler is ifort.

For information on the OpenMP* libraries and options used by the Intel® Fortran Compiler, see OpenMP* Support Libraries.

**Command-Line Examples, Windows***

To compile and link (build) the entire application with one command using the Compatibility libraries, specify the following Intel® Fortran Compiler command:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source, dynamic link</td>
<td>ifort /MD /Qopenmp hello.f90</td>
</tr>
</tbody>
</table>

When using the Microsoft* Visual C++* compiler, you should link with the Intel OpenMP compatibility library. You need to avoid linking the Microsoft* OpenMP run-time library (vcomp) and explicitly pass the name of the Intel OpenMP compatibility library as linker options (following /link):

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source, dynamic link</td>
<td>cl /MD /openmp hello.c /link /nodefaultlib:vcomp libiomp5md.lib</td>
</tr>
</tbody>
</table>
You can also use the Intel® Fortran Compiler with the Visual C++* compiler to compile parts of the application and create object files (object-level interoperability). In this example, the Intel® Fortran Compiler compiles and links the entire application:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources,</td>
<td>cl /MD /openmp /c f1.c f2.c</td>
</tr>
<tr>
<td>dynamic link</td>
<td>ifort /MD /Qopenmp /c f3.f f4.f</td>
</tr>
<tr>
<td></td>
<td>ifort /MD /Qopenmp f1.obj f2.obj f3.obj f4.obj /Feapp /</td>
</tr>
<tr>
<td></td>
<td>link /nodefaultlib:vcomp</td>
</tr>
</tbody>
</table>

The first command produces two object files compiled by Visual C++* compiler, and the second command produces two more object files compiled by the Intel® Fortran Compiler. The final command links all four object files into an application.

Alternatively, the third line below uses the Visual C++* linker to link the application and specifies the Compatibility library libomp5md.lib at the end of the third command:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources,</td>
<td>cl /MD /openmp /c f1.c f2.c</td>
</tr>
<tr>
<td>dynamic link</td>
<td>ifort /MD /Qopenmp /c f3.f f4.f</td>
</tr>
<tr>
<td></td>
<td>link f1.obj f2.obj f3.obj f4.obj /out:app.exe /</td>
</tr>
<tr>
<td></td>
<td>nodefaultlib:vcomp libomp5md.lib</td>
</tr>
</tbody>
</table>

The following example shows the use of interprocedural optimization by the Intel® Fortran Compiler on several files, the Visual C++* compiler compiles several files, and the Visual C++* linker links the object files to create the executable:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources,</td>
<td>ifort /MD /Qopenmp /O3 /Qipo /Qipo-c f1.f f2.f f3.f</td>
</tr>
<tr>
<td>dynamic link</td>
<td>cl /MD /openmp /O2 /c f4.c f5.c</td>
</tr>
<tr>
<td></td>
<td>cl /MD /openmp /O2 ipo_out.obj f4.obj f5.obj /Feapp /link /</td>
</tr>
<tr>
<td></td>
<td>nodefaultlib:vcomp libomp5md.lib</td>
</tr>
</tbody>
</table>

The first command uses the Intel® Fortran Compiler to produce an optimized multi-file object file named ipo_out.obj by default (the /Fe option is not required). The second command uses the Visual C++* compiler to produce two more object files. The third command uses the Visual C++* cl command to link all three object files using the Intel® Fortran Compiler OpenMP library.

**Command-Line Examples, Linux***

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® Fortran Compiler command on Linux* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source</td>
<td>ifort -openmp hello.f90</td>
</tr>
</tbody>
</table>

By default, the Intel® Fortran Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option -openmp-link static. The Intel® Fortran Compiler option -openmp-link controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and OS X* systems (default is -openmp-link dynamic).

You can also use the Intel® C++ Compiler icc/icpc with gcc/g++ compilers to compile parts of the application and create object files (object-level interoperability).
In this example, `gcc` compiles the C file `foo.c` (the `gcc` option `-fopenmp` enables OpenMP* support), and the Intel® Fortran Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c</code></td>
</tr>
<tr>
<td>C++ source</td>
<td><code>g++ -fopenmp -c foo.cpp</code></td>
</tr>
</tbody>
</table>

When using `gcc` or `g++` compiler to link the application with the Intel® Fortran Compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP library name using the `-l` option, the Linux* `pthread` library using the `-l` option, and path to the Intel® libraries where the Intel® C++ compiler is installed using the `-L` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c bar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>gcc foo.o bar.o -liomp5 -lpthread -L&lt;icc_dir&gt;/lib</code></td>
</tr>
</tbody>
</table>

You can mix object files, but it is easier to use the Intel® Fortran Compiler to link the application so you do not need to specify the `gcc`-`l` option, `-L` option, and the `-lpthread` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td><code>gcc -fopenmp -c foo.c</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -openmp -c bar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>icc -openmp foo.o bar.o</code></td>
</tr>
</tbody>
</table>

You can mix OpenMP* object files compiled with `gcc`, the Intel® C++ Compiler, and the Intel® Fortran Compiler.

**NOTE**
You cannot mix object files compiled by the Intel® Fortran compiler and the `gfortran` compiler.

The table illustrates examples of using the Intel® Fortran compiler or the GNU Fortran compiler to link all the objects:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td><code>icc -openmp -c ibar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>gcc -fopenmp -c gbar.c</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -openmp -c foo.f</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -openmp foo.o ibar.o gbar.o</code></td>
</tr>
</tbody>
</table>

When using the Intel® Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel® Fortran Compiler `ifort`, specify the `-nofor-main` option on the `ifort` command line during linking.

**NOTE**
Do not mix objects created by the Intel® Fortran Compiler (`ifort`) with the GNU Fortran Compiler (`gfortran`); instead, recompile all Fortran sources with the same Fortran compiler. The GNU Fortran Compiler is only available on Linux operating systems.
Similarly, you can mix object files compiled with the Intel® C++ Compiler, the GNU C/C++ compiler, and the GNU Fortran Compiler (gfortran), if you link the GNU Fortran Compiler (gfortran). When using GNU gfortran compiler to link the application with the Intel® Fortran Compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP compatibility library name and the Intel icrc libraries using the -l options, the Linux* pthread library using the -l option, and path to the Intel® libraries where the Intel® C++ Compiler is installed using the -L option. You do not need to specify the -fopenmp option on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and GNU Fortran sources</td>
<td>icc -openmp -c ibar.c</td>
</tr>
<tr>
<td></td>
<td>gcc -fopenmp -c gbar.c</td>
</tr>
<tr>
<td></td>
<td>gfortran -fopenmp -c foo.f</td>
</tr>
<tr>
<td></td>
<td>gfortran foo.o ibar.o gbar.o -lirc -liomp5 -lpthread -lc -L&lt;icc_dir&gt;/lib</td>
</tr>
</tbody>
</table>

Alternatively, you could use the Intel® Fortran Compiler to link the application, but need to pass multiple gfortran libraries using the -l options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td>gfortran -fopenmp -c foo.f</td>
</tr>
<tr>
<td></td>
<td>icc -openmp -c ibar.c</td>
</tr>
<tr>
<td></td>
<td>icc -openmp foo.o bar.o -lgfortranbegin -lgfortran</td>
</tr>
</tbody>
</table>

**Command-Line Examples, OS X***

To compile and link (build) the entire application with one command using the Intel OpenMP libraries, specify the following Intel® Fortran Compiler command on OS X* platforms:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran source</td>
<td>ifort -openmp hello.f90</td>
</tr>
</tbody>
</table>

By default, the Intel® Fortran Compiler performs a dynamic link of the OpenMP* libraries. To perform a static link (not recommended), add the option -openmp-link static. The Intel® Fortran Compiler option -openmp-link controls whether the linker uses static or dynamic OpenMP* libraries on Linux* and OS X* systems (default is -openmp-link dynamic).

You can also use the Intel® C++ Compiler icc/icpc/icl with gcc/g++ compilers to compile parts of the application and create object files (object-level interoperability).

**NOTE**

Mixed compiling using Intel® C++ Compiler with GCC compilers is possible only on older OS X* platforms. The latest OS X* v10.x platforms do not include the GCC compiler, and the Clang compiler included in the latest OS X* 10.x does not support OpenMP* implementation. Future versions of Clang compiler may support OpenMP* implementation.

In this example, or compiles the C file foo.c (the option -openmp enables OpenMP* support), and the Intel® Fortran Compiler links the application using the Intel OpenMP library:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td></td>
</tr>
</tbody>
</table>
You can mix object files, but it is easier to use the Intel® Fortran Compiler to link the application so you do not need to specify the `gcc-l` option, `-L` option, and the `-lpthread` option:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ source</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

GCC is absent on OS X® v10.9 and later (that is, Xcode 5.x and later). However, you may install GCC along with the Intel® C++ Compiler.

When using the Intel® Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel® Fortran Compiler `ifort`, specify the `-nofor-main` option on the `ifort` command line during linking.

Alternatively, you could use the Intel® Fortran Compiler to link the application, but need to pass multiple `gfortran` libraries using the `-l` options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>C source</td>
<td></td>
</tr>
</tbody>
</table>

When using the Intel® Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel® Fortran Compiler `ifort`, specify the `-nofor-main` option on the `ifort` command line during linking.

Alternatively, you could use the Intel® Fortran Compiler to link the application, but need to pass multiple `gfortran` libraries using the `-l` options on the link line:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mixed C and Fortran sources</td>
<td></td>
</tr>
</tbody>
</table>

**Thread Affinity Interface (Linux® and Windows®)**

The Intel® runtime library has the ability to bind OpenMP® threads to physical processing units. The interface is controlled using the `KMP_AFFINITY` environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

Thread affinity restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows® systems and versions of Linux® systems that have kernel support for thread affinity, but is not supported by OS X®.

The Intel OpenMP runtime library has the ability to bind OpenMP® threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP® threads to the processors based upon their physical location in the machine. This interface is controlled entirely by the `KMP_AFFINITY` environment variable.
- The mid-level affinity interface uses an environment variable to explicitly specifies which processors (labeled with integer IDs) are bound to OpenMP® threads. This interface provides compatibility with the `gcc*` `GOMP_AFFINITY` environment variable, but you can also invoke it by using the `KMP_AFFINITY` environment variable. The `GOMP_AFFINITY` environment variable is supported on Linux® systems only, but users on Windows® or Linux® systems can use the similar functionality provided by the `KMP_AFFINITY` environment variable.
The low-level affinity interface uses APIs to enable OpenMP* threads to make calls into the OpenMP* runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to `sched_setaffinity` and related functions on Linux* systems or to `SetThreadAffinityMask` and related functions on Windows* systems. In addition, you can specify certain options of the `KMP_AFFINITY` environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type `KMP_AFFINITY` to disabled, which disables the low-level affinity interface, or you could use the `KMP_AFFINITY` or `GOMP_AFFINITY` environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section:

- The total number of processing elements on the machine is referred to as the number of OS thread contexts.
- Each processing element is referred to as an Operating System processor, or OS proc.
- Each OS processor has a unique integer identifier associated with it, called an OS proc ID.
- The term package refers to a single or multi-core processor chip.
- The term OpenMP* Global Thread ID (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then \( n \)-threads-var - 1 new threads are created with GTIDs ranging from 1 to \( n \text{threads}-\text{var} - 1 \), and each thread’s GTID is equal to the OpenMP* thread number returned by function `omp_get_thread_num()`. The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID, and can be used by programs containing arbitrarily many levels of parallelism.

Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

### The KMP_AFFINITY Environment Variable

**NOTE**

You must set the `KMP_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

The `KMP_AFFINITY` environment variable uses the following general syntax:

```
KMP_AFFINITY=[<modifier>,...]<type>[,<permute>][,<offset>]
```

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a modifier of `verbose` and a type of `none`.

The following table describes the supported specific arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>modifier</td>
<td>noverbose</td>
<td>Optional. String consisting of keyword and specifier.</td>
</tr>
<tr>
<td></td>
<td>respect</td>
<td></td>
</tr>
<tr>
<td></td>
<td>granularity=core</td>
<td>takes the following specifiers:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>fine, thread, and core</td>
</tr>
<tr>
<td></td>
<td>norespect</td>
<td></td>
</tr>
<tr>
<td></td>
<td>noverbose</td>
<td></td>
</tr>
<tr>
<td></td>
<td>nowarnings</td>
<td></td>
</tr>
<tr>
<td></td>
<td>proclist={&lt;proc-list&gt;}</td>
<td></td>
</tr>
</tbody>
</table>
### Argument and Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• respect</td>
<td>• verbose</td>
<td>• warnings</td>
</tr>
</tbody>
</table>
| type | none | The syntax for `<proc-list>` is explained in **mid-level affinity interface**.
| Required string. Indicates the thread affinity to use. |
| • balanced | • compact | • disabled |
| • explicit | • none | • scatter |
| • logical (deprecated; instead use compact, but omit any permute value) | • physical (deprecated; instead use scatter, possibly with an offset value) |
| The **logical and physical** types are deprecated but supported for backward compatibility. |
| permute | 0 | Optional. Positive integer value. Not valid with type values of explicit, none, or disabled. |
| offset | 0 | Optional. Positive integer value. Not valid with type values of explicit, none, or disabled. |

### Affinity Types

Type is the only required argument.

**type = none (default)**

Does not bind OpenMP* threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP* thread affinity interface to determine machine topology. Specify `KMP_AFFINITY=verbose,none` to list a machine topology map.

**type = balanced**

Places threads on separate cores until all cores have at least one thread, similar to the scatter type. However, when the runtime must use multiple hardware thread contexts on the same core, the balanced type ensures that the OpenMP* thread numbers are close to each other, which scatter does not do. This affinity type is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.
NOTE
The OpenMP* environment variable `OMP_PROC_BIND=spread` is similar to `KMP_AFFINITY=balanced` and is available on all platforms, including multi-socket CPU systems.

**type = compact**

Specifying `compact` assigns the OpenMP* thread \( n+1 \) to a free thread context as close as possible to the thread context where the \( n \) OpenMP* thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

**type = disabled**

Specifying `disabled` completely disables the thread affinity interfaces. This forces the OpenMP* run-time library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as `kmp_set_affinity` and `kmp_get_affinity`, which have no effect and will return a nonzero error code.

**type = explicit**

Specifying `explicit` assigns OpenMP* threads to a list of OS proc IDs that have been explicitly specified by using the `proclist=` modifier, which is required for this affinity type. See Explicitly Specifying OS Proc IDs (`GOMP_CPU_AFFINITY`).

**type = scatter**

Specifying `scatter` distributes the threads as evenly as possible across the entire system. `scatter` is the opposite of `compact`; so the leaves of the node are most significant when sorting through the machine topology map.

**Deprecated Types: logical and physical**

Types `logical` and `physical` are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

For `logical` and `physical` affinity types, a single trailing integer is interpreted as an offset specifier instead of a permute specifier. In contrast, with `compact` and `scatter` types, a single trailing integer is interpreted as a permute specifier.

- Specifying `logical` assigns OpenMP* threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to `compact`, except that the `permute` specifier is not allowed. Thus, `KMP_AFFINITY=logical,n` is equivalent to `KMP_AFFINITY=compact,0,n` (this equivalence is true regardless of the whether or not a `granularity=fine` modifier is present).
- Specifying `physical` assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to `logical`. For systems where multiple thread contexts exist per core, `physical` is equivalent to `compact` with a `permute` specifier of 1; that is, `KMP_AFFINITY=physical,n` is equivalent to `KMP_AFFINITY=compact,1,n` (regardless of the whether or not a `granularity=fine` modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the `permute` specifier.

**Examples of Types compact and scatter**

The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Hyper-Threading Technology (HT Technology) enabled.

The following figure also illustrates the binding of OpenMP* thread to hardware thread contexts when specifying `KMP_AFFINITY=granularity=fine,compact`. 
Specifying `scatter` on the same system as shown in the figure above, the OpenMP* threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying `KMP_AFFINITY=granularity=fine,scatter`.

**permute and offset combinations**

For both `compact` and `scatter`, `permute` and `offset` are allowed; however, if you specify only one integer, the compiler interprets the value as a `permute` specifier. Both `permute` and `offset` default to 0.

The `permute` specifier controls which levels are most significant when sorting the machine topology map. A value for `permute` forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The `offset` specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying `KMP_AFFINITY=granularity=fine,compact,0,3`. 
Consider the hardware configuration from the previous example, running an OpenMP* application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP* threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using `KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.

The OpenMP* thread \( n+1 \) is bound to a thread context as close as possible to OpenMP* thread \( n \), but on a different core. Once each core has been assigned one OpenMP* thread, the subsequent OpenMP* threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.
Modifier Values for Affinity Types

Modifiers are optional arguments that precede type. If you do not specify a modifier, the noverbose, respect, and granularity=core modifiers are used automatically.

Modifiers are interpreted in order from left to right, and can negate each other. For example, specifying
KMP_AFFINITY=verbose,noverbose,scatter is therefore equivalent to setting
KMP_AFFINITY=noverbose,scatter, or just KMP_AFFINITY=scatter.

modifier = noverbose (default)

Does not print verbose messages.

modifier = verbose

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP* thread bindings to physical thread contexts.

Information about binding OpenMP* threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP* thread is printed as a set of OS processor IDs.

For example, specifying KMP_AFFINITY=verbose,scatter on a dual core system with two processors, with Hyper-Threading Technology (HT Technology) disabled, results in a message listing similar to the following when then program is executed:

<table>
<thead>
<tr>
<th>Verbose, scatter message</th>
</tr>
</thead>
</table>

```
...  
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
    {0,1,2,3}
KMP_AFFINITY: 4 available OS procs – Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
    KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
    KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0]
    KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0]
    KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0]
    KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}
    KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}
    KMP_AFFINITY: Internal thread 3 bound to OS proc set {3}
    KMP_AFFINITY: Internal thread 1 bound to OS proc set {1}
```

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

<table>
<thead>
<tr>
<th>Message String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;affinity capable&quot;</td>
<td>Indicates that all components (compiler, operating system, and hardware)</td>
</tr>
<tr>
<td></td>
<td>support affinity, so thread binding is possible.</td>
</tr>
<tr>
<td>&quot;using global cpuid info&quot;</td>
<td>Indicates that the machine topology was discovered by binding a thread to</td>
</tr>
<tr>
<td></td>
<td>each operating system processor and decoding the output of the cpuid</td>
</tr>
<tr>
<td></td>
<td>instruction.</td>
</tr>
<tr>
<td>&quot;using local cpuid info&quot;</td>
<td>Indicates that compiler is decoding the output of the cpuid instruction,</td>
</tr>
<tr>
<td></td>
<td>issued by only the initial thread, and is assuming a machine topology using</td>
</tr>
<tr>
<td></td>
<td>the number of operating system processors.</td>
</tr>
<tr>
<td>&quot;using /proc/cpuinfo&quot;</td>
<td>Linux* only. Indicates that cpuinfo is being used to determine machine</td>
</tr>
<tr>
<td></td>
<td>topology.</td>
</tr>
</tbody>
</table>
"using flat"  Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.

"uniform topology of"  The machine topology map is a full tree with no missing leaves at any level.

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP* thread context ID is printed next unless the affinity type is none. The thread level is contained in brackets (in the listing shown above). This implies that there is no representation of the thread context level in the machine topology map. For more information, see Determining Machine Topology.

**modifier = granularity**

Binding OpenMP* threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled; however, it is usually not beneficial to bind each OpenMP* thread to a particular thread context on a specific core. Granularity describes the lowest levels that OpenMP* threads are allowed to float within a topology map.

This modifier supports the following additional specifiers.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>core</td>
<td>Default. Broadest granularity level supported. Allows all the OpenMP* threads bound to a core to float between the different thread contexts.</td>
</tr>
<tr>
<td>fine or thread</td>
<td>The finest granularity level. Causes each OpenMP* thread to be bound to a single thread context. The two specifiers are functionally equivalent.</td>
</tr>
</tbody>
</table>

Specifying KMP_AFFINITY=verbose,granularity=core,compact on the same dual core system with two processors as in the previous section, but with HT Technology enabled, results in a message listing similar to the following when the program is executed:

**Verbose, granularity=core,compact message**

```
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
[0,1,2,3,4,5,6,7]
KMP_AFFINITY: 8 available OS procs – Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {1,5}
```
The affinity mask for each OpenMP* thread is shown in the listing (above) as the set of operating system processor to which the OpenMP* thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP* thread bindings.

In contrast, specifying KMP_AFFINITY=verbose,granularity=fine,compact or KMP_AFFINITY=verbose,granularity=thread,compact binds each OpenMP* thread to a single hardware thread context when the program is executed:
The OpenMP* to hardware context binding for this example was illustrated in the first example.

Specifying `granularity=fine` will always cause each OpenMP* thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

**modifier = respect (default)**

Respect the process’ original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP* run-time library. The behavior differs between Linux* and Windows*:

- **On Windows***: Respect original affinity mask for the process.
- **On Linux***: Respect the affinity mask for the thread that initializes the OpenMP* run-time library.

Specifying `KMP_AFFINITY=verbose,compact` for the same system used in the previous example, with HT Technology enabled, and invoking the library with an initial affinity mask of `{4,5,6,7}` (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with HT Technology disabled.

Because there are eight thread contexts on the machine, by default the compiler created eight threads for an OpenMP* parallel construct.

The brackets around thread 1 indicate that the thread context level is ignored, and is not present in the topology map. The following figure illustrates the corresponding machine topology map.
When using the local `cpuid` information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Hyper-Threading Technology (HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.

**modifier = norespect**

Do not respect original affinity mask for the process. Binds OpenMP* threads to all operating system processors.

In early versions of the OpenMP* run-time library that supported only the *physical* and *logical* affinity types, `norespect` was the default and was not recognized as a modifier.

The default was changed to `respect` when types `compact` and `scatter` were added; therefore, thread bindings for the *logical* and *physical* affinity types may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

**modifier = nowarnings**

Do not print warning messages from the affinity interface.

**modifier = warnings (default)**

Print warning messages from the affinity interface (default).

### Determining Machine Topology

On IA-32 and Intel® 64 architecture systems, if the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the `cpuid` instruction to obtain the *package id*, *core id*, and *thread context id*. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the `cpuid` instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the *package ID*, *core ID*, and *thread context ID*.

There are two ways to specify the APIC ID in the `cpuid` instruction - the legacy method in leaf 4, and the more modern method in leaf 11. Only 256 unique APIC IDs are available in leaf 4. Leaf 11 has no such limitation.

Normally, all *core ids* on a package and all *thread context ids* on a core are contiguous; however, numbering assignment gaps are common for *package ids*, as shown in the figure above.
If the compiler cannot determine the machine topology using any other method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be flat. For example, a flat topology assumes the operating system process \( N \) maps to package \( N \), and there exists only one thread context per core and only one core for each package.

If the machine topology cannot be accurately determined as described above, the user can manually copy /proc/cpuinfo to a temporary file, correct any errors, and specify the machine topology to the OpenMP* runtime library via the environment variable KMP_CPUINFO_FILE=<temp_filename>, as described in the section KMP_CPUINFO_FILE and /proc/cpuinfo.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.

**KMP_CPUINFO_FILE and /proc/cpuinfo**

One of the methods the Intel® C++ Compiler OpenMP runtime library can use to detect the machine topology on Linux* systems is to parse the contents of /proc/cpuinfo. If the contents of this file (or a device mapped into the Linux* file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file <temp_file>, correct it or extend it with the necessary information, and set KMP_CPUINFO_FILE=<temp_file>.

If you do this, the OpenMP* runtime library will read the <temp_file> location pointed to by KMP_CPUINFO_FILE instead of the information contained in /proc/cpuinfo or attempting to detect the machine topology by decoding the APIC IDs. That is, the information contained in the <temp_file> overrides these other methods. You can use the KMP_CPUINFO_FILE interface on Windows* systems, where /proc/cpuinfo does not exist.

The content of /proc/cpuinfo or <temp_file> should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in <temp_file> or /proc/cpuinfo:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processor</td>
<td>Specifies the OS ID for the processing element. The OS ID must be unique. The processor and physical id fields are the only ones that are required to use the interface.</td>
</tr>
<tr>
<td>physical id</td>
<td>Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the Intel compiler OpenMP run-time library’s model of the machine topology.</td>
</tr>
<tr>
<td>core id</td>
<td>Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core level will not exist in the machine topology map (even if some of the core ID fields are non-zero).</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread id</td>
<td>Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).</td>
</tr>
<tr>
<td>node_n id</td>
<td>This is an extension to the normal contents of /proc/cpuinfo that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels $n$ are supported. The node_0 level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on. Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.</td>
</tr>
</tbody>
</table>

**NOTE**

It is common for the thread id field to be missing from /proc/cpuinfo on many Linux* variants, and for a field labeled siblings to specify the number of threads per node or number of nodes per package. However, the Intel OpenMP runtime library ignores fields labeled siblings so it can distinguish between the thread id and siblings fields. When this situation arises, the warning message Physical node/pkg/core/thread ids not unique appears (unless the type specified is nowarnings).

### Windows* Processor Groups

On a 64-bit Windows* operating system, it is possible for multiple processor groups to accommodate more than 64 processors. Each group is limited in size, up to a maximum value of sixty-four (64) processors.

If multiple processor groups are detected, the default is to model the machine as a 2-level tree, where level 0 are for the processors in a group, and level 1 are for the different groups. Threads are assigned to a group until there are as many OpenMP* threads bound to the groups as there are processors in the group. Subsequent threads are assigned to the next group, and so on.

By default, threads are allowed to float among all processors in a group, that is to say, granularity equals the group [granularity=group]. You can override this binding and explicitly use another affinity type like compact, scatter, and so on. If you do so, the granularity must be sufficiently fine to prevent a thread from being bound to multiple processors in different groups.

### Using a Specific Machine Topology Modeling Method (KMP_TOPOLOGY_METHOD)

You can set the KMP_TOPOLOGY_METHOD environment variable to force OpenMP* to use a particular machine topology modeling method.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>

</tr>
</tbody>
</table>

### Explicitly Specifying OS Processor IDs (GOMP_CPU_AFFINITY)

**NOTE**

You must set the `GOMP_CPU_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

Instead of allowing the library to detect the hardware topology and automatically assign OpenMP* threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

This list may either be specified by using the proclist modifier along with the explicit affinity type in the `KMP_AFFINITY` environment variable, or by using the `GOMP_AFFINITY` environment variable (for compatibility with gcc) when using the OpenMP* Source Compatibility and Interoperability with Other Compilers.

On Linux* systems, when using the Intel OpenMP compatibility libraries enabled by the compiler option –openmp-lib compat, you can use the `GOMP_AFFINITY` environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by `libgomp` (assume that `<proc_list>` produces the entire `GOMP_AFFINITY` environment string):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;proc_list&gt;</code> :=</td>
<td>`&lt;entry&gt;</td>
</tr>
<tr>
<td><code>&lt;elem&gt;</code> :=</td>
<td>`&lt;proc_spec&gt;</td>
</tr>
<tr>
<td><code>&lt;proc_spec&gt;</code> :=</td>
<td><code>&lt;proc_id&gt;</code></td>
</tr>
<tr>
<td><code>&lt;range&gt;</code> :=</td>
<td>`&lt;proc_id&gt; - &lt;proc_id&gt;</td>
</tr>
<tr>
<td><code>&lt;proc_id&gt;</code> :=</td>
<td><code>&lt;positive_int&gt;</code></td>
</tr>
</tbody>
</table>

OS processors specified in this list are then assigned to OpenMP* threads, in order of OpenMP* Global Thread IDs. If more OpenMP* threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP* Global Thread ID \( n \) is bound to list element \( n \mod <list\_size> \).
Consider the machine previously mentioned: a dual core, dual-package machine without Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates six OpenMP* threads instead of 4 (the default), oversubscribing the machine. If `GOMP_AFFINITY=3,0-2`, then OpenMP* threads are bound as shown in the figure below, just as should happen when compiling with gcc and linking with libgomp:

![Diagram showing machine/node structure with OS proc IDs and OpenMP* global thread ID sets]

The same syntax can be used to specify the OS proc ID list in the proclist=\[<proc_list>\] modifier in the `KMP_AFFINITY` environment variable string. There is a slight difference: in order to have strictly the same semantics as in the gcc OpenMP* runtime library libgomp: the `GOMP_AFFINITY` environment variable implies `granularity=fine`. If you specify the OS proc list in the `KMP_AFFINITY` environment variable without a `granularity=` specifier, then the default `granularity` is not changed. That is, OpenMP* threads are allowed to float between the different thread contexts on a single core. Thus `GOMP_AFFINITY=<proc_list>` is an alias for `KMP_AFFINITY="granularity=fine,proclist=[<proc_list>],explicit"`.

In the `KMP_AFFINITY` environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP* thread may execute ("float") enclosed in brackets:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;proc_list&gt;</code></td>
<td>`&lt;proc_id&gt;</td>
</tr>
<tr>
<td><code>&lt;float_list&gt;</code></td>
<td>`&lt;proc_id&gt;</td>
</tr>
</tbody>
</table>

This allows functionality similarity to the `granularity=` specifier, but it is more flexible. The OS processors on which an OpenMP* thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the previous example, we may allow OpenMP* threads 2 and 3 to "float" between OS processor 1 and OS processor 2 by using `KMP_AFFINITY="granularity=fine,proclist=[3,0,\{1,2\},\{1,2\}],explicit"`, as shown in the figure below:
If `verbose` were also specified, the output when the application is executed would include:

```
KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"
```

| KMP_AFFINITY: Affinity capable, using global cpuid info |
|---------------------------------|---------------|
| KMP_AFFINITY: Initial OS proc set respected: {0,1,2,3} |
| KMP_AFFINITY: 4 available OS procs - Uniform topology of |
| KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores) |
| KMP_AFFINITY: OS proc to physical thread map ([] => level not in map): |
| KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0] |
| KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0] |
| KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0] |
| KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0] |
| KMP_AFFINITY: Internal thread 0 bound to OS proc set {3} |
| KMP_AFFINITY: Internal thread 1 bound to OS proc set {0} |
| KMP_AFFINITY: Internal thread 2 bound to OS proc set {1,2} |
| KMP_AFFINITY: Internal thread 3 bound to OS proc set {1,2} |
| KMP_AFFINITY: Internal thread 4 bound to OS proc set {3} |
| KMP_AFFINITY: Internal thread 5 bound to OS proc set {0}] |

**Low Level Affinity API**

Instead of relying on the user to specify the OpenMP* thread to OS proc binding by setting an environment variable before program execution starts (or by using the `kmp_settings` interface before the first parallel region is reached), each OpenMP* thread can determine the desired set of OS procs on which it is to execute and bind to them with the `kmp_set_affinity` API call.
**CAUTION**

When you use this affinity interface you take complete control of the hardware resources on which your threads run. To do that sensibly you need to understand in detail how the logical CPUs, the enumeration of hardware threads controlled by the OS, map to the physical hardware of the specific machine on which you are running. That mapping can be, and likely is, different on different machines, so you risk binding machine-specific information into your code, which can result in explicitly forcing bad affinities when your code runs on a different machine. And if you are concerned with optimization at this level of detail, your code is probably valuable, and therefore will probably move to another machine.

This interface may also allow you to ignore the resource limitations that were set by the program startup mechanism, such as MPI, specifically to prevent multiple OpenMP processes on the same node from using the same hardware threads. Again, this can result in explicitly forcing affinities that cause bad performance, and the OpenMP runtime will neither prevent this from happening, nor warn you when it does. These are expert interfaces and you must use them with caution.

It is recommended, therefore, to use the higher level affinity settings if you possibly can, because they are more portable and do not require this low level knowledge.

The Fortran API interfaces follow, where the type name `kmp_affinity_mask_t` is defined in `omp_lib.h` or `omp_lib.mod`:

**NOTE**

Some of these interfaces have offload equivalents. The offload equivalent takes two additional arguments to specify the target type and target number. For more information, see Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>integer function kmp_set_affinity(mask)</code></td>
<td>Sets the affinity mask for the current OpenMP* thread to <code>mask</code>, where <code>mask</code> is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td><code>integer kmp_get_affinity(mask)</code></td>
<td>Retrieves the affinity mask for the current OpenMP* thread, and stores it in <code>mask</code>, which must have previously been initialized with a call to <code>kmp_create_affinity_mask()</code>. Returns either a zero (0) upon success or a nonzero error code.</td>
</tr>
<tr>
<td><code>integer function kmp_get_affinity_max_proc()</code></td>

</tbody>
</table>

Once an OpenMP* thread has set its own affinity mask via a successful call to kmp_set_affinity(), then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to kmp_set_affinity().

Between parallel regions, the affinity mask (and the corresponding OpenMP* thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP* Application Program Interface. For more information, see the OpenMP* API specification (http://www.openmp.org), some relevant parts of which are provided below:

In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions.

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, you can mimic the behavior of the KMP_AFFINITY environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP* specification.

The following example shows how these low-level interfaces can be used. This code binds the executing thread to the specified logical CPU:

**Example**

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP* thread to physical processing element bindings could differ and you might be explicitly force a bad distribution.

OpenMP® Advanced Issues

This topic discusses how to use the OpenMP® library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP®.

OpenMP® provides specific function calls, and environment variables. See the following topics to refresh you memory about the primary functions and environment variable used in this topic:

- OpenMP® Run-time Library Routines
- OpenMP® Environment Variables

To use the function calls, include the *omp_lib.h* header file or specify *use omp_lib* to use the Fortran90 module file. These files are installed in the *INCLUDE* directory during the compiler installation, and compile the application using the *openmp* option.

The following example, which demonstrates how to use the OpenMP® functions to print the alphabet, also illustrates several important concepts:

1. When using functions instead of directives, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.
2. It becomes difficult to compile without OpenMP® support.
3. It is very easy to introduce simple bugs, as in the loop (below) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.
4. You lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.

```
#include "omp_lib.h"
integer i
integer LettersPerThread, ThisThreadNum, StartLetter, EndLetter

call omp_set_num_threads(4)
  !$OMP PARALLEL PRIVATE(i)
    ! OMP_NUM_THREADS is not a multiple of 26,
    ! which can be considered a bug in this code.
    LettersPerThread = 26 / omp_get_num_threads()
    ThisThreadNum = omp_get_thread_num()
    StartLetter = 'a'+ThisThreadNum*LettersPerThread
    EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread

    DO i = StartLetter, EndLetter - 1
      write( *,FMT='(A)',ADVANCE='NO') char(i)
    END DO
  !$OMP END PARALLEL
write(*,*)
end
```

Debugging threaded applications is a complex process because debuggers change the run-time performance, which can mask race conditions. Even *print* statements can mask issues, because they use synchronization and operating system functions. OpenMP® itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables, and inserts additional code. A debugger that supports OpenMP® can help you to examine variables and step through threaded code. You can use Intel® Inspector to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.
Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs.

The `DEFAULT(NONE)` clause, shown below, can be used to help find those hard-to-spot variables. If you specify `DEFAULT(NONE)`, then every variable must be declared with a data-sharing attribute clause.

**Example**

```
!$OMP PARALLEL DO DEFAULT(NONE) PRIVATE(x,y) SHARED(a,b)
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the `FIRSTPRIVATE` and `LASTPRIVATE` clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can’t find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn’t work, try setting the entire program to run in serial by setting the compiler-specific environment variable `KMP_LIBRARY=serial`.

If the code is still not working, and you are not using any OpenMP* API function calls, compile it without the `[Q]`openmp option to make sure the serial version works. If you are using OpenMP* API function calls, use the `[Q]openmp-stubs` option.

**Performance**

OpenMP* threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.

Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on \( n \) CPUs. With OpenMP*, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the `[Q]openmp` option to generate a single-threaded version, or build with the `[Q]openmp-stubs` option, and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code. If the overhead of a parallel region is large compared to the compute time, you may want to use an if clause to execute the section serially.
Interoperability with OpenMP* in C/C++

The Intel® Fortran Compiler does not support Fortran calling C/C++ or C/C++ calling Fortran when both caller and callee are using OpenMP* constructs.

Fortran code that uses OpenMP* constructs can call C/C++ as long as the C/C++ code does not use OpenMP* constructs.

<td>If the value does not conform to the specified format or the implementation cannot provide a stack of the specified size, then Intel's OpenMP* implementation sets the value of stacksize-var ICV to the default size, which is specified as being from 1MB to 4MB depending on the architecture.</td>
</tr>
<tr>
<td>OMP_MAX_ACTIVE_LEVELS environment variable</td>
<td>If the value is a negative integer or is greater than the number of parallel levels an implementation can support, then Intel's OpenMP* implementation sets the value of the max-active-levels-var ICV to the maximum number of parallel levels supported on a particular platform.</td>
</tr>
<tr>
<td>OMP_THREAD_LIMIT environment variable</td>
<td>If the requested value is greater than the number of threads an implementation can support, or if the value is a negative integer, then Intel's OpenMP* implementation sets the value of the thread-limit-var ICV to the maximum number of threads supported on a particular platform. If the requested value is zero then the implementation sets the value of the thread-limit-var ICV to 1.</td>
</tr>
</tbody>
</table>

Runtime library definitions

Intel's OpenMP* implementation provides both the include file `omp_lib.h` and the module `omp_lib`.

### OpenMP* Examples

The following examples show how to use several OpenMP* features.

#### A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The `END DO` has a `NOWAIT` because there is an implicit barrier at the end of the parallel region.

#### Example

```fortran
subroutine do_1(a,b,n)
  real a(n,n), b(n,n)
  !$OMP PARALLEL SHARED(A,B,N)
  !$OMP DO SCHEDULE(DYNAMIC,1) PRIVATE(I,J)
    do i = 2, n
      do j = 1, i
        ...
      end do
    end do
  end do
end subroutine do_1
```
Two Difference Operators: DO Loop Version

The example uses two parallel loops fused to reduce fork/join overhead. The first \texttt{END DO} directive has a \texttt{NOWAIT} clause because all the data used in the second loop is different than all the data used in the first loop.

Example

\begin{verbatim}
subroutine do_2(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
  !$OMP DO SCHEDULE(DYNAMIC,1)
    do i = 2, n
      do j = 1, i
        b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
      end do
    end do
  !$OMP END DO NOWAIT
  !$OMP DO SCHEDULE(DYNAMIC,1)
    do i = 2, m
      do j = 1, i
        d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
      end do
    end do
  !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end
\end{verbatim}

Two Difference Operators: SECTIONS Version

The example demonstrates the use of the \texttt{SECTIONS} directive. The logic is identical to the preceding \texttt{DO} example, but uses \texttt{SECTIONS} instead of \texttt{DO}. Here the speedup is limited to two because there are only two units of work whereas in the example above there are \((n-1) + (m-1)\) units of work.

Example

\begin{verbatim}
subroutine sections_1(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
  !$OMP SECTIONS
    !$OMP SECTION
      do i = 2, n
        do j = 1, i
          b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
        end do
      end do
    !$OMP SECTION
      do i = 2, m
        do j = 1, i
          d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
        end do
      end do
  !$OMP END SECTIONS
  !$OMP END PARALLEL
end
\end{verbatim}
Updating a Shared Scalar

This example demonstrates how to use a single construct to update an element of the shared array $a$. The optional `nowait` clause after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the single construct.
Coarrays

Using Coarrays

Coarrays are not supported on OS X* systems.

Coarrays, a data sharing concept standardized in Fortran 2008, enable parallel processing using multiple copies of a single program. Each copy, called an image, has ordinary local variables and also shared variables called coarrays or covariables. A covariable, which can be either an array or a scalar, is a variable whose storage spans across all the images in the program. In this Partitioned Global Address Space (PGAS) model, each image can access its own piece of a covariable as a local variable and can access those pieces that live on other images using coindices, which are enclosed in square brackets.

Intel® Fortran supports coarray programs that run using shared memory on a multicore or multiprocessor system. With an optional license, coarray programs can also run using distributed memory across a Linux* or Windows* cluster. They can also run on Linux* systems using Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Please refer to the product system requirements in the Release Notes for further details.

For more information on how to write programs using coarrays, see books on the Fortran 2008 language or the ISO Fortran 2008 standard.

Using Coarray Program Syntax

The additional syntax required by coarrays includes:

- CODIMENSION attribute and ”[cobounds]” to declare an object a coarray (covariable)
- [coindices] notation to reference covariables on other images
- SYNC ALL, SYNC IMAGES, and SYNC MEMORY statements to provide points where images must communicate to synchronize shared data
- CRITICAL and END CRITICAL statements to form a block of code executed by one image at a time
- LOCK and UNLOCK statements to control objects called locks, used to synchronize actions on specific images
- ERROR STOP statement to end all images
- ALLOCATE and DEALLOCATE statements may specify coarrays
- Intrinsic procedures IMAGE_INDEX, LCOBOUND, NUM_IMAGES, THIS_IMAGE, and UCOBOUND
- ATOMIC_DEFINE and ATOMICREFER for defining and referencing an atomic variable

Using the Coarray Compiler Options

You must use the [Q]coarray compiler option to enable the compiler to recognize coarray syntax. If you do not use this compiler option, a program that uses coarray syntax or features produces a compile-time error.

In the list that follows, only one option is valid on the command line; if multiple coarray compiler options are specified, the last one specified is used. An exception to this rule is the [Q]coarray compiler option using the single keyword; if specified, this option takes precedence regardless of where it appears on the command line.

- Using [Q]coarray with no keyword is equivalent to running on one node (shared memory).
- Using [Q]coarray with the shared keyword causes the underlying Intel® Message Passing Interface (MPI) parallelization to run on one node with multiple cores or processors with shared memory.
- Using [Q]coarray with the distributed keyword requires an Intel® Cluster Toolkit license to be installed and causes the underlying Intel® MPI Library parallelization to run in a multi-node environment (multiple CPUs with distributed memory).
- Using -coarray=coprocessor (Linux*) specifies a configuration where the first images runs on the host and other images run on the host or the target. A configuration file specifies your exact configuration and determines where the images will be run. Use the -coarray-config-file=filename compiler option to specify a configuration file.
Using [Q]coarray with the single keyword creates an executable that will not be replicated, resulting in a single running image. (This is in contrast to the self-replicating behavior that occurs when any other coarray keyword is specified.) This option is useful for debugging purposes.

No special procedure is necessary to run a program that uses coarrays; you simply run the executable file. The underlying parallelization implementation uses the Intel® MPI Library. Installation of the compiler automatically installs the necessary Intel® MPI run-time libraries to run on shared memory. The Intel® Cluster Toolkit installs the necessary Intel® MPI Library run-time libraries to run on distributed memory. Use of coarray applications with any other MPI implementation, or with OpenMP*, is not supported.

By default, the number of images created is equal to the number of execution units on the current system. You can override this by specifying a number using the [Q]coarray-num-images compiler option on the ifort command line that compiles the main program. You can also specify the number of images at execution time in the environment variable FOR_COARRAY_NUM_IMAGES.

Using a Configuration File
Use of the config-file option is appropriate only in a limited number of cases:

- As mentioned previously, you need to specify a configuration file when using the -coarray=coprocessor (Linux*) compiler option syntax.
- You can take advantage of Intel® MPI Library features in the coarray environment. To do so, specify the command line segments used by "mpixec -config filename" in a file named filename and pass that file name to the Intel® MPI Library using the /Qcoarray-config-file: compiler option. If the [Q]coarray-num-images compiler option also appears on the command line, it will be overridden by what is in the configuration file. Rules for using an MPI configuration files are as follows:
  - The format of a configuration file is described in the Intel® MPI Library documentation; you will need to add the MPI option ":genv FOR_ICAF_STATUS launched" in the configuration file in order for coarrays to work on multi-node (distributed memory) systems.
  - You can also set the environment variable FOR_COARRAY_CONFIG_FILE to be the filename and path of the Intel® MPI Library configuration file you want to use at execution time.

Examples on Windows*:
- /Qcoarray:shared /Qcoarray-num-images:8 runs a coarray program on shared memory using 8 images.
- /Qcoarray:shared /Qcoarray-config-file:filename runs a coarray program on shared memory using the MPI configuration detailed in filename.
- /Qcoarray:distributed /Qcoarray-config-file:filename runs a coarray program on distributed memory using the Intel® MPI Library configuration detailed in filename (the Intel® Cluster Toolkit license must be installed).

Examples on Linux*:
- -coarray=shared -coarray-num-images=8 runs a coarray program on shared memory using 8 images.
- -coarray=distributed -coarray-num-images=8 runs a coarray program on distributed memory across 8 images (the Intel® Cluster Toolkit license must be installed).
- -coarray=coprocessor -coarray-config-file=filename runs a coarray program on a configuration where the first images runs on the host processor and other images run on some combination of host processors or coprocessors based on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture). This command line specifies use of the Intel® MPI Library configuration detailed in filename.

Considerations When Running Coprocessors based on the Intel® MIC Architecture
The compiler installation provides the necessary Intel® MPI run-time libraries and binaries on the coprocessor's file system, but these must be manually copied to the card's file system whenever the card is rebooted.

Move to the mpirt directory and copy the Intel® MPI files as shown:
sudo scp lib/mic/libmpi_mt.so mic0:/lib64/libmpi_mt.so
sudo scp bin/mic/mpiexec.hydra mic0:/bin/mpiexec.hydra
sudo scp bin/mic/mpiexec.hydra mic0:/bin/mpi_proxy
From that same directory, the Intel® Fortran run-time libraries for coarray support should also be copied to the card’s file system:

```
sudo scp lib/mic/libmpi_mt.so mic0:/lib64/libmpi_mt.so
sudo scp bin/mic/mpiexec.hydra mic0:/bin/mpiexec.hydra
sudo scp bin/mic/pmi_proxy mic0:/bin/pmi_proxy
```

**Sample Coarray Configurations When Running on the Coprocessor**

Following are several sample configurations.

**Sample Configuration:** Images 1-N on coprocessors based on Intel® MIC Architecture

In this configuration, the coarray program runs all its images only on the coprocessor(s).

For this configuration, you would specify the following:

```
ifort -coarray -mmic myProg.f90 -o myProg.mic
```

There are two ways `myProg.mic` can be run.

You can use the micnativeloadex tool, as follows:

```
/opt/intel/mic/coi/tools/micnativeloadex/release/micnativeloadex myProg.mic
```

For more information on micnativeloadex, refer to the Intel® Many Integrated Core Platform Software Stack documentation.

The second way to run `myProg.mic` is to copy it to the card’s file system, and run it from the card itself.

This configuration does not require `-coarray=coprocessor` at compile time.

**Sample Configuration:** Image 1 on host; images 2-N on coprocessors based on Intel® MIC Architecture

In this configuration, the coarray program runs some of its images on the host and some of its images on coprocessors.

For this configuration, you would specify the following:

```
ifort -coarray=coprocessor -coarray-config-file=MixedPlatform.conf myProg.f90 -o myProg
```

This creates two executables; `myProg` and `myProgMIC`. Copy `myProgMIC` to the card’s file system, and specify that location in the configuration file.

The `MixedPlatform.conf` file would contain the following:

```
-n 1 -host <hostid-of-CPU> -genv FOR_ICAF_STATUS=T ./myProg : \
-n 4 -host <hostid-of-mic> genv FOR_ICAF_STATUS=T /home/mydir/myProgMIC
```

**Sample Configuration:** Image 1 on host processor; images 2-N spread on host processor, coprocessor(s)

This is a variant of the previous configuration. Here, the configuration file specifies additional images on either the host processor or coprocessor. The `-n X` option is used to specify the number of images associated with each type of host. For example, to run 4 images on the CPU and 2 images each on four coprocessors, the configuration file would contain the following:

```
-n 4 -host MYCPU -genv FOR_ICAF_STATUS=true ./myProg : \
-n 2 -host CARD1 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :\n-n 2 -host CARD2 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :\n-n 2 -host CARD3 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC :\n-n 2 -host CARD4 -genv FOR_ICAF_STATUS=true /home/mydir/myProgMIC
```

Given the configuration file listed above, `myProg` should expect `num_images()` to be 12.

**Sample Configuration:** Images 1-N on host processor, with offloaded code on coprocessor

In this configuration, all coarray images run on the host processor, but each image has offloaded code that is running on the coprocessors.
For this configuration, you would specify the following:

```plaintext
ifort -coarray -coarray-num-images=X myProg.f90 -o myProg
```

For this configuration, your code must contain offload regions, marked by directives, such as:

```plaintext
!DIR$ OFFLOAD BEGIN
<user code>
!DIR$ END OFFLOAD
```

There are further restrictions on your code:

- A coindexed object may not be used within an offload region
- An image control statement may not be used within an offload region
- A coindexed object may not be used within an OpenMP* region
- An image control statement may not be used within an OpenMP region

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Debugging a Coarray Application (Linux*)

*Steps to perform to debug a coarray application.*

For the following, you need an application with shared variables or coarrays whose storage spans across all the images in a program.

Follow these steps to debug your coarray application:

1. Add a stall loop to your application before the area of code you wish to debug.

   ```plaintext
   LOGICAL VOLATILE :: WAIT_FOR_DEBUGGER
   LOGICAL :: TICK
   DO WHILE(WAIT_FOR_DEBUGGER)
   TICK = .NOT. TICK
   END DO
   ! Code you want to debug is here
   ```

   The use of VOLATILE is required to ensure that the loop will not be removed by the compiler. If the problem is only found on one image, you can wrap the loop in `IF (THIS_IMAGE() .EQ. 4) THEN` or the like.

2. Compile and link with debug enabled (`-g`).

3. Create at least N+1 terminal windows on the machine where the application will be running, where N is the number of images your application will have.
4. In a terminal window, start the application.

```bash
linuxprompt> ./my_app
```

5. In each of the other terminal windows, set your default directory to be the same as the location of the application executable. Use the `ps` command in one of the windows to find out which processes are running your application:

```bash
linuxprompt> ps -ef | grep 'whoami' | grep my_app
```

There will be several processes. The oldest is the one you started in step 4 – it has run the MPI launcher and is now waiting for the others to terminate. Do not debug it.

The others will look like this:

```text
<your-user-name> 25653 25650 98 15:06 ? 00:00:49 my_app
<your-user-name> 25654 25651 97 15:06 ? 00:00:48 my_app
<your-user-name> 25655 25649 98 15:06 ? 00:00:49 my_app
```

The first number is the PID of the process (for example, 25653 in the first line). In the steps below, the PIDs of these N processes are referred to as P1, P2, and so on. When you type the commands, replace the text `<P1>` with the actual value of the PID for process 1, and so on.

6. In each window other than the first, start your debugger and set it to stop processes when attached:

```bash
linuxprompt> gdb
```

7. Attach to one of the processes. For example, attach to P1 in window 1, attach to P2 in window 2, and so on.

```bash
(gdb) attach <P1>
```

8. Get execution out of the stall loop:

```bash
(gdb) set WAIT_FOR_DEBUGGER = .false.
```

You are now ready to debug your coarray application.

You are now ready to debug your coarray application by examining the data and code paths in the various images.
Auto-Parallelization Overview

The auto-parallelization feature of the Intel® Fortran Compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP* directives. The OpenMP* and auto-parallelization features provide the performance gains from shared memory on multiprocessor and dual core systems.

The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel. This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.

The guided auto-parallelization feature of the Intel® Fortran Compiler helps you locate portions in your serial code that can be parallelized further. You can invoke guidance for parallelization, vectorization, or data transformation using specified compiler options of the [Q]guide series.

Automatic parallelization frees developers from having to:

- Find loops that are good worksharing candidates.
- Perform the dataflow analysis to verify correct parallel execution.
- Partition the data for threaded code generation as is needed in programming with OpenMP* directives.

Although OpenMP* directives enable serial applications to transform into parallel applications quickly, you must explicitly identify specific portions of your application code that contain parallelism and add the appropriate compiler directives. Auto-parallelization, which is triggered by the [Q]parallel option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort is needed.

NOTE
In order to execute a program that uses auto-parallelization on Linux* OS or OS X* systems, you must include the -parallel compiler option when you compile and link your program.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and OS X*), or [Q]x.

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.
Example 1: Original Serial Code

```fortran
subroutine ser(a, b, c)
    integer, dimension(100) :: a, b, c
    do i=1,100
        a(i) = a(i) + b(i) * c(i)
    enddo
end subroutine ser
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

Example 2: Transformed Parallel Code

```fortran
subroutine par(a, b, c)
    integer, dimension(100) :: a, b, c
    ! Thread 1
    do i=1,50
        a(i) = a(i) + b(i) * c(i)
    enddo
    ! Thread 2
    do i=51,100
        a(i) = a(i) + b(i) * c(i)
    enddo
end subroutine par
```

Auto-Vectorization and Parallelization

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts the sequential program to process 2, 4, 8, or (up to) 16 elements in one operation, depending on the data type. In some cases, auto-parallelization and vectorization can be combined for better performance results. For example, in the code below, thread-level parallelism can be exploited in the outermost loop, while instruction-level parallelism can be exploited in the innermost loop.

Example

```fortran
DO I = 1, 100     ! Execute groups of iterations in different threads (TLP)
    DO J = 1, 32    ! Execute in SIMD style with multimedia extension (ILP)
        A(J,I) = A(J,I) + 1
    ENDDO
ENDDO
```

With the relatively small effort of adding OpenMP* directives to existing code you can transform a sequential program into a parallel program. The [Q]openmp option must be specified to enable the OpenMP directives. The following example shows OpenMP* directives within the code.

Example

```fortran
!OMP$ PARALLEL PRIVATE(NUM), SHARED (X,A,B,C)
! Defines a parallel region
!OMP$ PARALLEL DO
! Specifies a parallel region that
! implicitly contains a single DO directive
    DO I = 1, 1000
        NUM = FOO(B(I), C(I))
        X(I) = BAR(A(I), NUM)
    ! Assume FOO and BAR have no other effect
ENDDO
```
Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Using Parallelism Reports

To generate a parallelism report, use the -opt-report-phase=par (Linux* and OS X*) or the /Qopt-report-phase:par option along with the -opt-report= n or /Qopt-report:n option. By default the auto-parallelism report generates a medium level of detail, where \( n=2 \). You can use /Qopt-report option along with the /Qopt-report-phase option if you want a greater or lesser level of detail. Specifying a value of ‘5’ generates the maximum diagnostic details.

Run the report by entering commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux*</td>
<td>ifort -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
<tr>
<td>OS X*</td>
<td>ifort -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp</td>
</tr>
</tbody>
</table>

The output, by default, produces a file with the same name as the object file, with .optrpt extension, and is written into the same directory as the object file. Using the above command-line entries, you will obtain an output file called sample.optrpt. Use the /Qopt-report-file option to specify any other name for the output file that captures the report results. Use the arguments stdout or stderr to send the optimization report to stdout or stderr.

For more information on options to generate reports see the Optimization Report Options topic.

Enabling Auto-parallelization

To enable the auto-parallelizer, use the \([Q]parallel\) option. This option detects parallel loops capable of being executed safely in parallel, and automatically generates multi-threaded code for these loops.
NOTE
You may need to set the KMP_STACKSIZE environment variable to an appropriately large size to enable parallelization with this option.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and OS X*), or [Q]x.

An example of the command using auto-parallelization is as follows:

**Commanding auto-parallelization in Linux***

ifort -c -parallel myprog.f

**Commanding auto-parallelization in Windows***

ifort -c /Qparallel myprog.f

**Commanding auto-parallelization in OS X***

ifort -c -parallel myprog.f

Auto-parallelization uses two specific directives: !DIR$ PARALLEL and !DIR$ NOPARALLEL.

The format of an auto-parallelization compiler directive is below:

**Syntax**

!DIR$ <directive>

Because auto-parallelization directives begin with an exclamation point, the directives take the form of comments if you omit the [Q]parallel option.

The !DIR$ PARALLEL directive instructs the compiler to ignore dependencies that it assumes may exist and that would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored. In addition, PARALLEL [ALWAYS] overrides the compiler heuristics that estimate the likelihood that parallelization of a loop increases performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the ASSERT keyword is added, as in !DIR$ PARALLEL [ALWAYS [ASSERT]], the compiler generates an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

The !DIR$ NOPARALLEL directive disables auto-parallelization.

For example, in the following code, the NOPARALLEL directive disables auto-parallelization.

**Example**

```fortran
program main
  parameter (n=100)
  integer x(n),a(n)
  !DIR$ NOPARALLEL
  do i=1,n
    x(i) = i
  enddo
  !DIR$ PARALLEL
  do i=1,n
```

### Programming with Auto-parallelization

The auto-parallelization feature implements some concepts of OpenMP*, such as the worksharing construct (with the PARALLEL DO directive). This section provides details on auto-parallelization.

### Guidelines for Effective Auto-parallelization Usage

A loop can be parallelized if it meets the following criteria:

- **The loop is countable at compile time:** This means that an expression representing how many times the loop will execute (loop trip count) can be generated just before entering the loop.
- **There are no FLOW (READ after WRITE), OUTPUT (WRITE after WRITE) or ANTI (WRITE after READ) loop-carried data dependencies.** A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler’s discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by run-time dependency testing.

The compiler may generate a run-time test for the profitability of executing in parallel for loop, with loop parameters that are not compile-time constants.

### Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:

- **Expose the trip count of loops whenever possible; use constants where the trip count is known and save loop parameters in local variables.**
- **Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.**
- **Insert the !DIR$ PARALLEL directive to disambiguate assumed data dependencies.**
- **Insert the !DIR$ NOPARALLEL directive before loops known to have insufficient work to justify the overhead of sharing among threads.**

### Auto-parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:

1. **Data flow analysis:** Computing the flow of data through the program.
2. **Loop classification:** Determining loop candidates for parallelization based on correctness and efficiency, as shown by Enabling Auto-parallelization.
3. **Dependency analysis:** Computing the dependency analysis for references in each loop nest.
4. **High-level parallelization:** Analyzing the dependency graph to determine loops that can execute in parallel, and computing run-time dependency.
5. **Data partitioning:** Examining data reference and partition based on the following types of access: SHARED, PRIVATE, and FIRSTPRIVATE.
6. **Multithreaded code generation:** Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel run-time routines for thread creation and synchronization.
Options that use OpenMP® are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP® constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Enabling Auto-parallelization

Enabling Further Loop Parallelization for Multicore Platforms
Parallelizing loops for multicore platforms is subject to certain conditions. Three requirements must be met for the compiler to parallelize a loop:

- The number of iterations must be known before entry into a loop to insure that the work can be divided in advance. A do while loop, for example, usually cannot be made parallel.
- There can be no jumps into or out of the loop.
- The loop iterations must be independent (no cross-iteration dependencies).

Correct results must not logically depend on the order in which the iterations are executed. There may be slight variations in the accumulated rounding error, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location, for example, if they depend on function arguments, run-time data, or the results of complex calculations.

If the compiler cannot prove that pointers or array references are safe, it will not parallelize the loop, except in limited cases when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at run-time.

If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the !DIR$ PARALLEL directive.

Parallelizing Loops with Cross-iteration Dependencies
Before the compiler can auto-parallelize a loop, it must prove that the loop does not have potential cross-iteration dependencies that prevent parallelization. A cross-iteration dependency exists if a memory location is written to in an iteration of a loop and accessed (read from or written to) in another iteration of the loop. Cross-iteration dependencies often occur in loops that access overlapping array ranges, such as a loop that reads from $a(1:100)$ and writes to $a(0:99)$.

Sometimes, even though a loop does not have cross-iteration dependencies, the compiler does not have enough information to prove it and does not parallelize the loop. In such cases, you can assist the compiler by providing additional information about the loop using the !DIR$ PARALLEL directive. Adding the !DIR$ PARALLEL directive before a DO loop informs the compiler that the loop does not have cross-iteration dependencies. Auto-parallelization analysis ignores potential dependencies that it assumes could exist; however, the compiler still may not parallelize the loop if heuristics estimate parallelization is unlikely to increase performance of the loop.

The Fortran DO CONCURRENT construct also specifies that there are no cross-iteration dependencies.

The !DIR$ PARALLEL ALWAYS directive has the same effect to ignore potential dependencies as the !DIR$ PARALLEL directive, but it also overrides the compiler heuristics that estimate the likelihood that parallelization of a loop would increase performance. It allows a loop to be parallelized even when the compiler estimates that parallelization might not improve performance.
The `!DIR$ NOPARALLEL` directive prevents auto-parallelization of the immediately following `DO` loop. Unlike `!DIR$ PARALLEL`, which is a hint, the `NOPARALLEL` directive is guaranteed to prevent parallelization of the following loop.

These directives take effect only if auto-parallelization is enabled by the option `parallel`.

**Parallelizing Loops with Private Clauses**

When you use the Guided Auto Parallelism feature, the compiler’s auto-parallelizer gives you advice on where to alter your program to enhance parallelization. For instance, you may get advice to check if a condition (that the compiler could not prove) is true, and if true, to insert `!DIR$ PARALLEL` in your source code so that the associated loop is parallelized when you recompile.

To specify that it is legal for each thread to create a new, private copy (not visible by other threads) of a variable, and replace the original variable in the loop with the new private variable, use the `!DIR$ PARALLEL` directive with the `private` clause. The `private` clause allows you to list scalar and array type variables and specify the number of array elements to privatize.

Use the `firstprivate` clause to specify private variables that need to be initialized with the original value before entering the parallel loop.

Use the `lastprivate` clause to specify those variables with a value you want to reuse after it exits a parallelized loop. When you use the `lastprivate` clause to handle a particular privatized variable, the value is copied to the original variable when it exits from the parallelized loop.

---

**NOTE**

Do not use the same variable in both `private` and `lastprivate` clauses for the same loop. You will get an error message.

**Parallelizing Loops with External Function Calls**

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependencies. Fortran90 programmers can use the PURE attribute to assert that subroutines and functions contain no side effects. You can invoke interprocedural optimization with the `ipo` option. Using this option gives the compiler the opportunity to analyze the called function for side effects.

**Parallelizing Loops with OpenMP**

When the compiler is unable to automatically parallelize loops you know to be parallel, use OpenMP*. OpenMP* is the preferred solution because you understand the code better than the compiler and can express parallelism at a coarser granularity. Alternatively, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

**Threshold Parameter to Parallelize Loops**

If a loop can be parallelized, it does not necessarily mean that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `par-threshold` compiler option adjusts this behavior. The threshold ranges from 0 to 100, where 0 instructs the compiler to always parallelize a safe loop and 100 instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `par-report` option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized and indicate probable reason(s) why. See OpenMP* and Parallel Processing Options for more information on the using these compiler options.

The following example illustrates using the options in combination.
Because the compiler does not know the value of \( k \), the compiler assumes the iterations depend on each other, for example if \( k \) equals -1, even if the actual case is otherwise. You can override the compiler by inserting the \!DIR$ PARALLEL directive.

**CAUTION**

Do not call this function with a value of \( k \) that is less than 10000; passing a value less than 10000 could lead to incorrect results.

**Automatic Vectorization Overview**

The automatic vectorizer (also called the auto-vectorizer) is a component of the Intel® compiler that automatically uses SIMD instructions in the Intel® Streaming SIMD Extensions (Intel® SSE, Intel® SSE2, Intel® SSE3 and Intel® SSE4), Supplemental Streaming SIMD Extensions (SSSE3) instruction sets, and the Intel® Advanced Vector Extensions (Intel® AVX, Intel® AVX2) instruction sets. The vectorizer detects operations in the program that can be done in parallel and converts the sequential operations to parallel; for example, the vectorizer converts the sequential SIMD instruction that processes up to 16 elements into a parallel operation, depending on the data type.

Automatic vectorization occurs when the Intel® Compiler generates packed SIMD instructions to unroll a loop. Because the packed instructions operate on more than one data element at a time, the loop executes more efficiently. This process is referred to as auto-vectorization only to emphasize that the compiler identifies and optimizes suitable loops on its own, without requiring any special action by you. However, it is useful to note that in some cases, certain keywords or directives may be applied in the code for auto-vectorization to occur.

The compiler supports a variety of auto-vectorizing hints that can help the compiler to generate effective vector instructions. Automatic vectorization is supported on IA-32 and Intel® 64 architectures. Intel® Advisor XE, a separate tool included in some editions of Intel® Parallel Studio XE, provides a Vectorization Advisor feature that can analyze the compiler’s optimization reports and make recommendations for enhancing vectorization.

---

**NOTE**

Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and OS X*), or `[-Qx]`.

---

**Programming Guidelines for Vectorization**

The goal of including the vectorizer component in the Intel® Fortran Compiler is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help by supplying the compiler with additional information; for example, by using auto-vectorizer hints or directives.

---

**NOTE**

Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and OS X*), or `[-Qx]`.

---

**Guidelines to Vectorize Innermost Loops**

Follow these guidelines to vectorize innermost loop bodies.

**Use:**

- straight-line code (a single basic block).
• vector data only; that is, arrays and invariant expressions on the right hand side of assignments. Array references can appear on the left hand side of assignments.
• only assignment statements.

Avoid:
• function calls (other than math library calls).
• non-vectorizable operations (either because the loop cannot be vectorized, or because an operation is emulated through a number of instructions).
• mixing vectorizable types in the same loop (leads to lower resource utilization).
• data-dependent loop exit conditions (leads to loss of vectorization).

To make your code vectorizable, you will often need to make some changes to your loops. You should only make changes needed to enable vectorization, and avoid these common changes:
• loop unrolling, which the compiler performs automatically.
• decomposing one loop with several statements in the body into several single-statement loops.

Restrictions
There are a number of restrictions that you should consider. Vectorization depends on two major factors: hardware and style of source code.

<table>
<thead>
<tr>
<th>Factor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware</td>
<td>The compiler is limited by restrictions imposed by the underlying hardware. In the case of Intel® Streaming SIMD Extensions (Intel® SSE), the vector memory operations are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.</td>
</tr>
<tr>
<td>Style of source code</td>
<td>The style in which you write source code can inhibit vectorization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.</td>
</tr>
</tbody>
</table>

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, pointer arithmetic, and memory operations within the loop bodies.

By understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization.

Guidelines for Writing Vectorizable Code
Follow these guidelines to write vectorizable code:
• Use simple DO loops. Avoid complex loop termination conditions – the upper iteration limit must be invariant within the loop. For the innermost loop in a nest of loops, you could set the upper limit iteration to be a function of the outer loop indices.
• Write straight-line code. Avoid branches such as DO, GOTO, or ASSIGN statements; most function calls; or IF constructs that can not be treated as masked assignments.
• Avoid dependencies between loop iterations or at the least, avoid read-after-write dependencies.
• Try to use array notations instead of the use of pointers. Without help, the compiler often cannot tell whether it is safe to vectorize code containing pointers.
• Wherever possible, use the loop index directly in array subscripts instead of incrementing a separate counter for use as an array address.
• Access memory efficiently:
- Favor inner loops with unit stride.
- Minimize indirect addressing.
- Align your data to 16-byte boundaries (for Intel® SSE instructions).
- Choose a suitable data layout with care. Most multimedia extension instruction sets are rather sensitive to alignment. The data movement instructions of Intel® SSE, for example, operate much more efficiently on data that is aligned at a 16-byte boundary in memory. Therefore, the success of a vectorizing compiler also depends on its ability to select an appropriate data layout which, in combination with code restructuring (like loop peeling), results in aligned memory accesses throughout the program.
- Use aligned data structures: Data structure alignment is the adjustment of any data object in relation with other objects.

**CAUTION**

Use this hint with care. Incorrect usage of aligned data movements result in an exception when using Intel® SSE.

- Use structure of arrays (SoA) instead of array of structures (AoS): An array is the most common type of data structure that contains a contiguous collection of data items that can be accessed by an ordinal index. You can organize this data as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization is excellent for encapsulation it can be a hindrance for use of vector processing. To make vectorization of the resulting code more effective, you can also select appropriate data structures.

**Dynamic Alignment Optimizations**

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

To enable or disable dynamic data alignment optimizations, specify the option `Qopt-dynamic-align[-]` (Windows) or `[no-]qopt-dynamic-align[-]` (Linux).

**Using Aligned Data Structures**

Data structure alignment is the adjustment of any data object with relation to other objects. The Intel® Fortran Compiler may align individual variables to start at certain addresses to speed up memory access. Misaligned memory accesses can incur large performance losses on certain target processors that do not support them in hardware.

Alignment is a property of a memory address, expressed as the numeric address modulo of powers of two. In addition to its address, a single datum also has a size. A datum is called 'naturally aligned' if its address is aligned to its size, otherwise it is called 'misaligned'. For example, an 8-byte floating-point datum is naturally aligned if the address used to identify it is aligned to eight (8).

A data structure is a way of storing data in a computer so that it can be used efficiently. Often, a carefully chosen data structure allows a more efficient algorithm to be used. A well-designed data structure allows a variety of critical operations to be performed, using as little resources - both execution time and memory space - as possible.

In the example data structure above, if the type `short` is stored in two bytes of memory then each member of the data structure is aligned to a boundary of two bytes. `Data1` would be at offset 0, `Data2` at offset 2 and `Data3` at offset 4. The size of this structure is six bytes. The type of each member of the structure usually has a required alignment, meaning that it is aligned on a pre-determined boundary, unless you request otherwise. In cases where the compiler has taken sub-optimal alignment decisions, you can use the declaration `declspec(align(base,offset))`, where 0 <= offset < base and base is a power of two, to allocate a data structure at offset from a certain base.

If the first element of both arrays is aligned at a 16-byte boundary, then either an unaligned load of elements from `b` or an unaligned store of elements into `a` must be used after vectorization.
NOTE
In this case, peeling off an iteration will not help.

However, you can enforce the alignment shown below, which results in two aligned access patterns after vectorization (assuming an 8-byte size for doubles):

Run-time optimization provides a generally effective way to obtain aligned access patterns at the expense of a slight increase in code size and testing. If incoming access patterns are guaranteed to be aligned at a 16-byte boundary, you can avoid this overhead with the hint

`__assume_aligned(x, 16);`

in the function to convey this information to the compiler.

CAUTION
Use this hint with care. Incorrect use of aligned data movements result in an exception for Intel® SSE.

---

Using Structure of Arrays versus Array of Structures

The most common and well-known data structure is the array that contains a contiguous collection of data items, which can be accessed by an ordinal index. This data can be organized as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization works excellently for encapsulation, for vector processing it works poorly.

You can select appropriate data structures to make vectorization of the resulting code more effective. To illustrate this point, compare the traditional array of structures (AoS) arrangement for storing the \( r, g, b \) components of a set of three-dimensional points with the alternative structure of arrays (SoA) arrangement for storing this set.

With the AoS arrangement, a loop that visits all components of an RGB point before moving to the next point exhibits a good locality of reference because all elements in the fetched cache lines are utilized. The disadvantage of the AoS arrangement is that each individual memory reference in such a loop exhibits a non-unit stride, which, in general, adversely affects vector performance. Furthermore, a loop that visits only one component of all points exhibits less satisfactory locality of reference because many of the elements in the fetched cache lines remain unused.

In contrast, with the SoA arrangement the unit-stride memory references are more amenable to effective vectorization and still exhibit good locality of reference within each of the three data streams. Consequently, an application that uses the SoA arrangement may ultimately outperform an application based on the AoS arrangement when compiled with a vectorizing compiler, even if this performance difference is not directly apparent during the early implementation phase.

Before you start vectorization, try out some simple rules:
• Make your data structures vector-friendly.
• Make sure that inner loop indices correspond to the outermost (last) array index in your data (row-major order).
• Use structure of arrays over array of structures.

For instance, when dealing with three-dimensional coordinates, use three separate arrays for each component (SoA), instead of using one array of three-component structures (AoS). To avoid dependencies between loops that will eventually prevent vectorization, use three separate arrays for each component (SoA), instead of one array of three-component structures (AoS). When you use the AoS arrangement, each iteration produces one result by computing XYZ, but it can at best use only 75% of the SSE unit because the forth component is not used. Sometimes, the compiler may use only one component (25%). When you use the SoA arrangement, each iteration produces four results by computing XXXX, YYYY and ZZZZ, using 100% of the SSE unit. A drawback for the SoA arrangement is that your code will likely be three times as long. On the other hand, the compiler might not be able to vectorize AoS arranged code at all.

If your original data layout is in AoS format, you may even want to consider a conversion to SoA on the fly, before the critical loop. If it gets vectorized, it may be worth the effort!

To summarize:
• Use the smallest data types that gives the needed precision to maximize potential SIMD width. (If only 16-bits are needed, using a short rather than an int can make the difference between 8-way or four-way SIMD parallelism, respectively.)
• Avoid mixing data types to minimize type conversions.
• Avoid operations not supported in SIMD hardware.
• Use all the instruction sets available for your processor. Use the appropriate command line option for your processor type, or select the appropriate IDE option (Windows* only):
  • Project > Properties > Visual Fortran > Code Generation > Intel Processor-Specific Optimization, if your application runs only on Intel® processors.
  • Project > Properties > Visual Fortran > Code Generation > Enable Enhanced Instruction Set, if your application runs on compatible, non-Intel processors.
  • Vectorizing compilers usually have some built-in efficiency heuristics to decide whether vectorization is likely to improve performance. The Intel® Fortran Compiler disables vectorization of loops with many unaligned or non-unit stride data access patterns. If experimentation reveals that vectorization improves performance, you can override this behavior using the !DIR$ VECTOR ALWAYS hint before the loop; the compiler vectorizes any loop regardless of the outcome of the efficiency analysis (provided, of course, that vectorization is safe).

Using Automatic Vectorization
Automatic vectorization is supported on IA-32 and Intel® 64 architectures. The information below will guide you in setting up the auto-vectorizer.

Vectorization Speed-up
Where does the vectorization speedup come from? Consider the following sample code fragment, where a, b and c are integer arrays:
If vectorization is not enabled (that is, you compile using °1 or [Q]vec- options), for each iteration, the compiler processes the code such that there is a lot of unused space in the SIMD registers, even though each of the registers could hold three additional integers. If vectorization is enabled (compiled using °2 or higher options), the compiler may use the additional registers to perform four additions in a single instruction. The compiler looks for vectorization opportunities whenever you compile at default optimization (°2) or higher.

**NOTE**
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), –m (Linux* and OS X*), or [Q]x.

**TIP**
To allow comparisons between vectorized and not-vectorized code, disable vectorization using the / Qvec- (Windows*) or -no-vec (Linux* or OS X*) option; enable vectorization using the °2 option.

To get information on whether a loop was vectorized or not, enable generation of the optimization report using the options Qopt-report:1 Qopt-report-phase:vec (Windows) or qopt-report=1 qopt-report-phase=vec (Linux and OS X) options. These options generate a separate report in an *.optrpt file that includes optimization messages. In Visual Studio, the program source is annotated with the report's messages, or you can read the resulting .optrpt file using a text editor. A message appears for every loop that is vectorized, such as:

**Example: Vectorization Report**

```
> ifort /Qopt-report1 matvec.f90
> type matvec.optrpt
```

```
... LOOP BEGIN at C:\Projects\vec_samples\matvec.f90(38,6)
   remark #15300: LOOP WAS VECTORIZED
LOOP END
```

The source line number (38 in the above example) refers to either the beginning or the end of the loop.

To get details about the type of loop transformations and optimizations that took place, use the [Q]opt-report-phase option by itself or along with the [Q]opt-report option.

How significant is the performance enhancement? To evaluate performance enhancement yourself, run vec_samples:

1. Open an Intel® Compiler command line window.

   - On Windows*: Under the Start menu item for your Intel product, select an icon under Compiler and Performance Libraries > Command Prompt with Intel Compiler
   - On Linux* and OS X*: Source an environment script such as compilervars.sh or the compilervars.csh in the <installdir>/bin directory and use the attribute appropriate for the architecture.
2. Navigate to the `<install-dir>\Samples\<locale>\Fortran\` directory. On Windows, unzip the sample project `vec_samples.zip` to a writable directory. This small application multiplies a vector by a matrix using the following loop:

**Example: Vector Matrix Multiplication**

```fortran
do i=1,size1
   c(i) = c(i) + a(i,j) * b(j)
end do
```

3. Build and run the application, first without enabling auto-vectorization. The default O2 optimization enables vectorization, so you need to disable it with a separate option. Note the time taken for the application to run.

**Example: Building and Running an Application without Auto-vectorization**

```fortran
// (Linux* and OS X* with EDG compiler)
ifort -no-vec  driver.f90 matvec.f90 -o NoVectMult
./NoVectMult

// (Windows*)
ifort /Qvec- driver.f90 matvec.f90 /exe:NoVectMult
NoVectMult
```

4. Now build and run the application, this time with auto-vectorization. Note the time taken for the application to run.

**Example: Building and Running an Application with Auto-vectorization**

```fortran
// (Linux* and OS X* with EDG compiler)
ifort driver.f90 matvec.f90 -o VectMult
./VectMult

// (Windows*)
ifort driver.f90 matvec.f90 /exe:VectMult
VectMult
```

When you compare the timing of the two runs, you may see that the vectorized version runs faster. The time for the non-vectorized version is only slightly faster than would be obtained by compiling with the O1 option.

**Obstacles to Vectorization**

The following do not always prevent vectorization, but frequently either prevent it or cause the compiler to decide that vectorization would not be worthwhile.

- **Non-contiguous memory access:** Four consecutive integers or floating-point values, or two consecutive doubles, may be loaded directly from memory in a single SSE instruction. But if the four integers are not adjacent, they must be loaded separately using multiple instructions, which is considerably less efficient. The most common examples of non-contiguous memory access are loops with non-unit stride or with indirect addressing, as in the examples below. The compiler rarely vectorizes such loops, unless the amount of computational work is large compared to the overhead from non-contiguous memory access.

**Example: Non-contiguous Memory Access**

```fortran
! arrays accessed with stride 2
do I=1,SIZE,2; B(I)=B(I)+(A(I)*X(I)); end do

! inner loop accesses a A with stride SIZE
do J=1,SIZE
   do I=1,SIZE
```
The typical message from the vectorization report is: vectorization possible but seems inefficient, although indirect addressing may also result in the following report: Existence of vector dependence.

- **Data dependencies**: Vectorization entails changes in the order of operations within a loop, since each SIMD instruction operates on several data elements at once. Vectorization is only possible if this change of order does not change the results of the calculation.

  - The simplest case is when data elements that are written (stored to) do not appear in any other iteration of the individual loop. In this case, all the iterations of the original loop are independent of each other, and can be executed in any order, without changing the result. The loop may be safely executed using any parallel method, including vectorization. All the examples considered so far fall into this category.

  - When a variable is written in one iteration and read in a subsequent iteration, there is a "read-after-write" dependency, also known as a flow dependency, as in this example:

    **Example: Flow Dependency**

    ```fortran
    A(2)=A(1)+1
    A(3)=A(2)+1
    A(4)=A(3)+1
    A(5)=A(4)+1
    ```

    So the value of j gets propagated to all A(J). This cannot safely be vectorized: if the first two iterations are executed simultaneously by a SIMD instruction, the value of A(2) is used by the second iteration before it has been calculated by the first iteration.

  - When a variable is read in one iteration and written in a subsequent iteration, this is a write-after-read dependency, also known as an anti-dependency, as in the following example:

    **Example: Write-after-read Dependency**

    ```fortran
do J=2,MAX; A(J-1)=A(J)+1; end do
    ! this is equivalent to:
    A(1)=A(2)+1
    A(2)=A(3)+1
    A(3)=A(4)+1
    A(4)=A(5)+1
    ```

    This write-after-read dependency is not safe for general parallel execution, since the iteration with the write may execute before the iteration with the read. However, for vectorization, no iteration with a higher value of j can complete before an iteration with a lower value of j, and so vectorization is safe (that is, it gives the same result as non-vectorized code) in this case. The following example, however, may not be safe, since vectorization might cause some elements of A to be overwritten by the first SIMD instruction before being used for the second SIMD instruction.

    **Example: Unsafe Vectorization**

    ```fortran
do J=1,MAX
    A(J-1)=A(J)+1
    B(J)=A(J)*2
    ```
Example: Unsafe Vectorization

```
end do

! this is equivalent to:
A(1)=A(2)+1
A(2)=A(3)+1
A(3)=A(4)+1
A(4)=A(5)+1
```

- Read-after-read situations are not really dependencies, and do not prevent vectorization or parallel execution. If a variable is unwritten, it does not matter how often it is read.
- Write-after-write, or ‘output’, dependencies, where the same variable is written to in more than one iteration, are in general unsafe for parallel execution, including vectorization.
- One important exception, that apparently contains all of the above types of dependency:

Example: Dependency Exception

```
MYSUM=0
do J=1,MAX; MYSUM = MYSUM + A(J)*B(J); end do
```

Although MYSUM is both read and written in every iteration, the compiler recognizes such reduction idioms, and is able to vectorize them safely. The loop in the first example was another example of a reduction, with a loop-invariant array element in place of a scalar.

These types of dependencies between loop iterations are sometimes known as loop-carried dependencies.

The above examples are of proven dependencies. The compiler cannot safely vectorize a loop if there is even a potential dependency. Consider the following example:

Example: Potential Dependency

```
real, pointer :: A(:),B(:),C(:)
...
do I=1,SIZE; C(I)=A(I)*B(I); end do
```

In the above example, the compiler needs to determine whether, for some iteration I, C(I) might refer to the same memory location as A(I) or B(I) for a different iteration. Such memory locations are sometimes said to be aliasing. For example, if A(I) pointed to the same memory location as C(I-1), there would be a read-after-write dependency as in the earlier example. If the compiler cannot exclude this possibility, it will not vectorize the loop unless you provide the compiler with hints. You can also avoid this problem by making the arrays ALLOCATABLE instead of POINTER, as the compiler knows these cannot be aliased.

Vectorization and Loops

This topic provides more information on the interaction between the auto-vectorizer and loops.

Interactions with Loop Parallelization

Combine the [Q]parallel and [Q]x options to instruct the Intel® Fortran Compiler to attempt both Auto-Parallelization and automatic loop vectorization in the same compilation.
NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and OS X*), or [Q]x.

NOTE
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows*), -m (Linux* and OS X*), or [Q]x.

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

In some rare cases, a successful loop parallelization (either automatically or by means of OpenMP* directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where the qopt-report:2qopt-report-phase:vec (Windows) or qopt-report=2qopt-report-phase=vec (Linux and OS X) options indicate that loops were not successfully vectorized.

Types of Vectorized Loops
For integer loops, the 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) and the Intel® Advanced Vector Extensions (Intel® AVX) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types, with limited support for the 64-bit integer data type.

Vectorization may proceed if the final precision of integer wrap-around arithmetic is preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the Intel® SSE and the Intel® AVX instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators:

- addition (+)
- subtraction (-)
- multiplication (*)
- division (/)

Additionally, Intel® SSE provide SIMD instructions for the binary MIN and MAX and unary SQRT operators. SIMD versions of several other mathematical operators (like the trigonometric functions SIN, COS, and TAN) are supported in software in a vector mathematical run-time library that is provided with the Intel® Fortran C ++ Compiler.

To be vectorizable, loops must be:

- **Countable**: The loop trip count must be known at entry to the loop at runtime, though it need not be known at compile time (that is, the trip count can be a variable but the variable must remain constant for the duration of the loop). This implies that exit from the loop must not be data-dependent.

- **Innermost loop of a nest**: The only exception is if an original outer loop is transformed into an inner loop as a result of some other prior optimization phase, such as unrolling, loop collapsing or interchange, or an original outermost loop is transformed to an innermost loop due to loop materialization.
- **Without function calls**: Even a `print` statement is sufficient to prevent a loop from getting vectorized. The vectorization report message is typically: non-standard loop is not a vectorization candidate. The two major exceptions are for intrinsic math functions and for functions that may be inlined.

Intrinsic math functions such as `sin()`, `log()`, `fmax()`, and so on, are allowed, because the compiler runtime library contains vectorized versions of these functions. See the table below for a list of these functions; most exist in both float and double versions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>acos</code></td>
<td><code>ceil</code></td>
<td><code>fabs</code></td>
<td><code>round</code></td>
</tr>
<tr>

<tr>
<td><code>cbrt</code></td>
<td><code>exp2</code></td>
<td><code>pow</code></td>
<td></td>
</tr>
</tbody>
</table>

The loop in the following example may be vectorized because `sqrt()` is vectorizable and `func()` gets inlined. Inlining is enabled at default optimization for functions in the same source file. An inlining report may be obtained by setting the options `Qopt-report=2Qopt-report-phase:ipo` (Windows) or `qopt-report=2qopt-report-phase=ipo` (Linux).

**Statements in the Loop Body**

The vectorizable operations are different for floating-point and integer data.

**Integer Array Operations**

The statements within the loop body may be arithmetic or logical operations (again, typically for arrays). Arithmetic operations are limited to such operations as addition, subtraction, `ABS`, `MIN`, and `MAX`. Logical operations include bitwise `AND`, `OR`, and `XOR` operators. You can mix data types but this may potentially cost you in terms of lowering efficiency.

**Other Operations**

No statements other than the preceding floating-point and integer operations are valid. The loop body cannot contain any function calls other than the ones described above.

**Data Dependency**

Data dependency relations represent the required ordering constraints on the operations in serial loops. Because vectorization rearranges the order in which operations are executed, any auto-vectorizer must have at its disposal some form of data dependency analysis.

An example where data dependencies prohibit vectorization is shown below. In this example, the value of each element of an array is dependent on the value of its neighbor that was computed in the previous iteration.

**Example 1: Data-dependent Loop**

```fortran
subroutine dep(data, n)
  real :: data(n)
  integer :: i
  do i = 1, n-1
    data(i) = data(i-1)*0.25 + data(i)*0.5 + data(i+1)*0.25
  end do
end subroutine dep
```
The loop in the above example is not vectorizable because the WRITE to the current element DATA(I) is dependent on the use of the preceding element DATA(I-1), which has already been written to and changed in the previous iteration. To see this, look at the access patterns of the array for the first two iterations as shown below.

**Example 2: Data-dependency Vectorization Patterns**

I=1: READ DATA(0)
    READ DATA(1)
    READ DATA(2)
    WRITE DATA(1)
I=2: READ DATA(1)
    READ DATA(2)
    READ DATA(3)
    WRITE DATA(2)

In the normal sequential version of this loop, the value of DATA(1) read from during the second iteration was written to in the first iteration. For vectorization, it must be possible to do the iterations in parallel, without changing the semantics of the original loop.

**Example 3: Data Independent Loop**

    do i=1,100
        a(i)=b(i)
    end do

    ! which has the following access pattern
    read b(1)
    write a(1)
    read b(2)
    write b(2)

**Data Dependency Analysis**

Data dependency analysis involves finding the conditions under which two memory accesses may overlap. Given two references in a program, the conditions are defined by:

- whether the referenced variables may be aliases for the same (or overlapping) regions in memory.
- for array references, the relationship between the subscripts.

The data dependency analyzer for array references is organized as a series of tests, which progressively increase in power as well as in time and space costs.

First, a number of simple tests are performed in a dimension-by-dimension manner, since independency in any dimension will exclude any dependency relationship. Multidimensional arrays references that may cross their declared dimension boundaries can be converted to their linearized form before the tests are applied.

Some of the simple tests that can be used are the fast greatest common divisor (GCD) test and the extended bounds test. The GCD test proves independency if the GCD of the coefficients of loop indices cannot evenly divide the constant term. The extended bounds test checks for potential overlap of the extreme values in subscript expressions.

If all simple tests fail to prove independency, the compiler will eventually resort to a powerful hierarchical dependency solver that uses Fourier-Motzkin elimination to solve the data dependency problem in all dimensions.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or
Optimization Notice

effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Loop Constructs
Loops can be formed with the usual DO-END DO and DO WHILE, or by using an IF/GOTO and a label. Loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized.

Example: Vectorizable structure

```
subroutine vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
    if (a(i) .lt. 0.0) a(i) = 0.0
    i = i + 1
  enddo
end subroutine vec
```

The following example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.

Example: Non-vectorizable structure

```
subroutine no_vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
    ! The next statement allows early exit from the loop and prevents vectorization of the loop.
    if (a(i) .lt. 0.0) go to 10
    i = i + 1
  enddo
end subroutine no_vec
```
<table>
<thead>
<tr>
<th>Example: Non-vectorizable structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>enddo</td>
</tr>
<tr>
<td>10 continue</td>
</tr>
<tr>
<td>end subroutine no_vecN</td>
</tr>
<tr>
<td>END</td>
</tr>
</tbody>
</table>

### Loop Exit Conditions

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable; in other words, the number of iterations must be expressed as one of the following:

- A constant.
- A loop invariant term.
- A linear function of outermost loop indices.

In the case where a loops exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable.

<table>
<thead>
<tr>
<th>Example: Countable Loop</th>
</tr>
</thead>
<tbody>
<tr>
<td>subroutine cnt1 (a, b, c, n, lb)</td>
</tr>
<tr>
<td>dimension a(n), b(n), c(n)</td>
</tr>
<tr>
<td>integer n, lb, i, count</td>
</tr>
<tr>
<td>! Number of iterations is &quot;n - lb + 1&quot;</td>
</tr>
<tr>
<td>count = n</td>
</tr>
<tr>
<td>do while (count .ge. lb)</td>
</tr>
<tr>
<td>a(i) = b(i) * c(i)</td>
</tr>
<tr>
<td>count = count - 1</td>
</tr>
<tr>
<td>i = i + 1</td>
</tr>
<tr>
<td>enddo ! lb is not defined within loop</td>
</tr>
<tr>
<td>end</td>
</tr>
</tbody>
</table>

The following example demonstrates a different countable loop construct.

<table>
<thead>
<tr>
<th>Example: Countable Loop</th>
</tr>
</thead>
<tbody>
<tr>
<td>! Number of iterations is (n-m+2)/2</td>
</tr>
<tr>
<td>subroutine cnt2 (a, b, c, m, n)</td>
</tr>
<tr>
<td>dimension a(n), b(n), c(n)</td>
</tr>
<tr>
<td>integer i, l, m, n</td>
</tr>
<tr>
<td>i = 1;</td>
</tr>
<tr>
<td>do l = m,n,2</td>
</tr>
<tr>
<td>a(i) = b(i) * c(i)</td>
</tr>
<tr>
<td>i = i + 1</td>
</tr>
<tr>
<td>enddo</td>
</tr>
<tr>
<td>end</td>
</tr>
</tbody>
</table>

The following examples demonstrates a loop construct that is non-countable due to dependency loop variant count value.

<table>
<thead>
<tr>
<th>Example: Non-Countable Loop</th>
</tr>
</thead>
<tbody>
<tr>
<td>! Number of iterations is dependent on a(i)</td>
</tr>
<tr>
<td>subroutine foo (a, b, c)</td>
</tr>
<tr>
<td>dimension a(100), b(100), c(100)</td>
</tr>
<tr>
<td>integer i</td>
</tr>
<tr>
<td>i = 1</td>
</tr>
</tbody>
</table>
Strip-mining and Cleanup

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encodings of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- By increasing the temporal and spatial locality in the data cache if the data are reusable in different passes of an algorithm.
- By reducing the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. In the case of Streaming SIMD Extensions, this vector or strip-length is reduced by four times: four floating-point data items per single Intel® SSE single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the following loop:

Example: Before Vectorization

```
i = 1
do while (i<=n)
    a(i) = b(i) + c(i) ! Original loop code
    i = i + 1
end do
```

The compiler might handle the strip mining and loop cleaning by restructuring the loop in the following manner:

Example: After Vectorization

```
! The vectorizer generates the following two loops
i = 1
do while (i < (n - mod(n,4)))
    ! Vector strip-mined loop.
    a(i:i+3) = b(i:i+3) + c(i:i+3)
    i = i + 4
end do

do while (i <= n)
    a(i) = b(i) + c(i) ! Scalar clean-up loop
    i = i + 1
end do
```

Loop Blocking

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, thereby maximizing data reuse.
Consider the following example. The two-dimensional array $A$ is referenced in the $j$ (column) direction and then in the $i$ (row) direction (column-major order); array $B$ is referenced in the opposite manner (row-major order). Assume the memory layout is in column-major order; therefore, the access strides of array $A$ and $B$ for the code would be 1 and $\text{MAX}$, respectively. $\text{BS} = \text{block}\_\text{size}; \text{MAX}$ must be evenly divisible by $\text{BS}$.

Consider the following loop example code:

**Example: Original loop**

```fortran
REAL A(MAX,MAX), B(MAX,MAX)
DO I = 1, MAX
  DO J = 1, MAX
    A(I,J) = A(I,J) + B(J,I)
  ENDDO
ENDDO
```

The arrays could be blocked into smaller chunks so that the total combined size of the two blocked chunks is smaller than the cache size, which can improve data reuse. One possible way of doing this is demonstrated below:

**Example: Transformed Loop after blocking**

```fortran
REAL A(MAX,MAX), B(MAX,MAX)
DO I = 1, MAX, BS
  DO J = 1, MAX, BS
    DO II = I, I+MAX, BS-1
      DO JJ = J, J+MAX, BS-1
        A(II, JJ) = A(II, JJ) + B(JJ, II)
      ENDDO
    ENDDO
  ENDDO
ENDDO
```

**Loop Interchange and Subscripts: Matrix Multiply**

Loop interchange is often used for improving memory access patterns. Matrix multiplication is commonly written as shown in the following example:

**Example: Typical Matrix Multiplication**

```fortran
subroutine matmul_slow(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do i = 1, n
    do j = 1, n
      do k = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j);
      end do
    end do
  end do
end subroutine matmul_slow
```

The use of $B(K,J)$ is not a stride-1 reference and therefore will not be vectorized efficiently. If the loops are interchanged, however, all the references will become stride-1 as shown in the following example.
Example: Matrix Multiplication with Stride-1

```fortran
subroutine matmul_fast(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do j = 1, n
    do k = 1, n
      do i = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      enddo
    enddo
  enddo
end subroutine matmul_fast
```

Interchanging is not always possible because of dependencies, which can lead to different results.

### User-mandated or SIMD Vectorization

User-mandated or SIMD vectorization supplements automatic vectorization just like OpenMP* parallelization supplements automatic parallelization. The following figure illustrates this relationship. User-mandated vectorization is implemented as a single-instruction-multiple-data (SIMD) feature and is referred to as SIMD vectorization.

**NOTE**

The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and OS X*), or `[Q]x`.

The following figure illustrates how SIMD vectorization is positioned among various approaches that you can take to generate vector code that exploits vector hardware capabilities. The programs written with SIMD vectorization are very similar to those written using auto-vectorization hints. You can use SIMD vectorization to minimize the amount of code changes that you may have to go through in order to obtain vectorized code.
SIMD vectorization uses the !DIR$ SIMD directive to effect loop vectorization. You must add this directive to a loop and recompile for the loop to get vectorized (the option [Q]simd is enabled by default).

Consider an example in Fortran where the compiler does not automatically vectorize the loop due to the unknown data dependence distance "X". You can use the data dependence assertion via the auto-vectorization hint !DIR$ IVDEP, to let the compiler decide to vectorize the loop or not, or you can enforce vectorization of the loop using !DIR$ SIMD.

**Example: without !DIR$ SIMD**

[D:/simd] cat example1.f
subroutine add(A, N, X)
integer N, X
real    A(N)
DO I=X+1, N
   A(I) = A(I) + A(I-X)
ENDDO
end

[D:/simd] ifort example1.f -nologo -Qvec-report2
D:\simd\example1.f(6): (col. 9) remark: loop was not vectorized: existence of vector dependence.

**Example: with !DIR$ SIMD**

[D:/simd] cat example1.f
subroutine add(A, N, X)
integer N, X
real    A(N)
!DIR$ SIMD
DO I=X+1, N
   A(I) = A(I) + A(I-X)
ENDDO
end
The one big difference between using the SIMD directive and auto-vectorization hints is that with the SIMD directive, the compiler generates a warning when it is unable to vectorize the loop. With auto-vectorization hints, actual vectorization is still under the discretion of the compiler, even when you use the !DIR$ VECTOR ALWAYS hint.

The SIMD directive has optional clauses to guide the compiler on how vectorization must proceed. Use these clauses appropriately so that the compiler obtains enough information to generate correct vector code. For more information on the clauses, see the !DIR$ SIMD description.

Additional Semantics

Note the following points when using !DIR$ SIMD directive.

- A variable may belong to at most one of private, linear, or reduction (or none of them).
- Within the vector loop, an expression is evaluated as a vector value if it is private, linear, reduction, or it has a sub-expression that is evaluated to a vector value. Otherwise, it is evaluated as a scalar value (that is, broadcast the same value to all iterations). Scalar value does not necessarily mean loop invariant, although that is the most frequently seen usage pattern of scalar value.
- A vector value may not be assigned to a scalar L-value. It is an error.
- A scalar L-value may not be assigned under a vector condition. It is an error.
- The computed GOTO statement is not supported.

Using vector Declaration

Consider the following Intel® Visual Fortran example code for a program to compare serial and vector computations using a user-defined function, foo().

---

**Example: Where user-defined function is not vectorized**

```fortran
!! file simdmain.f90
program simdtest
! Test vector function in external file.
implicit none
interface
    integer function foo(a, b)
    integer a, b
    end function foo
end interface
integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1
integer, dimension(M,N) :: a2
integer, dimension(M,N) :: s_a3
integer, dimension(M,N) :: v_a3
logical :: err_flag = .false.

! compute random numbers for arrays
```
Example: Where user-defined function is not vectorized

```fortran
Example: Where user-defined function is not vectorized

do j = 1, N
do i = 1, M
    a1(i,j) = rand() * M
    a2(i,j) = rand() * M
end do
end do

! compute serial results
do j = 1, N
!dir$ novector
    do i = 1, M
        s_a3(i,j) = foo(a1(i,j), a2(i,j))
    end do
end do

! compute vector results
do j = 1, N
    do i = 1, M
        v_a3(i,j) = foo(a1(i,j), a2(i,j))
    end do
end do

! compare serial and vector results
do j = 1, N
    do i = 1, M
        if (s_a3(i,j) .ne. v_a3(i,j)) then
            err_flag = .true.
            print *, s_a3(i, j), v_a3(i,j)
        end if
    end do
end do

if (err_flag .eq. .true.) then
    write(*,*) "FAILED"
else
    write(*,*) "PASSED"
end if
end program

!! file: vecfoo.f90
integer function foo(a, b)
    implicit none
    integer, intent(in) :: a, b
    foo = a - b
end function
```

When you compile the above code, the loop containing the `foo()` function is not auto-vectorized because the auto-vectorizer does not know what `foo()` does unless it is inlined to this call site.

In such cases where the function call is not inlined, you can use the `!DIRS` attributes `vector::function-name-list` declaration to vectorize the loop and the function `foo()`. All you need to do is add the vector declaration to the function declaration, and recompile the code. The loop and function are vectorized.
Example: Where loop with user-defined function with vector declaration is auto-vectorized

```f90
!! file simdmain.f90
program simdtest
! Test vector function in external file.
implicit none
interface
  integer function foo(a, b)
!dir$ attributes vector :: foo
  integer a, b
  end function foo
end interface

integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1, a2, s_a3, v_a3
logical :: err_flag = .false.

! compute random numbers for arrays
do j = 1, N
  do i = 1, M
    a1(i,j) = rand() * M
    a2(i,j) = rand() * M
  end do
end do

! compute serial results
!dir$ novector
do j = 1, N
  s_a3(i,j) = foo(a1(i,j), a2(i,j))
end do

! compute vector results
do j = 1, N
  v_a3(i,j) = foo(a1(i,j), a2(i,j))
end do

! compare serial and vector results
do j = 1, N
  do i = 1, M
    if (s_a3(i,j) .ne. v_a3(i,j)) then
      err_flag = .true.
      print *, s_a3(i, j), v_a3(i,j)
    end if
  end do
end do
if (err_flag .eq. .true.) then
  write(*,*) "FAILED"
else
  write(*,*) "PASSED"
end if
```

Example: Where loop with user-defined function with vector declaration is auto-vectorized

```fortran
end program

!! file: vecfoo.f90
integer function foo(a, b)
!dir$ attributes vector :: foo
implicit none
integer, intent(in) :: a, b
foo = a - b
end function

[49 C:/temp] ifort -Qvec-report simdmain.f90 vecfoo.f90 simdmain.f90 vecfoo.f90
C:\temp\simdmain.f90(3): (col. 3) remark: LOOP WAS VECTORIZED.
C:\temp\vecfoo.f90(3): (col. 3) remark: FUNCTION WAS VECTORIZED.
```

Restrictions on Using vector declaration

Vectorization depends on two major factors: hardware and the style of source code. When using the vector declaration, the following features are not allowed:

- Thread creation and joining through `_Cilk_spawn`, `_Cilk_for`, OpenMP* parallel/for/sections/task, and explicit threading API calls
- Using setjmp, longjmp, EH, SEH
- Inline ASM code and VML
- Calling non-vector functions (note that all SVML functions are considered vector functions)
- Locks, barriers, atomic construct, critical sections (presumably this is a special case of the previous one)
- The GOTO statement
- Intrinsics (for example, SVML intrinsics)
- Function call through function pointer and virtual function
- Any loop/array notation constructs
- Struct access
- The computed GOTO statement is not supported

Formal parameters must be of the following data types:

- (un)signed 8, 16, 32, or 64-bit integer
- 32- or 64-bit floating point
- 64- or 128-bit complex

SIMD Loop Directive directive
Function Annotations and the SIMD Directive for Vectorization

Function Annotations and the SIMD Directive for Vectorization

This topic presents specific Fortran language features that better help to vectorize code.

**NOTE**

The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and OS X*), or `[Q]x`. 
The `!DIR$ ATTRIBUTES ALIGN: N` directive enables you to overcome hardware alignment constraints. The `restrict` qualifier and the auto-vectorization hints address the stylistic issues due to lexical scope, data dependency, and ambiguity resolution. The SIMD feature's directive allows you to enforce vectorization of loops.

You can use the `!DIR$ ATTRIBUTES VECTOR[:clauses]::function-name-list` directive to vectorize user-defined functions and loops. For SIMD usage, a function with the `VECTOR` attribute is called from a loop that is being vectorized.

You can use the `cord declarations to provide a user-defined vector implementation for a function.`

The usage model of the `VECTOR` attribute is that the code generated for the function actually takes a small section ( `VECTORLENGTH` ) of the array, by value, and exploits SIMD parallelism, whereas the implementation of task parallelism is done at the call site.

The following table summarizes the language features that help vectorize code.

<table>
<thead>
<tr>
<th>Language Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>!DIR$ ATTRIBUTES ALIGN : n :: var</code></td>
<td>Directs the compiler to align the variable to an <code>n</code>-byte boundary. Address of the variable is <code>address mod n=0</code>.</td>
</tr>
<tr>
<td><code>!DIR$ ATTRIBUTES VECTOR [: clauses] :: function-name-list</code></td>
<td>Provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. The clauses are:</td>
</tr>

Guided Auto Parallelism Overview

The Guided Auto Parallelism (GAP) feature of the Intel® Fortran Compiler is a tool that offers selective advice to improve the performance of serially-coded applications by suggesting changes that will take advantage of the compiler’s ability to automatically vectorize and parallelize your code as well as improve the efficiency of data operations. Despite having the words “auto parallelism” in the name, this tool does not require you to implement threaded code in order to improve the execution performance of your code nor does it require that your code is already threaded or parallel code.

You do not need to use any advanced optimization techniques such as inter-procedural analysis or profile-guided feedback to use this feature. Using the [Q]guide set of options in addition to the compiler options you normally use is sufficient to enable the GAP feature, with the requirement that you must compile with -O2 or higher optimization levels. The compiler does not generate any object files or executables during the GAP run.

In debug mode (/Zi on Windows* OS, -g on Linux* OS), the compiler’s optimization level defaults to /Od (on Windows* OS) or -O0 (on Linux* OS and OS X*); thus O2 (or a higher level optimization) must be specified explicitly on the command-line.

NOTE
You can use the [Q]diag-disable option along with the [Q]guide option to direct the compiler to suppress specific diagnostic messages.

For example, the options:

// (Windows* OS) /Qguide, /Qdiag-disable:30534

// (Linux* OS and OS X*)
-guide, -diag-disable:30534

tells the compiler not to emit the 30534 diagnostic. The [Q]diag-disable mechanism works the same way as it does for compiler-warnings.

If you decide to follow the advice offered by the GAP tool by making the suggested code changes and/or using the suggested compiler options, you must then recompile the program without the [Q]guide option.

Any advice generated by the compiler when using the GAP tool is optional; you can either implement it or reject it. The advice typically falls under three broad categories:

- **Advice for source modifications:** The compiler advises you to make source changes that are localized to a loop-nest or a routine. For example, the tool may recommend that you use a local-variable for the upper-bound of a loop or that you should initialize a local variable unconditionally at the top of the loop-body.

- **Advice to apply directives:** The compiler advises you to apply a new directive on a certain loop-level if the directive semantics can be satisfied (you must verify this). In many cases, you may be able to apply the directive (thus implicitly asserting new program/loop properties) that the compiler can then take advantage of to perform enhanced optimizations.

- **Advice to add compiler options:** The compiler advises you to add command-line options that assert new properties.

NOTE
These suggested compiler options apply to the entire file. It is your responsibility to check that the properties asserted by these options are valid for the entire file, and not just the loop in question.
If you use GAP options along with option [Q]parallel, the compiler may suggest options to further parallelize your application. The compiler may also offer advice on enabling other optimizations of your application, including vectorization.

If you use the GAP options without enabling auto parallelism (without using the [Q]parallel option), the compiler may only suggest enabling optimizations such as vectorization for your application. This approach is recommended when you wish to improve the performance of a single-threaded code without the use of parallelization or when you want to improve the performance of threaded applications that do not rely on the compiler for auto parallelism.

Using Guided Auto Parallelism

The Guided Auto Parallelism feature of the Intel® Fortran Compiler is a tool offering selective advice to improve the performance of serially-coded applications. The tool suggests changes that take advantage of the compiler’s ability to automatically vectorize and parallelize code as well as improve the efficiency of data operations. The tool does not require that you implement threaded code to improve the execution performance of your code, nor does it require that your code is already threaded or parallel code.

To invoke this tool, use the compiler option [Q]guide [=n]. Using this option causes the compiler to generate messages suggesting ways to optimize the performance of your application. You can also use more specific compiler options such as [Q]guide-vec, [Q]guide-par, and [Q]guide-data-trans, to perform individual guided optimizations for vectorizing, parallelizing, and data transformation of your application.

When any guided auto parallelism option is used, the compiler provides only diagnostic advice. Object files or executables are not created in this mode. See the table below for descriptions of the options.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]guide</td>
<td>Allows you to set a level of guidance for auto-vectorization and data transformation analysis. To obtain guidance for auto parallelism, you must use the [Q]parallel option along with the [Q]guide option. Allows you to set a level of guidance only for auto parallelism analysis.</td>
</tr>
<tr>
<td>[Q]guide-par</td>
<td>NOTE You must use the [Q]parallel option along with the [Q]guide-par option to get this advice.</td>
</tr>
<tr>
<td>[Q]guide-vec</td>
<td>Allows you to set a level of guidance for auto-vectorization analysis only.</td>
</tr>
<tr>
<td>[Q]guide-data-trans</td>
<td>Allows you to set a level of guidance for data transformation analysis only.</td>
</tr>
</tbody>
</table>

For all of the above options, the optional argument n specifies the level of guidance. The argument n takes the values 1-4. When n is not specified, the default is 4. If you specify n=1 or 2, a standard level of guidance is provided.

When you use n=3 or n=4, you may get advanced messages. For example, you may get messages about how to optimize a particular loop-nest or get a message on how exception-handling inside a loop-nest affects optimizations for that loop-nest. Or you may get a message on how to provide extra information to the compiler on cost-modeling (expected values of trip-counts, and so on).

If you simultaneously specify a level of guidance for the general [Q]guide option and also for one or more of the other specific guide options, the level of guidance (n) for the specific guide option overrides the general [Q]guide option setting.
If you do not specify a level of guidance for the general \texttt{[Q]guide} option, but do set a level of guidance for one or more of the specific guide options, the \texttt{[Q]guide} option is set equal to the greatest value passed to the specific guide options.

**Capturing Guidance Messages**

The guided auto parallelism tool analyzes all of your serial code or individual parts of your code and generates advisory messages. By default, messages that are generated by the guided auto parallelism tool are output to \texttt{stderr}.

To capture messages in a file, use the options listed in the following table.

\begin{table}[h]
\centering
\begin{tabular}{|l|p{0.7\textwidth}|}
\hline
Syntax & Description \\
\hline \texttt{[Q]guide-file} & Gathers all messages generated during a guided auto-parallelization run into the specified file. \\
\texttt{[Q]guide-file-append} & Allows you to specify the file into which all messages generated during a guided auto parallelism run should be appended. \\
\hline
\end{tabular}
\end{table}

For the above options, the \texttt{file_name} argument can also include a path. If a path is not specified, the file is created in the current working directory. If there is already a file named \texttt{file_name}, it is overwritten when you use the \texttt{[Q]guide-file} option. If you do not include an extension as part of the \texttt{file_name}, the extension \texttt{.guide} is appended.

**Configuring Code Regions for GAP Messages**

To limit guided auto parallelism analysis to specific regions (hotspots) in your application, use the options mentioned in the table below.

\begin{table}[h]
\centering
\begin{tabular}{|l|p{0.7\textwidth}|}
\hline
Syntax & Description \\
\hline \texttt{[Q]guide-opts} & Allows you to analyze specified code elements, identified by \texttt{string}. \\
\texttt{[Q]guide-profile} & Allows you to specify a loop profiler data file (or a set of files) when used with \texttt{[Q]guide} option. \\
\hline
\end{tabular}
\end{table}

You must use the \texttt{[Q]guide-opts} option along with one of the guided auto parallelism options, such as \texttt{[Q]guide}, \texttt{[Q]guide-vec}, \texttt{[Q]guide-par}, and \texttt{[Q]guide-data-trans}. Use the \texttt{string} parameter to provide information about known areas of interest (hotspots). The \texttt{string} parameter takes one or more of the following variables: \texttt{filename}, \texttt{routine}, \texttt{range}. The compiler parses the \texttt{string} parameter and generates syntax errors if there are any.

**Windows* OS Syntax**

\texttt{/Qguide-opts:string}

**Linux* OS and OS X* Syntax**

\texttt{-guide-opts=string}

Follow these guidelines when using the \texttt{string} parameter:

- Use only valid file names, routine names, and line numbers. The guided auto parallelism tool ignores invalid values and issues a diagnostic message stating what was ignored.
• Enclose routine names within single quotation marks. Specify original source names (demangled names) as routine names. A routine name alone may not always be sufficient to uniquely identify a routine. You may need to specify additional parameter information to uniquely identify the routine. For example:

**Linux* OS and OS X***:

```
-guide-opts="foo.cpp,'CLHEP::StaticRandomSta::restore(std::basic_istream<char,std::char_traits<char>>&)'"
-guide-opts="bar.f90,'module_1::routine_name'"
-guide-opts="baz.c,'c_routine_name'"
```

**Windows* OS**:

```
/Qguide-opts:"foo.cpp,'CLHEP::StaticRandomSta::restore(std::basic_istream<char,std::char_traits<char>>&)'"
/Qguide-opts:"bar.f90,'module_1::routine_name'"
/Qguide-opts:"baz.c,'c_routine_name'"
```

For any specified routine name, the GAP tool first tries to uniquely identify the routine using specified routine information. If that is not possible, then it selects all routines with the specified routine name. The GAP tool uses the parameter information, if specified, to narrow the selection.

• When inlining is involved, use the callee line numbers. The generated messages also use the callee line numbers.

Alternatively, you can automate and narrow down the targeted regions to specific hotspots in your application code by using the `[Q]guide-profile` option with the `[Q]guide` option.

**Windows* OS Syntax**

```
/Qguide-profile:filename | dir [, [filename|dir]...]
```

**Linux* OS and OS X*** Syntax

```
-guide-profile=filename | dir [, [filename|dir] ... ]
```

The region targeted by the `[Q]guide` option, when used along with the `[Q]guide-profile` option, is configured by processing the XML data file(s) produced from a loop-profiler-instrumented run. The loop profiler result files are specified as the actual loop profiler data file, or as the directory name where loop profile data files are stored.

**Guided Auto Parallelism Messages**

**Guided Auto Parallelism Messages Overview**

The Guided Auto Parallelism (GAP) messages provide advice that should improve optimizations.

The messages provide suggestions for:

• Automatic parallelization of loop nests
Automatic vectorization of inner loops
Data transformation

You must decide whether to follow a particular suggestion. For example, if the advice is to apply a particular directive, you must understand the semantics of the directive and carefully consider whether it can be safely applied to the loop (or loop nest) in question.

If you apply the directive improperly, the compiler may generate incorrect code, causing the application to execute incorrectly.

If you do not fully understand the suggested advice, please refer to the relevant topics in the compiler documentation before applying that advice.

Once you apply the suggested advice, the compiler assumes that it is correct and it does not perform any checks or issue any warnings.

In general, messages that relate to loops tend to target vectorization and/or parallelization of loops. If you are not familiar with loop optimizations, please refer to the compiler documentation on this kind of optimization.

Optimizations can be helped or hindered when data is fetched from or stored to memory. Sometimes these fetch and store operations are referred to as reads and writes, but do not confuse these with READ and WRITE input/output statements. A READ statement (input) is only one of many ways to cause a store to memory, and a WRITE statement (output) is only one of many ways to cause a fetch from memory. Values in an expression must be fetched from (read from) memory before the expression can be evaluated. Variables on the left-hand side of an assignment will be the target of a store to (write to) memory. Actual arguments passed to called procedures can be fetched from and stored to memory.

GAP Message (Diagnostic ID 30506)

Message
If the following operations(s) can be safely performed unconditionally, the loop at line %d will be vectorized by adding a "%s ivdep" statement right before the loop: %s.

Advice
Add "!DIR$ IVDEP" before the specified loop.

This directive enables the vectorization of the loop at the specified line. Insure that any conditional divide, sqrt, and inverse sqrt operations will not alter the exception semantics expected by the program when they are performed unconditionally.

Example
Consider the following:

```fortran
subroutine foo(a, n)
    integer n
    real a(n)
    do i=1,n
        if (a(i) .gt. 0) then
            a(i) = 1 / a(i)
        endif
    enddo
end
```
In this case, the compiler is unable to vectorize the loop since the condition "a(i) .gt. 0" may be guarding floating-point exceptions for the divide.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, n)
   integer n
   real a(n)
   !dir$ ivdep
   do i=1,n
      if (a(i) .gt. 0) then
         a(i) = 1 / a(i)
      endif
   enddo
end
```

**Verify**

Confirm that the program operands have safe values for all iterations.

**GAP Message (Diagnostic ID 30513)**

**Message**

Insert a "%s ivdep" statement right before the loop at line %d to vectorize the loop.

**Advice**

Add "!DIR$ IVDEP" before the specified loop. This directive enables the vectorization of the loop at the specified line by ignoring some of the assumed cross-iteration data dependencies.

**Example**

Consider the following:

```fortran
subroutine foo(a, m, n)
   real a(n)
   do i=1,n
      a(i) = a(i+m) + 1
   enddo
end
```

In this case, the compiler is unable to vectorize the loop because m could be -1, where each iteration is dependent on the previous iteration. If m is known to be positive, you can vectorize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, m, n)
   real a(n)
   !dir$ ivdep
   do i=1,n
      a(i) = a(i+m) + 1
   enddo
end
```

**Verify**

Confirm that any arrays in the loop do not have unsafe cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop. Make sure that there are no such dependencies, or that any cross-iteration dependencies can be safely ignored.
**GAP Message (Diagnostic ID 30515)**

**Message**
Assign a value to the variable(s) "\%s" at the beginning of the body of the loop in line \%d. This will allow the loop to be vectorized.

**Advice**
You should unconditionally initialize the scalar variables at the beginning of the specified loop. This allows the vectorizer to privatize those variables for each iteration and vectorize the loop. You must ensure that all the uses of those variables see the same values before and after the source code change.

**Example**
Consider the following:

```fortran
subroutine foo(a, n)
  integer n
  do i=1,n
    if (a(i) .gt. 0) then
      b = a(i)
      a(i) = 1 / a(i)
    endif
    if (a(i) .gt. 1) then
      a(i) = a(i) + b
    endif
  enddo
end
```

In this case, the compiler is unable to vectorize the loop because it failed to privatize the variable \(b\). Vectorization is assisted when assignment to \(b\) occurs in each iteration where the value of \(b\) is used. One of the ways to do this is to assign the value in every iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```fortran
subroutine foo(a, n)
  integer n
  real a(n), b
  do i=1,n
    b = a(i)
    if (a(i) .gt. 0) then
      a(i) = 1 / a(i)
    endif
    if (a(i) .gt. 1) then
      a(i) = a(i) + b
    endif
  enddo
end
```

**Verify**
Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

**GAP Message (Diagnostic ID 30519)**

**Message**
Insert a "\%s parallel" statement right before the loop at line \%d to parallelize the loop.
Advice
Add "$DIR$ PARALLEL" before the specified loop. This directive enables the parallelization of the loop at the specified line by ignoring assumed cross-iteration data dependencies.

Example
Consider the following:

```fortran
void foo(float *a, int m, int n) {
    int i;
    for (i=0; i<n; i++) {
        a[i] = a[i+m]+1;
    }
    return;
}
subroutine foo(a, m, n)
    real a(n)
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```

In this case, the compiler is unable to parallelize the loop without further information about \( m \). For example, if \( m \) is negative, then each iteration will be dependent on the previous iteration. However, if \( m \) is known to be greater than \( n \), you can parallelize the loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo(a, m, n)
    real a(n)
    !dir$ parallel
    do i=1,n
        a(i) = a(i+m) + 1
    enddo
end
```

Verify
Confirm that any arrays in the loop do not have cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop.

GAP Message (Diagnostic ID 30521)

Message
Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

Advice
Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

Example
Consider the following:

```fortran
subroutine foo (A, B, cond1, cond2)
    integer, parameter :: N = 100000
    integer I
```
in this case, the compiler does not parallelize the loop because it cannot privatize the variable \( t \) without further information. if you know that \( \text{cond1} \) or \( \text{cond2} \) is true, or both \( \text{cond1} \) and \( \text{cond2} \) are true, then you can assist the parallelizer by ensuring that any iteration that uses \( t \) also writes to \( t \) before its use in the same iteration. one of the ways to do this is to assign a value to \( t \) at the top of each iteration.

if you determine it is safe to do so, you can modify the program code as follows:

```fortran
subroutine foo (A, B, cond1, cond2)
    integer, parameter :: N = 100000
    integer I
    real(8) A(N), B(N), T
    logical cond1, cond2
    do I = 1, N
        T = 0
        if (cond1) T = i + 1
        if (cond2) T = i - 1
        A(I) = T
    end do
end
```

**Verify**

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

**See Also**

GAP Message (Diagnostic ID 30523)

GAP Message (Diagnostic ID 30522)

**Message**

Insert a "%s parallel private(%s)" statement right before the loop at line %d to parallelize the loop.

**Advice**

Add "DIR$ PARALLEL PRIVATE" before the specified loop. This directive enables the parallelization of the loop at the specified line.

In this case, the compiler does not parallelize the loop since it cannot determine whether \( m1 \geq m2 \).

If you know that this property is true, and that no element of \( W \) is fetched before it is written to after the loop, then you can use the recommended directive.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo (A, B, C, n, m1, m2)
    real (4) A(10000, 10), B(10000, 10), C(10000, 10)
    integer n, m1, m2
    real W(1000)
    integer i, j
    !DIR$ PARALLEL PRIVATE (W)
    do i=1,n
```

```
do j=1,m1
   \text{W}(j) = A(j,i) \times B(j,i)
end do
do j=1,m2
   C(j,i) = W(j) + 1.0
end do
end
```

**Verify**

Before an element of an array can be fetched in the loop, there must have been a previous store to it during the same loop iteration. In addition, if an element is fetched after the loop, there must have been a previous write to it before the fetch after the loop.

**GAP Message (Diagnostic ID 30523)**

**Message**

Assign a value to the variable(s) "\(\text{s}\)" at the beginning of the body of the loop in line \(\text{d}\). This will allow the loop to be parallelized.

**Advice**

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a PARALLEL directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

**Verify**

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration or have been privatized by means of the private clause of a PARALLEL directive.

**See Also**

GAP Message (Diagnostic ID 30521)

**GAP Message (Diagnostic ID 30525)**

**Message**

Insert a "\(\text{s}\) loop count min(\(d\))" statement right before the loop at line \(\text{d}\) to parallelize the loop.

**Advice**

Add "!DIR$ LOOP COUNT" before the specified loop. This directive indicates the minimum trip count (number of iterations) of the loop that enables the parallelization of the loop.

**Example**

Consider the following:

```
subroutine foo (n)
   integer, parameter :: N2 = 10000
   real (8) :: A(N2), B(N2)
   integer :: i
   do i =1, n
      A(i) = B(i) \times B(i)
   end do
end subroutine foo
```
In this case, if the trip count of the loop at line 5 is greater than 128, then use the LOOP COUNT directive to parallelize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```fortran
subroutine foo (n)
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    integer :: i
    !dir$ loop count min(128)
    do i =1, n
        A(i) = B(i) * B(i)
    end do
end subroutine foo
```

Make sure that the loop has a minimum of 128 iterations.

**Verify**

Confirm that the loop has the minimum number of iterations, as specified in the diagnostic message.

**See Also**

*Guided Auto Parallelism Messages Overview* provides advice for improving optimizations

**GAP Message (Diagnostic ID 30526)**

**Message**

To parallelize the loop at line %d, annotate the routine %s with %s.

**Advice**

If the loop contains a call to a function, the compiler cannot parallelize the loop without more information about the function being called.

However, if the function being called in the loop is an elemental function or a function specified with `ATTRIBUTES CONCURRENCY_SAFE`, then the call does not inhibit parallelization of the loop.

**Example**

Consider the following:

```fortran
subroutine foo ()
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    interface
        function bar (k)
            integer :: bar, k
        end function bar
    end interface
    integer :: i
    do i =1, N2
        A(i) = B(i) * bar(N2)
    end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine `bar` as elemental.

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```fortran
subroutine foo ()
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    interface
```

```
```
Example
Consider the following:

Verify
Confirm the routine satisfies the semantics of this annotation. A weaker annotation able to achieve a similar effect is `ATTRIBUTES CONCURRENCY_SAFE(PROFITABLE)`.

See Also
GAP Message (Diagnostic ID 30528)

GAP Message (Diagnostic ID 30528)

Message
Add "%s" to the declaration of routine "%s" in order to parallelize the loop at line %d. Adding "%s" achieves a similar effect.

Advice
Confirm that the routine specified is indeed an elemental function or an `ATTRIBUTES CONCURRENCY_SAFE` function before following the advice to add the annotation.

If the routine is not one of these kinds of functions, try to inline it with a `FORCEINLINE RECURSIVE` directive. This action may or may not be beneficial.

Example
Consider the following:

```
subroutine foo ()
integer, parameter :: N2 = 10000
real (8) :: A(N2), B(N2)
interface
   function bar (k)
      integer :: bar, k
   end function bar
end interface

integer :: i
do i =1, N2
   A(i) = B(i) * bar(N2)
end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine `bar` as elemental.
If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```fortran
subroutine foo ()
    integer, parameter :: N2 = 10000
    real (8) :: A(N2), B(N2)
    interface
        function bar (k)
            !dir$ attributes concurrency_safe : profitable
            integer :: bar, k
        end function bar
    end interface
    integer :: i
    do i = 1, N2
        A(i) = B(i) * bar(N2)
    end do
end subroutine foo
```

**Verify**

Confirm that the routine satisfies the semantics of this declaration. Another way to help the loop being parallelized is to inline the routine with the `FORCEINLINE RECURSIVE` directive, but this method does not guarantee parallelization.

**See Also**

GAP Message (Diagnostic ID 30526)

GAP Message (Diagnostic ID 30531)

**Message**

Store the value of the upper-bound expression of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = upper-bound of loop" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

**Advice**

Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler cannot output the exact upper-bound variable to be replaced.

**Verify**

Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

**See Also**

GAP Message (Diagnostic ID 30532)

GAP Message (Diagnostic ID 30532)

**Message**

Store the value of the upper-bound expression (%s) of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = %s" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".
Advice
Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which in turn enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler can output the exact upper-bound variable to be replaced.

Verify
Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

See Also
GAP Message (Diagnostic ID 30531)

GAP Message (Diagnostic ID 30533)

Message
Compile with the %s option to vectorize and/or parallelize the loop at line %d.

Advice
Use the [Q]opt-subscript-in-range option for the specified file during compilation.

This option helps the compiler vectorize and parallelize the loop at the specified line. You must verify that the loops in the file do not contain very large integers and are not likely to generate very large integers in intermediate computations. A very large integer is loosely defined as follows: On an n-bit machine, a very large integer is typically >= 2^{n-2}. For example, on a 32-bit machine, a very large integer would be >= 2^{30}.

Verify
Confirm that no loop in the program contains or generates very large integers (typically very large integers are >= 2^{30}).

GAP Message (Diagnostic ID 30538)

Message
Moving the block of code that consists of a function-call (line %d), if-condition (line %d), and an early return (line %d) to outside the loop may enable parallelization of the loop at line %d.

Advice
Move the function call and an associated return from inside the loop (perhaps by inserting them before the loop) to help parallelize the loop.

This kind of function-leading-to-return inside a loop usually handles some error-condition inside the loop. If this error check can be done before starting the execution of the loop without changing the program semantics, the compiler may be able to parallelize the loop thus improving performance.

Verify
Confirm that the function call does not rely on any computation inside the loop and that restructuring the code as suggested above, retains the original program semantics.
Overview: Intel® MIC Architecture

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The Intel® Fortran Compiler provides several elements to enable programming for and building binaries to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture), including:

- language extensions
- compiler options
- environment variables
- OpenMP® considerations

Code that is defined for offloading runs on an Intel® Xeon® processor-based host, running Linux® or Windows®, and on targets supporting Intel® MIC Architecture.

Programming for Intel® MIC Architecture

You can write parallel programs that offload sections of code to run on the Intel® MIC Architecture, or alternatively, that run natively on Intel® MIC Architecture. Compiling a source file that contains extensions to facilitate programming for the Intel MIC Architecture creates what is called a fat binary which contains both the host binary and an offload binary. Fat binaries can be objects, archives, or executables depending on the options used at compilation. Refer to the documentation on the Offload Extract Tool (offload_extract) for information on how to extract the offload binary from the fat binary.

The compiler provides the following language extensions to facilitate programming for Intel® MIC Architecture:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLOAD directive</td>
<td>Directives to control the data transfer between the CPU and the coprocessor.</td>
</tr>
<tr>
<td>OFFLOAD_ATTRIBUTE directive</td>
<td></td>
</tr>
<tr>
<td>OFFLOAD_TRANSFER directive</td>
<td></td>
</tr>
<tr>
<td>OFFLOAD_WAIT directive</td>
<td></td>
</tr>
<tr>
<td>OFFLOAD BEGIN and END OFFLOAD directive</td>
<td></td>
</tr>
<tr>
<td>PREFETCH/NOPREFETCH directive</td>
<td></td>
</tr>
<tr>
<td>ATTRIBUTES OFFLOAD directive</td>
<td>A directive for placing variables and functions on the coprocessor.</td>
</tr>
<tr>
<td><strong>MIC</strong> preprocessor symbol</td>
<td>Predefined preprocessor symbols you can use when programming for Intel® MIC Architecture.</td>
</tr>
<tr>
<td><strong>KNC</strong> preprocessor symbol</td>
<td></td>
</tr>
<tr>
<td>__INTEL_OFFLOAD preprocessor symbol</td>
<td></td>
</tr>
<tr>
<td>APIs in mic_lib.f90</td>
<td>A set of functions for:</td>
</tr>
</tbody>
</table>
Building for Intel® MIC Architecture

The compiler provides the following compiler options and environment variables that you can use when building a binary for Intel® MIC Architecture:

<table>
<thead>
<tr>
<th>Compiler Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The negative form of <code>qoffload</code>, <code>Qoffload</code></td>
<td>Ignores language constructs for offloading.</td>
</tr>
<tr>
<td><code>Qmic</code> (Windows*)</td>
<td>Builds an application that runs natively on Intel® MIC Architecture.</td>
</tr>
<tr>
<td><code>mmic</code> (Linux*)</td>
<td></td>
</tr>
<tr>
<td><code>Qoffload ATTRIBUTE-TARGET</code>, <code>qoffload ATTRIBUTE-TARGET</code></td>
<td>Flags every global routine and global data object in the source file with the offload attribute <code>target(mic)</code>.</td>
</tr>
<tr>
<td><code>Qoffload-option</code>, <code>qoffload-option</code></td>
<td>Specifies options to be used for the specified target and tool.</td>
</tr>
<tr>
<td><code>Qopt-report-phase:offload</code>, <code>qopt-report-phase=offload</code></td>
<td>Specifies the offload optimizer phase to use when optimization reports are generated.</td>
</tr>
<tr>
<td><code>Qopt-assume-safe-padding</code>, <code>qopt-assume-safe-padding</code></td>
<td>Determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.</td>
</tr>
<tr>
<td><code>Qopt-streaming-cache-evict</code>, <code>qopt-streaming-cache-evict</code></td>
<td>Specifies the cache eviction level to be used by the compiler for streaming loads and stores.</td>
</tr>
<tr>
<td><code>Qopt-threads-per-core</code>, <code>qopt-threads-per-core</code></td>
<td>Informs the compiler about the number of hardware threads per core that will be used for an application.</td>
</tr>
<tr>
<td><code>Qopt-gather-scatter-unroll</code>, <code>qopt-gather-scatter-unroll</code></td>

Programming for Intel® MIC Architecture

Overview: Heterogeneous Programming

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

About Heterogeneous Programming

The compiler includes language extensions that simplify writing parallel programs that can offload sections to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Execution begins on the host CPU and, based on user-defined code, some sections are offloaded to the coprocessor.

Heterogeneous programming must deal with two differences from traditional CPU programming:

- The instruction sets on the CPU and the coprocessor are similar, but not identical.
- The host CPU and the coprocessor do not share common system memory.

Programming Model

The compiler deals with the lack of shared system memory by using directives with the prefix OFFLOAD_.

This model is appropriate for dealing with flat data structures such as scalars, arrays and structs that are bit-wise copyable.

Data in this model is copied back and forth between the CPU and the coprocessor around regions of offloaded code. The data selected for transfer is a combination of variables implicitly transferred because they are lexically referenced within offload constructs, and variables explicitly listed in clauses in the directive.
Specifying that a construct should run on the coprocessor does not guarantee that it will. The presence of an Intel® MIC Architecture-based subsystem and its availability at the offload point determines if the offload succeeds. When an offload fails, the program exits with an error message.

### Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Overview: Using a Directive

OFFLOAD

Restrictions on Offloaded Code Using a Directive

Dealing with Multiple Coprocessors in a System

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Use the functions described in this section to determine:

- the number of coprocessors in a system
- the coprocessor on which a program is running

Use the header file mic_lib.f90 to define the interfaces for these functions and their usage. Include it with USE mic_lib.

**NOTE**

In a system with multiple coprocessors, you need to specify the `target-number` argument when using the `offload` directive to reliably use data persistence. When you use `alloc_if` or `free_if` to implement data persistence on the coprocessor, but do not specify `target-number`, the compiler runtime randomly chooses a coprocessor, so the chosen coprocessor could be one on which the data is not available.

### Determining the Number of Coprocessors in a System

To determine the number of coprocessors in the system, use the function `result = OFFLOAD_NUMBER_OF_DEVICES()`.

The function returns an integer equal to the number of coprocessors installed and working in the system. If none are installed and working, the return value is 0.

### Determining the Coprocessor on Which a Program is Running

To determine the coprocessor that is executing the program, use the function `result = OFFLOAD_GETDEVICE_NUMBER()`.

The function returns an integer equal to the number of the coprocessor executing the program, where 0 is the first card. If the program is executing on the CPU, the return value is -1.
Determining if Code has Completed Running on a Coprocessor

To determine if a section of offloaded code has completed running on a given coprocessor, you can use the API `OFFLOAD_SIGNALED()`. The syntax for this API is:

`OFFLOAD_SIGNALED(target_number, signal)`

OFFLOAD directive

Offload Using a Directive

Overview: Using a Directive

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This programming model is suitable when the data exchanged between the CPU and the coprocessor consists of scalars, arrays, and Fortran derived types that can be copied from one variable to another using a simple `memcpy`.

Data that flows between the CPU and the coprocessor must have a flat structure.

Data that is created and used entirely on the CPU, or used entirely within the offloaded regions, can be arbitrarily complex, including multi-dimensional arrays, and any composition of data structures using pointers, arrays and Fortran derived types.

You control the data transfer between the CPU and the coprocessor. The data transfer consists of densely packed data structures. You can select the data to be transferred at the point of offload, without needing to declare or allocate it in any special way.

OFFLOAD_WAIT

OFFLOAD BEGIN and END OFFLOAD

Rules for Placement of Directives

Initiating an Offload

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can place the OFFLOAD directive before a subroutine call statement, a function call statement of the form `x = func()` or an OpenMP* parallel directive.

For example:

```plaintext
!DIR$ OFFLOAD BEGIN target(mic : target_id) &
     inout(numEs) in(all_Vals) out(E_vals)
     do k = 1, MAXSZ
         if ( MODULO(all_Vals(k),2) == 0 ) then
             numEs = numEs + 1
             E_vals(numEs) = all_Vals(k)
         endif
     enddo
!DIR$ END OFFLOAD
```

This code excerpt finds the even numbers and then puts those numbers into an array. The code excerpt begins with `!DIR$ OFFLOAD BEGIN`, and ends with `!DIR$ END OFFLOAD`. The compiler builds the code block to run on both the host and target.
While the instruction sets for the host and targets are similar, they do not share the same system memory. This means that the variables used by the code block must exist on both the host and the target. To ensure that they do, the directives use specifiers to define the variables to copy between the host and target.

- The **in** specifier defines a variable as strictly an input to the target. The value is not copied back to the host.
- The **out** specifier defines a variable as strictly an output of the target. The host does not copy the variable to the target.
- The **inout** specifier defines a variable that is both copied from the host to the target and back from the target to the host.

The directive also has the target (`mic:target_number`) specifier to direct the code to a specific target in a system with multiple targets.

When the main program has offload constructs, by default the compiler builds an application that runs on both the host and target. However, you can also build the same source code to run on just the CPU, using the negative form of the `[	exttt{Q}]offload` compiler option.

**Placing Variables and Functions on the Coprocessor**

These attributes ensure that variables and functions are available on the coprocessor.

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The statement following the offload directive is converted into an outlined function that runs on the coprocessor. This code is permitted to call other functions. To ensure that these called functions are also available on the coprocessor, you must specify one of the following special function attributes, using the ATTRIBUTES OFFLOAD directive:

```fortran
!DIR$ ATTRIBUTES OFFLOAD: target-name :: routine-name[, routine-name] ...
```

All functions in the program are always compiled for the CPU and are available to be called on the CPU. However, only functions marked with the special attribute are available to be called by offloaded code, and only these functions can be called on the coprocessor.

Global variables are treated in a similar fashion. All global variables are always present in the CPU code. But only global variables with the target attribute are compiled into the binary offloaded to the coprocessor.

Compiling only functions and data explicitly marked with the target attribute into the Intel® MIC Architecture binary ensures that the code on the coprocessor is as small as possible.

The compiler issues warnings for functions and data referenced within offloaded code that do not have the target attribute.

**Example**

```fortran
module offload_test
public

!DIR$ ATTRIBUTES OFFLOAD:mic :: global_value
integer :: global_value

contains
  !DIR$ ATTRIBUTES OFFLOAD:mic :: incr_global
  integer function incr_global
  global_value = global_value + 1
  incr_global = global_value
  return
```
program main
  use offload_test
  integer i
  i = incr_global()
  print *, "global = ", global_value, "i = ", i, " (should be the same)"
end program main

NOTE
The presence of a function call within an offloaded construct with a target attribute does not automatically declare that function as available on that target. The function definition must include the appropriate target attribute to ensure that the function is available on the target.

NOTE
The definition and all declarations of a variable or function with a target attribute must be consistent with each other across all compilation units.

ATTRIBUTES OFFLOAD
OPTIONS Directive

Managing Memory Allocation for Pointer and Allocatable Variables

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Creating Fortran pointer targets and allocatable variables is referred to here as dynamic memory variables.

Memory management on the CPU for dynamic memory variables used in offloaded programs is the same as non-offload programs. That is, the offload directives do not affect memory allocation and freeing on the CPU. As usual, you, the programmer, must do this.

Memory management on the coprocessor for dynamic memory variables named in in and out clauses of !DIR$ OFFLOAD is done automatically by the compiler and runtime system.

Target Memory Management for Input Dynamic Memory Variables

For in variables of a !DIR$ OFFLOAD the default behavior is to do a fresh memory allocation for each dynamic memory variable. On return from the construct the memory is de-allocated. In order to retain data between offloads, you can use the alloc_if and free_if qualifiers to modify the memory allocation defaults on the coprocessor.

The alloc_if qualifier specifies a logical condition that controls whether the dynamic memory variables in the in clause are allocated a fresh block of memory on the target when the construct is executed on the target. If the expression evaluates to .true., a fresh memory allocation is performed for each variable listed in the clause. If the condition evaluates to .false., the existing pointer values on the target are reused. You must ensure that a block of memory of sufficient size has been previously allocated for the variables on the target by using a free_if(.false.) clause on an earlier offload.

The free_if qualifier specifies a logical condition which controls whether to free the memory allocated for the dynamic memory variables in an in clause. If the expression evaluates to .true., the memory pointed to by each variable listed in the clause is freed. If the condition evaluates to .false., no action is taken on the memory pointed to by the variables in the list. A subsequent clause will be able to reuse the allocated memory.

The alloc_if and free_if logical expressions are evaluated on the CPU at the point the construct is offloaded to the target.
Target Memory Management for Output Dynamic Memory Variables

By default an \texttt{out} variable is allocated fresh memory on the target at the start of an offload and the memory is freed at the end of the offload. The \texttt{alloc if} and \texttt{free if} modifiers change the defaults. The expressions are evaluated on the host and used to control coprocessor memory allocation.

When the output value is received on the host, no memory allocation is done. The variables listed in \texttt{out} clauses must point to allocated memory of sufficient size to receive the results on the host.

Transferring Data into Pre-allocated Memory on the Target

As described in the previous section a dynamic memory variable in an \texttt{in}, \texttt{out}, \texttt{inout}, or \texttt{nocopy} clause can retain the target memory allocation when you set the \texttt{free if} modifier to \texttt{false}. You can reuse that memory in subsequent offloads by using \texttt{in}, \texttt{out}, \texttt{inout}, or \texttt{nocopy} and specifying \texttt{alloc if}(.false.).

When target memory is allocated it is associated with the value of the CPU dynamic memory variable used as the destination in the \texttt{in}, \texttt{out}, \texttt{inout}, or \texttt{nocopy} clause. When target memory is to be reused, it is located using the value of the CPU dynamic memory variable that is the destination of that transfer. The associations between the CPU address used when target memory is allocated and the target memory are automatically maintained by the offload runtime library. The associations are created or dropped along with target memory allocation or deallocation. Create the association at allocation time using \texttt{alloc if}(.true.) \texttt{free if}(.false.) and delete the association at de-allocation time using \texttt{free if}(.true.).

Pointers to static data on the CPU are special-cased. The \texttt{alloc if} and \texttt{free if} modifiers are ignored when the following are both true:

- The CPU address used during creation of a target memory association points to statically allocated data.
- The variable is also available in the target binary because it has \texttt{ATTRIBUTES OFFLOAD:mic}.

The target's statically allocated memory is used as the destination of the transfer. This target memory is not dynamically allocated and never freed.

There is only one block of target memory associated with a CPU address. It is an error to call \texttt{alloc if}(.true.) to create a second association for a CPU address before freeing the existing one. The new association overwrites the earlier one, which has the potential for causing memory leaks on the target.

It is an error to call \texttt{free if}(.true.) for transferred dynamic memory if a matching association is not found. The attempt removal of an association is silently ignored. An association can be made with a CPU address, and a certain length, and another association made with a different CPU address within that range. Since origin addresses are different, you can use \texttt{alloc if} and \texttt{free if} to create distinct target allocations.

Alignment of Dynamic Memory Variables

When memory is allocated for a dynamic memory variable on the target, it is aligned at the natural boundary for the declared type. Sometimes it may be necessary to request that the data be aligned on larger boundaries, for example, when the program expects to use assembly code or intrinsic functions or vectorization, that operate on data with more stringent alignment requirements. In these cases, the \texttt{align} modifier may be used to specify an alignment. The operand of the \texttt{align} modifier must be an integral expression which evaluates to a power of two. The expression is evaluated on the host and the region of memory allocated for the dynamic memory on the target is aligned at a boundary that is greater than or equal to the value of the expression. When the output value is received on the host, no memory allocation is done. The variables listed in \texttt{out} clauses must point to allocated memory of sufficient size to receive the results.

\textbf{NOTE}

For optimal data transfer performance, by default, the target memory address for a transfer through dynamic memory is made to match the offset within 64 bytes of the CPU data. That is, if the CPU source address is 16 bytes past a 64 byte boundary, the target data address will also be 16 bytes past a 64 byte boundary.
The align modifier overrides this default and aligns the target memory at the requested alignment. To get the benefits of fast data transfer and the necessary alignment on the target, ensure that the CPU data is aligned on the same boundary as the alignment needed on the target. Doing so meets the requirements for fast data transfer and the requirements for target data alignment.

Examples

The following example illustrates the default behavior, which is no data persistence on the coprocessor. The compiler allocates and frees data around the offload. No alloc or free modifiers are necessary.

```fortran
real, dimension(:), pointer :: p
!DIR$ ATTRIBUTES OFFLOAD:mic :: p
real, dimension(10), target :: targ
!DIR$ ATTRIBUTES OFFLOAD:mic :: targ

p->targ
!DIR$ OFFLOAD TARGET (mic) in (p)
```

The following examples illustrate keeping data on the coprocessor between offloads.

The following code allocates memory for `p` as part of this offload, and keeps the memory allocated for `p` after the offload.

Notice that alloc is the default, and you do not need to explicitly specify it.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.true.) free_if(.false.))
```

The following code reuses the memory allocated for `p` previously. It only transfers fresh data into that memory, and after the offload completes, it continues to retain the memory.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.false.) &
!DIR$ free_if(.false.))
```

The following code reuses the memory allocated for `p` previously. However, it frees the memory for `p` after this offload.

Notice that free is the default, and you do not need to explicitly specify it.

```fortran
!DIR$ OFFLOAD TARGET (mic) in (p : alloc_if(.false.) free_if(.true.))
```

The following code uses a pointer to create a memory allocation on the target. Then the pointer value is passed to another function. Through the pointer value, the target memory can be reused. Notice that the offload_transfer directive uses subscript notation. The length modifier is not required when a variable is specified in array notation.

```fortran
! Transfer through a routine argument
Module m
integer, allocatable :: p(:)
!dir$ attributes offload:mic :: p
 contains
 subroutine foo (arg_p, count)
 !dir$ attributes offload:mic :: foo
 integer, allocatable :: arg_p(:)
 integer count
 end subroutine foo
end module m

program test
 use m
 allocate(p(100000))
```
The following transfers static data to the target. The target static data allocation for the matching CPU variable is automatically used.

! When bar is called with array_cpu_only, dynamic memory is used on target!
! when bar is called with array_both, the target array_both is used

module m
    integer array_both(1000)
    !dir$ attributes offload : mic :: array_both
    integer array_cpu_only(1000)
end module m

subroutine foo()
use m
    call bar(array_cpu_only, 1000)
    call bar(array_both, 1000)
end subroutine foo

subroutine bar(iarray, count)
    integer iarray(count)
    !dir$ offload begin target (mic:0) in(iarray : &
    !dir$ alloc_if(.false.))
    iarray=4
    !dir$ end offload
end subroutine bar

The following code shows the use of dummy arguments for allocatable arrays mixed between the CPU and the target.

module mod
    integer, target, allocatable :: arr(:)
    integer, pointer, dimension(:) :: ptr
    !dir$ attributes offload:mic :: ptr, arr
end module mod

program main
    use mic_lib
    use mod
    implicit none
    integer i, bar1, bar2
    allocate(arr(1000))
    ptr => arr(1:100)
    ! copies array to target
    !dir$ offload begin target(mic:0) in(arr : free_if(.false.))
    arr = (/ (i, i=1,1000) /) ! 1, 2, 3, ...
    !dir$ end offload
    ! bar2 will use dynamically allocated memory on the target
    print *, bar2() ! 0
    ! bar1 will use allocated "arr" from above
    print *, bar1(ptr, 100) ! /= 0
end program main
integer function bar2()
  implicit none
  integer i, bar1
  integer, allocatable :: my_p(:)

  allocate (my_p(100))
  ! first 100 elements of my_p are allocated & transferred to target ("in" implies alloc_if(.true.))
  !dir$ offload begin target(mic:0) in(my_p:length(100) &
  !dir$ free_if(.false.))
      my_p = (/ (0, i=1,100) /) ! 0, 0, 0, ...
  !dir$ end offload

  bar2 = bar1(my_p, 100)
  return
end function bar2

integer function bar1(iarray, len)
  implicit none
  integer :: iarray(len)
  integer len, sum, i

  !dir$ offload begin target(mic:0) in(iarray:length(0) &
  !dir$ alloc_if(.false.) free_if(.false.))
      sum = 0
      do i = 1, len
          sum = sum + iarray(i)
      end do
  !dir$ end offload

  bar1 = sum
  return
end function bar1

Writing Target-Specific Code Using a Directive

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can write functions that you intend to run on a target, and sections of offloaded code, to take advantage of target-specific functions.

When the compiler generates code for the coprocessor, it defines the macro __MIC__. You can write target-specific code within a !DIR$ if defined __MIC__ section.

NOTE
Do not use the __MIC__ macro inside the statement following a !DIR$ OMP OFFLOAD statement. You can, however, use this macro in a subprogram called from the directive.

Example

The implementation of the class F32vec is specialized for the CPU and the coprocessor. The offloaded code can use the specialized version if it runs on the coprocessor. If the offload fails and the construct runs on the CPU, it uses the CPU version.

!DIR$ ATTRIBUTES OFFLOAD : mic :: foo
integer function foo()
  implicit none
!DIR$ if defined (__MIC__)
  foo = 1 ! Code is running on coprocessor
!DIR$ else
  foo = 0 ! Code is running on host
program main
  implicit none

    ! Local variables
    integer :: result
    integer :: foo

    !DIR$ ATTRIBUTES OFFLOAD : mic :: foo

    ! Call foo on host
    result = foo()

    ! Print results
    if ( result ) then
      write (*,*) "Code ran on coprocessor"
    else
      write (*,*) "Code ran on host"
    end if

    ! Call foo on MIC
    !DIR$ OFFLOAD TARGET(mic)
    result = foo()

    ! Print results
    if ( result ) then
      write (*,*) "Code ran on coprocessor"
    else
      write (*,*) "Code ran on host"
    end if
end program main

Writing Code that Should Not Be Built for CPU-Only Execution

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
You can write code that should not be built when the target is a CPU-only executable.
By default, the compiler defines the macro __INTEL_OFFLOAD. You can write code within an #ifdef __INTEL_OFFLOAD section when the source code is customized for running on the coprocessor, either heterogeneously or natively.
For example, you can use this macro to protect code on the host that should only be executed for an offload build, such as calls to the omp_set_num_threads_target family of APIs in mic_lib.f90.

Example

The section for the host compiler works only when you compile with the [Q]offload compiler option with the keyword optional, or the Qmic (Windows*) or mmic (Linux*) compiler option.

```fortran
#ifdef __INTEL_OFFLOAD
  #ifdef __MIC__
    PRINT *,"Using offload compiler : Hello from the coprocessor"
  #else  /* __MIC__ */
    PRINT *,"Using offload compiler : Hello from the CPU"
  #endif  /* __MIC__ */
#endif /* __INTEL_OFFLOAD */
```

Allocating Memory for Parts of Arrays

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic discusses using the ALLOC modifier with the OFFLOAD set of directives

The ALLOC modifier contains an array section reference. When you specify it, then the allocation on the coprocessor is limited to that shape of array. Only unit stride is allowed in the section. When a section has a rank greater than one, the second and subsequent index expressions must specify all elements at that dimension. The array section must be contiguous.

Data is transferred into that portion of the array specified by the IN or OUT expression. Thus memory allocation and the data transfer can use separate array slice references.

When the lower bound of the first dimension of a section used in the ALLOC modifier is non-zero, then the memory allocation begins with that element. The memory preceding the lower bound is unallocated and should not be referenced by your program. By not referencing it, you enable a smaller section of the array to be transferred to the coprocessor without requiring that the entire array be allocated.

Example

In the following example,

- The array A has 15 elements on the CPU, A(1:15).
- The ALLOC modifier allocates 8 elements A(3:10), the blue and orange regions on the coprocessor.
- On the coprocessor, the elements A(1:2), the gray region, are uninitialized.
- The IN clause transfers elements A(4:8), the orange region, from the CPU to the coprocessor.

```
INTEGER :: A (15)
!               8 elements allocated
!               5 data elements transferred starting at element 4
!DIR$ OFFLOAD ... IN ( A(4:8) : ALLOC ( (3:10) ) ...
```

```
```

```
INTEGER, ALLOCATABLE :: B (:,:) ALLOCATE (B (5,4))

! On the coprocessor: 16 elements allocated (rows 2 through 5)
!  Shape of array is 5x4, first row is unallocated
!  Data is transferred into row 3 only
!DIR$ OFFLOAD ... IN ( B (3, :) : ALLOC ( 2:5, : ) ...
```

In the diagram below:

- B is allowed 5 rows, 4 columns on the CPU.
- On the coprocessor, the `ALLOC` modifier allocates rows 2 through 5, the blue and orange regions, all columns.
- On the coprocessor, row 1, the gray region, is not allocated.
- The `IN` clause transfers the third row (3: :), the orange region, to the coprocessor.

### Moving Data from One Variable to Another

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

This topic discusses using the `INTO` modifier with the `OFFLOAD` set of directives.

The `INTO` modifier enables you to transfer data from a variable on the CPU to another on the coprocessor, and the reverse, from a variable on the coprocessor to another on the CPU. Only one item is allowed in the `variable-ref` list when using the `INTO` modifier. Thus a one to one correspondence is established between a single source and destination.

When you use `INTO` with the `IN` clause, data is copied from the CPU object to the coprocessor object. The `ALLOC_IF`, `FREE_IF`, and `ALLOC` modifiers apply to the `INTO` expression.

When you use `INTO` with the `OUT` clause, data is copied from the coprocessor object to the CPU object. The `ALLOC_IF`, `FREE_IF`, and `ALLOC` modifiers apply to the `OUT` expression.

The `INTO` modifier is not allowed with `INOUT` and `NOCOPY` clauses.

When you use the `INTO` modifier, the source expression generates a stream of elements to be copied into the memory ranges specified by the `INTO` expression. Overlap between the source and destination memory ranges leads to undefined behavior. No ordering can be assumed between transfers from different `IN` and `OUT` clauses.

### Example

In the following example:

- The "Partial copy" case copies the first 500 elements of `P` to the last 500 elements of `P1`.
- The "Overlapping copy" case copies the first 600 elements of `P` into `P1` but then tries to copy the last 400 elements of `P` into `P1(100)` and beyond, but `P1(100)` was initialized by the previous `IN` clause.
The "rank change" is an error because rank 2 data on the coprocessor is being copied back to rank 1 data on the CPU, even though the sizes are the same.

```
INTEGER :: P (1000), P1 (2000)
INTEGER :: RANK1 (1000), RANK2 (10, 100)

! Partial copy
!DIR$ OFLOAD ... IN ( P (1:500) : INTO ( P1 (501:1000) ) ) ...

! Overlapping copy; result undefined
!DIR$ OFFLOAD ... IN ( P (1:600) : INTO ( P1 (1:600) ) ) &
& IN ( P (601:1000) : INTO ( P1 (100:499) ) ) ...

! Rank change is not allowed - error
!DIR $ OFFLOAD ... OUT ( RANK1, OUT (RANK2) ) ...
```

Restrictions on Offloaded Code Using a Directive
This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Offloaded code has the following restrictions:

- Exception handling may be done as usual within code running on the CPU and within code running on the coprocessor. So exceptions can be raised, caught and handled on the CPU, or raised, caught and handled on the coprocessor. However it is not possible to propagate an exception from the coprocessor to the CPU.

- Do not use the __MIC__ macro inside the statement following a !DIR$ OMP OFFLOAD statement. You can, however, use this macro in a subprogram called from the directive.

- The compiler does not inline functions inside statements following an OFFLOAD directive statement, including functions marked with the FORCEINLINE directive. However, inline function expansion might occur at the compiler's discretion inside a subprogram called from the OFFLOAD directive.

- Multiple host CPU threads can execute concurrently while one host CPU thread offloads a section of code. In this case synchronization mechanisms such as locks, atomic, mutexes, OpenMP atomic operations, OpenMP critical, OpenMP taskwait, OpenMP barriers, etc. do not work between host CPU code and code offloaded to the target. However, if parallelism on the host CPU is enabled using OpenMP, then OpenMP synchronization at the end of a parallel region is guaranteed to work even if some part of the OpenMP parallel region has been offloaded to the target.

- Global variables referenced by functions called from within offloaded code must be declared with matching target attributes to ensure that the variables are available on the target. You must also explicitly send and receive the value of these variables with explicit in/out/inout clauses to sync their values between the host and target. Global variables visible within the lexical scope of the offload pragma do not require declaration with matching target attributes, and their associated values are sent and received by default. Global pointer variables used in lexical scope of the offload pragma do require being specified within in/out/inout clauses and this is enforced by the compiler.

By default, pointer variables are assumed to point to a single element of the corresponding type. The offloaded code may dereference the pointer and access a single element. The data element pointed to is automatically copied into target memory and the pointer value adjusted accordingly. The `element-count-expr` expression available with in / out / inout parameters enable variable-length data to be copied back and forth.

- Only pointers to non-pointer types are supported. These non-pointer types must have the TARGET attribute. Pointers to pointer variables are not supported. The compiler enforces this restriction.

- Arrays are supported provided the array element type is a scalar or bitwise copyable derived type. Pointer arrays are supported provided the target is contiguous.
• Because pointers are not copied across the host-target interface, but instead the data they point to is copied, do not assume that the relative distance between pointers that point to distinct variables remains the same between the host and target. Pointers within the same data structure still have the same distance between them after offload. Thus, some pointer comparisons and arithmetic that were meaningful on the host CPU can no longer be used reliably on the target.

• Unions containing a combination of pointer and non-pointer members are treated as holding the non-pointer value type. Thus, no special treatment is given to the pointer, and the data pointed to is not copied to the target.

• Unions consisting entirely of pointer members are not allowed to be copied between the host and the target.

• If an offload region calls a function defined in a separate file and that function references global variables, care must be taken to ensure that those global variables are copied in and/or out as needed.

  If the global variables are referenced only in the external function and not directly within the offloaded region, then they will not be copied because the references outside the current compilation unit are not known to the compiler.

  If the variables referenced from the external function are also referenced in the offloaded region, then they will be copied.

  When global variables are file-scope static variables, then they cannot be named in the `in` or `in` clauses. You need to access their values using one of the following methods:

  • Make them external and add them to the `in` or `out` clauses in the offload specification.
  • Fetch the variable values into local variables using functions designed specifically for that purpose, and then add the local variables to the `in` or `out` clauses.
  • You cannot use objects that are not bitwise copyable, inside a `!DIR$ OFFLOAD` region. The compiler enforces this restriction and issues an error.
  • The offload region in an internal procedure cannot contain a host associated variable.

Restrictions When Programming on Windows* for Intel® MIC Architecture

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Several programming features that are specific to Windows® might result in errors when you use them in an offload compilation for Intel® MIC Architecture, even if you do not use these features in the code or data that is actually offloaded. When you use code with these features in your application, you must correctly structure the code so that it is not visible in a target compilation.

These features include, but are not limited to:

• Windows calling conventions. For example:

  ```fortran
  !DIR$ ATTRIBUTES STDCALL :: PROCX
  ```

• The attributes `DLLEXPORT` and `DLLIMPORT`. For example:

  ```fortran
  !DIR$ ATTRIBUTES DLLIMPORT :: VARX
  ```

• Module files or libraries that are specific to Windows, such as `IFNLS` or `IFQWIN`.

In addition, you must take care to ensure that code does not depend on specific data size or order of allocation of data, as these can vary between the host and the target.

About Asynchronous Computation

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

By default, the `OFFLOAD` directive causes the CPU thread that encounters the directive to wait for completion of the offload before continuing to the next statement. You can execute an asynchronous offload computation, which enables the CPU to initiate the offload and immediately continue to the next statement.
To specify an asynchronous offloaded computation, specify a `signal` clause in the `OFFLOAD` directive to initiate the computation, and subsequently use the `OFFLOAD_WAIT` directive to wait for completion of the offloaded computation.

Alternatively, you can use the non-blocking API `OFFLOAD_SIGNALLED()` to also determine if a section of offloaded code has completed running on a specific target device.

**NOTE**

The `signal` and `wait` clauses, the `OFFLOAD_WAIT` construct and the `OFFLOAD_SIGNALLED()` API refer to a specific target device, so you must specify `target-number` in the `target()` clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where the signal was actually initiated for target device 1. The signal was initiated for target device 1, so there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

---

**Example: Asynchronous Computation**

The following example enables the CPU to issue offloaded computations and continue concurrent activity without using any additional CPU threads:

```fortran
integer signal_var
integer counter
counter = 10000
!DIR$ ATTRIBUTES OFFLOAD:MIC :: long_running_mic_compute
do while (counter .gt. 0)
   !DIR$ OFFLOAD TARGET(MIC:0) SIGNAL(signal_var)
      call long_running_mic_compute()
      call concurrent_cpu_activity()
   !DIR$ OFFLOAD_WAIT TARGET(MIC:0) WAIT (signal_var)
   counter = counter - 1
end do
end
```

OFFLOAD
OFFLOAD_TRANSFER
OFFLOAD_WAIT

**About Asynchronous Data Transfer**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

To transfer data between the CPU and the coprocessor, use the `OFFLOAD_TRANSFER` directive with either all `in` clauses or all `out` clauses. Without a `signal` clause the data transfer is synchronous: The next statement is executed only after the data transfer is complete.

`OFFLOAD_TRANSFER` with a `signal` makes the data transfer asynchronous. The tag specified in the `signal` clause is an address expression associated with that dataset. The data transfer is initiated and the CPU can continue past the directive statement.

A later directive written with a `wait` clause causes the activity specified in the directive to begin only after all the data associated with the tag has been received. The data is placed into the variables specified when the data transfer was initiated. These variables must still be accessible.

Alternatively, you can use the non-blocking API `OFFLOAD_SIGNALLED()` to also determine if a section of offloaded code has completed running on a specific target device.
NOTE

The `signal` and `wait` clauses, the `OFFLOAD_WAIT` construct and the `OFFLOAD_SIGNEDALED()` API refer to a specific target device, so you must specify `target-number` in the `target()` clause.

Querying a signal before the signal has been initiated results in undefined behavior, and a runtime abort of the application. For example, consider a query of a signal (SIG1) on target device 0, where the signal was actually initiated for target device 1. The signal was initiated for target device 1, so there is no signal (SIG1) associated with target device 0, and therefore the application aborts.

If, during an asynchronous offload, a signal is created in one thread, Thread A, and waited for in a different thread, Thread B, you are responsible for ensuring that Thread B does not query the signal before Thread A has initiated the asynchronous offload to set up the signal. Thread B querying the signal before Thread A has initiated the asynchronous offload to set up the signal, results in a runtime abort of the application.

If `if-specifier` evaluates to false and you use a `signal` (tag) clause, then the signal is undefined and any wait on this signal has undefined behavior.

Asynchronous Data Transfer From the CPU to the Coprocessor

To transfer data asynchronously from the CPU to the coprocessor, use a `signal` clause in an `OFFLOAD_TRANSFER` directive with `in` clauses. The variables listed in the `in` clauses form a data set. The directive initiates the data transfer of those variables from the CPU to the coprocessor. A subsequent `OFFLOAD` directive with a `wait` clause that uses the same value for `tag` as that used in the `signal` clause causes the statement controlled by the directive to begin execution on the coprocessor only after the data transfer is complete.

Asynchronous Data Transfer from the Coprocessor to the CPU

To transfer data asynchronously from the coprocessor to the CPU, use the `signal` and `wait` clauses in two different directives. The first offload directive performs the computation, but only initiates the data transfer. The second directive causes a wait for the data transfer to complete.

Examples: CPU to Coprocessor

In the following example, the data transfer of the floating-point array f1 is initiated at line 10, and f2 is initiated at line 12. The offloads do not initiate a computation. Their only purpose is to start transferring f1 and f2 to the coprocessor. At line 14 the CPU initiates the computation of the function `foo` on the coprocessor. The function uses the data f1 and f2, whose transfer was initiated earlier. The execution of the offloaded region on the coprocessor begins only after the transfer of f1 and f2 completes. The variable `result` returns the results of the computation.

```fortran
01   integer, parameter:: n=4086
02   real, allocatable :: f1(:), f2(:), result
03   !dir$ attributes offload:mic :: f1, f2, foo
04   integer :: signal_1, signal_2
05   !dir$ attributes align : 64 :: f1
06   !dir$ attributes align : 64 :: f2
07   allocate(f1(n))
08   allocate(f2(n))
09   f1 = 1.0
10   !dir$ offload_transfer target (mic:0) in(f1) signal(signal_1)
11   f2 = 3.14
12   !dir$ offload_transfer target (mic:0) in(f2) signal(signal_2)
13   !dir$ offload_begin target(mic:0) wait (signal_1, signal_2)
14   result = foo(n, f1, f2)
15   !dir$ end offload
```
Multiple independent asynchronous data transfers can occur at any time. The example below uses \texttt{offload\_transfer} to send \texttt{f1} and \texttt{f2} to the coprocessor at different times, first \texttt{f1} in line 10, and then \texttt{f2} in line 13.

01  program main
02  integer, parameter:: n=4086
03  real, allocatable :: f1(:,), f2(:,), result
04  !dir$ attributes offload:mic :: f1, f2, foo
05  integer :: signal_1, signal_2
06  !dir$ attributes align : 64 :: f1
07  !dir$ attributes align : 64 :: f2
08  allocate(f1(n))
09  allocate(f2(n))
10  !dir$ offload begin target(mic:0) in (f1 ) nocopy (f2) signal(signal_1)
11  call foo(N, f1, f2)
12  !dir$ end offload
13  !dir$ offload\_transfer target(mic:0) wait(signal_1) out (f2)
14  end program main

\textbf{Examples: Coprocessor to CPU}

In the following example, the data transfer of the floating-point arrays \texttt{in1} and \texttt{in2} is initiated at line 15. The offload does not initiate a computation. Its only purpose is to start transferring \texttt{in1} to the coprocessor. Within the \texttt{do} loop, either \texttt{in1} or \texttt{in2} is transferred to the coprocessor, and computation starts on whichever set has already been transferred. At line 20 the CPU initiates the computation of the function \texttt{compute} on the coprocessor, and tells it to work on \texttt{in1}. At line 24, the CPU initiates the computation of the function \texttt{compute} on the coprocessor, but tells it to work on \texttt{in2}, which was transferred at line 23.

The following example double buffers inputs to an offload.

01  module M
02  integer, parameter :: NNN = 100
03  integer, parameter ::  count = 25000000
04  integer ::  arr(NNN)
05  real ::  dd
06  !dir$ attributes offload:mic::arr, dd
07  end module M

08  subroutine do\_async\_in()
09  !dir$ attributes offload:mic :: compute
10  use m
11  integer i, signal_1, signal_2, iter
12  real, allocatable :: in1(:), in2(:)
13  real, allocatable :: out1(:), out2(:)
14  iter = 10
15  !dir$ offload\_transfer target(mic:0) in(in1 : length(count) alloc_if(.false.) free_if(.false.) ) signal(signal_1)
16  do i=1, iter
17    if (mod(i,2) == 0) then
18      !dir$ offload\_transfer target(mic:0) if(i .ne. iter) in(in2 : length(count) alloc_if(.false.) free_if(.false.) ) signal(signal_2)
19      !dir$ offload target(mic:0) nocopy(in1) wait(signal_1) out(out1 : length(count) alloc_if(.false.) free_if(.false.) )
20      call compute(in1, out1)
21    else
22      !dir$ offload\_transfer target(mic:0) if(i .ne. iter) in(in1 : length(count) alloc_if(.false.) free_if(.false.) ) signal(signal_1)
23      !dir$ offload target(mic:0) nocopy(in2) wait(signal_2) out(out2 : length(count) alloc_if(.false.) free_if(.false.) )

Controlling the Coprocessor's Execution Environment

Overview: Controlling the Coprocessor's Execution Environment
This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
You can modify the coprocessor's execution environment using the following mechanisms:

- Setting environment variables for the coprocessor on the CPU, and passing them to the coprocessor
- calling functions from the CPU

In general, function calls override environment variables.

See Also
Setting Environment Variables on the CPU to Modify the Coprocessor's Execution Environment
Calling Functions on the CPU to Modify the Coprocessor's Execution Environment

Setting Environment Variables on the CPU to Modify the Coprocessor's Execution Environment
This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
By default, all environment variables defined in the environment of an executing CPU program are replicated
to the coprocessor's execution environment when an offload occurs. You can modify this behavior by defining
the environment variable MIC_ENV_PREFIX. When you set MIC_ENV_PREFIX to a specific prefix, then not all
CPU environment variables are replicated to the coprocessor, but only those environment variables that
begin with the value of the MIC_ENV_PREFIX environment variable. The environment variables set on the
coprocessor have the prefix value removed. You thus have independent control of OpenMP® and other
execution environments that use common environment variable names.

Setting Multiple Environment Variables on All Coprocessors
You can send multiple variables, each with its own value to all coprocessors.
To do so, use the following form:

```
mic_prefix_VAR=variable1=value1|variable2=value2|variable3=value3|...
```

Where `variableN` is the variable, and `valueN` is its value.

Specifying a Particular Coprocessor
You can specify a particular coprocessor, which is useful when you have multiple coprocessors installed.
To do so, use the following form:

```
mic_prefix_card_number_VAR=value
```

Where the value of `card_number` is 0 for the first device, 1 for the second, and so on.
Similarly, when setting multiple environment variables, specify a particular coprocessor, using `card_number`. 
Example: Setting a Single Environment Variables on All Coprocessors

The following environment variable definitions set `OMP_NUM_THREADS` on both the CPU and all installed coprocessors, but with different values.

```
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_OMP_NUM_THREADS=124
```

Example: Setting Multiple Environment Variables on All Coprocessors

The following environment variable definition sets `X=x` and `Y=y` on all coprocessors.

```
MIC_ENV_PREFIX=ABC
ABC_VAR=X=x|Y=y
```

Example: Setting a Single Environment Variables on a Particular Coprocessor

The following environment variable definitions set `OMP_NUM_THREADS` on both the CPU and the fifth coprocessor installed, but with different values.

```
MIC_ENV_PREFIX=ABC
OMP_NUM_THREADS=8
ABC_4_OMP_NUM_THREADS=124
```

Example: Setting Multiple Environment Variables on a Particular Coprocessor

The following environment variable definition sets `X=x` and `Y=y` on the fifth coprocessor installed.

```
MIC_ENV_PREFIX=ABC
ABC_4_VAR=X=x|Y=y
```

Supported Environment Variables

Calling Functions on the CPU to Modify the Coprocessor’s Execution Environment

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Some CPU APIs have offload equivalents, each of which take two additional arguments to specify the target type and target number, defined by the following arguments:

```
target_type

`target_type` is static. It is recommended to use the following pre-defined default:

default_target_type

```

```
target_number

The specific coprocessor to target.

An expression whose value is interpreted as follows:

```
target = target-number % number_of_targets
```

```
target > 0
```

Executes the statement on a specified target according to the following formula:
For example, in a system with four targets:

- Specifying 2 or 6 tells the runtime systems to execute the code on target 2, because the result of 2 % 4 and 6 % 4 is 2.
- Specifying 1000 tells the runtime systems to execute the code on target 0, because the result of 1000 % 4 is 0.

-1 or no value

Executes the statements on a target selected by the runtime system.

<-1

Reserved.

The mic_lib.f90 header file defines all the function calls that can be made from the CPU to affect the coprocessor's environment.

This topic uses the CPU API `omp_set_num_threads` and its offload variations as an example. See also the topics listed below for more CPU APIs.

Example

### CPU API

```fortran
subroutine omp_set_num_threads (num_threads)       &
  bind (C, name = "omp_set_num_threads")
  import :: c_int
  integer (kind=c_int), value :: num_threads
end subroutine omp_set_num_threads
```

### Offload API

```fortran
subroutine omp_set_num_threads_target (target_type, &
  target_number, &
  num_threads) &
  bind (C, name = "omp_set_num_threads_target")
  import :: c_int
  integer (kind=c_int), value :: target_type, target_number, num_threads
end subroutine omp_set_num_threads_target
```

```fortran
use mic_lib
use omp_lib

integer :: result, value

value = 66
call omp_set_num_threads_target &
  (TARGET_MIC, 0, value)
!DIR$ OMP OFFLOAD target(mic) out(result)
!$omp parallel
!$omp master
result = omp_get_num_threads()
!$omp end master
!$omp end parallel
print "(A, I)", "Number of threads on target", result
stop
end
```

Using Libraries With Offloaded Code

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The heterogeneous compilation environment consists of a host CPU compilation environment and a target compilation environment. Each environment consists of the compiler, linker and standard libraries. Code for the host CPU is compiled within the host environment and offloaded code within the target environment. The target environment may supply its own sets of standard libraries and these would be available to be called from offloaded code with no need to use special syntax or runtime features.

Some common libraries, such as the Intel® Math Kernel Library (Intel® MKL) and Intel® Performance Primitives (Intel® IPP) will be available in CPU versions as well as target versions.

When the target is available, the target executable is loaded when the CPU version of the executable is loaded, or when the first offload is attempted. At this time the libraries linked with the target code are initialized. The loaded target executable remains in the target memory until the host program terminates. Thus, any global state maintained by the library is maintained across offload instances.

When you offload code only within shared libraries, you must link the main program with the [Q]offload compiler option.

NOTE
Separate copies of libraries are linked or loaded with the host program and the offloaded target code. So there are two sets of global state: One on the host CPU and one on the target. The host CPU code only sees the host CPU state and the offloaded code only sees the state of the library on the target.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

About Creating Offload Libraries with xiar and xild

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Using xiar or the equivalent xild -lib to create a static archive library containing routines with offload code requires the following actions:

- Specify the -qoffload-build option, which causes xiar to create both a library that for the CPU, lib.a, and a corresponding library for the coprocessor, libMIC.a.
- When supplying the name of the library and the list of its member files to xiar or xild, include only the file names associated with the CPU library and CPU object files, such as lib.a and file.o.xiar and xild automatically manipulate the corresponding coprocessor library and member files, libMIC.a and fileMIC.o, respectively.
- Use the same options available to ar, including d (Delete), r (Replace), m (Move) and x (Extract). For more information, see the man page for ar.

The syntax to use these options is as follows:

xiar -qoffload-build ar optionsarchive [member...]

xild -lib -qoffload-build ar optionsarchive [member...]
When linking a static archive that contains offload code, use the linker options `-L path` and `-l libname`. The compiler driver automatically incorporates the corresponding coprocessor library, `libMIC.a`, into the linking phase.

**Example**

The following `xiar` command creates or modifies the CPU library `libsample.a` and coprocessor library `libsampleMIC.a`:

```
xiar -qoffload-build rcs libsample.a obj1.o obj2.o
```

`libsample.a` contains the CPU object files `obj1.o` and `obj2.o`. `libsampleMIC.a` contains the coprocessor object files `obj1MIC.o` and `obj2MIC.o`.

Either of the following commands compiles and links `myprogram.f90` with the static library:

```
ifort myprogram.f90 libsample.a
ifort myprogram.f90 -lsample
```

**Special Cases**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**Thread-private variables**

When a statement is offloaded, thread-private variable values from the CPU thread that does the offload are copied to the target, and then copied back when default in and out are in effect. Copies of thread-private variables in other CPU threads are not modified.

**See Also**

Writing Target-Specific Code Using a Directive

**OpenMP® Considerations**

**OpenMP® Defaults**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

The OpenMP® runtime has the following default on Intel® MIC Architecture:

- The OpenMP® runtime creates four threads per core by default under the coprocessor OS.
- If you do not specify the number of threads, the OpenMP® runtime uses the number of logical processors available in the affinity mask of the thread that initially goes parallel. In the offload environment this behavior normally is set to avoid the last physical core in the machine, which is where logical processors 0 and N-3, N-2, N-1 run. Therefore, on a coprocessor with 32 cores, for offloaded code, the runtime defaults to creating 124 OpenMP® threads.

To override this behavior, and explicitly use all 128 threads to run offloaded code, use an explicit affinity and the `norespect` modifier in the affinity specification, to force the runtime to ignore the affinity mask it was given.

When natively executing code on the coprocessor, no initial affinity mask is set, and the OpenMP® runtime defaults to using all available hardware threads. For example, it will use 128 threads on a 32 core machine.

**See Also**

Thread Affinity Interface (Linux® and Windows®)

Supported Environment Variables
OpenMP® Affinity Specifications

The coprocessor OS kernel on the coprocessor uses the logical processor number in `/proc/cpuinfo`, the calls to `sched_{get,set}affinity()` and `sched_getcpu()`, and the `taskset` command. The OpenMP® runtime library uses the logical processor number if you explicitly specify affinity using a `proclist`.

The logical processor number used by the coprocessor OS on Intel® MIC Architecture is different from that on the host, and probably not what you expect. There is one logical processor for each hardware thread context. Logical processor 0 is placed on the first hardware context of the highest numbered core. Logical processors from 1 up to the highest, minus three, are placed consecutively on core 0 context 0, core 0 context 1, core 0 context 2, core 0 context 3, core 1, context 0 and so on, with the last three logical processors being on the highest numbered core, with hardware thread contexts 1, 2, and 3.

The simple way to think of this is that you should start enumerating the logical processors to use at logical processor 1, not logical processor 0.

Balanced Affinity Type

The affinity type `balanced` is particularly useful on the Intel® MIC Architecture. It is supported on the CPU only for single socket systems.

**NOTE**

The OpenMP® environment variable `OMP_PROC_BIND=spread` is similar to `KMP_AFFINITY=balanced` and is available on all platforms, including multi-socket CPU systems.

Under this setting, the OpenMP® runtime places threads on separate cores until all cores have at least one thread, similar to the `scatter` type. However, when the runtime must use multiple hardware thread contexts on the same core, the `balanced` type ensures that the OpenMP® thread numbers are close to each other, which `scatter` does not do.

The following diagrams illustrate the allocation of six OpenMP® threads across a 3-core system with the `compact`, `scatter`, and `balanced` affinity types.

**Allocation with the compact affinity type**

![Diagram showing the allocation of six OpenMP® threads across a 3-core system with the compact affinity type.](image-url)
On the Intel® MIC Architecture, it is normally beneficial to use cores before threads, so the compact affinity type is unlikely to yield the best results, because it leaves cores unused.

**Allocation with the scatter affinity type**

The thread allocation under scatter is likely to be better than compact, because it uses cores before threads. However, scatter allocates thread IDs such that threads with IDs in close numerical proximity are on different cores, and therefore do not share caches. Because threads with neighboring IDs often operate on closely related data, placing them on different cores is unlikely to be the best way to allocate them.

**Allocation with balanced affinity type**
The thread allocation under balanced is balanced over the cores and the threads allocated to a core are neighbors of each other. Therefore, cache utilization should be efficient if the threads access data that is near in store.

**Allocation with balanced affinity type for 9 OpenMP* threads**

![Diagram of thread allocation]

Tuning affinity is a complicated and machine specific process. Using the balanced affinity type is a reasonable starting point on Intel® MIC Architecture.

The balanced affinity type is also recognized and supported by the OpenMP* runtime on the CPU, but only for single socket systems.

Using the balanced type with the environment variable KMP_AFFINITY propagates to the coprocessor when MIC_ENV_PREFIX is not set. However, this may generate the following runtime warning on a multi-socket CPU:

```
OMP: Warning #230: KMP_AFFINITY: Affinity balanced is not available.
```

To set the balanced affinity type for only the Intel® MIC Architecture environment, assign a specific prefix using the MIC_ENV_PREFIX=prefix and then set prefix_KMP_AFFINITY with balanced.

Setting Environment Variables on the CPU to Modify the Coprocessor’s Execution Environment

**Setting the Number of OpenMP* Threads on the Coprocessor**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Several methods exist to override the default number of threads per core on the coprocessor.

**Using the OpenMP* API**

The OpenMP* API specification provides the following standard ways to change the desired number of threads on the coprocessor:

- Calling the function `omp_set_num_threads(n)` before the `omp parallel region`
- Using the clause `!omp$ parallel num_threads(n)`
- Setting the environment variable `OMP_NUM_THREADS=n`

For more information, refer to the OpenMP* API Specification at http://www.openmp.org.
Using the Intel® Compiler

In addition to the standard methods that the OpenMP* API specification provides, listed below, you can use the environment variable MIC_ENV_PREFIX to define a custom-prefixed environment variable to control the number of OpenMP* threads on the coprocessor separately from the host CPU. For example, the following environment variable definitions set OMP_NUM_THREADS on both the CPU and the coprocessor, but with different values.

OMP_NUM_THREADS=8
ABC_OMP_NUM_THREADS=124
MIC_ENV_PREFIX=ABC

Direct calls on the coprocessor to APIs in libiomp5.so to establish a specific runtime setting override any setting previously set by a CPU environment variable that is replicated on the coprocessor.

Data Alignment for Intel® MIC Architecture

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Unlike the IA-32 and Intel® 64 architectures, the Intel® MIC Architecture requires all data accesses to be properly aligned according to their size, otherwise the program may behave unpredictably.

For example, an integer variable, which requires four bytes of storage, has to be allocated on an address that is a multiple of four. Likewise, a double-precision floating point variable, which requires eight bytes of storage, has to be allocated on an address that is a multiple of eight.

You can align data in the following ways:

- The compiler option align can force the alignment of local and global data, arrays, scalars, and fields of defined types, dummy arguments of procedures, data with the ALLOCATABLE or POINTER attribute, common block entities, and fields in SEQUENCE derived types. Natural alignment, where the data is properly aligned according to its size, is usually the default.
- Data objects may be misaligned because of their position in common blocks, because of EQUIVALENCE statements, or because they are fields in SEQUENCE derived types. Even if all of the fields of a defined type are naturally aligned, if the size of the object of defined type is not a multiple of the alignment of the largest field, arrays elements of this defined type would sometimes be misaligned.
- Entities in common blocks can be forced onto aligned addresses with the align *common compiler options. Fields of a SEQUENCE derived type can be forced onto aligned addresses with the align sequence compiler option. Use of these compiler options may affect the correctness of your program unless you apply them consistently to all program units that reference the data being aligned.
- The compiler option warn alignments is the default and displays a warning if a data object is misaligned.
- You can use the directives ATTRIBUTES ALIGN, ASSUME_ALIGNED, and ASSUME to align data or tell the compiler that the data should be treated as if aligned.

On the Intel® MIC Architecture, data alignment is so important that alignment warnings are turned into errors so the compilation will fail. Those alignment errors must be corrected before the program will compile.

Using HBW Memory

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Certain Intel® Xeon Phi™ coprocessors come equipped with a limited amount of Multi-Channel DRAM (MCDRAM). On Linux*, you can specify use of this high-bandwidth memory for allocatable scalars or arrays using the FASTMEM attribute. High bandwidth (HBW) memory is not large so choose the objects you place there carefully – objects that require repeated and rapid access are best placed in HBW memory. If the hardware is not available to allocate the object to HBW memory, or if enough HBW memory is not available to satisfy the allocation, then allocation is performed using non-HBW memory.

When you use the ATTRIBUTES FASTMEM directive in a program, you must specify the following on the compiler or linker command line:

- -lmemkind
The memkind library does not ship with Intel Fortran. The memkind webpage is here: http://memkind.github.io/memkind/

From there you can find links to source and binary RPM’s: http://download.opensuse.org/repositories/home:/cmcantalupo/

libmemkind.so must be in the linking path so if you install the binary RPM, it will be in your linking path and the link option `–lmemkind` is sufficient when you create a program that uses FASTMEM. If you build or put libmemkind.so in some other directory, you must specify that location with `–L` when you create a program that uses FASTMEM.

If the libraries required for HBW memory support are not linked successfully, no warning will be given but the application will still run correctly using non-HBW memory in place of HBW memory.

ATTRIBUTES FASTMEM directive

Generating an Offload Report

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

You can measure the amount of time it takes to execute an offload region of code, as well as the amount of data transferred during the execution of the offload region.

You can print an offload report, which contains information about an offload as the execution proceeds on the host and on the target. An offload report includes the following information:

- the amount of time it takes to execute an offload region of code
- the amount of data transferred between the host and the target
- additional details, including device initialization, and individual variable transfers

The following mechanisms enable and disable offload reporting:

- the OFFLOAD_REPORT environment variable.
- the _Offload_report API.

A compiler offload report line starts with `[Offload]` to clearly mark prints from compiler offloads, as opposed to other offloads, such as those from the Intel® Math Kernel Library.

Activities on the host are marked with `[HOST]`, while activities on the target are marked with `[MIC n]` where `n` is the logical number of the coprocessor to which the offload is sent. The top of the report shows the mapping of logical devices to physical devices. (Note that

NOTE
An offloaded program can use a subset of physical devices when you specify the OFFLOAD_DEVICES environment variable.

Because multiple offloads may be in progress concurrently, either when multiple host threads initiate offloads or when asynchronous offloads are used, it is necessary to tag all the output associated with a specific offload directive. Otherwise the reports from several concurrent offloads would be interleaved, making it impossible to determine to which offload a particular line of output belongs. A tag of the form `[Tag n]` uniquely identify lines in the offload report that belong to a particular offload.

For each offload, the first two report lines are the source file name and the line number of the offload directive. After that, a line that assigns a Tag to that offload is printed. Subsequent report lines printed for that offload each use the tag `[Tag n]` to associate that line with that offload.

The rest of the report contains a line for each major activity. These lines contain an annotation of the activity after the tag that identifies which offload the activity belongs to. The annotations are as follows:

<table>
<thead>
<tr>
<th>Line Marker</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[State]</td>
<td>Activity being performed as part of the offload.</td>
</tr>
</tbody>
</table>
### Table: Offload Report Output

<table>
<thead>
<tr>
<th>Line Marker</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Var]</td>
<td>The name of a variable transferred and the direction(s) of transfer.</td>
</tr>
<tr>
<td>[CPU Time]</td>
<td>The total time measured for that offload directive on the host.</td>
</tr>
<tr>
<td>[MIC Time]</td>
<td>The total time measured for executing the offload on the target. This excludes the data transfer time between the host and the target, and counts only the execution time on the target.</td>
</tr>
<tr>
<td>[CPU-&gt;MIC Data]</td>
<td>The number of bytes of data transferred from the host to the target.</td>
</tr>
<tr>
<td>[MIC-&gt;CPU Data]</td>
<td>The number of bytes of data transferred from the target to the host.</td>
</tr>
</tbody>
</table>

The various activities printed after [State] describe the internal operation of the Offload Library and are helpful in diagnosing the point at which a runtime failure may occur. In most cases the description is self-explanatory.

### Example

For this example, example.F90, the offload report output is explained below.

```
1  integer function Hysum(abc,efg,siz)
2  use mic_lib
3
4  integer, dimension(:) :: abc
5  integer, dimension(:) :: efg
6  integer :: siz
7
8  integer :: sumT
9  integer :: k
10
11  !DIR$ OFFLOAD BEGIN target(mic:0) &
12      IN(abc : length(siz )) &
13      OUT(efg : length(siz/2)) &
14      nocopy(k)
15
16  if (OFFLOAD_GET_DEVICE_NUMBER() > -1) then
17      print "(A,I0)","On device : ",OFFLOAD_GET_DEVICE_NUMBER()
18  endif
19
20  sumT = 0
21  do k=1,(siz/2)
22      efg(k) = abc(k) + abc(k + (siz/2))
23      sumT = sumT + efg(k)
24  enddo
25  !DIR$ END OFFLOAD
26
27  Hysum = sumT
28
29  return
30  end function Hysum
31
32  program example
33
34  integer, allocatable, dimension(:) :: tuv
35  integer, allocatable, dimension(:) :: xyz
```
The compiler option \texttt{OPT-REPORT-PHASE} with the \texttt{offload} keyword provides summary information about data transfers between the host and the target. There are two reports for each offload code section defined in the source code. The first report beginning with \texttt{Offload to target MIC} is from the host compilation. The second report beginning with \texttt{Outlined offload region} is from the target compilation. The information in this report option reflects similar information in the output when the \texttt{OFFLOAD_REPORT} environment variable is set to 3.

```fortran
example.F90(11-11):OFFLOAD:hysum_: Offload to target MIC <expr>
  hysum_$SUMT_V$31, default of INOUT changed to OUT
  hysum_$SIZ_V$2f, default of INOUT changed to IN
  hysum_$SUMT_V$31, default of INOUT changed to OUT
  hysum_$SIZ_V$2f, default of INOUT changed to IN
Data sent from host to target
  hysum$_ABC_V$2d, pointer to dope-vector with element count (<expr>) elements
  hysum$_SIZ_V$2f, pointer to (<expr>) elements
Data received by host from target
  hysum$_EFG_V$2e, pointer to dope-vector with element count (<expr>) elements
  hysum$_SUMT_V$31, scalar size 4 bytes

example.F90(11-11):OFFLOAD:hysum_: Outlined offload region
  hysum$_SUMT_V$31, default of INOUT changed to OUT
  hysum$_SIZ_V$2f, default of INOUT changed to IN
  hysum$_SUMT_V$31, default of INOUT changed to OUT
  hysum$_SIZ_V$2f, default of INOUT changed to IN
Data received by target from host
  hysum$_ABC_V$2d, pointer to dope-vector with element count (<expr>) elements
  hysum$_SIZ_V$2f, pointer to (<expr>) elements
```
The rest of this example explains the offload report for the source program shown above.

**NOTE**
The host and the target execute independently, so once an offload has been initiated the sequence between host prints and target prints is unpredictable, and can vary from run to run. However, all the host prints will be in the same sequence, as well as all the target prints.

Here, the target device is initialized, and the report shows the mapping between logical and physical devices:

```
[Offload] [HOST] [State] Initialize logical card 0 = physical card 0
[Offload] [HOST] [State] Initialize logical card 1 = physical card 1
```

Offload code in example.F90 at line number 11 has started executing on the target.

```
[Offload] [MIC 0] [File] example.F90
[Offload] [MIC 0] [Line] 11
```

Tag value Tag0 is assigned to this offload to enable identifying reports printed for this offload.

```
[Offload] [MIC 0] [Tag] Tag0
```

The offload is initiated on the host.

```
[Offload] [HOST] [Tag 0] [State] Start Offload
```

The target function corresponding to this offload.

```
[Offload] [HOST] [Tag 0] [State] Initialize function __offload_entry_example_F90_11hysum_
```

Create data transfer buffers for pointer data:
- Four buffers for abc: 2 for dope vector and 2 for memory.
- Four buffers for efg: 2 for dope vector and 2 for memory.
- Two buffers for sumt: This variable was added to the OUT clause by default. The variable sumt is used in the offload region.

```
[Offload] [HOST] [Tag 0] [State] Create buffer from Host memory
[Offload] [HOST] [Tag 0] [State] Create buffer from MIC memory
[Offload] [HOST] [Tag 0] [State] Create buffer from Host memory
[Offload] [HOST] [Tag 0] [State] Create buffer from MIC memory
[Offload] [HOST] [Tag 0] [State] Create buffer from Host memory
[Offload] [HOST] [Tag 0] [State] Create buffer from MIC memory
[Offload] [HOST] [Tag 0] [State] Create buffer from Host memory
[Offload] [HOST] [Tag 0] [State] Create buffer from MIC memory
[Offload] [HOST] [Tag 0] [State] Create buffer from Host memory
[Offload] [HOST] [Tag 0] [State] Create buffer from MIC memory
```

Pointer data sent from the host to the target using DMA, for the two dope vectors, and the variables abc and siz.

```
[Offload] [HOST] [Tag 0] [State] Send pointer data
[Offload] [HOST] [Tag 0] [State] CPU->MIC pointer data 188
```

Non-pointer data is collected together and sent from host to target.

```
[Offload] [HOST] [Tag 0] [State] Gather copyin data
[Offload] [HOST] [Tag 0] [State] CPU->MIC copyin data 0
```

The offloaded code (line 11) on the target is started.

```
[Offload] [HOST] [Tag 0] [State] Compute task on MIC
```

The offload has completed. Start receiving data from target.
Pointer data from the variable *efg* received from the target using DMA.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[HOST]</th>
<th>[Tag 0]</th>
<th>[State]</th>
<th>Receive pointer data</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[HOST]</td>
<td>[Tag 0]</td>
<td>[State]</td>
<td>MIC-&gt;CPU pointer data 20</td>
</tr>
</tbody>
</table>

This is output from the target. The offload code is invoked on the target.

| [Offload] | [MIC 0] | [Tag 0] | [State] | Start target function __offload_entry_example_F90_1hysum__ |

The variable *abc* is an **IN** for this offload. The two entries are a result of a dope vector for an adjustable array *abc* and memory for *abc*.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[MIC 0]</th>
<th>[Tag 0]</th>
<th>[Var]</th>
<th>hysum_$ABC_V$2d</th>
<th>IN</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[MIC 0]</td>
<td>[Tag 0]</td>
<td>[Var]</td>
<td>hysum_$ABC_V$2d</td>
<td>IN</td>
</tr>
</tbody>
</table>

The variable *efg* is an **OUT** for this offload. It is a dope vector for an adjustable array *efg* that must be transferred to the target, hence the two entries.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[MIC 0]</th>
<th>[Tag 0]</th>
<th>[Var]</th>
<th>hysum_$EFG_V$2e</th>
<th>IN</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[MIC 0]</td>
<td>[Tag 0]</td>
<td>[Var]</td>
<td>hysum_$EFG_V$2e</td>
<td>OUT</td>
</tr>
</tbody>
</table>

The variable *sumT* is an **OUT** for this offload.

| [Offload] | [MIC 0] | [Tag 0] | [Var] | hysum_$SUMT_V$31 | OUT |

The variable *siz* is an **IN** for this offload.

| [Offload] | [MIC 0] | [Tag 0] | [Var] | hysum_$SIZ_V$2f | IN |

On the target, non-pointer data is copied into target memory.

| [Offload] | [MIC 0] | [Tag 0] | [State] | Scatter copyin data |

User program output:

On device : 0

On the target, non-pointer data, the variable *sumT*, is gathered and sent from the target to the host.

<table>
<thead>
<tr>
<th>[Offload]</th>
<th>[MIC 0]</th>
<th>[Tag 0]</th>
<th>[State]</th>
<th>Gather copyout data</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Offload]</td>
<td>[MIC 0]</td>
<td>[Tag 0]</td>
<td>[State]</td>
<td>MIC-&gt;CPU copyout data 4</td>
</tr>
</tbody>
</table>

Non-pointer data is copied into target memory.

| [Offload] | [HOST] | [Tag 0] | [State] | Scatter copyout data |

**No** host time on the target.

| [Offload] | [MIC 0] | [CPU Time] | 0.000000 (seconds) |

The total amount of pointer and non-pointer data, the variables *abc* and *siz*, transferred from host to target.

| [Offload] | [MIC 0] | [CPU->MIC Data] | 188 (bytes) |

Computation time on the target.

| [Offload] | [MIC 0] | [MIC Time] | 0.000918 (seconds) |

The total amount of pointer and non-pointer data, the variables *efg* and *sumT*, transferred from target to host.

| [Offload] | [MIC 0] | [MIC->CPU Data] | 24 (bytes) |

User Program output:

```
xyz(1)=5   xyz(2)=7   xyz(3)=9   xyz(4)=11   xyz(5)=13
sum total=45
```

Cleanup at end of program:

Supported Environment Variables

_Offload_report

Controls printing offload execution time and the amount of data transferred. This function only applies to Intel® MIC Architecture.

Syntax

_Offload_report(integer)

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>integer</td>
<td>Possible values: 1, 2 or 3.</td>
</tr>
</tbody>
</table>

1: Prints the offload computation time, in seconds.

2: In addition to the information produced with value 1, adds the amount of data transferred between the CPU and the coprocessor, in bytes.

3: In addition to the information produced at value 2, gives additional details on offload activity, including device initialization, and individual variable transfers.

Description

This API enables you to time offload regions and measure the amount of data transferred during their execution.

Using this API is equivalent to setting the environment variable OFFLOAD_REPORT.

Example

In the following example if the OFFLOAD_REPORT environment variable is set, the report is produced for offloads before line 19 but suppressed from line 19 to line 28.

Reporting is turned back on at line 28, and subsequent offloads have reporting enabled.

```
01 subroutine foo()
02   !dir$ ATTRIBUTES OFFLOAD:mic:: foo
... 13 !dir$ offload begin target(mic:0) in(SIZ) & 14   in(pc: length(SIZ) alloc_if(.true.) free_if(.false.))
... 19  call Offload_report(0)   ! turn off Offload_report
21 !dir$ offload begin target(mic:0) & _
... 28 call Offload_report(1)   ! turn on Offload_report
29 !dir$ offload_transfer target(mic:0) & _
... 40 end
```

The following examples of output are just to give you an idea of the type of output you can expect for each setting. These output examples are not connected to the code examples above.
Here is an example of output for `_Offload_report(1)`:  

<table>
<thead>
<tr>
<th>Type</th>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offload</td>
<td>[MIC 0] [File]</td>
<td>test.f90</td>
</tr>

Calling exit() From an Offload Region

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

When calling exit() from within an offload region, the application reports an offload error stating the process on the device exited unexpectedly.

Building for Intel® MIC Architecture

Setting Stack Size on Coprocessors

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Each CPU thread that offloads code executes the offloaded code in a coprocessor thread dedicated to that CPU thread. The default stack size for that coprocessor thread is fairly small, 2 MB.

To increase the stack size allocated to offloaded code, set the environment variable MIC_STACKSIZE to a size sufficient for the offloaded code. MIC_STACKSIZE is always honored. It does not require the variable MIC_ENV_PREFIX to be set.

Specify the value for MIC_STACKSIZE as follows:

| integerB | A value, in bytes. |
| integerK | A value, in kilobytes. |
| integerM | A value, in megabytes. |
| integerG | A value, in gigabytes. |
| integerT | A value, in terabytes. |

For example, the following shell BASH and C shell commands set the maximum stacksize for the main coprocessor thread to 50MB:

```
export MIC_STACKSIZE=50M    #(BASH shell)
setenv MIC_STACKSIZE  50M    #(C shell)
```

**NOTE**

OpenMP* runtime libraries have their own environment variables for adjusting the sizes of the stacks used by additional OpenMP threads. MIC_STACKSIZE does not apply to such threads. For example, to increase the available stack size for every OpenMP thread except the main thread to 3 MB using the BASH shell, enter:

```
export OMP_STACKSIZE=3M
```

(affects OpenMP threads on both host and coprocessor) or

```
export MIC_ENV_PREFIX=ABC export ABC_OMP_STACKSIZE=3M
```

(affects coprocessor OpenMP threads only).

About Building Native Intel® MIC Architecture Applications
This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
You can build a binary to run natively on Intel® MIC Architecture, without building one to run on the CPU at all.
To build a native Intel® MIC Architecture binary, include the mmic (Linux*) or Qmic (Windows*) compiler option when you invoke the compiler. You can use the MIC_LIBRARY_PATH environment variable to add additional paths to search for libraries needed to build the native binary.

NOTE
When you specify Windows* option /Qmic, you must specify any other options on the command line in the Linux* form. This is because all other options are passed directly to the native Intel® MIC Architecture compiler, which is a Windows*-hosted Linux* compiler.
For example, when debugging applications for Intel® MIC Architecture on Windows*, you should use:

```
ifort /Qmic -g
```

The following information also applies to native Intel® MIC Architecture applications:
- Setting the compiler environment.
- Debugging native Intel® MIC Architecture applications. See debugger documentation.
- Class Libraries for Intel® Many Integrated Core (Intel® MIC) Architecture.
- Intrinsics Supporting Intel® Initial Many Core Instructions (Intel® IMCI).

Profile-Guided Optimization (PGO)

Profile-Guided Optimizations Overview

Profile-guided Optimization (PGO) improves application performance by shrinking code size, reducing branch mispredictions, and reorganizing code layout to reduce instruction-cache problems. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. Instrument the program. The compiler creates and links an instrumented program from your source code and special code from the compiler.
2. Run the instrumented executable. Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.
3. Final compilation. When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.

See Profile-guided Optimization Options for information about the supported options and Profile an Application for specific details about using PGO from the command line.

PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.
Detect and do not vectorize loops that execute only a small number of iterations, reducing the run time overhead that vectorization might otherwise add.

Interprocedural optimization (IPO) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about inline function expansion, which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. If you modify your program the compiler issues a warning that the dynamic information does not correspond to a modified function.
- Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.
- Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.
- Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance, execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile an Application

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking

   Use \texttt{[Q]prof-gen} to produce an executable with instrumented information included. Use \texttt{/Qcov-gen} (Windows) option to obtain minimum instrumentation only for code coverage.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and OS X</td>
<td>\texttt{ifort -prof-gen -prof-dir /usr/profiled} a1.f90 a2.f90 a3.f90 \texttt{ifort -oal a1.o a2.o a3.o}</td>
</tr>
</tbody>
</table>
Use the `/Qprof-dir` or `/Qcov-dir` (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

The compiler gathers extra information when you use the `-prof-gen=srcpos` (Linux and OS X) or `/Qprof-gen:srcpos` (Windows) option; however, the extra information is collected to provide support for specific Intel tools, including the code coverage Tool. If you do not expect to use such tools, do not specify `-prof-gen=srcpos` (Linux and OS X) or `/Qprof-gen:srcpos` (Windows); the extended option does not provide better optimization and could slow parallel compile times. If you are interested in using the instrumentation only for code coverage, use the `/Qcov-gen` (Windows) option, instead of the `/Qprof-gen:srcpos` (Windows) option, to minimize instrumentation overhead.

PGO data collection is optimized for collecting data on serial applications at the expense of some loss of precision on areas of high parallelism. However, you can specify the `threadsafe` keyword with the `-prof-gen` (Linux* and OS X*) or the `/Qprof-gen` (Windows) compiler option for files or applications that contain parallel constructs using OpenMP* or Intel® Cilk™ Plus features, for example. Using the `threadsafe` keyword produces instrumented object files that support the collection of PGO data on applications that use a high level of parallelism but may increase the overhead for data collection. On applications specific to Intel® 64 architecture targeting Intel® MIC Architecture, the only valid mode for using the PGO `-prof-gen` (Linux and OS X) or `/Qprof-gen` (Windows) compiler option is to use the keyword `threadsafe`.

**NOTE**
Unlike serial programs, parallel programs using OpenMP* or Intel® Cilk™ Plus may involve dynamic scheduling of code paths, and counts collected may not be perfectly reproducible for the same training data set.

### 2. Instrumented execution

Run your instrumented program with a representative set of data to create one or more dynamic information files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and OS X</td>
<td><code>./a1.out</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>a1.exe</code></td>
</tr>
</tbody>
</table>

Executing the instrumented applications generates a dynamic information file that has a unique name and `.dyn` suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

By default, the `.dyn` filename follows this naming convention: `<timestamp>_<pid>.dyn`. The `.dyn` file is either placed into a directory specified by an environment variable, a compile-time specified directory, or the current directory.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>ifort /Qprof-gen /Qprof-dir:c:\profiled a1.f90 a2.f90 a3.f90 ifort a1.obj a2.obj a3.obj</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>ifort /Qcov-gen /Qcov-dir:c:\cov_data a1.f90 a2.f90 a3.f90 ifort a1.obj a2.obj a3.obj</td>
</tr>
</tbody>
</table>
To make it easy to distinguish files from different runs, you can specify a prefix for the .dyn filename in the environment variable, `INTEL_PROF_DYN_PREFIX`. In such a case, executing the instrumented application generates a .dyn filename as follows: `<prefix>_timestamp_<pid>.dyn`, where `<prefix>` is the identifier that you have specified. Be sure to set the `INTEL_PROF_DYN_PREFIX` environment variable prior to starting your instrumented application.

**NOTE**
The value specified in `INTEL_PROF_DYN_PREFIX` environment variable must not contain `< > : " / \ | ? *` characters. The default naming scheme will be used if an invalid prefix is specified.

### 3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with `[Q]prof-use`; the option instructs the compiler to use the generated dynamic information to guide the optimization:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and OS X</td>
<td><code>ifort -prof-use -ipo -prof-dir /usr/ profiled a1.f90 a2.f90 a3.f90</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>ifort /Qprof-use /Qipo /Qprof-dir:c: \profiled a1.f90 a2.f90 a3.f90</code></td>
</tr>
</tbody>
</table>

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations, `O2`, for phase 1, and specify more advanced optimizations, `[Q]ipo`, during the phase 3 (final) compilation. The example shown above used `O2` in step 1 and `[Q]ipo` in step 3.

**NOTE**
The compiler ignores the `[Q]ipo` or `[Q]ip` option during phase 1 with `[Q]prof-gen`.

### Profile Function or Loop Execution Time

This topic describes how to profile an application for function or loop execution time. Using the instrumentation method to profile function or loop execution time provides an easy means of getting a view of where cycles are being spent in your application. The Intel® compiler inserts instrumentation code into your application to collect the time spent in various locations. Such data helps you to identify hotspots that may be candidates for optimization tuning or targeting parallelization.

Different levels of instrumentation are available because of the difference in the overhead associated with the inserted probe points that read the CPU cycle counter. The instrumentation levels, in increasing amount of collected data, are grouped as follows:

- Function level
- Function and loop level
- Loop body level

You do not need to profile the entire application but it is recommended that the same level of instrumentation is used for all instrumented files. Compile your application with the command line options described below for all the files that require profile information.

After the instrumented application is run, data files containing a summary of the collected data are created in the working directory. View these data files to identify the time proportions of the different parts of your application.
**Compiler Options to Obtain Instrumented Program**

Use the following command-line compiler options to instrument your application code to profile execution times for functions/loops. When you compile your application using any one of these options, you get an instrumented program.

<table>
<thead>
<tr>
<th>Instrumentation Level</th>
<th>Linux* or OS X* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
</table>
| Function level        | -profile-functions               | /Qprofile-functions        | Instruments function entry/exit points only.  
  - Inserts instrumentation calls on the function entry and exit points to collect the cycles spent within the function.  
  - Data collection is supported for single-threaded applications only.  
  - The collected data from execution of the instrumented application is placed in the file, `loop_prof_funcs_<timestamp>.dump` in the current working directory. |
| Function and loop level | -profile-loops=<arg>             | /Qprofile-loops:<arg>      | Instruments function and loop entry/exit points:  
  - The `<arg>` argument allows you to specify the types of the loops to be instrumented. The `<arg>` value must be one of the following:  
    - Inner: Instrument inner loops.  
    - Outer: Instrument outer loops.  
    - All: Instrument both inner and outer loops.  
  - Inserts instrumentation calls for function entry and exit points, and before and after instrumentable loops as listed in the `<arg>` argument.  
  - Data collection is supported for single-threaded applications only.  
  - The collected data from execution of the instrumented application is placed in the files, `loop_prof_funcs_<timestamp>.dump` and `loop_prof_loops_<timestamp>.dump` in the current working directory for the function data and loop data, respectively. |

**NOTE**
The compiler may be unable to instrument some loops.
<table>
<thead>
<tr>
<th>Instrumentation Level</th>
<th>Linux* or OS X* Operating System</th>
<th>Windows* Operating System</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loop body level</td>
<td>-profile-loops-report=[n]</td>
<td>/Qprofile-loops-report:[n]</td>
<td>Controls level of instrumentation for loop bodies where:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Specifying n=1 collects the cycle counts on entry and exits of loops. This is the default value if no value is specified for n.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Specifying n=2 inserts additional instrumentation for collecting loop iteration counts to compute loop min/max and average iteration counts. Such instrumentation increases overhead in the instrumented application.</td>
</tr>
</tbody>
</table>

**NOTE**
Because the instrumentation takes place after many compiler transformations have taken place, loops that have been restructured or replicated by the compiler may result in multiple entries in the generated reports. Additionally, functions may have been inlined into other functions, which may cause the same loop to be listed in multiple functions.

**NOTE**
Because instrumentation takes place after compiler transformations have taken place, the loop trip count is based on the generated form of the loop, which may be unrolled, and may be different from the original source form.

**NOTE**
Because this instrumentation relies on the CPU time stamp counter for collecting timing information, only single threaded applications should be profiled with these options. Using these options with other compiler options that enable parallel code generation is not supported.
Output Formats Obtained on Running Instrumented Program

After compiling your application using the options, you obtain an instrumented program. Run this instrumented program with a representative set of data to create one or more data files.

The output files are produced by a routine that is registered with the `atexit()` routine, and are created only when the program exits via a standard exit procedure. Two formats of the output files are created:

- A plain text file using ‘tab’ delimiters, which can be viewed within a text editor or a spreadsheet.
- An XML data file that can be loaded into the data viewer application.

Text Output Format

The text output is written into separate files in the current directory. The filenames are `loop_prof_func_<timestamp>.dump` and `loop_prof_loops_<timestamp>.dump` for functions and loops respectively. The `<timestamp>` value is the same for both files to indicate they are from the same instrumentation run.

You can load the text files into a spreadsheet by specifying that the data is delimited with ‘tab’ delimiters.

The function report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (abs)</td>
<td>Total accumulated cycles spent between function entry and exit.</td>
</tr>
<tr>
<td>Time %</td>
<td>Percentage of total application time for cycles between function entry and exit.</td>
</tr>
<tr>
<td>Self (abs)</td>
<td>Accumulated cycles spent between function entry and exit less the cycles spent within calls to other instrumented functions.</td>
</tr>
</tbody>
</table>

**NOTE**
Time spent in calls to routines or libraries that were not instrumented are included within this cycle count value.

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Self %</td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td>Call count</td>
<td>Number of times the function was entered.</td>
</tr>
<tr>
<td>Exit count</td>
<td>Number of times the function exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a function without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
<tr>
<td>Loop ticks (%)</td>
<td>The percentage of total application time for the self-time cycles of loops within the function. This field is relevant only when you use <code>[Q]profile-loops</code> compiler option.</td>
</tr>
<tr>
<td>Function</td>
<td>Demangled function name</td>
</tr>
<tr>
<td>File:line</td>
<td>Source file containing the code for the function, and the line number the function begins on.</td>
</tr>
</tbody>
</table>

The loop report file contains the following columns:

<table>
<thead>
<tr>
<th>Column Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (abs)</td>
<td>Total accumulated cycles spent between loop entry and exit.</td>
</tr>
<tr>
<td>Time %</td>
<td>Percentage of total application time for cycles between loop entry and exit.</td>
</tr>
<tr>
<td>Self (abs)</td>
<td>Accumulated cycles spent between loop entry and exit less the cycles spent within calls to other instrumented functions/loops.</td>
</tr>
<tr>
<td>Column Heading</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Self %</td>
<td>Percentage that self(abs) represents of total application time.</td>
</tr>
<tr>
<td>Loop entries</td>
<td>Number of times the loop was entered.</td>
</tr>
<tr>
<td>Loop exits</td>
<td>Number of times the loop exit instrumentation was invoked. In some instances, such as cases involving exception handling, it may be possible for control to transfer out of a loop without the exit instrumentation being seen, resulting in this being different than the call count value.</td>
</tr>
<tr>
<td>Min iteration counts</td>
<td>The smallest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Avg iteration counts</td>
<td>The average iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Max iteration counts</td>
<td>The largest iteration count for an invocation of the loop. This field is relevant only when you use instrumentation level = 2, using the <code>[Q]profile-loops-report=2</code> compiler option.</td>
</tr>
<tr>
<td>Function</td>
<td>Demangled function name that executed the loop; this may be different from the function that contained the loop source code, if that function was inlined into another function.</td>
</tr>
<tr>
<td>Function file:line</td>
<td>The name of the source file containing the function that executed the loop, and the line number the function begins on.</td>
</tr>
<tr>
<td>Loop file:line</td>
<td>The name of the source file containing the loop body, and the line number the loop body begins on.</td>
</tr>
</tbody>
</table>

**XML Output Format**

The `INTEL_LOOP_PROF_XML_DUMP` environment variable is used to control the creation of the XML output format. When `INTEL_LOOP_PROF_XML_DUMP = 0`, no XML file is created.

The XML output file, named `loop_prof_<timestamp>.xml`, is written into the current directory. This file is viewed with the data viewer utility. The XML data file contains both the function and loop level data.

Remember, using the environment variable with a value of 0 implies that the data viewer utility is not going to be used since no XML data files are created.

**Data Viewer Utility**

You must have the Java Runtime Environment, version 1.6 installed on your system to use the data viewer utility. The JRE v1.6 is not included with the Intel® Compiler package.

The Data Viewer displays the data collected for the functions and loops in a sequence of columns that allows for sorting of individual columns. The Data Viewer also provides the ability to filter the function or loops to only display items that meet some threshold amount (total time % or self-time %) of the total application time, or to only show loops that are associated with a particular function.

To launch the Data Viewer utility, or use the following commands from the command line:

**On Windows* operating system:**

`loopprofileviewer[.bat] <datafile>`

**On Linux* and OS X* operating systems:**

`loopprofileviewer.sh <datafile>`

or

`loopprofileviewer.csh <datafile>`
The main user interface displays an upper pane, **Function Profile**, containing function level data, and a lower pane, **Loop Profile**, containing loop level data. If the XML data file is created using only function level instrumentation, the lower pane is not displayed. Drag the separator between individual panes to resize them or click the up/down arrows available on the separator line.

The **Function Profile** pane and **Loop Profile** pane contain the set of columns described in the section, Text Output Format. Click on any of these columns to sort the data based on that column.

The Data Viewer utility has two specific menus - the **View** menu and the **Filter** menu - in the menu bar besides the generic **File** and **Help** menus.

**View Menu**

The **View** menu allows you to open a window that shows the source code for the line you have selected in the table (these menus are grayed out if no line is selected). To use the **View** menu:

1. Select a line in the **Function Profile** pane.
2. Go to **View > Function source for selected function** to see the source code for the selected function.
3. Select a line in the **Loop Profile** pane.
4. Go to **View > Function source for selected loop** to see the source code for the selected function.
5. Go to **View > Loop source for selected loop** to see the source code for the selected loop.

When the cursor is within the **Function Profile** pane or the **Loop Profile pane**, right-click on any line to display a popup menu that gives access to these **View** menu options.
By default, the Data Viewer utility displays the most relevant columns based on the data file loaded. Go to View > Select Columns to display or hide the columns. In the dialog box that opens, columns not available for the currently loaded data file are grayed out.

**Filter Menu**

The Filter menu allows you to limit the data displayed in the tables to items that meet some criteria. As an example, you can use the Filter menu as follows:

1. Go to Filter > Function Profile > “Self time > 1.00%” to list only the functions in the Function Profile pane that represented more than 1.0 % of the application time.
2. Go to Filter > Set thresholds to modify the default thresholds used when enabling the filters for total time % or self-time %.

To display only the loops of a particular function, do the following:

1. Select a function in the Function column of the Function Profile pane.
2. Go to Filter > Loop Profile > Show loops for selected function to display the loops for the selected function.

When the cursor is within the Function Profile pane or the Loop Profile pane, you can right-click any function to display a popup menu that gives access to these Filter menu options.

**Profile-Guided Optimization Report**

The PGO report can help identify where and how the compiler used profile information to optimize the source code. The PGO report is most useful when combined with the PGO compilation steps outlined in the topic, Profile an Application. Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including -prof-use (Linux* and OS X*) or /Qprof-use (Windows*). The following syntax examples demonstrate how to run the report using the combined options.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Syntax Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* OS</td>
<td>ifort -prof-use -opt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>OS X*</td>
<td>ifort -prof-use -opt-report-phase=pgo pgotools_sample.c</td>
</tr>
<tr>
<td>Windows* OS</td>
<td>ifort pgotools_sample.c /Qprof-use /Qopt-report-phase=pgo</td>
</tr>
</tbody>
</table>

By default the PGO report generates a medium level of detail (where the [Q]opt-report argument \(n=2\)). You can use the -opt-report=\(n\) (Linux and OS X) or /Qopt-report:\(n\) option along with the [Q]opt-report-phase option if you want a greater or lesser level of diagnostic detail.

The output, by default, comes out to a file with the same name as the object file but with an .optrpt extension and is written into the same directory as the object file. Using the entries in the example above, the output file will be pgotools_sample.optrpt. Use the -opt-report-file (Linux and OS X) or the /Qopt-report-file (Windows) option to specify any other name for the output file that captures the report results, or to specify that the output should go to stdout or stderr.

Profile an Application
PGO API Support

Resetting Profile Information

The `_PGOPTI_Prof_Reset_All()` function clears the profile information collected by the instrumented application. The prototype of the function call is listed below.

One of the activities performed under profile-guided optimization is value-profiling. With value-profiling, the compiler inserts instrumentation to obtain a sample of the variable values in the program. Based upon this sampling, the compiler optimizes the user's code using frequently-observed values.

In effect, during a run of an instrumented executable, the segment maintained for each routine executed during that run stores the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the `_PGOPTI_Prof_Reset()` function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>void _PGOPTI_Prof_Reset_All(void);</td>
</tr>
</tbody>
</table>

The older version of this function, `_PGOPTI_Prof_Reset()`, is deprecated.

When `_PGOPTI_Prof_Reset_All()` function is called, it insures that all the counters within the main application and all the instrumented shared libraries are cleared. All the counters for block execution counts and value profiling information is reset to 0.

**NOTE**

For routines that were in progress when the reset call was made, the counts for portions of the routine that executed following the call to the reset function may have higher counts than portions of the routine that executed prior to the reset call.

Dumping Profile Information

The `_PGOPTI_Prof_Dump_All()` function dumps the profile information collected by the instrumented application. The prototype of the function call is listed below.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>void _PGOPTI_Prof_Dump_All(void);</td>
</tr>
</tbody>
</table>

An older version of this function, `_PGOPTI_Prof_Dump()`, is deprecated and no longer used.

The new function, `_PGOPTI_Prof_Dump_All()`, operates much like the deprecated function, except on Linux* operating systems, when it is used in connection with shared libraries (.so). When `_PGOPTI_Prof_Dump_All()` is called, it insures that a .dyn file is created for all shared libraries needing to create a .dyn file. Use `_PGOPTI_Prof_Dump_All()` on Linux OS to insure portability and correct functionality.

The profile information is generated in a .dyn file (generated in phase 2 of PGO).

The environment variables that affect the `_PGOPTI_Prof_Dump_All()` function are PROF_DIR, COV_DIR, PROF DPI, and COV DPI. Set the PROF_DIR or COV_DIR environment variable to specify the directory to which the .dyn file must be stored. Alternately, you can use the -Q prof_dir compiler option, when building with -Q prof-gen, to specify this directory without setting the PROF_DIR or COV_DIR variable.
Set the PROF_DPI or COV_DPI environment variables to specify an alternative .dpi filename. The default filename is pgopti.dpi. You can also use the -prof_dpi profmerge tool option, when merging the .dyn files, to specify the filename for the summary .dpi file.

**Recommended Usage**

If your application does not use a standard exit() call, insert a single call to this function in the body of the function that terminates the user application. Normally, _PGOPTI_Prof_Dump_All() should be called just once. It is also possible to use this function in conjunction with _PGOPTI_Prof_Reset_All() function to generate multiple .dyn files (presumably from multiple sets of input data).

**NOTE**

If the data is not reset between the dumps with a call to the _PGOPTI_Prof_Reset_All() function, the counters will continue accumulating data, resulting in the subsequent .dyn file containing data that was previously dumped.

**Example**

```fortran
! Selectively collect profile information
! for the portion of the application
! involved in processing input data.
input_data = get_input_data()

do while (input_data)
    call _PGOPTI_Prof_Reset()
    call process_data(input_data)
    call _PGOPTI_Prof_Dump_All()

    input_data = get_input_data()
end do

end program
```

**Dumping Profile Data**

This discussion provides an example of how to call the C PGO API routines from Fortran.

As part of the instrumented execution phase of PGO, the instrumented program writes profile data to the dynamic information file (.dyn file).

The profile information file is written after the instrumented program returns normally from PROGRAM() or calls the standard exit function.

Programs that do not terminate normally, can use the _PGOPTI_Prof_Dump_All() function. During the instrumentation compilation, using the -prof-gen (Linux* and OS X*) or /Qprof-gen (Windows*) option, you can add a call to this function to your program using a strategy similar to the one shown below:
**Interval Profile Dumping**

The `_PGOPTI_Set_Interval_Prof_Dump()` function activates Interval Profile Dumping and sets the approximate frequency at which dumps occur. This function is used in non-terminating applications.

The prototype of the function call is listed below.

**Syntax**

```c
void _PGOPTI_Set_Interval_Prof_Dump(int interval);
```

This function is used in non-terminating applications.

The `interval` parameter specifies the time interval at which profile dumping occurs and is measured in milliseconds. For example, if interval is set to 5000, then a profile dump and reset will occur approximately every 5 seconds. The interval is approximate because the time-check controlling the dump and reset is only performed upon entry to any instrumented function in your application.

Setting the interval to zero or a negative number will disable interval profile dumping, and setting a very small value for the interval may cause the instrumented application to spend nearly all of its time dumping profile information. Be sure to set interval to a large enough value so that the application can perform actual work and substantial profile information is collected.

You can use the profmerge and proforder Tools tool to merge the .dyn files.

**Recommended usage**

Call this function at the start of a non-terminating user application to initiate interval profile dumping. Note that an alternative method of initiating interval profile dumping is by setting the environment variable `INTEL_PROF_DUMP_INTERVAL` to the desired interval value prior to starting the application.

Using interval profile dumping, you should be able to profile a non-terminating application with minimal changes to the application source code.

To control the behavior during dumping, you may use the environment variable `INTEL_PROF_DUMP_CUMULATIVE`. When `INTEL_PROF_DUMP_INTERVAL` is used without `INTEL_PROF_DUMP_CUMULATIVE`, the counters are reset after each dump, and a new .dyn file will be created containing the data collected during each interval. This may result in a potentially large number of .dyn files that need to be stored and merged together by profmerge.
When \texttt{INTEL_PROF_DUMP_CUMULATIVE} is set (to any value), the .\texttt{dyn} file dump will be created at a specified interval as before, but the data will not be reset following the dump, and only the most recent .\texttt{dyn} file will be kept on the file system. This allows for the ability to create a .\texttt{dyn} file for a non-terminating application that contains all the accumulated counts to that point, but without the need for storage and merging of a large set of .\texttt{dyn} files.

\textbf{Resetting the Dynamic Profile Counters}

The \_\texttt{PGOPTI_Prof_Reset()} function resets the dynamic profile counters. The prototype of the function call is listed below.

\begin{verbatim}
void _PGOPTI_Prof_Reset(void);
\end{verbatim}

This function is now deprecated. See \_\texttt{PGOPTI_Prof_Reset_All()} function, which can be used instead.

One of the activities performed under profile-guided optimization is value-profiling. With value-profiling, the compiler inserts instrumentation to obtain a sample of the variable values in the program. Based upon this sampling, the compiler optimizes the user’s code using frequently observed values.

In effect, during a run of an instrumented executable, the segment maintained for each routine executed during that run stores the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the \_\texttt{PGOPTI_Prof_Reset()} function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

\textbf{Recommended Usage}

Use this function to clear the profile counters prior to collecting profile information on a section of the instrumented application. See the example under Dumping Profile Information.

\textbf{Dumping and Resetting Profile Information}

The \_\texttt{PGOPTI_Prof_Dump_And_Reset()} function dumps the profile information to a new .\texttt{dyn} file and then resets the dynamic profile counters. Then the execution of the instrumented application continues.

The prototype of the function call is listed below.

\begin{verbatim}
void _PGOPTI_Prof_Dump_And_Reset(void);
\end{verbatim}

This function is used in non-terminating applications and may be called more than once. Each call will dump the profile information to a new .\texttt{dyn} file.

\textbf{Recommended Usage}

Periodic calls to this function enables a non-terminating application to generate one or more profile information files (.\texttt{dyn} files). These files are merged during the \textit{feedback phase} of profile-guided optimizations. The direct use of this function enables your application to control precisely when the profile information is generated.
High-Level Optimization (HLO) Overview

High-level Optimizations (HLO) exploit the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. While the default optimization level, option `O2`, performs some high-level optimizations, specifying the `O3` option provides the best chance for performing loop transformations to optimize memory accesses.

**NOTE**

Loop optimizations may result in calls to library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The optimizations performed can also be affected by certain options, such as `/arch` (Windows*), `-m` (Linux* and OS X*), or `[Q]x` options. Additional HLO transformations may be performed for Intel® microprocessors than for non-Intel microprocessors.

Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Predicate Optimization
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Memset Combining, Memory Layout Change
- Loop Rerolling
- Memset andMemcpy Recognition
- Statement Sinking for Creating Perfect Loopnests
- Multiversioning: Checks include Pointer Dependency and Trip Counts
- Loop Collapsing
Interprocedural Optimization (IPO) Overview

Interprocedural Optimization (IPO) is an automatic, multi-step process that allows the compiler to analyze your code to determine where you can benefit from specific optimizations.

The compiler may apply the following optimizations:

- address-taken analysis
- array dimension padding
- alias analysis
- automatic array transposition
- automatic memory pool formation
- common block variable coalescing
- common block splitting
- constant propagation
- dead call deletion
- dead formal argument elimination
- dead function elimination
- formal parameter alignment analysis
- forward substitution
- indirect call conversion
- inlining
- mod/ref analysis
- partial dead call elimination
- passing arguments in registers to optimize calls and register usage
- routine key-attribute propagation
- specialization
- stack frame alignment
- structure splitting and field reordering
- symbol table data promotion
- un-referenced variable removal
- whole program analysis

IPO Compilation Models

IPO supports two compilation models - single-file compilation and multi-file compilation.

Single-file compilation uses the `ip` compiler option, and results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the `O2` default optimization level; additionally the compiler may perform some inlining for the `O1` optimization level, like inlining functions marked with inlining directives.
Multi-file compilation uses the `ipo` option, and results in one or more mock object files rather than normal object files. (See the Compilation section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files.

**NOTE**

Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see Profile an Application.

OS X*: Intel®-based systems running OS X do not support a multiple object compilation model.

**Compiling with IPO**

As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file. The mock object files contain the IR instead of the normal object code. Mock object files can be ten times or more larger than the size of normal object files.

During the IPO compilation phase only the mock object files are visible.

**Linking with IPO**

When you link with the `ipo` compiler option the compiler is invoked a final time. The compiler performs IPO across all mock object files. The mock objects must be linked with the Intel compiler or by using the Intel linking tools. While linking with IPO, the Intel compilers and other linking tools compile mock object files as well as invoke the real/true object files linkers provided on the user's platform.

Link-time optimization using the `-ffat-lto-objects` compiler option is provided for GCC compatibility. During IPO compilation, you can specify `-ffat-lto-objects` option, for the compiler to generate a fat link-time optimization (LTO) object that has both a real/true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.

You can specify the `-fno-fat-lto-objects` option for the compiler to generate a link-time optimization (LTO) object that only has a discardable intermediate language section; no real/true object is generated. These files are inserted into archives in the form in which they were created. Using this option may improve compilation time and save space for objects.

If you use `ld` rather than `xild` to link objects or `ar` instead of `xiar` to create an archive, the real/true object, generated during fat link-time optimization guarantees that there will be no impediment to linking/building the archive. However, cross-file optimizations are lost in this case. The extra true object also takes additional space and takes compile time to generate it, so using `-fno-fat-lto-objects` compiler option is an advantage provided that you link the IPO mock object files with `xild` and archive them with `xiar`.

**Whole Program Analysis**

The compiler supports a large number of IPO optimizations that can be applied or have its effectiveness greatly increased when the whole program condition is satisfied.

During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis - object reader method and table method. Most optimizations can be applied if either type of whole program analysis determines that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

**Object reader method**
In the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

**Table method**

In the table method the compiler analyzes the mock object files and generates a call-graph. The compiler contains detailed tables about all of the functions for all important language-specific libraries, like the Fortran runtime libraries. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls by finding each an entry for each unresolved function in the compiler tables. If the compiler can resolve the functions call, the whole program condition exists.

Using IPO

**Using IPO**

This topic discusses how to use IPO from the command line.

**Compiling and Linking Using IPO**

To enable IPO, you first compile each source file, then link the resulting source files.

First, compile your source files with [Q]ipo compiler as shown below:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* and OS X*</td>
<td>ifort -ipo -c a.f90 b.f90 c.f90</td>
</tr>
<tr>
<td>Windows*</td>
<td>ifort /Qipo /c a.f90 b.f90 c.f90</td>
</tr>
</tbody>
</table>

The output of the above example command differs according to operating system:

- Linux and OS X: The commands produce a.o, b.o, and c.o object files.
- Windows: The commands produce a.obj, b.obj, and c.obj object files.

Use the c compiler option to stop compilation after generating .o or .obj files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.

Second, link the resulting files. The following example command will produce an executable named app:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and OS X</td>
<td>ifort -o app a.o b.o c.o</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:app a.obj b.obj c.obj</td>
</tr>
</tbody>
</table>
The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the xild (Linux and OS X) or xilink (Windows) tool, with the appropriate linking options.

**Combining the Steps**

The separate compile and link commands demonstrated above can be combined into a single command, as shown in the following examples:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and OS X</td>
<td>ifort -ipo -o app a.f90 b.f90 c.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /Qipo /exe:app a.f90 b.f90 c.f90</td>
</tr>
</tbody>
</table>

The `ifort` command, shown in the examples above, calls GCC ld (Linux and OS X) or link.exe (Windows only) to link the specified object files and produce the executable application, which is specified by the `-o` (Linux and OS X) or `/exe` (Windows) option.

**Capturing Intermediate IPO Output**

The `[Q]ipo-c` and `[Q]ipo-S` compiler options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.

- Use the `[Q]ipo-c` compiler option to optimize across files and produce an object file. The option performs optimizations as described for the `[Q]ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.o` (Linux and OS X) or `ipo_out.obj` (Windows).
- Use the `[Q]ipo-S` compiler option to optimize across files and produce an assembly file. The option performs optimizations as described for `[Q]ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and OS X) or `/exe` (Windows) option to specify a different name. These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and OS X) or `/exe` (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and OS X) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `[Q]ipo-c` option, but you will not get the full benefit of whole program optimizations if you use this option.

The object file created using the `[Q]ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. It does not contain the IR information needed to fully optimize the application using IPO.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

IPO-Related Performance Issues

There are some general optimization guidelines for IPO that you should keep in mind:

- Using IPO on very large programs might trigger internal limits of other compiler optimization phases.
- Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to the general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

- Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. The Intel® Compiler cannot inspect mock object files generated by other compilers for optimization opportunities.
- Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and OS X, replace all instances of `ld` with `xild`; for Windows, replace all instances of `link` with `xilink`.

IPO for Large Programs

In most cases, IPO generates a single true object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use [Q]ipo compiler option on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple true object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

- Use the [Q]ipoN compiler option and pass an integer value in the place of N.
- Use the [Q]ipo-separate compiler option.

The number of true object files generated by the link-time compilation is invisible to you unless the [Q]ipo-c or [Q]ipo-S compiler option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the desired results then experiment with generating more object files.

You can use the [Q]ipo-jobs compiler option to control the number of commands, or jobs, executed during parallel builds.

Using [Q]ipoN to Create Multiple Object Files

If you specify [Q]ipo0, which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications.

If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass a value that exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files.

The following example commands demonstrate how to use [Q]ipo2 option to compile large programs.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td>ifort /Qipo2 /c a.f90 b.f90</td>
</tr>
<tr>
<td>Linux*</td>
<td>ifort -ipo2 -c a.f90 b.f90</td>
</tr>
</tbody>
</table>
Operating System  | Example Command
--- | ---
OS X*  | `ifort -ipo2 -c a.f90 b.f90`

In executing the above commands, the compiler generates object files using an OS-dependent naming convention. On Linux* and OS X*, the example command results in object files named `ipo_out.o`, `ipo_out1.o`, and `ipo_out2.o`. On Windows*, the file names follow the same convention; however, the file extensions will be `.obj`.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

Creating the Maximum Number of Object Files

Using `[Q]ipo-separate` allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation. The maximum number of true object files is the equal to the number of mock object files passed on the link line.

For example, you can pass example commands similar to the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td><code>ifort a.obj b.obj c.obj /Qipo-separate /Qipo-c</code></td>
</tr>
<tr>
<td>Linux*</td>
<td><code>ifort a.o b.o c.o -ipo-separate -ipo-c</code></td>
</tr>
<tr>
<td>OS X*</td>
<td><code>ifort a.o b.o c.o -ipo-separate -ipo-c</code></td>
</tr>
</tbody>
</table>

The compiler generates multiple object files that use the same naming convention discussed above.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

Understanding Code Layout and Multi-Object IPO

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

If you are generating an executable in the link step, the compiler does all of this automatically. However, if you are generating object files instead of an executable, the compiler generates a layout script, which contains the correct information needed to optimally link the executable when you are ready to create it.

This linking tool script must be taken into account if you use either the `[Q]ipo-c` or `[Q]ipo-S` compiler option. With these options, the IPO compilation and actual linking are done by different invocations of the compiler. When this occurs, the compiler issues a message indicating that it is generating an explicit linker script, `ipo_layout.script`.

The Windows linker (link.exe) automatically collates these sections lexigraphically in the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system: Windows:
The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on.

Linux:

The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on. It then generates a linker script that tells the linker to first link contributions from `.text00001`, then `.text00002`.

When `ipo_layout.script` is generated, you should modify your link command if you want to use the script to optimize code layout:

```
Example
--script=ipo_layout.script
```

If your application already requires a custom linker script, you can place the necessary contents of `ipo_layout.script` in your script.

The layout-specific content of `ipo_layout.script` is at the beginning of the description of the `.text` section. For example, to describe the layout order for 12 routines:

```
Example output

.text :
[
*(.text00001) *(.text00002) *(.text00003) *(.text00004) *(.text00005)
*(.text00006) *(.text00007) *(.text00008) *(.text00009) *(.text00010)
*(.text00011) *(.text00012)
...]
```

For applications that already require a linker script, you can add this section of the `.text` section description to the customized linker script. If you add these lines to your linker script, it is desirable to add additional entries to account for future development.

If you choose to not use the linker script your application will still build, but the layout order will be random. This may have an adverse affect on application performance, particularly for large applications.

Creating a Library from IPO Objects

Linux* and OS X*

Libraries are often created using a library manager such as `xiar` for Linux*/OS X* or `lib` for Windows. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

```
Example
xiar cru user.a a.o b.o
```

The above command creates a library named `user.a` containing the `a.o` and `b.o` objects.

If the objects have been created using `[Q]ipo -c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file.
The commands generate mock objects files, which when placed in archive will also be accompanied by a true object file.

Using xiar is the same as specifying xild -lib.

**OS X* Only**
When using xilibtool, specify -static to generate static libraries, or specify dynamic to create dynamic libraries. For example, the following example command will create a static library named mylib.a that includes the a.o, b.o, and c.o objects.

**Example**
```
xilibtool -static -o mylib.a a.o b.o c.o
```
Alternately, the following example command will create a dynamic library named mylib.dylib that includes the a.o, b.o, and c.o objects.

**Example**
```
xilibtool -dynamic -o mylib.dylib a.o b.o c.o
```
Specifying xilibtool is the same as specifying xild -libtool.

**Windows* Only**
Create libraries using xilib or xilink -lib to create libraries of IPO mock object files and link them on the command line.

For example, assume that you create three mock object files by using a command similar to the following:

**Example**
```
ifort /c /Qipo a.obj b.obj c.obj
```
Further assume a.obj contains the main subprogram. You can enter commands similar to the following to create a library.

**Example**
```
xilib -out:main.lib b.obj c.obj
or
xilink -lib -out:main.lib b.obj c.obj
```
You can link the library and the main program object file by entering a command similar to the following:

**Example**
```
xilink -out:result.exe a.obj main.lib
```

Requesting Compiler Reports with the xi* Tools

The compiler option \texttt{[Q]opt-report} generates optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a file (instead of stderr), and request reports from all routines with names containing a specific string as part of their name.

The xi* tools are used with inter-procedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported xi* tools are:

- Linker tools: \texttt{xilink} (Windows*) and \texttt{xild} (Linux* and OS X*)
- Library tools: \texttt{xilib} (Windows*), \texttt{xiar} (Linux* and OS X*), \texttt{xilibtool} (OS X*)

The following tables lists the compiler report options that can be used with the xi* tools during the final IPO compilation.

<table>
<thead>
<tr>
<th>Optimization Report Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| \texttt{-opt-report[=n]} (Linux* and OS X*) \texttt{/Qopt-report[:n]} (Windows*) \texttt{-opt-report-file=filename} (Linux* and OS X*) \texttt{/Qopt-report-file:filename} (Windows*) \texttt{-opt-report-phase[=list]} (Linux* and OS X*) \texttt{/Qopt-report-phase:list} (Windows*) \texttt{-opt-report-routine=substring} (Linux* and OS X*) \texttt{/Qopt-report-routine:substring} (Windows*) \texttt{-opt-report-filter=string} (Linux* and OS X*) \texttt{/Qopt-report-filter:string} (Windows*) \texttt{-opt-report-help} (Linux* and OS X*) \texttt{/Qopt-report-help} (Windows*) \texttt{-opt-report-names} (Linux* and OS X*) | Enables optimization report generation with different levels of detail. Valid values for \textit{n} are 0 through 5. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail. Higher numbers give greater levels of detail.
Generates an optimization report and directs the report output to the specified \textit{filename}. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.
Specifies a comma separated \textit{list} of optimization phases to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phases by using the [Q]opt-report-help option.
To generate a report for the IPO phase, use the \textit{-opt-report-phase=ipo} (Linux* and OS X*) or \texttt{/Qopt-report-phase:ipo} (Windows) option.
Generates reports for all routines with names containing \textit{substring} as part of their name. You can also specify a sequence of substrings separated by commas. If you do this, the compiler generates an optimization report for each of the routines whose name contains one or more of these substrings.
If \textit{substring} is not specified, the compiler generates reports on all routines.
Tells the compiler to find the indicated parts of your application specified by \textit{string}, and generate optimization reports for them.
If both \texttt{-opt-report-routines=string1} and \texttt{opt-report-filter=string2} are specified, it is treated as \texttt{-opt-report-filter=string1;string2}.
Displays the optimization phases available to use when using the [Q]opt-report-phase option.
Specifies whether mangled or unmangled names appear in the optimization report. If this option is not specified, unmangled names are used by default. |
### Optimization Report Option

<table>
<thead>
<tr>
<th>Optimization Report Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/Qopt-report-names</td>
<td>If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing. If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing. If you use this option, you do not have to specify option -qopt-report (Linux* OS and OS X*) or /Qopt-report (Windows* OS).</td>
</tr>
</tbody>
</table>

### Inline Expansion of Functions

#### Inline Function Expansion

Inline function expansion does not require that the applications meet the criteria for whole program analysis normally required by IPO; so this optimization is one of the primary optimizations used in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the Intel® compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion typically favors relatively small user functions over functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying the [Q]ip compiler option, single-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying the [Q]ipo compiler option, multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

**CAUTION**

Using the [Q]ip and [Q]ipo (Windows*) options can, in some cases, significantly increase compile time and code size.

The Intel compiler does a certain amount of inlining at the default level. Although such inlining is similar to what is done when you use the [Q]ip option, the amount of inlining done is generally less than when you use the option.
Selecting Routines for Inlining

The compiler attempts to select the routines whose inline expansions provide the greatest benefit to program performance. The selection is done using default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use options for Profile-Guided Optimizations (PGO): [Q]prof-use compiler option.

When you use PGO with [Q]ip or [Q]ipo (Windows), the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

Using IPO with PGO

Combining IPO and PGO typically produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.

Compiler Directed Inline Expansion of Functions

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance. See Inline Function Expansion for more information.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits.

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>inline-level (Linux* and OS X*) or Ob (Windows*)</td>
<td>Specifies the level of inline function expansion. Note that the option /Ob2 on Windows* is equivalent to -inline-level=2 on Linux* and OS X*.</td>
</tr>
<tr>
<td>[Q]ip-no-inlining</td>
<td>Disables only inlining enabled by the [Q]ip, [Q]ipo, or Ob2 options.</td>
</tr>
<tr>
<td>[Q]ip-no-pinlining</td>
<td>Disables partial inlining enabled by the [Q]ip or [Q]ipo options. No other IPO optimizations are disabled.</td>
</tr>
<tr>
<td>fno-builtin (Linux* and OS X*) or Oi- (Windows)</td>
<td>Disables inlining for intrinsic functions. Disables the by-name recognition support of intrinsic functions and the resulting optimizations. Use this option if you redefine standard library routines with your own version and your version of the routine has the same name as the standard library routine. By default, the compiler automatically inlines (expands) a number of standard and math library functions at the point of the call to that function, which usually results in faster computation.</td>
</tr>
</tbody>
</table>
Many routines in the libirc, libm, or svml library are more highly optimized for Intel microprocessors than for non-Intel microprocessors. Indicates that the source position information for an inlined function should be retained, rather than replaced, by that of the call which is being inlined.

Developer Directed Inline Expansion of User Functions

In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options and directives that allow you to more precisely direct when and if inline function expansion should occur.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

Typically, the compiler targets functions that have been marked for inlining based on the following:

- **Inlining keywords**: provides a hint to the compiler to inline the specified function. For example, `__inline`, `__forceinline`.
- **Statement-specific inlining directives**: indicates to the compiler to inline calls within the targeted statement if it is legal to do so. For example, `!DIR$ ATTRIBUTE INLINE, !DIR$ ATTRIBUTE FORCEINLINE`.
- **GCC function attributes for inlining**: indicates to the compiler to inline the function even when no optimization level is specified. For example, `__attribute__((always_inline))`.

The following developer directed inlining options and directives provide the ability to change the boundaries used by the inliner to distinguish between small and large functions.

In general, you should use the `[-Q]inline-factor` option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

If your code hits an inlining limit, the compiler issues a warning. The warning specifies which of the inlining limits have been hit, and the compiler option and/or directives needed to get a full report. For example, you could get a message as follows:

```
Inlining inhibited by limit max-total-size. Use -opt-report -opt-report-phase=ipo for full report.
```

Messages in the report refer directly to the command line options or directives that can be used to overcome the limits.

The following table lists the options you can use to fine-tune inline expansion of functions. The directives associated with the options are documented in the **Effect** column.
<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]inline-factor</td>
<td>Controls the multiplier applied to all inlining options that define upper limits: <code>inline-max-size</code>, <code>inline-max-total-size</code>, <code>inline-max-per-routine</code>, and <code>inline-max-per-compile</code>. While you can specify an individual increase in any of the upper-limit options, this single option provides an efficient means of controlling all of the upper-limit options with a single command. By default, this option uses a multiplier of 100, which corresponds to a factor of 1. Specifying 200 implies a factor of 2, and so on. Experiment with the multiplier carefully. You could increase the upper limits to allow too much inlining, which might result in your system running out of memory.</td>
</tr>
<tr>
<td>[Q]inline-forceinline</td>
<td>Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so. Without this option, the compiler treats functions declared with the <code>__inline</code> keyword as merely being recommended for inlining. When this option is used, it is as if they were declared with the <code>__forceinline</code> keyword.</td>
</tr>
<tr>
<td>[Q]inline-min-size</td>
<td>Redefines the maximum size of small routines; routines that are equal to or smaller than the value specified are more likely to be inlined.</td>
</tr>
<tr>
<td>[Q]inline-max-size</td>
<td>Redefines the minimum size of large routines; routines that are equal to or larger than the value specified are less likely to be inlined.</td>
</tr>
<tr>
<td>[Q]inline-max-total-size</td>
<td>Limits the expanded size of inlined functions. You can also use !DIR$ATTRIBUTES OPTIMIZATION_PARAMETER:“INLINE_MAX_TOTAL_SIZE=N” to control the size an individual routine can grow through inlining.</td>
</tr>
<tr>
<td>[Q]inline-max-per-routine</td>
<td>Limits the number of times inlining can be applied within a routine. You can also use !DIR$ATTRIBUTES OPTIMIZATION_PARAMETER:“INLINE_MAX_PER_ROUTINE=N” to control the number of times inlining may be applied to a routine.</td>
</tr>
<tr>
<td>[Q]inline-max-per-compile</td>
<td>Limits the number of times inlining can be applied within a compilation unit. The compilation unit limit depends on the whether or not you specify the [Q]ipo compiler option. If you enable IPO, all source files that are part of the compilation are considered one compilation unit. For compilations not involving IPO each source file is considered an individual compilation unit.</td>
</tr>

Intel(R) Fortran Language Extensions Overview

Intel® Fortran provides a number of additional implementation features designed to simplify or enhance application development. The features in the section are varied; your choice to employ each feature depends on your application and development needs.

The Fortran Language Reference contains a section showing a summary of all the language extensions (non-standard features).

Fortran Language Extensions

64-bit Addressing Support (Linux*)

Specifying Memory Models to use with Systems Based on Intel® 64 Architecture (Linux* OS)

This topic only applies to Linux* OS.

Applications designed to take advantage of Intel® 64 architecture can be built with one of three memory models:

- small (-mcmodel=small)
  This causes code and data to be restricted to the first 2GB of address space so that all accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- medium (-mcmodel=medium)
  This causes code to be restricted to the first 2GB; however, there is no restriction on data. Code can be addressed with IP-relative addressing, but access of data must use absolute addressing.

- large (-mcmodel=large)
  There are no restrictions on code or data; access to both code and data uses absolute addressing.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. This can affect code size and performance. (IP-relative addressing is somewhat faster.)

Additional Notes on Memory Models and on Large Data Objects

- When you specify the medium or large memory models, you must also specify the -shared-intel compiler option to ensure that the correct dynamic versions of the Intel run-time libraries are used.
- When you build shared objects (.so), Position-Independent Code (PIC) is specified (that is, -fPIC is added by the compiler driver) so that a single .so can support all three memory models. However, code that is to be placed in a static library, or linked statically, must be built with the proper memory model specified. Note that there is a performance impact to specifying the medium or large memory models.
- The use of the memory model (medium, large) option and the -shared-intel option is required as a by-product of the code models stipulated in the 64-bit Application Binary Interface (ABI), which is written specifically for processors with the 64-bit memory extensions. Both the compiler and the GNU linker (ld) are responsible for generating the proper code and necessary relocations on this platform according to the chosen memory model.
• The 2GB restriction on Intel® 64 architecture involves not only arrays greater than 2GB, but also COMMON blocks and local data with a total size greater than 2GB. The Compiler Options reference contains additional discussion of the supported memory models and offers details about the 2GB restrictions for each model. See the \texttt{-mcmodel} options page.

• If, during linking, you fail to use the appropriate memory model and dynamic library options, an error message in this format occurs:

\begin{verbatim}
<some lib.a library>(some .o): In Function <function>:
  : relocation truncated to fit: R_X86_64_PC32 <some symbol>
\end{verbatim}

**Traceback**

**Using Traceback Information Overview**

When a Fortran program terminates due to a severe error condition, the Fortran run-time system displays additional diagnostic information after the run-time message.

The Fortran run-time system attempts to walk back up the call chain and produce a report of the calling sequence leading to the error as part of the default diagnostic message report. This is known as traceback. The minimum information displayed includes:

- The standard Fortran run-time \textit{Run-Time Message Display and Format} text that explains the error condition.
- A tabular report that contains one line per call stack frame. This information includes at least the image name and a hexadecimal PC in that image.

The information displayed under the Routine, Line, and Source columns depends on whether your program was compiled with the \texttt{traceback} option.

For example, if the \texttt{traceback} option is specified, the displayed information might resemble the following:

\begin{verbatim}
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat

<table>

\end{verbatim}

If the same program is \textit{not} compiled with the \texttt{traceback} option:

- The Routine name, Line number, and Source file columns would be reported as "Unknown."
- A link map file is usually needed to locate the cause of the error.

The \texttt{traceback} option provides program counter (PC) to source file line correlation information to appear in the displayed error message information, which simplifies the task of locating the cause of severe run-time errors.

For Fortran objects generated with the \texttt{traceback} option, the compiler generates additional information used by the Fortran run-time system to automatically correlate PC values to the routine name in which they occur, Fortran source file, and line number in the source file. This information is displayed in the run-time error diagnostic report.

Automatic PC correlation is only supported for Fortran code. For non-Fortran code, only the hexadecimal PC locations are reported.
Tradeoffs and Restrictions in Using Traceback

This topic describes tradeoffs and restrictions that apply to using traceback.

Effect on Image Size

Using the `traceback` option to get automatic PC correlation increases the size of an image. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PCs with a map file is acceptable.

The approach of providing automatic correlation information in the image was used so that no run-time penalty is incurred by building the information "on the fly" as your application executes. No run-time diagnostic code is invoked unless your application is terminating due to a severe error.

C Compiler Omit Frame Pointer Option on Systems Using IA-32 Architecture

The following routines are used to walk the stack:

- For Windows OS, the Windows API routine `StackWalk( )` in `imagehlp.dll`
- For Linux OS and for OS X, `_Unwind_ForcedUnwind( )`, `_Unwind_GetIP( )`, `_Unwind_GetRegionStart( )` and `_Unwind_GetGr( )` routines in `libunwind.so`

In an environment using IA-32 architecture, there are no firm software calling standards documented. Compiler developers are under no constraints to use machine registers in any particular way or to hook up procedures in any particular way. The stack walking routines listed above use a set of heuristics to determine how to walk the call stack. That is, they make a "best guess" to determine how a program reached a particular point in the call chain. With C code that has been compiled with Visual C++* using the Omit Frame Pointer option -- either `-fomit-frame-pointer` (Linux OS and OS X) or `/Oy` (Windows OS) -- this "best guess" is not usually the correct one.

If you are mixing Fortran and C code and you are concerned about stack tracing, consider disabling the `-fomit-frame-pointer` or `/Oy` option in your C compilations. Otherwise, traceback will most likely not work for you.

Stack Trace Failure

Programs can fail for a number of reasons, often with unpredictable consequences. Memory corruption by erroneously executing code is one possibility. Stack memory can be corrupted in such a way that the attempt to trace the call stack will result in access violations or other undesirable consequences. The stack-tracing run-time code is guarded with a local exception filter. If the traceback attempt fails due to a hard detectable condition, the run-time will report this in its diagnostic output message as:

```
Stack trace terminated abnormally
```

Be forewarned, however: It is also possible for memory to be corrupted in such a way that a stack trace can seem to complete successfully with no hint of a problem. The bit patterns it finds in corrupted memory where the stack used to be, and then uses to access memory, may constitute perfectly valid memory addresses for the program to be accessing. They just do not happen to have any connection to what the stack used to look like. So, if it appears that the stack walk completed normally, but the reported PCs make no sense to you, then consider ignoring the stack trace output in diagnosing your problem.

Another condition that will disable the stack trace process is your program exiting because it has exhausted virtual memory resources.

The stack trace can fail if the run-time system cannot dynamically load `libunwind.so` (Linux OS and OS X) or `imagehlp.dll` (Windows OS) or cannot find the necessary routines from that library. In this case, you still get the basic run-time diagnostic message; you will not get any call stack information.
Linker /incremental:no Option on Windows Operating Systems

The following applies to Windows operating systems only.

When incremental linking is enabled, automatic PC correlation does not work. Use of incremental linking always disables automatic PC correlation even if you specify /traceback during compilation.

When you use incremental linking, the default hexadecimal (hex) PC values will still appear in the output. To correlate from the hexadecimal PC values to routine containing the PC addresses requires use of a linker map file. However, if you request a map file during linking, incremental linking becomes disabled. Thus to allow any PC values generated for a run-time problem to be helpful, incremental linking must be disabled.

In the integrated development environment, you can use the Call stack display, so incremental linking is not a problem.

Sample Programs and Traceback Information

The following sections provide sample programs that show the use of traceback to locate the cause of the error:

- Example: End-of-File Condition, Program teof
- Example: Machine Exception Condition, Program ovf
- Example: Using Traceback in Mixed Fortran/C Applications, Program FPING and CPONG

Note that the hex PC's and contents of registers displayed in these program outputs are meant as representative examples of typical output. The PC's will change over time, as the libraries and other tools used to create an image change.

Example: End-of-File Condition, Program teof

In the following example, a READ statement creates an End-Of-File error, which the application has not handled:

```fortran
program teof
  integer*4 i, res
  i=here()
end

integer*4 function here()
  here = we()
end

integer*4 function we()
  we = go()
end

integer*4 function go()
  go = again()
end

integer*4 function again()
  integer*4 a
  open(10, file='xxx.dat', form='unformatted', status='unknown')
  read(10) a
  again = a
end
```

The diagnostic output that results when this program is built with traceback enabled and linked against the single-threaded, shared Fortran run-time library on the IA-32 architecture platform is similar to the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

<table>
<thead>
<tr>
<th>Image</th>
<th>PC</th>
<th>Routine</th>
<th>Line</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>libifcorert.dll</td>
<td>1000A3B2</td>

<td>Unknown</td>
</tr>
<tr>
<td>libifcorert.dll</td>
<td>10024193</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>
```
The first line of the output is the standard Fortran run-time error message. What follows is the result of walking the call stack in reverse order to determine where the error originated. Each line of output represents a call frame on the stack. Since the application was compiled with the traceback option, the PCs that fall in Fortran code are correlated to their matching routine name, line number and source module. PCs that are not in Fortran code are not correlated and are reported as "Unknown."

The first five frames show the calls to routines in the Fortran run-time library (in reverse order). Since the application was linked against the single threaded, shared version of the library, the image name reported is either libifcore.so (Linux* OS and OS X*) or libifcorer.dll (Windows* OS). These are the run-time routines that were called to do the READ and upon detection of the EOF condition, were invoked to report the error. In the case of an unhandled I/O programming error, there will always be a few frames on the call stack down in run-time code like this.

The stack frame of real interest to the Fortran developer is the first frame in image teof.exe which shows that the error originated in the routine named AGAIN in source module teof.for at line 21. Looking in the source code at line 21, you can see the Fortran READ statement that incurred the end-of-file condition.

The next four frames show the trail of calls in the Fortran user code that led to the routine that got the error (TEOF->HERE->WE->GO->AGAIN).

Finally, the bottom three frames are routines which handled the startup and initialization of the program.

If this program had been linked against the single-threaded, static Fortran run-time library, the output would then look like:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image          PC        Routine        Line     Source
---          ---        ---          ---     ---
teof.exe       004067D2  Unknown        Unknown  Unknown
              0040659F  Unknown        Unknown  Unknown
              00405754  Unknown        Unknown  Unknown
              004059C5  Unknown        Unknown  Unknown
              00403543  Unknown        Unknown  Unknown
              004011A9  AGAIN               21  teof.for
              004010DD  GO                  15  teof.for
              004010A7  WE                  11  teof.for
              00401071  HERE                 7  teof.for
              00401035  TEOF                 3  teof.for
              004013D9  Unknown         Unknown  Unknown
              004012DF  Unknown         Unknown  Unknown
KERNEL32.dll   77F1B304  Unknown        Unknown  Unknown
```

Notice that the initial five stack frames now show routines in image teof.exe, not libifcore.so (Linux OS and OS X) or libifcorer.dll (Windows OS). The routines are the same five run-time routines as previously reported for the shared library case but since the application was linked against the archive library libifcore.a (Linux OS and OS X) or the static Fortran run-time library libifcore.lib (Windows OS), the object modules containing these routines were linked into the application image (teof.exe). You can use a Generating Listing and Map Files to determine the locations of uncorrelated PCs.

Now suppose the application was compiled without traceback enabled and, once again, linked against the single-threaded, static Fortran library. The diagnostic output would appear as follows:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image          PC        Routine       Line     Source
---          ---        ---          ---     ---
teof.exe       00406792  Unknown       Unknown  Unknown
```

Notice that the initial five stack frames have been replaced by routines in image teof.exe, not libifcore.so (Linux OS and OS X) or libifcorer.dll (Windows OS). This is because the application was compiled without traceback enabled, and the object modules containing the routines were linked into the application image (teof.exe).
Without the correlation information in the image that option traceback previously supplied, the Fortran run-time system cannot correlate PC’s to routine name, line number, and source file. You can still use the Generating Listing and Map Files to at least determine the routine names and what modules they are in.

Remember that compiling with the traceback option increases the size of your application’s image because of the extra PC correlation information included in the image. You can see if the extra traceback information is included in an image (checking for the presence of a .trace section) by entering:

<table>
<thead>
<tr>
<th>Command</th>
<th>OS</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objdump -h your_app.exe</code></td>
<td>Linux</td>
</tr>
<tr>
<td><code>otool -l your_app.exe</code></td>
<td>OS X</td>
</tr>
<tr>
<td><code>link -dump -summary your_app.exe</code></td>
<td>Windows</td>
</tr>
</tbody>
</table>

Build your application with and without traceback and compare the file size of each image. Check the file size with a simple directory command.

For this simple teof.exe example, the traceback correlation information adds about 512 bytes to the image size. In a real application, this would probably be much larger. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PC’s with a map file is acceptable.

If an error occurs when traceback was requested during compilation, the run-time library will produce the correlated call stack display.

If an error occurs when traceback was disabled during compilation, the run-time library will produce the uncorrelated call stack display.

If you do not want to see the call stack information displayed, you can set the Supported Environment Variable FOR_DISABLE_STACK_TRACE to true. You will still get the Fortran run-time error message:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

**Example: Machine Exception Condition, Program ovf**

The following program generates a floating-point overflow exception when compiled with the fpe option value 0:

```fortran
program ovf
  real*4 a
  a=1e37
  do i=1,10
    a=hey(a)
  end do
  print *, 'a= ', a
end

real*4 function hey(b)
  real*4 b
  hey = watch(b)
end

real*4 function watch(b)
  real*4 b
  watch = out(b)
end
```
real*4 function out(b)  
  real*4 b  
  out = below(b)  
end  

real*4 function below(b)  
  real*4 b  
  below = b*10.0e0  
end

Assume this program is compiled with the following:

- Option fpe value 0
- Option traceback
- Option -O0 (Linux OS and OS X) or /Od (Windows OS)

On a system based on IA-32 architecture, the traceback output is similar to the following:

```
forrtl: error (72): floating overflow
Image          PC        Routine          Line     Source
ovf.exe        00401161  BELOW                29  ovf.f90
ovf.exe        0040113C  OUT                  24  ovf.f90
ovf.exe        0040111B  WATCH                19  ovf.f90
ovf.exe        004010FA  HEY                  14  ovf.f90
ovf.exe        0040105B  OVF                   7  ovf.f90
ovf.exe        00432429  Unknown         Unknown  Unknown
ovf.exe        00426C74  Unknown         Unknown  Unknown
KERNEL32.dll    77F1B9EA  Unknown         Unknown  Unknown
```

Notice that unlike the previous example of an unhandled I/O programming error, the stack walk can begin right at the point of the exception. There are no run-time routines on the call stack to dig through. The overflow occurs in routine BELOW at PC 00401161, which is correlated to line 29 of the source file ovf.f90.

When the program is compiled at a higher optimization level of O2, along with option fpe value 0 and the traceback option, the traceback output appears as follows:

```
forrtl: error (72): floating overflow
Image          PC        Routine        Line       Source
ovf.exe        00401070  OVF                 29    ovf.f90
ovf.exe        004323E9  Unknown        Unknown    Unknown
ovf.exe        00426C34  Unknown        Unknown    Unknown
KERNEL32.dll    77F1B9EA  Unknown        Unknown    Unknown
```

With O2, the entire program has been inlined.

The main program, OVF, no longer calls routine HEY. While the output is not quite what one might have expected intuitively, it is still entirely correct. You need to keep in mind the effects of compiler optimization when you interpret the diagnostic information reported for a failure in a release image.

If the same image were executed again, this time with the environment variable called TBK_ENABLE_VERBOSE_STACK_TRACE set to True, you would also see a dump of the exception context record at the time of the error. Here is an excerpt of how that might appear on a system using IA-32 architecture:

```
forrtl: error (72): floating overflow
Hex Dump Of Exception Record Context Information:
Exception Context:  Processor Control and Status Registers.
  EFlags:  00010212

```
Example: Using Traceback in Mixed Fortran/C Applications, Program FPING and CPONG

Consider the following example that shows how the traceback output might appear in a mixed Fortran/C application. The main program is a Fortran program named FPING. Program FPING triggers a chain of function calls which are alternately Fortran and C code. Eventually, the C routine named Unlucky is called, which produces a floating divide-by-zero error.

Source module FPING.FOR contains the Fortran function definitions, each of which calls a C routine from source module CPONG.C. The program FPING.FOR is compiled with the following options:

- Option fpe value 0
- Option traceback
- Option -O0 (Linux OS and OS X) or /Od (Windows OS)

On the IA-32 architecture platform, the program traceback output resembles the following:

```
forrtl: error (73): floating divide by zero
```

Notice that the stack frames contributed by Fortran routines can be correlated to a routine name, line number, and source module but those frames contributed by C routines cannot be correlated. Remember, even though the stack can be walked in reverse, and PCs reported, the information necessary to correlate the PC to a routine name, line number, and so on, is contributed to the image from the objects generated by the Fortran compiler. The C compiler does not have this capability. Also remember that you only get the correlation information if you specify the traceback option for your Fortran compiles.

The top stack frame cannot be correlated to a routine name because it is in C code. You can examine the map file for the application; if you do so, you will see that the reported PC, 00401161, is greater than the start of routine _Unlucky, but less than the start of routine _down1_C. This means that the error occurred in routine _Unlucky.

In a similar manner, the other PCs reported as "Unknown" can be correlated to a routine name using the map file.

When examining traceback output (or any type of diagnostic output, for that matter), it is important to keep in mind the effects of compiler optimization. The Fortran source module in the above example was built with optimization turned off. Look at the output when optimizations are enabled with the O2 option:

```
forrtl: error (73): floating divide by zero
```

<table>
<thead>
<tr>
<th>Image</th>
<th>PC</th>
<th>Routine</th>
<th>Line</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>fping.exe</td>
<td>00401111</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>fping.exe</td>
<td>0040109D</td>
<td>DOWN4</td>
<td>58</td>
<td>fping.for</td>
</tr>
</tbody>
</table>
From the traceback output, it would appear that routine DOWN1 was never called. In fact, it has not been called. At the higher optimization level, the compiler has inlined function DOWN1 so that the call to routine down1_C is now made from FPING. The correlated line number still points to the correct line in the source code.

Finally, suppose the example Fortran code is redesigned with each of the Fortran routines split into separate source modules. Here is what the traceback output would look like with the redesigned code:

```
forrtl: error (73): floating divide by zero
Image            PC        Routine      Line     Source
fpingmain.exe    00401171  Unknown      Unknown  Unknown
fpingmain.exe    004010ED  DOWN4             12  fping4.for
fpingmain.exe    0040119F  Unknown      Unknown  Unknown
fpingmain.exe    004010C1  DOWN3             11  fping3.for
fpingmain.exe    00401191  Unknown      Unknown  Unknown
fpingmain.exe    00401099  DOWN2             11  fping2.for
fpingmain.exe    00401183  Unknown      Unknown  Unknown
fpingmain.exe    00401073  DOWN1             11  fping1.for
fpingmain.exe    0040104B  FPING              5  fpingmain.for
fpingmain.exe    004013C9  Unknown      Unknown  Unknown
fpingmain.exe    004012BF  Unknown      Unknown  Unknown
KERNEL32.dll     77F1B304  Unknown      Unknown  Unknown
```

Notice that the line number and source file correlation information has changed to reflect the new design of the code.

Here are the sources used in the above examples:

```

**Allocating Common Blocks**

Use the [Q]dyncom option to dynamically allocate common blocks at run time.

This option designates a common block to be dynamic. The space for its data is allocated at run time rather than at compile time. On entry to each routine containing a declaration of the dynamic common block, a check is performed to see whether space for the common block has been allocated. If the dynamic common block is not yet allocated, space is allocated at the check time.

The following command-line example specifies the dynamic common option with the names of the common blocks to be allocated dynamically at run time:

```bash
ifort -dyncom "blk1,blk2,blk3" test.f (Linux OS and OS X)
ifort /Qdyncom"BLK1,BLK2,BLK3" test.f (Windows OS)
```

where BLK1, BLK2, and BLK3 are the names of the common blocks to be made dynamic.

**Guidelines for Using the [Q]dyncom Option**

The following are some limitations that you should be aware of when using the [Q]dyncom option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

**Why Use a Dynamic Common Block?**

A main reason for using dynamic common blocks is to enable you to control the common block allocation by supplying your own allocation routine. To use your own allocation routine, you should link it ahead of the Fortran run-time library. This routine must be written in the C language to generate the correct routine name.

The routine prototype is:

```c
void _FTN_ALLOC(void **mem, int *size, char *name);
```

where
mem is the location of the base pointer of the common block that must be set by the routine to point to the block of memory allocated.

size is the integer number of bytes of memory that the compiler has determined are necessary to allocate for the common block as it was declared in the program.

You can ignore this value and use whatever value is necessary for your purpose. You must return the size in bytes of the space you allocate. The library routine that calls the default or Fortran run-time function ensures that all other occurrences of this common block fit in the space you allocated. You can return the size in bytes of the space you allocate by modifying size.

name is the name of the common block being dynamically allocated.

The default routine _FTN_ALLOC must be written in the C language to generate the correct routine name. To use your own allocation routine, you should link it ahead of the Fortran run-time library.

You can also use the Fortran run-time function FOR__SET_FTN_ALLOC to use your own allocation routine. This method is especially helpful when you are using shared libraries. If you choose this method, it overrides the default routine _FTN_ALLOC.

NOTE
For offload applications, routines FOR__SET_FTN_ALLOC and _FTN_ALLOC will work on native Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

However, they will not work across the boundary between a host CPU and an Intel® MIC Architecture coprocessor. For example, if you use FOR__SET_FTN_ALLOC in the host-side code, it will work on COMMON allocations in other host-side code. The same is true if both are on the coprocessor side.

But if you change the allocation routine on the host, it won't be changed on the coprocessor and vice versa.

Allocating Memory to Dynamic Common Blocks

The run-time library routine, f90_dyncom, performs memory allocation. The compiler calls this routine at the beginning of each routine in a program that contains a dynamic common block. In turn, this library routine calls _FTN_ALLOC to allocate memory. By default, the compiler passes the size in bytes of the common block as declared in each routine to f90_dyncom, and then on to _FTN_ALLOC. The Fortran run-time library contains a default version of _FTN_ALLOC, which simply allocates the requested number of bytes and returns.

If you use the nonstandard extension having the common block of the same name declared with different sizes in different routines, you may get a run-time error depending on the order in which the routines containing the common block declarations are invoked.

You can now create your own routine to dynamically allocate common blocks, which is especially useful when you are sharing libraries. To use your own routine, you must specify the run-time function FOR__SET_FTN_ALLOC.

FOR__SET_FTN_ALLOC

Generating Listing and Map Files

Compiler-generated assembler output listings and linker-generated map files can help you understand the effects of compiler optimizations and see how your application is laid out in memory. They may also help you interpret the information provided in a stack trace at the time of an error.
How to Generate Assembler Output

When compiling from the command line, specify the -S option:

```
ifort -S file.f90 (Linux OS and OS X)
ifort file.f90 /S (Windows OS)
```

On Linux* OS and on OS X*, the resulting assembly file name has a .s suffix. On Windows OS, the resulting assembly file name has an .asm suffix.

Additionally, on Windows* OS, you can use the Microsoft Visual Studio* integrated development environment:

1. Select Project > Properties.
2. Click the Fortran tab.
3. In the Output Files category, change the Assembler Output settings according to your needs. You can choose from a number of options such as No Listing, Assembly-only Listing, and Assembly, Machine Code and Source.

How to Generate a Link Map (.map) File

When compiling from the command line, specify the -Xlinker and -M options (Linux OS and OS X) or the /map (Windows OS) option:

```
ifort file.f90 -Xlinker -M  (Linux OS and OS X)
ifort file.f90 /map (Windows)
```

Additionally, on Windows systems, you can use the Visual Studio integrated development environment:

1. Select Project>Properties.
2. Click the Linker tab.
3. In the Debug category, select Generate Map File.

How to Generate a Source File Listing

You can use the list compiler option to create a listing of the source file. The listing can contain the following information: a display of INCLUDE files, a symbol list with a line number cross reference for each routine, and a list of compiler options used for the compilation.

Use the show compiler option to control the contents of the listing file.

Additionally, on Windows systems, you can use the Visual Studio integrated development environment to create a source file listing:

1. Select Project > Properties.
2. Click the Fortran tab.
3. In the Output Files category, change the Source Listing setting to Yes.

Ability to Create Shared Libraries

You can create a shareable library by using one of the following compiler options.

<table>
<thead>
<tr>
<th>Compiler Option</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>-shared (Linux* OS)</td>
<td>mylib.so</td>
</tr>
<tr>
<td>/libs:dll (Windows* OS)</td>
<td>mylib.dll</td>
</tr>
<tr>
<td>-dynamiclib (OS X*)</td>
<td>mylib.dylib</td>
</tr>
</tbody>
</table>

When you use any of these options, do not specify the c option.
See Also
shared compiler option
dynamiclib compiler option

Creating Shared Libraries
Storing Routines in Shareable Libraries
Using Shared Libraries on OS X*

Specifying Alternative Tools and Locations
The default tools are summarized in the table below.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Default</th>
<th>Provided with Intel® Fortran Compiler?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assembler for IA-32 architecture-based applications and Intel® 64 architecture-based applications</td>
<td>MASM* (Windows* OS) operating system assembler, as (Linux* OS and OS X*)</td>
<td>No</td>
</tr>
<tr>
<td>Linker</td>
<td>Microsoft* linker (Windows OS)</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>System linker, ld(1) (Linux OS and OS X)</td>
<td>No</td>
</tr>
</tbody>
</table>

The Intel® Fortran Compiler lets you specify alternatives to default tools and locations for preprocessing, compilation, assembly, and linking. In addition, you can invoke options specific to the alternate tools on the command line. This functionality is provided by the Qlocation and Qoption options.

Qlocation compiler option
Qoption compiler option

Temporary Files Created by the Compiler or Linker
Temporary files created by the compiler or linker reside in the directory used by the operating system to store temporary files.

To store temporary files, the driver first checks for the TMP environment variable. If defined, the directory that TMP points to is used to store temporary files.

If the TMP environment variable is not defined, the driver then checks for the TMPDIR environment variable. If defined, the directory that TMPDIR points to is used to store temporary files.

If the TMPDIR environment variable is not defined, the driver then checks for the TEMP environment variable. If defined, the directory that TEMP points to is used to store temporary files.

If the TEMP environment variable is not defined, the current working directory is used to store temporary files. For Linux* OS and OS X*, if the TEMP environment variable is not defined, the /tmp directory is used to store temporary files.

Temporary files are usually deleted. Use the [Q]save-temps compiler option to save temporary files created by the compiler in the current working directory. This option only saves intermediate files that are normally created during compilation.

For performance reasons, use a local drive (rather than a network drive) to contain temporary files.

To view the file name and directory where each temporary file is created, use the all keyword for the watch option.

To create object files in your current working directory, use the c option.

Any object files that you specify on the command line are retained.
Using the Intel® Fortran COM Server (Windows*)

Fortran COM Server Overview (Windows*)

This topic only applies to Windows* operating systems.

This section assumes that you are familiar with the COM-related terms and concepts presented in Using the Intel® Fortran Module Wizard Overview and related sections, such as Understanding COM and Automation Objects. These sections (starting with Using the Intel® Fortran Module Wizard Overview) discuss using COM and Automation objects from an Intel® Fortran application, using the Fortran COM Server.

The Component Object Model (COM) supports a model of client server interaction between a user of an object, the client, and the implementor of the object, the server.

This section discusses creating a COM server using Intel Fortran.

Advantages of a COM Server (Windows*)

This topic only applies to Windows* operating systems.

A COM server consists of the implementation of one or more object classes. An object class is a type that describes the complete public calling interface ("signature") of an object. It describes the functionality that you want to make available to the users of the object. The COM server creates instances of the class, called objects, at the request of clients.

Some of the advantages of implementing your Fortran code as a COM server include:

- A COM server is a reusable component, which allows multiple applications to use the server. The classes specified by the server define a "contract" between the server and its clients. The server can change the specific implementation of the functionality without breaking the contract. That is, without requiring clients to be changed or rebuilt.
- A COM server is programming-language independent. Multiple development tools can be used to access the server's functionality, including Microsoft Visual Basic*, C++, and Fortran.
- A COM server is self-describing. The server provides a type library that describes the classes and interfaces. Many tools can take advantage of this information and relieve the client programmer from needing to understand low-level invocation details, such as calling conventions. This is a great improvement over multi-language programming with DLLs, where the client programmer has to understand the details of data types and calling conventions.
- A COM server is self-registering. The clients do not need to worry about where the server is located on their system, as COM finds this information in the system registry.
- A COM server can be implemented as an in-process server. Like a DLL, it is loaded into the client's process. A COM server can also be implemented as a separate application and can even reside on a separate machine.

Intel Fortran provides the Fortran COM Server application wizard and special editor for modifying the COM Server structure and generating Fortran code necessary to implement a COM server. This allows you to concentrate on the code that is specific to the functionality that your server provides to its clients.

As explained in Understanding COM and Automation Objects, COM supports two types of servers: COM servers and Automation servers. The Fortran COM Server Wizard can only create a COM server or a server that supports dual interfaces. The wizard cannot create an Automation-only interface.

For more information about creating COM servers, see Creating the Fortran COM Server.

Understanding COM Server Concepts (Windows*)

This topic only applies to Windows* operating systems.
The Fortran COM Server application wizard generates an initial Visual Studio project and creates a COM Hierarchy file, which describes the infrastructure of a COM server. You can modify this file with the COM Server Hierarchy Editor to define the implementation of one or more object classes, including its interface(s), and method(s).

When you save the hierarchy file, the Fortran source files are generated. You then need to write code to implement each method.

**What Information You Need to Provide**

When you create the COM Server project, you will need to describe the COM server classes that you want to implement.

A class implements one or more COM interfaces. In COM terminology, an interface is a semantically related set of functions. The interface as a whole represents a "feature", or set of related functionality, that is implemented by the class. An interface contains methods, otherwise known as member functions. A method is a routine that performs one of the actions that make up the feature. As far as the Fortran COM Server is concerned, methods are Fortran functions that take arguments and return a value like any other Fortran function.

Consider a simple example of a class that you will create using the Fortran COM Server Application Wizard, called *AddingMachine*. The class contains a single interface that we call IAdd. By convention, all interface names begin with a capital letter "I". You can define three methods in the IAdd interface:

- **Clear**, which takes no arguments and sets the current value of the adding machine to 0.
- **Add**, which takes a single REAL argument, the amount to add to the current value.
- **GetValue**, which returns the current value.

These methods allow you to perform specific, distinct tasks with the IAdd interface from any language that supports a COM client. The Fortran COM Server Editor provides a user interface to enter this information about the class (in this case the AddingMachine class), which is discussed later in Creating the Fortran COM Server.

An interface can also contain properties. Properties are method pairs that set or return information about the state of an object. Properties must currently be implemented using the get_Method and put_Method and the same DISPID property.

In terms of the data associated with an object, a key concept of object-oriented programming is encapsulation. Encapsulation means that all of the details about how the object is implemented, including the data that it uses and the logic that it uses to perform its work, is hidden from the client. The client's only access to the object is through the interfaces that the object supports.

You need to define the data that the object uses and code the logic of the methods. For the data, the Fortran COM Server Application Wizard uses the model that each instance of the object has an associated instance of a Fortran derived-type. The code generated by the wizard takes care of creating and destroying the instances of the derived-type as objects are created and destroyed.

You define the fields of the derived-type. For example, with our AddingMachine, each AddingMachine object needs to store the current value. The derived-type associated with each AddingMachine object would contain a single field of type REAL. We name it *CurrentValue*. Note that each instance of the AddingMachine object has its own instance of the derived-type and its own *CurrentValue*. This means that the server could support multiple clients simultaneously and each client would see its own AddingMachine. That is, each client is unaffected by the existence of other clients. The derived-type associated with each object is discussed in detail in Creating the Fortran COM Server.

To summarize, at a high level, what you need to do to create a COM server:

- Create the COM Server project using the COM Server Application Wizard.
- Define the class(es), interface(s), method(s), and properties using the COM Server Hierarchy Editor to create the Hierarchy file.
- Define the fields in the derived-type that is associated with each instance of a class.
- Write code that initializes the fields in the derived-type (if necessary), and code that releases any resources used by the fields in the derived-type (if necessary).
Write the code that implements the methods.

**What the COM Server Will Provide**

The Fortran COM Server Editor generates source files that implement all of the infrastructure, or "plumbing", of the COM server. The generated files take care of such tasks as:

- Defining the GUIDs that uniquely identify your classes and interfaces. For a discussion of GUIDs, see [Getting a Pointer to an Objects Interface](#).
- Registering the server and your classes and interfaces on the system.
- Implementing the class factory that creates instances of your object.
- Creating the Interface Definition Library (IDL) and type library that describes your classes and interfaces. For a discussion of type libraries, see [Using the Module Wizard to Generate Code](#).
- Implementing the IUnknown and IDispatch interfaces for your object. All of the interfaces created by the Fortran COM Server Editor are derived from IUnknown or IDispatch (dual interfaces).
- Creating and destroying instances of the derived-type associated with your object.
- Invoking the Fortran routines that implement your object's methods.

The majority of these source files are generated fully by the Fortran COM Server Editor and are not modified by you. Other files contain the skeleton or template of your derived-type and methods. You edit these Fortran source files to fill in your implementation. A walk-through of the AddingMachine example will show you how it's done.

**Creating the Fortran COM Server (Windows*)**

This topic only applies to Windows* operating systems.

This section shows how to create a project, specify the COM server characteristics, generate code for, and implement a sample Fortran COM server project called Adder.

The first step in creating a Fortran COM Server is to create a new project.

**Creating a Fortran COM Server Project using the Visual Studio* IDE:**

1. Start the Visual Studio IDE. Choose **File > New > Project**.
2. In the **New Project** dialog box, expand the Intel(R) Visual Fortran item and click **COM Server**.
To create the sample project, choose **In-process Server (DLL)**. Now do the following:

1. Enter **Adder** as the name of the project.
2. Accept or modify the project folder location.
3. Click **OK**.

You can use the project AppWizard once per project to create the project files and skeleton template. The Fortran COM Server AppWizard displays default text for the interface name and class derived type name.
Now do the following:

1. Enter class name `AddingMachine`.
2. Shorten the default interface name to `IAdd`.
3. Accept the default class derived type name.
4. Click **Finish**. (If you click **Cancel**, project creation is terminated.)

The project is created and the COM Server Hierarchy file (`adder.hie`) is opened in the COM Hierarchy Editor.

**Using the COM Hierarchy Editor to Define your COM Server**

The COM Hierarchy Editor lets you interactively define the attributes (for example, classes, interfaces, and methods) for your COM server. The user interface contains two panes:

- The top pane is a tree control that displays attribute information in a hierarchy.
- The bottom pane is a panel that displays the IDL definition for a selected element in the hierarchy.

You can use "right-click" context menus to insert, delete, and modify items in the hierarchy. Context menus also let you change item properties. For example, you can right-click the `IAdd` element and select **Properties** to see the `IAdd` interface properties. You could then change the `Is Dual` property value to `False`; this indicates that the `Adder` example only supports a COM server interface.

An explanation of the hierarchy follows:

- The root is the COM server itself.
The immediate children of the COM server are classes. The hierarchy initially contains a single class, AddingMachine. You can add additional classes to the COM server.

- The immediate children of a class are interfaces and the class derived-type. In the example, the hierarchy contains the interface IAdd and the class derived-type AddingMachine_InstanceData. Each class contains one, and only one, class derived-type. You can add additional interfaces to the class.
- The immediate children of an interface are methods (one or more).
- The immediate children of a method are the method arguments (one or more).

**To add a class, interface, method, property, or argument:**

1. Select the parent item, right-click and select the appropriate Add... item.

**To delete an item:**

1. Select the item to be deleted, right-click and select Delete.
2. Click the Delete button.

Continuing with the Adder COM server example, add methods to the IAdd interface:

1. Right-click the IAdd interface and select Add Method.
2. Enter Clear as the name of the method.
3. Repeat steps 1 and 2, this time entering the name of Add.

The Add method requires an argument. To add the Operand argument named Operand:

1. Right-click on the Add method and select Add Argument.
2. Enter the argument name, Operand.

The default data type of an argument is INTEGER(4).

Proceeding with this example, use the Properties Window to change the Fortran Type property value to REAL(4):
To add a third (and in this example, the last) method:

1. Right-click on the IAdd interface and select Add Method.
2. Enter GetValue as the name for the method.

The GetValue method requires an argument, CurrentValue. To add the CurrentValue argument:

1. Right-click on the GetValue method and select Add Argument.
2. Enter CurrentValue as the name of the argument.

For the CurrentValue argument:

1. Set Fortran Type property value to REAL(4).
2. Set Intent property values to [out, retval].

The screen appears as follows:
The server definition is now complete for this example. When you save the file using **File > Save adder.hie**, the Fortran sources will be regenerated.

For detailed information about the property pages (right pane) for the server, class, interface, method, argument, or instance properties, see **Description of Property Pages**.

To change the definition of your server, open **adder.hie** in the Editor.

**Working with the Hierarchy Pane**

As you have seen in the *AddingMachine* example, the hierarchy pane represents the definition of your server; that is, the classes, interfaces, methods, and so on. The hierarchy pane's user interface supports the following functionality:

- **Expand/contract an area**
  - Click the plus sign (+) next to an item to display its children and the - to hide the children.

- **Add a new entry**
  - Select the entry that will precede the new entry in the hierarchy, right-click and select one of the **New...** menu options.

- **Delete an entry**
  - Select the item to be deleted, right-click and select **Delete**. All of an item's children are deleted when the item is deleted.
Rename a member
Select the item to be renamed, right-click and select Rename.

Change the order of items
The hierarchy pane supports drag-and-drop to allow you to change the order of items. The order of some of the entries in the hierarchy is very important. In particular:

- The order of the methods in an interface defines the order of the methods in the class' Vtbl. Changing the order of the methods will break an existing client.
- The order of the arguments in a method define the order of the arguments in the method's interface. Changing the order of the arguments will break an existing client.

Description of Property Pages
Property pages appear in the Properties Window. Property pages are available for the following:

- Server Properties
- Class Properties
- Interface Properties
- Method Properties
- Argument Properties
- Instance Type Properties

Server Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type Library GUID</td>
<td>The unique identifier of the server's type library. There is usually no reason to change this from the default value generated by the Fortran COM Server Wizard.</td>
</tr>
<tr>
<td>Type Library Version</td>
<td>The current version of the Type Library.</td>
</tr>
<tr>
<td>HelpString</td>
<td>A string used to set the library's help string attribute in the IDL file.</td>
</tr>
</tbody>
</table>

Class Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProgID</td>
<td>The version independent program ID (or text alias) for the class. The ProgID can be used in calls such as COMCreateObjectByProgID.</td>
</tr>
<tr>
<td>Version</td>
<td>The current version of the class. It is appended to the ProgID to define the version-specific ProgID.</td>
</tr>
<tr>
<td>Short name</td>
<td>A short name for the class. It is used in some of the generated file names.</td>
</tr>
<tr>
<td>Description</td>
<td>A string used as the default value of the class' ProgID keys in the registry. This string is often used by tools, such as the OLE-COM Object Viewer, that display a list of the objects that are registered on the system.</td>
</tr>
<tr>
<td>Help String</td>
<td>A string used to set the class' help string attribute in the IDL file.</td>
</tr>
<tr>
<td>Threading model</td>
<td>The threading model of the class. The two choices are Apartment and Single. See Threading Models in Advanced COM Server Topics for information about the implications of this choice.</td>
</tr>
<tr>
<td>CLSID</td>
<td>The unique identifier of the class. There is usually no reason to change this from the default value generated by the Wizard.</td>
</tr>
</tbody>
</table>

Interface Properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Dual</td>
<td>If true, then the dual interface attribute is set in the IDL file. A dual interface supports both COM and Automation clients.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Is OleAutomation</td>
<td>If true, then the interface uses only Automation-compatible data types as described in <a href="#">Fortran COM Server Interface Design Considerations</a>.</td>
</tr>
<tr>
<td>Is Default</td>
<td>If true, then the default interface attribute is set for this interface in the IDL file. The default attribute represents the default programmability interface of the object, and is intended for use by macro languages.</td>
</tr>
<tr>
<td>Help String</td>
<td>A string used to set the interface's help string attribute in the IDL file.</td>
</tr>
<tr>
<td>IID</td>
<td>The unique identifier of the interface. There is usually no reason to change this from the default value generated by the Wizard.</td>
</tr>
</tbody>
</table>

**Method Properties:**

- **DISPID**
  - The identifier of the method used by Automation clients.
- **Help string**
  - A string used to set the method's help string attribute in the IDL file.
- **Property Method**
  - If checked, then the method is the get_ or put_ method of a property.

**Argument Properties:**

- **Fortran data type**
  - The Fortran data type of the argument. Select one of the data types from the list, or type in the data type. See [Fortran COM Server Interface Design Considerations](#) for a discussion of the implications of your choice.
- **IDL type**
  - The IDL data type. If you select one of the Fortran data types from the predefined list, then this field defaults to the corresponding IDL data type. Select one of the data types from the list, or type in the data type. See [Fortran COM Server Interface Design Considerations](#) for a discussion of the implications of your choice.
- **Intent**
  - The INTENT of the argument, one of the following list:
    - [in] - the argument value is read but not modified by the method
    - [out] - the argument value is not read, but is modified by the method
    - [in, out] - the argument value is both read and modified by the method
    - [out, retval] - the argument represents the return value of the method
- **By Reference**
  - Indicates that an argument is passed by reference rather than by value. Only valid with Intent In. Intent Out and Intent InOut are automatically passed by reference.
- **Is Optional**
  - If true, then the argument is optional. Optional arguments are passed using the Variant data type.
- **Dimensions**
  - Number of array dimensions (0 if the argument is scalar).

**Instance Type Properties:**

- **Module name**
  - The name used for the module defined in the `UclassnameTY.f90` file.
- **Constructor name**
  - The name used for the class constructor defined in the `UclassnameTY.f90` file.
- **Destructor name**
  - The name used for the class destructor defined in the `UclassnameTY.f90` file.

**Modifying the Generated Code**
When you save the hierarchy file, Fortran sources are generated (or regenerated). Source files are stored as follows:

- Source files that you will need to modify are placed in the **Source Files** folder.
- Files that are complete and need no modification are placed in the **Do Not Edit** folder.

Modify the following files in the Source Files folder:

- **UAddingMachineTY.f90**, which contains a module that defines your class derived-type.
- **UIAdd.f90**, which contains the implementation of the *IAdd* methods.

Initially, the file **UAddingMachineTY.f90** contains the following code:

```fortran
module AddingMachine_USE
  type Adder_InstanceData
    sequence
      ! <BnDEF> DO NOT REMOVE THIS LINE
      ! TODO: Add fields and remove "dummy" integer dummy
      ! <EnDEF> DO NOT REMOVE THIS LINE
    end type
  contains
    ! Constructor
    function AddingMachine_CONSTRUCTOR( ObjectData ) result (hresult)
      use ifivity
      implicit none
      type(Adder_InstanceData) ObjectData
      dec$ attributes reference :: ObjectData
      integer(LONG) hresult
      hresult = 5_OK
      ! <BnDEF> DO NOT REMOVE THIS LINE
      ! TODO: Add field initialization code
      ! <EnDEF> DO NOT REMOVE THIS LINE
    end function
  end module AddingMachine_USE
end
```

The file contains a module named `AddingMachine_USE` (in the form `classname_USE`). There are three places in this module where you may need to add code specific to your class:

- The first entry in the module, marked by `<BnDEF>` and `<EnDEF>`, is your class derived-type. Initially it contains an "integer dummy" field to allow the module to be compiled without error. If your class has per-object data, remove the "integer dummy" field line and add your data to the derived-type. For the `AddingMachine` class, we add the following where the object stores the current value:

```fortran
real (4) CurrentValue
```
The module also contains two module procedures, \texttt{AddingMachine\_CONSTRUCTOR} and \texttt{AddingMachine\_DESTRUCTOR} (referred to as \textit{classname\_CONSTRUCTOR} and \textit{classname\_DESTRUCTOR} below). The former delineated with \texttt{<BnCON>} and \texttt{<EnCON>}; the latter is delineated with \texttt{<BnDES>} and \texttt{<EnDES>}.

The \textit{classname\_CONSTRUCTOR} procedure is called immediately after an instance of the class derived-type is created because of the creation of a new object. This function is where you initialize the fields of the class derived-type, if necessary. The new derived-type is passed as an argument to the function. For the \texttt{AddingMachine} class, initialize the current value to 0 by adding the following statement:

\begin{verbatim}
  ObjectData%CurrentValue = 0
\end{verbatim}

The \textit{classname\_DESTRUCTOR} procedure is called immediately before an instance of the class derived-type is destroyed because an object is being destroyed. This function is where you release any resources used by the fields of the class derived-type, if necessary. The derived-type is passed as an argument to the function. For the \texttt{AddingMachine} class, there is nothing that needs to be added.

Now modify the other source file called \texttt{UIAdd.f90}. The original file \texttt{UIAdd.f90} contains the following code:

A file by the name \textit{Uinterfacename.f90} (for example \texttt{UIadd.f90}) is created for each interface defined by the class. The file contains the methods of the class. Each method is named \textit{interfacename\_methodname}, for example: \texttt{IAdd\_Clear}. Each method is a function that is passed to the class derived-type as the first argument. This gives the function access to the per-object data. Each function returns a 32-bit COM status code called an HRESULT. \texttt{S\_OK} is a parameter that defines a success status. For additional information on COM status codes, see Fortran COM Server Interface Design Considerations.
Replace the ! TODO: Add implementation line in each method with the code for the method. For the IAdd interface, the implementation of its three methods is as follows:

For IAdd_Clear: ObjectData%CurrentValue = 0
For IAdd_Add: ObjectData%CurrentValue = ObjectData%CurrentValue + Operand
For IAdd_GetValue: CurrentValue = ObjectData%CurrentValue

Save the file and, from the Build menu, click Build Solution to build the server. The COM server is now complete.

COM Server Projects and the MIDL Compiler

During the creation of a COM Server project -- either In-process Server (DLL) or Out-of-process Server (EXE), as described in this section -- the application wizard determines whether Visual C++* is installed. If it is installed, the MIDL compiler uses the Visual C++ C preprocessor. This is both the default and recommended setting. If Visual C++ is not installed, the application wizard specifies that the MIDL compiler use the Fortran preprocessor for preprocessing MIDL source files. It does this by setting the Additional Options property of the MIDL compiler to include the following: /cpp_cmdifort /cpp_opt"/nologo /fpp /P /E /Qoption,fpp,/no-fort-cont".

If, later, you install Visual C++ and want to specify that MIDL use the Visual C++ C preprocessor, remove these options from the MIDL compiler Additional Options property.

Fortran COM Server Interface Design Considerations (Windows*)

This topic only applies to Windows* operating systems.
This section provides information that should be considered when designing a Fortran COM server. It contains the following topics:

- Method and Property Data Types
- COM Status Codes: HRESULT
- Visual Basic*, Visual C++*, and Intel® C++ Client Notes

**Method and Property Data Types**

COM places some restrictions on the data types used in COM methods and properties. The reason for the restrictions is that COM can pass arguments between threads, processes and machines. This raises issues that are not present in older technologies, such as DLLs, that always run in the same address space as the caller.

COM defines set of data types called Automation-compatible data types. These are the only data types that can be used in Automation and Dual interfaces. There are two advantages to restricting your COM interface to these data types:

- Your server will be usable from clients written in the largest set of languages, including Intel® Fortran, Visual Basic, and Visual C++.
- COM will automatically handle the passing of arguments between threads, processes and machines. This is called *Type Library Marshalling*. For more information, see Marshalling, Proxies and Stubs in Advanced COM Server Topics.

To restrict your server to Automation-compatible data types:

1. Select Use only Automation data types on the Interface property page. When defining a dual interface, this is automatically set.
2. Use only the following combinations of Fortran data type and Interface data type on the Argument property page.
   
   Note that Intel Fortran does not support the Currency, Decimal, or User Defined Type, Automation-compatible data types.

<table>
<thead>
<tr>
<th>Fortran Date Type</th>
<th>Interface Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(1)</td>
<td>unsigned char</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>short</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>long</td>
</tr>
<tr>
<td>SCODE</td>
<td>Int</td>
</tr>
<tr>
<td>INTEGER(INT_PTR_KIND())</td>
<td>IUnknown*</td>
</tr>
<tr>
<td></td>
<td>IDispatch*</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>float</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>double</td>
</tr>
<tr>
<td>DATE</td>
<td></td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td>VARIANT_BOOL</td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td>long</td>
</tr>
<tr>
<td>CHARACTER(1)</td>
<td>unsigned char</td>
</tr>
<tr>
<td>CHARACTER(*)</td>
<td>BSTR</td>
</tr>
</tbody>
</table>
If you decide not to restrict your interface to Automation-compatible data types, the next approach is to restrict your interface to data types that can be described in the Interface Description Language (IDL).

The Fortran COM Server Application Wizard automatically generates the IDL file from the description of your server. The MIDL compiler compiles the IDL file into a type library. MIDL can also automatically generate the code needed to handle the passing of arguments between threads, processes, and machines. Note, however, that a C compiler is required to use this option. For more information, see Discussion of Wizard Code Generation in Advanced COM Server Topics.

If you decide not to restrict your interface to IDL data types, your only remaining options are:

- Implement Custom Marshalling - For more information, see Marshalling, Proxies and Stubs in Advanced COM Server Topics.
- Decide that you will never use your server across apartment, thread, or process boundaries. The server will not be usable in this manner because there is no way to pass the arguments across these boundaries.

**COM Status Codes: HRESULT**

Each function returns a 32-bit COM status code called an HRESULT. An HRESULT is divided into fields:

- The top bit (31) indicates whether the function succeeded or failed. The bit is set if the function failed. In Fortran, you can compare the HRESULT to < 0 as a test to see if a function failed.
- Bits 16 to 27 contain a facility code to indicate the facility that issued the HRESULT. Microsoft pre-defines a number of facility codes for its own use. If you create your own status codes, use FACILITY_ITF. All other facility codes are reserved by Microsoft.
- The first 16 bits, or low word, contain the error code specific to the error that occurred.

A typical HRESULT error value could be a value such as 0x80070057. The first hex digit, 8, indicates that bit 31 is set and that this is an error value. Bits 16 to 27 contain the value 7. This indicates the facility FACILITY_WIN32. The low word contains the value 0057. This is the specific code that identifies the error as E_INVALIDARG.

To view the text description that corresponds to a system HRESULT value, use the Error Lookup tool in the Intel® Fortran program folder. For example, entering the value 0x80070057 retrieves the text message "The parameter is incorrect", as shown below:

You can also search for HRESULT values in the WINERROR.H file in the \VC\INCLUDE directory.
Visual Basic*, Visual C++*, and Intel® C++ Client Notes

To use an object from Visual Basic, you must add a "reference" to the object to the Visual Basic project. Use the References item in the Project menu to display a list of the registered objects. Select the object in the list to inform Visual Basic that you will be using the object.

Here are some points to be aware of when writing a server that can be used with Visual Basic clients:

- Use only the Automation-compatible data types (see Method and Property Data Types).
- Arguments to a method can be passed ByVal, ByRef, or they can be the function return value.
- An argument to be passed ByVal, must be defined with Intent set to In.
- An argument to be passed ByRef, must be defined with Intent set to InOut.
- A function return value must be defined with Intent set to Out. It must have the Return Value field checked. The argument must be the final argument of the method.
- An array is always passed as a SafeArray ByRef. Therefore it must be defined with Intent set to InOut.
- To use an argument of the Visual Basic Boolean data type, set the Fortran data type to LOGICAL(2) and set the Interface data type to VARIANT_BOOL.

To use an object from C++, use the #import directive. The syntax of the #import directive is:

```plaintext
#import "filename" [attributes]
#import <filename> [attributes]
```

The filename is the name of the file containing the type library information. The directive makes the information in the type library available to your source file as a set of C++ classes.

Advanced COM Server Topics (Windows*)

This topic only applies to Windows* operating systems.

Advanced topics about Fortran COM Servers described in this section include:

- Choosing Between DLL or EXE COM Servers
- DLL Server Surrogates
- Discussion of Wizard Code Generation
- Threading Models
- Marshalling, Proxies and Stubs
- A Map of the Generated "Do Not Edit" Code

Choosing Between DLL or EXE COM Servers

The basic tradeoff in choosing between a DLL (in-process) COM server and an EXE (out-of-process) COM server is one of performance vs. robustness:

- A DLL server provides the advantage of performance over an EXE server. Since the DLL server is loaded into the client's address space, there is less overhead involved in method calls. If the client code and the server object live in the same COM apartment, method calls are as efficient as DLL routine calls.
- An EXE server provides the advantage of robustness over a DLL server. Since the server object lives in a separate address space, the object cannot be affected by client memory handling bugs, and vice-versa. If the server crashes, the client doesn't necessarily crash – as long as the client checks the results of all method calls and takes steps to recover from a "dead" object.

In addition to the tradeoff between performance and robustness, the following factors should also be considered:

- With an EXE server, the object can run in a separate security context from the client. With a DLL server, the code of the object's methods executes using the client's access token.
- An EXE server can be run on a remote machine using COM distributed object support.

You can load a DLL server into a surrogate to gain the benefits of an EXE server. This is explained in the next section.
DLL Server Surrogates

An in-process DLL server can be run in a separate process with the help of a surrogate. A surrogate runs as a separate process, loads the DLL server, and provides all of the mechanism that allows the DLL server to act as a local server. Windows provides a standard surrogate named DLLHOST.EXE. The primary advantage of using a surrogate is fault isolation. That is, if the server crashes it does not crash the client, and vice versa. The disadvantage is performance. There is significant performance overhead in executing methods in a separate application, as opposed to in a DLL.

A DLL server is associated with a surrogate via entries in the system registry. This is done by associating the DLL server with an AppID. An AppID is a GUID. When using the standard surrogate, you can use the CLSID of a class in the DLL as the AppID, or a newly generated GUID. To generate a new GUID, use GUIDGEN.EXE in the Developer Studio Tools subdirectory:

1. Under the HKEY_CLASSES_ROOT\CLSID\{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}\ key of the class, add an AppID entry with the value of the CLSID. Using the AddingMachine class as an example, the registry key would be HKEY_CLASSES_ROOT\CLSID\{904245FC-DD6D-11D3-9835-0000F875E193}\ and the AppID value would be \{904245FC-DD6D-11D3-9835-0000F875E193\}.

2. Under the HKEY_CLASSES_ROOT\AppID key, add a key using the AppID. Using the AddingMachine class as an example, the registry key would be HKEY_CLASSES_ROOT\AppID\{904245FC-DD6D-11D3-9835-0000F875E193\}. Use the class name for the default value of the key, for example, "AddingMachine Class". Add a "DllSurrogate" entry with an empty string for the value.

The client must request CLSCTX_LOCAL_SERVER rather than CLSCTX_INPROC_SERVER to use the surrogate rather than loading the DLL server in-process. Using a surrogate requires that the DLL server have a proxy/stub registered since the method invocations are between different processes. For information on proxies/stubs, see Marshalling, Proxies and Stubs.

It is also possible to write a custom surrogate. See the Windows Platform SDK documentation for information.

Discussion of Wizard Code Generation

The COM Server Application Wizard generates the code for your project from the files in the subdirectory of your project named templates. The project-name.hie file contains the definition of your COM server in an undocumented text language. You should not manually edit the project-name.hie file; the Wizard does this for you.

Most of the other files in the templates directory are templates of the source files generated for your project. These templates contain source code that is copied "as-is" to the generated sources, and embedded directives that guide the Wizard in generating the code specific to the COM server that you define. The directives use the information in the project-name.hie file. The directives are undocumented and subject to change.

When you create a new Fortran COM Server project, the AppWizard creates the templates directory and copies the templates from the Fortran COM Server templates directory, ...\Intel Fortran\Templates \COMServer.

The files in the templates directory may change with each release, but the templates in your templates directory are never automatically updated. For example, if you create a COM server using Intel® Fortran Version 13.0 and the next release of Intel® Fortran (such as Version 13.1) contains updated templates, the templates for your COM server are not automatically updated to the new 13.1 templates. If you modify the definition of your server, your project continues to use the templates that it was created with. This has the advantage of not introducing different code into a project that you have developed and tested.

However, there are two cases where you may want to modify the templates that are used by your project:

- A new release of Intel® Fortran may contain additional features that can be used in your COM server project. Some of the new features may depend upon the new templates. These features will not be available to a pre-existing project unless you update the templates in the templates directory. You do this by copying all of the files in the Fortran COM Server templates directory ...\Intel Fortran
\Templates\COMServer into the templates directory, replacing all files with the same name. Your project will then use the new templates the next time that the definition of your server is modified and the project sources are regenerated.

- When you want to modify the code generated by the Wizard. You may edit a template in your templates directory. Editing code that is copied "as-is" is straightforward. Attempting to modify the embedded directives is unsupported and could cause the Wizard to fail when using the modified template. The embedded directives begin with an @ (at-sign) character. The next character determines the type of directive. The end of many directives is also delimited by an @ character followed by the matching end character for the type of directive. For example, @[ and @] are the delimiters for one type of directive.

The advantage of modifying a template is that you can customize the code generated by the Wizard. The disadvantages of modifying a template are:

- You must be very careful not to modify a template in a manner that causes the Wizard to generate bad code or fail.
- You will not be able to update the project templates with the templates from a new release of Intel® Fortran without having to re-apply your modifications to the new templates.

**Threading Models**

The Wizard supports two COM threading models for the classes that you create in a DLL COM server, Apartment and Single. The Wizard uses the Apartment threading model (also known as the Single Threaded Apartment model "STA") by default. The basic rules of the Apartment threading model are:

- If two objects, A and B, are created in the same STA thread, and A is processing a method call, no other client can call either A or B until A completes.
- If B is created in a different thread from A, B can accept a method call while A is still processing and vice versa.

This means that if the class shares any global data among its objects, the global data must be protected from simultaneous access using thread synchronization primitives. This is because two instances of the class could be running in different threads. However the per-object instance data, that is, the fields in the class derived-type, are protected from simultaneous access by COM mechanisms. This is true except in the case where an object calls out to another object that triggers a reentrant invocation of the first object.

A class using the Single threading model need not worry about simultaneous access to class global data, as well as per-object data. All objects of the class are created in a single thread and therefore only a single object of the class can be executing at any time.

An EXE COM server generated by the wizard is single threaded. All method invocations are serialized by the server's message queue. Therefore, with an EXE server, you need not worry about simultaneous access to class global data, as well as per-object data.

Explaining the COM threading models in detail is beyond the scope of this documentation. See the Windows Platform SDK documentation for additional information.

**Marshalling, Proxies and Stubs**

COM supports the use of objects in separate processes (as when using an EXE server or a DLL surrogate), and the threading models described above, by the use of marshalling, proxies and stubs. This section presents an overview of marshalling, proxies and stubs.

**Marshalling** is the process of reading the parameters for a method call and preparing them for transmission to another execution context (for example, thread, process, or machine). Marshalling is done by a proxy. From the client's perspective, a proxy has the same interface as the object itself. The proxy's job is to make the object look like an object in the same execution context as the client.

Proxies allow client code to be unconcerned about where the object actually lives. A proxy marshalls method parameters and transmits them to a stub associated with the object in the server. The stub unmarshalls the parameters and invokes the method in the server. From the server's perspective, this is no different than...
when it is called from a client in the same execution context. A server that is not an in-process DLL server always requires a proxy/stub pair. An in-process DLL server requires a proxy/stub pair when the client and object are in different apartments.

There are three ways to assign a proxy/stub pair to a server:

**Type Library Marshalling:** If you use only Automation-compatible data types in your methods and properties, COM can automatically use the "Universal Marshaller" as the proxy/stub for the server. The Universal Marshaller uses the description of the server in the type library to decide how to marshal the parameters. This is known as type library marshalling. Using type library marshalling requires no effort on your part, other than restricting your server to Automation-compatible data types.

**MIDL-based Marshalling:** Your project uses the MIDL compiler to compile the IDL description of the server into a type library. At the same time, the MIDL compiler also generates the C source code necessary to build a proxy/stub DLL for the server. You must have a C compiler to build a proxy/stub DLL from the MIDL generated code. The proxy/stub DLL is itself an in-process DLL server and needs to be registered with the system. You would need to use MIDL-based marshalling if your server uses non-Automation-compatible data types, and is used by a client in a different execution context.

**Custom Marshalling:** Your server can implement its own marshalling by implementing the IMarshall interface. This approach typically involves a lot of work and is done for performance reasons.

### A Map of the Generated "Do Not Edit" Code

This section presents an overview of which parts of the COM server functionality are implemented as "Do Not Edit" source files generated by the application wizard:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server.idl</td>
<td>Contains the IDL description of the server. It is compiled by the MIDL compiler to produce the server's type library.</td>
</tr>
<tr>
<td>servernameglobal.f90</td>
<td>Contains the global data and functions for the server.</td>
</tr>
<tr>
<td>dllmain.f90</td>
<td>Contains the exported functions that are required of all COM Server DLLs. This includes DllMain, DllRegisterServer, DllUnregisterServer, DllGetClassObject, and DllCanUnloadNow.</td>
</tr>
<tr>
<td>exemain.f90</td>
<td>Contains the main entry point of an EXE server. It also processes the command-line argument.</td>
</tr>
<tr>
<td>serverhelper.f90</td>
<td>Contains helper functions for the server.</td>
</tr>
<tr>
<td>clsfactty.f90</td>
<td>Contains definitions of the IClassFactory interface that is used to create instances of the classes defined by the server.</td>
</tr>
<tr>
<td>clsfact.f90</td>
<td>Contains methods of the IClassFactory interface that is used to create instances of the classes defined by the server.</td>
</tr>
<tr>
<td>classnameTY.f90</td>
<td>Defines a module that contains definitions of parameters and types used in the implementation of the class. It also contains the implementation of the IUnknown methods of the class. A separate instance of this file is generated for each class defined in the server.</td>
</tr>
</tbody>
</table>
Deploying the COM Server on Another System (Windows*)

This topic only applies to Windows* operating systems.

When you have finished developing the COM server, you may want to deploy it on another system. Besides the server itself, you need to install the Fortran run-time DLLs and register the server:

1. Install (or copy) the COM server to an appropriate directory.
2. Register the server:
   - To register a DLL server, use the REGSVR32.EXE system tool, a command-line tool. To register the DLL server, specify the path to the DLL and its file name (dll_path) by typing the following command:
     ```
     REGSVR32 dll_path
     ```
   - The file REGSVR32.EXE is in your system directory, such as the \Winnt\System32 on Windows NT* or Windows 2000 systems. If this directory is not in your PATH, include its path before the REGSVR32 command.
   - To register a an EXE server, run the server with the /REGSERVER command-line opton. For example:
     ```
     exe_path /REGSERVER
     ```

If you are using MIDL-based Marshalling or Custom Marshalling, then the marshalling DLL also needs to be installed and registered. For information on marshalling, see Advanced COM Server Topics.

Using the Intel® Fortran Module Wizard (COM Client) (Windows*)

Using the Intel® Fortran Module Wizard Overview (Windows*)

This topic only applies to Windows* operating systems.

Intel® Fortran provides a wizard to simplify the use of Component Object Model (COM) and Automation (formerly called OLE Automation) objects. The Intel® Fortran Module Wizard generates Standard Fortran modules that simplify calling COM and Automation services from Fortran programs. This Fortran code lets you invoke methods of an Automation object and member functions of a Component Object Model (COM) object.

The following sections describe the use of COM and Automation objects as clients with Intel Fortran:

- Understanding COM and Automation Objects
- The Role of the Module Wizard
- Using the Module Wizard to Generate Code
- Calling the Routines Generated by the Module Wizard
- Getting a Pointer to an Objects Interface
- Additional Resources about COM and Automation

Understanding COM and Automation Objects (Windows*)

This topic only applies to Windows* operating systems.

This section provides a brief overview of:

- COM Objects
Automation Objects

Object Servers

COM Objects

The Component Object Model (COM) provides mechanisms for creating reusable software components. COM is an object-based programming model designed to promote software interoperability; that is, to allow two or more applications or components to easily cooperate with one another, even if they were written by different vendors at different times, in different programming languages, or if they are running on different machines running different operating systems.

With COM, components interact with each other and with the system through collections of function calls, also known as methods or member functions or requests, called interfaces. An interface is a semantically related set of member functions. The interface as a whole represents a feature of an object. The member functions of an interface represent the operations that make up the feature. In general, an object can support multiple interfaces and you can use COMQueryInterface (W*32 W*64) to get a pointer to any of them.

The Intel Fortran COM routines provide a Fortran interface to basic COM functions.

Automation Objects

The capabilities of an Automation object resemble those of a COM object. An Automation object is in fact a COM object that implements the interface IDispatch. An Automation object exposes:

- **Methods**, which are functions that perform an action on an object. These are very similar to the member functions of COM objects.
- **Properties**, which hold information about the state of an object. A property can be represented by a pair of methods; one for getting the property’s current value, and one for setting the property’s value.

The Intel Visual Fortran AUTO routines provide a Fortran interface to invoking an automation object’s methods and setting and getting its properties.

Object Servers

COM and Automation objects are made available to users by COM and Automation servers. A COM or Automation server can be implemented either as:

- A DLL that is loaded into your process
- A separate executable program. The separate executable program can reside on the same system as your application or on a different system.

The Role of the Module Wizard (Windows*)

This topic only applies to Windows* operating systems.

To use COM and Automation objects from a Fortran program:

1. Find or install the object server on the system. COM and Automation objects can be registered:
   - By other programs you install.
   - By creating the object server yourself, for example, by using Visual C++*, or Visual Basic*.

   For example, the Microsoft visual development environment registers certain objects during installation (see the documentation on the Common Environment Object Model).

   Creating an object server involves deciding what type of object and what type of interfaces or methods should be available. The object’s server must be designed, coded, and tested like any other application. For information about object server creation, see Creating the Fortran COM Server.

2. Determine:
   - Whether the object has a COM interface, Automation interface, or both.
   - Where the object’s type information is located.

   You should be able to obtain this information from the object’s documentation. You can use the OLE/COM Object Viewer tool from the development environment Tools menu to determine the characteristics of an object on your system.

3. Use the Intel® Fortran Module Wizard to generate code.
The module wizard is an application that allows you to select a COM or Automation object and set generated code options. The information collected by the module wizard is used in the generated code. To learn about using the Intel® Fortran module wizard, see Using the Module Wizard to Generate Code.

4. Write a Fortran program to invoke the code generated by the Intel® Fortran module wizard.

To understand more about calling the interfaces and jacket routines created by the module wizard, see Calling the Routines Generated by the Module Wizard.

Using the Module Wizard to Generate Code (Windows*)

This topic only applies to Windows* operating systems.

To run the Intel® Fortran Module Wizard, select Tools > Intel Compiler > Intel® Fortran Module Wizard. The module wizard displays a series of dialog boxes allowing you to select the COM or Automation object and provide additional information.

COM and automation objects are self-describing, using type information. An object's type information contains programming language independent descriptions of the object's interfaces. Type information can be obtained from the object’s type library.

A type library is a collection of type information for any number of object classes, interfaces, and so on. You can store a type library in a file of its own (usually with an extension of .TLB) or it can be part of another file. For example, the type library that describes a DLL can be stored in the DLL itself.

After you start the module wizard, the COM tab of the dialog box displays the list of type libraries that are registered on your system. (There is also a .NET tab, which is explained in Using .NET Components.)

The list has three columns:
The component name
• The component version number
• The path to the type library

You may select a single component from the list, or click the Browse for Type Library... button to find a type library on your system.

The dialog box also provides the Generate code that uses Automation interfaces option. If the option is not selected, the Wizard will generate code to use the COM interfaces of the component.

The documentation of the component should tell you whether the component implements COM interfaces, Automation interfaces, or dual interfaces. A dual interface supports both COM and Automation interfaces. For a component that supports dual interfaces, you can check the Generate code that uses Automation interfaces option, or leave it unchecked. The COM interfaces tend to be more efficient (better run-time performance).

ActiveX controls implement an Automation interface. When using an ActiveX control, check the Generate code that uses Automation interfaces option.

After you select a component from the list or by browsing using the Browse for Type Library... button, click Next>.

This dialog box lists the members that are defined in the type library. Click the Select All button to select all of the members of the type library, or select individual members from the list. The Wizard uses the selected members.

This dialog box also contains two options regarding the code to be generated by the Wizard:

• Select Generate DLLEXPORT statements if you plan to place the generated module in a DLL for use by other projects. The Wizard will generate the DLLEXPORT statements to make the routines in the module visible outside of the DLL.
Check for exception return status (Automation only) is active if you checked the Generate code that uses Automation interfaces option in the first dialog box. Select this option if you want the Wizard to generate code to check the return status of each Automation method or property invocation, and to display a dialog box when an error is generated.

Change the module name if desired and select Finish.

**Using .NET Components**

The .NET tab is available on the first dialog box. The module wizard cannot directly read the type information of a .NET component. However, the .NET Framework Tools (provided with Visual Studio*) contain the Type Library Exporter (Tlbexp.exe). The Type Library Exporter generates a COM type library that describes the types defined in a .NET component (also known as a common language runtime assembly).

Select the .NET tab to view the assemblies that are registered in your system’s Global Assembly Cache (GAC). The list contains the same three columns as the COM tab, as well as a Browse for Assembly button. Select a .NET component from the list, or use the Browse for Assembly button to select a .NET component on your system.

Press Next > to run the Type Library Exporter tool to create a type library from the .NET component. If the tool returns an error message, the message is displayed in a dialog box and the Wizard returns to its first dialog box. In this case, no Fortran module is generated. If the tool succeeds, the second Wizard dialog box is displayed with the members found in the type library. There are restrictions on the .NET components that can be used with the Type Library Exporter tool. For example, a common error message returned by Type Library Exporter tool is:

You cannot use Tlbexp.exe to produce a type library from an assembly that was imported using the Type Library Importer (Tlbimp.exe). Instead, you should refer to the original type library that was imported with Tlbimp.exe.

In this case, the .NET assembly was created from the information in a type library, and you must obtain the original type library from the assembly provider in order to use it with the Module Wizard.

See the .NET Framework Tools documentation for details.

The Wizard runs the Type Library Exporter tool with the /nologo/silent options. You can also run the tool to create a type library before running the Module Wizard if you prefer.

**Intel® Fortran Module Wizard Command Line Interface**

The Intel® Fortran Module Wizard also has a command-line interface. The MODWIZ command has the following form:

```
MODWIZ [options] typeinfo-name
```

For a list of MODWIZ command options and an explanation of typeinfo-name, type the following command in a Fortran command prompt (available from the Intel® Fortran Compiler program folder):

```
MODWIZ /?
```

**See Also**

Using .NET Components

**Calling the Routines Generated by the Module Wizard (Windows*)**

This topic only applies to Windows* operating systems.

Although Standard Fortran does not support objects, it does provide Standard Fortran `modules`. A module is a set of declarations that are grouped together under a global name, and are made available to other program units by using the `USE` statement.

The Intel® Fortran Module Wizard generates a source file containing one or more modules. The types of information placed in the modules include:

- **Derived-type definitions** are Fortran equivalents of data structures that are found in the type information.
• **Constant definitions** are Fortran PARAMETER declarations that include identifiers and enumerations found in the type information.

• **Procedure interface definitions** are Fortran interface blocks that describe the procedures found in the type information.

• **Procedure definitions** are Fortran functions and subroutines that are jacket routines for the procedures found in the type information.

The jacket routines make the external procedures easier to call from Fortran by handling data conversion and low-level invocation details.

The use of modules allows the Intel® Fortran Module Wizard to encapsulate the data structures and procedures exposed by an object or DLL in a single place. You can then share these definitions in multiple Fortran programs.

The appropriate USE statement needs to be added in your program, as well as function invocations or subroutine calls.

The routines generated by the Intel® Fortran Module Wizard are designed to be called from Fortran. These routines in turn call the appropriate system routines (not designed to be called from Fortran), thereby simplifying the coding needed to use COM and Automation objects.

Intel® Visual Fortran provides a set of run-time routines that present to the Fortran programmer a higher level abstraction of the COM and Automation functionality. The Fortran interfaces that the wizard generates hide most of the differences between Automation objects and COM objects.

Depending on the options specified, the following routines can be present in the generated code:

### IFCOM Routines (COMxxxxx)

<table>
<thead>
<tr>
<th>Routine Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMAddObjectReference</td>
<td>Adds a reference to an object's interface.</td>
</tr>
<tr>
<td>COMCLSIDFromProgID</td>
<td>Passes a programmatic identifier and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCLSIDFromString</td>
<td>Passes a class identifier string and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCreateObject</td>
<td>A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.</td>
</tr>
<tr>
<td>COMCreateObjectByGUID</td>
<td>Passes a class identifier and creates an instance of an object. It returns a pointer to the object's interface.</td>
</tr>
<tr>
<td>COMCreateObjectByProgID</td>
<td>Passes a programmatic identifier and creates an instance of an object. It returns a pointer to the object's IDispatch interface.</td>
</tr>
<tr>
<td>COMGetActiveObjectByGUID</td>
<td>Pass a class identifier and returns a pointer to the interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetActiveObjectByProgID</td>
<td>Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.</td>
</tr>
<tr>
<td>COMInitialize</td>
<td>Initializes the COM library. You must initialize the library before calling any other COM or AUTO routine.</td>
</tr>
<tr>
<td>COMIsEqualGUID</td>
<td>Determines if two GUIDs are the same.</td>
</tr>
<tr>
<td>COMGetFileObject</td>
<td>Passes a file name and returns a pointer to the IDispatch interface of an Automation object that can manipulate the file.</td>
</tr>
<tr>
<td>COMQueryInterface</td>
<td>Passes an interface identifier and it returns a pointer to an object's interface.</td>
</tr>
<tr>
<td>COMReleaseObject</td>
<td>Indicates that the program is done with a reference to an object's interface.</td>
</tr>
<tr>
<td>COMStringFromGUID</td>
<td>Passes a GUID and returns the corresponding string representation.</td>
</tr>
</tbody>
</table>
ICOM Routines (COMxxxx)

COMUninitialize
Uninitializes the COM library. This must be the last COM routine that you call.

IFAUTO Automation Routines (AUTOxxxx)

AUTOAddArg
(W*32 W*64)
Passes an argument name and value and adds the argument to the argument list data structure.

AUTOAllocateInvokeArgs
(W*32 W*64)
Allocates an argument list data structure that holds the arguments that you will pass to AUTOInvoke.

AUTODEallocateInvokeArgs
(W*32 W*64)
Deallocates an argument list data structure.

AUTOGetExceptionInfo
(W*32 W*64)
Retrieves the exception information when a method has returned an exception status.

AUTOGetProperty
(W*32 W*64)
PASSES the name or identifier of the property and gets the value of the Automation object's property.

AUTOGetPropertyByID
(W*32 W*64)
PASSES the member ID of the property and gets the value of the Automation object's property into the argument list's first argument.

AUTOGetPropertyInvokeArgs
(W*32 W*64)
PASSES an argument list data structure and gets the value of the Automation object's property specified in the argument list's first argument.

AUTOInvoke
(W*32 W*64)
PASSES the name or identifier of an object's method and an argument list data structure. It invokes the method with the passed arguments.

AUTOSetProperty
(W*32 W*64)
PASSES the name or identifier of the property and a value. It sets the value of the Automation object's property.

AUTOSetPropertyByID
(W*32 W*64)
PASSES the member ID of the property and sets the value of the Automation object's property using the argument list's first argument.

AUTOSetPropertyInvokeArgs
(W*32 W*64)
PASSES an argument list data structure and sets the value of the Automation object's property specified in the argument list's first argument.

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard. This code is generated from the COM type information for the Save method of the IGeneric Document interface.

```
INTERFACE
! Saves the document to disk.
1 INTEGER*4 FUNCTION IGenericDocument_Save($OBJECT, vFilename, &
   vBoolPrompt, pSaved) 2
USE IFWINTY
INTEGER (INT_PTR_KIND()), INTENT(IN) :: $OBJECT     ! Object Pointer
3
!DIR$ ATTRIBUTES VALUE    :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename   ! (Optional Arg)
4
!DIR$ ATTRIBUTES REFERENCE      :: vFilename
!DIR$ ATTRIBUTES VALUE    :: vBoolPrompt
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt   ! (Optional Arg)
!DIR$ ATTRIBUTES REFEREENCE :: vBoolPrompt
INTEGER, INTENT(OUT) :: pSaved          ! DsSaveStatus
5
!DIR$ ATTRIBUTES REFEREENCE :: pSaved
!DIR$ ATTRIBUTES STDCALL    :: IGenericDocument_Save
END FUNCTION IGenericDocument_Save

END INTERFACE
POINTER(IGenericDocument_Save_PTR, IGenericDocument_Save) ! routine pointer
```
Notes for this example:

1 If the type information provides a comment that describes the member function, then the comment is placed before the beginning of the procedure.

2 The first argument to the procedure is always $OBJECT. It is a pointer to the object's interface. The remaining argument names are determined from the type information. For information on how to get a pointer to an object's interface, see Getting a Pointer to an Objects Interface.

3 This is an example of an ATTRIBUTES directive statement used to specify the calling convention of an argument.

4 A VARIANT is a data structure that can contain any type of Automation data. It contains a field that identifies the type of data and a union that holds the data value. The use of a VARIANT argument allows the caller to use any data type that can be converted into the data type expected by the member function.

5 Nearly every COM member function returns a status of type HRESULT. Because of this, if a COM member function produces output, it uses output arguments to return the values. In this example, the "pSaved" argument returns a routine specific status value.

6 The interface of a COM member function looks very similar to the interface for a dynamic link library function with one major exception. Unlike a DLL function, the address of a COM member function is never known at program link time. You must get a pointer to an object's interface at run-time, and the address of a particular member function is computed from that.

The following code shows an annotated version of the wrapper generated by the Intel® Fortran Module Wizard for the "Save" function. The name of a wrapper is the same as the name of the corresponding member function, prefixed with a "$" character.

```fortran
! Saves the document to disk.
INTEGER*4 FUNCTION $IGenericDocument_Save($OBJECT, vFilename, &
  vBoolPrompt, pSaved)
IMPLICIT NONE
INTEGER(INT_PTR_KIND()), INTENT(IN) :: $OBJECT    ! Object Pointer
!DIR$ ATTRIBUTES VALUE :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename
!DIR$ ATTRIBUTES REFERENCE :: vFilename
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt
!DIR$ ATTRIBUTES REFERENCE :: vBoolPrompt
INTEGER, INTENT(OUT)    :: pSaved    ! DsSaveStatus
!DIR$ ATTRIBUTES REFERENCE :: pSaved
INTEGER(4) $RETURN
INTEGER(INT_PTR_KIND()) $VTBL            ! Interface Function Table
POINTER($VPTR, $VTBL)
TYPE (VARIANT) :: $VAR_vFilename
TYPE (VARIANT) :: $VAR_vBoolPrompt
IF (PRESENT(vFilename)) THEN
  $VAR_vFilename = vFilename
ELSE
  $VAR_vFilename = OPTIONAL_VARIANT
END IF
IF (PRESENT(vBoolPrompt)) THEN
  $VAR_vBoolPrompt = vBoolPrompt
ELSE
  $VAR_vBoolPrompt = OPTIONAL_VARIANT
END IF
$VPTR = $OBJECT           ! Interface Function Table
$VPTR = $VTBL + 84    ! Add routine table offset
IGenericDocument_Save_PTR = $VTBL
$RETURN = IGenericDocument_Save($OBJECT, $VAR_vFilename, &
  $VAR_vBoolPrompt, pSaved)
$IGenericDocument_Save = $RETURN
END FUNCTION $IGenericDocument_Save
```

Notes for this example:
The wrapper takes the same argument names as the member function interface.

The wrapper computes the address of the member function from the interface pointer and an offset found in the interface's type information. In implementation terms, an interface pointer is a pointer to a pointer to an array of function pointers called an "Interface Function Table."

Arguments to a COM or Automation routine can be optional. The wrapper handles the invocation details for specifying an optional argument that is not present in the call.

The offset of the "Save" member function is 84. The code assigns the computed address to the function pointer IGenericDocument_Save_PTR, which was declared with the interface shown above, and then calls the function.

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard from Automation type information for the Rebuild All method of the IApplication interface.

```
! Rebuilds all files in a specified configuration.
SUBROUTINE IApplication_RebuildAll($OBJECT, Configuration, $STATUS) 1
  IMPLICIT NONE
  INTEGER(INT_PTR_KIND()), INTENT(IN) :: $OBJECT        ! Object Pointer
  !DIR$ ATTRIBUTES VALUE :: $OBJECT
  TYPE (VARIANT), INTENT(IN), OPTIONAL :: Configuration
  !DIR$ ATTRIBUTES REFERENCE :: Configuration
  INTEGER(4), INTENT(OUT), OPTIONAL :: $STATUS       ! Method status
  !DIR$ ATTRIBUTES REFERENCE :: $STATUS
  INTEGER(INT_PTR_KIND) invokeargs
  invokeargs = AUTOALLOCATEINVOKEARGS() 2
  IF (PRESENT(Configuration)) CALL AUTOADDARG(invokeargs, '$ARG1', &
    Configuration, AUTO_ARG_IN)
  $$STATUS = AUTOINVOKE($OBJECT, 28, invokeargs) 3
  IF (PRESENT($STATUS)) $STATUS = $$STATUS
  CALL AUTODEALLOCATEINVOKEARGS (invokeargs) 4
END SUBROUTINE IApplication_RebuildAll
```

Notes for this example:

1 The first argument to the procedure is always $OBJECT. It is a pointer to an Automation object's IDispatch interface. The last argument to the procedure is always $STATUS. It is an optional argument that you can specify if you wish to examine the return status of the method. The IDispatch Invoke member function returns a status of type HRESULT. An HRESULT is a 32-bit value. It has the same structure as a Windows error code. In between the $OBJECT and $STATUS arguments are the method arguments' names determined from the type information. Sometimes, the type information does not provide a name for an argument. The Fortran Module Wizard creates a "$ARGn" name in this case.

2 AUTOAllocateInvokeArgs allocates a data structure that is used to collect the arguments that you will pass to the method. AUTOAddArg adds an argument to this data structure.

3 AUTOInvoke invokes the named method passing the argument list. This returns a status result.

4 If the caller supplied a status argument, the code copies the status result to it.

5 AUTODEAllocateInvokeArgs deallocates the memory used by the argument list data structure.

**Getting a Pointer to an Object's Interface (Windows*)**

This topic only applies to Windows* operating systems.

To get a pointer to an object's interface, you need to know the object's unique identifier.

**Object Identification**

Object identification enables the use of COM objects created by disparate groups of developers. To provide a method of uniquely identifying an object class regardless of where it came from, COM uses *globally unique identifiers* (GUIDs). A GUID is a 16-byte integer value that is guaranteed (for all practical purposes) to be unique across space and time. COM uses GUIDs to identify object classes, interfaces, and other things that require unique identification.
To create an instance of an object, you need to tell COM what the GUID of the object is. While using 16-byte integers for identification is fine for computers, it poses a challenge for the typical developer. So, COM also supports the use of a less precise, textual name called a *programmatic identifier* (ProgID). A ProgID takes the form:

```
application_name .object_name .object_version
```

**Obtaining the Pointer to an Object's Interface**

To use the routines generated by the Module Wizard, your application must get a pointer to an object's interface. This pointer is used as the value of the $OBJECT argument, which is the first argument of every interface generated by the Module Wizard.

Typically, your application obtains its first pointer to an object's interface by calling the COM routine COMCreateObject. COMCreateObject creates a new instance of an object class and returns a pointer to it. COMCreateObject is the generic name of the two subroutines COMCreateObjectByProgID and COMCreateObjectByGUID.

- Use **COMCreateObjectByProgID** to create Automation objects. It accepts the progID of an object and returns a pointer to the object's IDispatch interface.
- Use **COMCreateObjectByGUID** to create both COM and Automation objects. It takes a GUID and returns a pointer to the object's interface (either Automation or COM - see below)

The arguments to COMCreateObjectByGUID are as follows:

- The first argument is a class identifier (CLSID) that uniquely identifies the object's class. The Module Wizard defines a GUID parameter for each class selected from the Type library. These are given the name in the form: `CLSID_class-name`
- The second argument allows you to limit the type(s) of server that the call will accept. Most of the time you can use CLSCTX_ALL to accept any type of server.
- The third argument is an interface identifier (IID) that specifies the particular object interface you are requesting:
  - To request an Automation interface, use IID_IDispatch.
  - To request a COM interface, the Module Wizard defines a GUID parameter for each interface selected from the type library. These are given a name in the form: `IID_interface-name`.
- The fourth argument is an output parameter that returns the object's interface pointer.

The COMCreateObjectByProgID and COMCreateObjectByGUID subroutines return an interface pointer of an object that the server has defined as being externally creatable. However, not all objects are externally creatable. Often, a server implements a hierarchy of objects, or *object model*. COMCreateObject is called to obtain a pointer to an interface of the root object in the hierarchy. Methods and/or properties of the root object are used to obtain pointers to child objects, and so on, down the hierarchy.

All objects must implement the IUnknown interface. Every object also implements one or more additional interfaces. You can always get a pointer to any of the object's interfaces from any of the object's interface pointers by using the COMQueryInterface subroutine. It is important that you have a pointer to the correct object interface when calling a routine generated by the Module Wizard. If not, your application will likely terminate unexpectedly.

**Releasing the Pointer to an Object's Interface**

When you have finished using an object's interface pointer, you must call **COMReleaseObject** with the pointer. This includes object pointers that you have received using any method, including COMCreateObject, COMQueryInterface, or by calling an object's method.

**Additional Resources about COM and Automation (Windows*)**

This topic only applies to Windows* operating systems.
There are a number of published books and articles about COM and Automation. Some of these are listed here as additional resources to assist customers who want to learn more about the subject matter. This list does not comment -- either negatively or positively -- on any documents listed or not yet listed. Books and related resources about COM and Automation include:

- *Inside COM+ Base Services* by Guy Eddon, Henry Eddon. Published by Microsoft Press (Redmond, Washington) 1999
- *Understanding COM+* by David S. Platt. Published by Microsoft Press (Redmond, Washington) 1999
- *Inside COM* by Dale Rogerson. Published by Microsoft Press (Redmond, Washington) 1996
- *Understanding ActiveX and OLE* by David Chappell. Published by Microsoft Press (Redmond, Washington) 1996
- *Platform SDK* online version. Relevant titles include *Platform SDK, COM and ActiveX Object Services*.
- *Visual C++ User’s Guide* online version
Using the fpp Preprocessor

The Fortran compiler preprocessor, fpp, is provided as part of the Intel® Fortran product. When you use a preprocessor for Intel® Fortran source files, the generated output files are used as input source files by the Compiler.

Preprocessing performs such tasks as preprocessor symbol (macro) substitution, conditional compilation, and file inclusion. Intel Fortran predefined symbols are described in Using Predefined Preprocessor Symbols.

fpp has some of the capabilities of the ANSI C preprocessor and supports a similar set of directives. Directives must begin in column 1 of any Fortran source files. Preprocessor directives are not part of the Fortran language and not subject to the rules for Fortran statements. Syntax for directives is based on that of the C preprocessor.

The compiler includes a limited conditional compilation capability, based on directives, that does not require use of fpp. The IF directive construct provides the capability of limited conditional compilation.

Note that you can also specify an alternate Fortran preprocessor instead of the Intel® Fortran fpp preprocessor. For more information, see option fpp-name.

Automatic Preprocessing by the Compiler

By default, the preprocessor is not run on files before compilation. However, the Intel Fortran compiler automatically calls fpp when compiling source files that have the .fpp, .F, .F90, .FOR, .FTN, or .FPP. For example, the following command preprocesses a source file that contains fpp preprocessor directives, then passes the preprocessed file to the compiler and linker:

```fortran
ifort source.fpp
```

If you want to preprocess files that have other Fortran extensions than those listed, you have to explicitly specify the preprocessor with the fpp compiler option.

The fpp preprocessor can process both free- and fixed-form Fortran source files. By default, filenames with the suffix of .F, .f, .for, or .fpp are assumed to be in fixed form. Filenames with a suffix of .F90 or .f90 (or any other suffix not specifically mentioned here) are assumed to be free form. You can use the free compiler option to specify free form and the fixed compiler option to explicitly specify fixed form.

The fpp preprocessor recognizes tab format in a source line in fixed form.

Running fpp to Preprocess Files

You can explicitly run fpp in these ways:

- On the ifort command line, use the ifort command with the fpp compiler option. By default, the specified files are then compiled and linked. To retain the intermediate (.i or .i90) file, specify the [Q]save-temps compiler option.
- On the command line, use the fpp command. In this case, the compiler is not invoked. When using the fpp command line, you need to specify the input file and the intermediate (.i or .i90) output file. For more information, type fpp -help (Linux OS and OS X) or fpp /help (Windows OS) on the command line.
- In the Microsoft Visual Studio® IDE, set the Preprocess Source File option to Yes in the Fortran Preprocessor Option Category. To retain the intermediate files, add /Qsave-temp to Additional Options in the Fortran Command Line Category.

The following lists some common cpp features that are supported by fpp; it also shows common cpp features that are not supported.
Supported cpp features:

#define, #undef, #ifdef, #ifndef, #if, #elif, #else, #endif,
#include, #error, #warning, #line

# (stringsize) and ## (concatenation) operators

! as negation operator

Unsupported cpp features:

#pragma and #ident

spaces or tab characters preceding the initial "#" character

# followed by empty line

\ backslash-newline

Unlikecpp, fpp does not merge continued lines into a single line when possible.

You do not usually need to specify preprocessing for Fortran source programs unless your program uses fpp preprocessing commands, such as those listed above.

---

CAUTION

Using a preprocessor that does not support Fortran can damage your Fortran code, especially with "FORMAT (\I4)" with cpp changes the meaning of the program because the double backslash "\\" indicates end-of-record with most C/C++ preprocessors.

---

fpp Source Files

A source file can contain fpp tokens in the following forms:

- fpp directive names
  
  For more information on fpp directives, see Using fpp Directives.

- symbolic names including Fortran keywords
  
  fpp permits the same characters in names as Fortran. For more information on symbolic names, see Using Predefined Preprocessor Symbols.

- constants
  
  Integer, real, double, and quadruple precision real, binary, octal, hexadecimal (including alternate notation), character, and Hollerith constants are allowed.

- special characters, space, tab, and newline characters

- comments, including:
  
  - Fortran language comments. A fixed form source line containing one of the symbols C, c, *, d, or D in the first position is considered a comment line. The ! symbol is interpreted as the beginning of a comment extending to the end of the line except when the ! occurs within a constant-expression in an #if or #elif directive. Within such comments, macro expansions are not performed, but they can be switched on by -f-com=no.
  
  - fpp comments between /* and */. They are excluded from the output and macro expansions are not performed within these symbols. fpp comments can be nested: for each /* there must be a corresponding */. fpp comments are useful for excluding from the compilation large portions of source instead of commenting every line with a Fortran comment symbol.
  
  - C++-like line comments that begin with // (double-slash).

A string that is a token can occupy several lines, but only if its input includes continued line characters using the Fortran continuation character s. fpp will not merge such lines into one line.

Identifiers are always placed on one line by fpp. For example, if an input identifier occupies several lines, it will be merged by fpp into one line.
**fpp Output**

Output consists of a modified copy of the input, plus lines of the form:

```
#line_number  file_name
```

These are inserted to indicate the original source line number and filename of the output line that follows. Use the `fpp P` preprocessor option to disable the generation of these lines.

**Diagnostics**

There are three kinds of fpp diagnostic messages:

- **warnings**: preprocessing of source code is continued and the fpp return value is 0
- **errors**: fpp continues preprocessing but sets the return value to a nonzero value which is the number of errors
- **fatal errors**: fpp stops preprocessing and returns a nonzero return value.

The messages produced by fpp are intended to be self-explanatory. The line number and filename where the error occurred are displayed along with the diagnostic on stderr.

**Using fpp Directives**

All fpp directives start with the number sign (`#`) as the first character on a line. White space (blank or tab characters) can appear after the initial "#" for indentation.

fpp directives (beginning with the # symbol in the first position of lines) can be placed anywhere in a source code, in particular before a Fortran continuation line. However, fpp directives within a macro call may not be divided among several lines by means of continuation symbols.

fpp directives can be grouped according to their purpose.

**Directives for string substitution**

fpp contains directives that result in substitutions in a user's program:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__FILE__</code></td>
<td>Replaces this string with the input file name (a character string literal).</td>
</tr>
<tr>
<td><code>__LINE__</code></td>
<td>Replaces this string with the current line number in the input file (an integer constant).</td>
</tr>
<tr>
<td><code>__DATE__</code></td>
<td>Replaces this string with the date that fpp processed the input file (a character string literal in the form <code>Mmm dd yyyy</code>).</td>
</tr>
</tbody>
</table>
Directive

<table>
<thead>
<tr>
<th>Directive</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TIME</strong></td>
<td>Replaces this string with the time that fpp processed the input file (a character string literal in the form hh:mm:ss).</td>
</tr>
<tr>
<td><strong>TIMESTAMP</strong></td>
<td>Replaces this string with the timestamp that fpp processed the input file (a character string literal in the form &quot;day date time year&quot;, where day is a 3-letter abbreviation, date is Mmm dd, time is hh:mm:ss and year is yyyy).</td>
</tr>
</tbody>
</table>

Directive for inclusion of external files

There are two forms of file inclusion:

```
#include "filename"
#include <filename>
```

This directive reads in the contents of the named file into this location in the source. The lines read in from the file are processed by fpp just as if they were part of the current file.

When the <filename> notation is used, filename is only searched for in the standard "include" directories. See the fpp -I and the -Y options in Using Fortran Preprocessor Options. No additional tokens are allowed on the directive line after the final "" or "">

Files are searched for in the following order:

- for #include "filename":
  - in the directory in which the source file resides
  - in the directories specified by the -I or -Y option
  - in the default directory
- for #include <filename>:
  - in the directories specified by the -I or -Y option
  - in the default directory

Directive for line control

This directive takes the following form:

```
#line-number "filename"
```

This directive generates line control information for the Fortran compiler. line-number is an integer constant that is the line number of the next line. "filename" is the name of the file containing the line. If "filename" is not provided, the current filename is assumed.

Directive for fpp variable and macro definitions

The #define directive, used to define both simple string variables and more complicated macros, takes the two forms.

The first form is the definition of an fpp variable:

```
#define nametoken-string
```

In the above, occurrences of name in the source file will be substituted with token-string.

The second form is the definition of an fpp macro.

```
#define name(argument[,argument] ... ) token-string
```

In the above, occurrences of the macro name followed by the comma-separated list of actual arguments within parentheses are replaced by token-string with each occurrence of each argument in token-string replaced by the token sequence representing the corresponding "actual" argument in the macro call.
An error is produced if the number of macro call arguments is not the same as the number of arguments in the corresponding macro definition. For example, consider this macro definition:

```c
#define INTSUB(m, n, o) call mysub(m, n, o)
```

Any use of the macro INTSUB must have three arguments. In macro definitions, spaces between the macro name and the open parenthesis "(" are prohibited to prevent the directive from being interpreted as an fpp variable definition with the rest of the line beginning with the open parenthesis "(" being interpreted as its token-string.

An fpp variable or macro definition can be of any length and is limited only by the newline symbol. It can be defined in multiple lines by continuing it to the next line with the insertion of "\". The occurrence of a newline without a macro-continuation signifies the end of the macro definition.

Example:

```c
#define long_macro_name(x,\n    y) x*y
```

The scope of a definition begins from the #define and encloses all the source lines (and source lines from #include files) to the end of the current file, except for:

- files included by Fortran INCLUDE statements
- fpp and Fortran comments
- Fortran IMPLICIT statements that specify a single letter
- Fortran FORMAT statements
- numeric, typeless, and character constants

**Directive for undefining a macro**

This directive takes the following form:

```c
#undef name
```

This directive removes any definition for name (produced by the D options, #define directives, or by default). No additional tokens are permitted on the directive line after name.

If name has not been defined earlier, then the #undef directive has no effect.

**Directive for macro expansion**

If, during expansion of a macro, the column width of a line exceeds column 72 (for fixed format) or column 132 (for free format), fpp inserts appropriate Fortran continuation lines.

For fixed format, there is a limit on macro expansions in label fields (positions 1-5):

- a macro call (together with possible arguments) should not extend beyond column 5
- a macro call whose name begins with one of the Fortran comment symbols is considered to be part of a comment
- a macro expansion may produce text extending beyond column 5. In this case, a warning will be issued

In fixed format, when the fpp -Xw option has been specified, an ambiguity may occur if a macro call occurs in a statement position and a macro name begins or coincides with a Fortran keyword. For example, consider the following:

```c
#define callp(x) call f(x)
call p(0)
```

fpp cannot determine how to interpret the "call p" token sequence above. It could be considered as a macro name. The current implementation does the following:

- the longer identifier is chosen (callp in this case)
- from this identifier the longest macro name or keyword is extracted
- if a macro name has been extracted a macro expansion is performed. If the name begins with some keyword, fpp issues an appropriate warning
the rest of the identifier is considered as a whole identifier

In the previous example, the macro expansion is performed and the following warning is produced:

warning: possibly incorrect substitution of macro callp

This situation appears only when preprocessing a fixed format source code and when the space symbol is not interpreted as a token delimiter.

In the following case, a macro name coincides with a beginning of a keyword:

```fortran
#define INT INTEGER*8
INT k
```

The INTEGER keyword will be found earlier than the INT macro name. There will be no warning when preprocessing such a macro definition.

**Directives for conditional selection of source text**

There are three forms of conditional selection of source text.

**Form 1:**

```
#if condition_1 block_1
#elif condition_2 block_2
#elif ...
#else
block n
#endif
```

**Form 2:**

```
#define name block_1
#elif condition block_2
#elif ...
#else
block n
#endif
```

**Form 3:**

```
#undef name block_1
#elif condition block_2
#elif ...
#else
block n
#endif
```

The #elif and #else parts are optional in all three forms. There can be more than one #elif part in each form.

**Conditional expressions**

`condition_1`, `condition_2`, etc. are logical expressions involving fpp constants, macros, and intrinsic functions. The following items are permitted:

- C language operations: `<`, `>`, `==`, `!=`, `>=`, `<=`, `+`, `-`, `/`, `*`, `%`, `<`, `>`, `&`, `~`, `|`, `&&`, `||` They are interpreted by fpp in accordance to the C language semantics (this facility is provided for compatibility with "old" Fortran programs using cpp)
- Fortran language operations: `.AND., .OR., .NEQV., .XOR., .EQV., .NOT., .GT., .LT., .LE., .GE., .NE., .EQ., ** (power).
- Fortran logical constants: `.TRUE., .FALSE.
- the fpp intrinsic function "defined": defined(name) or defined name which returns .TRUE. if name is defined as an fpp variable or a macro or returns .FALSE. if the name is not defined

`#ifdef` is a shorthand for `#if defined(name)` and `#ifndef` is a shorthand for `#if .not. defined(name).`
Only these items, integer constants, and names can be used within a constant-expression. A name that has not been defined with the `-D` option, a `#define` directive, or by default, has a value of 0. The C operation `!=` (not equal) can be used in the `#if` or `#elif` directive, but not in the `#define` directive, where the symbol `!` is considered to be the Fortran comment symbol by default.

**Conditional constructs**
The following table summarizes conditional constructs.

<table>
<thead>
<tr>
<th>Construct</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#if condition</code></td>
<td>Subsequent lines up to the matching <code>#else</code>, <code>#elif</code>, or <code>#endif</code> directive appear in the output only if condition evaluates to <code>.TRUE.</code>.</td>
</tr>
<tr>
<td><code>#ifdef name</code></td>
<td>Subsequent lines up to the matching <code>#else</code>, <code>#elif</code>, or <code>#endif</code> appear in the output only if <code>name</code> has been defined, either by a <code>#define</code> directive or by the <code>-D</code> compiler option, with no intervening <code>#undef</code> directive. No additional tokens are permitted on the directive line after name.</td>
</tr>
<tr>
<td><code>#ifndef name</code></td>
<td>Subsequent lines up to the matching <code>#else</code>, <code>#elif</code>, or <code>#endif</code> appear in the output only if <code>name</code> has not been defined, or if its definition has been removed with an <code>#undef</code> directive. No additional tokens are permitted on the directive line after name.</td>
</tr>
<tr>
<td><code>#elif condition</code></td>
<td>Subsequent lines up to the matching <code>#else</code>, <code>#elif</code>, or <code>#endif</code> appear in the output only if all of the following occur:</td>
</tr>
<tr>
<td></td>
<td>• The condition in the preceding <code>#if</code> directive evaluates to <code>.FALSE.</code> or the name in the preceding <code>#ifdef</code> directive is not defined, or the name in the preceding <code>#ifndef</code> directive is defined.</td>
</tr>
<tr>
<td></td>
<td>• The conditions in all of the preceding <code>#elif</code> directives evaluate to <code>.FALSE.</code></td>
</tr>
<tr>
<td></td>
<td>• The condition in the current <code>#elif</code> evaluates to <code>.TRUE.</code></td>
</tr>
<tr>
<td></td>
<td>Any condition allowed in an <code>#if</code> directive is allowed in an <code>#elif</code> directive. Any number of <code>#elif</code> directives may appear between an <code>#if</code>, <code>#ifdef</code>, or <code>#ifndef</code> directive and a matching <code>#else</code> or <code>#endif</code> directive.</td>
</tr>
<tr>
<td><code>#else</code></td>
<td>Subsequent lines up to the matching <code>#endif</code> appear in the output only if all of the following occur:</td>
</tr>
<tr>
<td></td>
<td>• The condition in the preceding <code>#if</code> directive evaluates to <code>.FALSE.</code> or the name in the preceding <code>#ifdef</code> directive is not defined, or the name in the preceding <code>#ifndef</code> directive is defined.</td>
</tr>
<tr>
<td></td>
<td>• The conditions in all of the preceding <code>#elif</code> directives evaluate to <code>.FALSE.</code></td>
</tr>
<tr>
<td><code>#endif</code></td>
<td>End a section of lines begun by one of the conditional directives <code>#if</code>, <code>#ifdef</code>, or <code>#ifndef</code>. Each such directive must have a matching <code>#endif</code>.</td>
</tr>
</tbody>
</table>

- `fpp` compiler option
- Using Fortran Preprocessor Options

**Using Predefined Preprocessor Symbols**
Preprocessor symbols (macros) let you substitute values in a program before it is compiled. The substitution is performed in the preprocessing phase.
The preprocessor symbols shown in the table below are predefined by the compiler system and are available to compiler directives and to fpp. If you want to use other symbol names, you need to specify them on the command line.

You can use the `d` compiler option to define the symbol names to be used during preprocessing. This option performs the same function as the `#define` preprocessor directive.

Preprocessing with fpp replaces every occurrence of the defined symbol name with the specified value. Preprocessing compiler directives only allow IF and IF DEFINED.

If you want to disable symbol replacement (also known as macro expansion) during the preprocessor step, you can specify the `macro=no` preprocessor option for the fpp compiler option.

Disabling preprocessor symbol replacement is useful for running fpp to perform conditional compilation (using `#ifdef`, etc.) without replacement.

You can use the `U` preprocessor option to suppress an automatic definition of a preprocessor symbol. This option suppresses any symbol definition currently in effect for the specified `name`. This option performs the same function as an `#undef` preprocessor directive.

The symbols in the following table can be used in both fpp and the Fortran compiler conditional compilations.

<table>

qoffload, Qoffload compiler option

**Using Fortran Preprocessor Options**

The Fortran preprocessor (fpp) may be invoked automatically or by specifying the fpp compiler option. The following options are available if you use the fpp compiler option. On Linux* OS and OS X*, the preprocessor options must start with a dash (-); for example, -macro=no. On Windows* OS, the preprocessor options must start with a slash (/); for example, /macro=no.

<table>
<thead>
<tr>
<th>fpp Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Specifies that C++-style comments should not be recognized.</td>
</tr>
<tr>
<td>C</td>
<td>Specifies that C-style comments should not be recognized. This is the same as specifying c_com=no.</td>
</tr>
</tbody>
</table>
### fpp Option

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_com={yes</td>
<td>no}</td>
</tr>
<tr>
<td>Dname</td>
<td>Defines the preprocessor variable name as 1 (one). This is the same as if a Dname=1 option appeared on the fpp command line, or as if a #define name 1 line appeared in the source file processed by fpp.</td>
</tr>
<tr>
<td>Dname=val</td>
<td>Defines name as if by a #define directive. This is the same as if a #define name var line appeared in the source file processed by fpp. The D option has lower precedence than the U option. That is, if the same name is used in both a U option and a D option, the name will be undefined regardless of the order of the options.</td>
</tr>
<tr>
<td>e</td>
<td>For fixed form source files, tells the compiler to accept extended source lines, up to 132 characters long.</td>
</tr>
<tr>
<td>e80</td>
<td>For fixed form source files, tells the compiler to accept extended source lines, up to 80 characters long.</td>
</tr>
<tr>
<td>f_com={yes</td>
<td>no}</td>
</tr>
<tr>
<td>f77</td>
<td>Tells the compiler to assume FORTRAN 77 language input source.</td>
</tr>
<tr>
<td>f90</td>
<td>Tells the compiler to assume Fortran 90 language input source.</td>
</tr>
<tr>
<td><strong>fpp Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------</td>
<td>----------------</td>
</tr>
<tr>
<td>fixed</td>
<td>Tells the compiler to assume fixed format in the source file.</td>
</tr>
<tr>
<td>free</td>
<td>Tells the compiler to assume free format in the source file.</td>
</tr>
<tr>
<td>help</td>
<td>Displays information about fpp options.</td>
</tr>
<tr>
<td>Idir</td>
<td>Inserts directory <code>dir</code> into the search path for files with names not beginning with &quot;/&quot;. The <code>#include dir</code> is inserted ahead of the standard list of &quot;include&quot; directories so that #include files with names enclosed in double-quotes (&quot;) are searched for first in the directory of the file with the #include line, then in directories named with <code>I</code> options, and lastly, in directories from the standard list. For #include files with names enclosed in angle-brackets (&lt; &gt;), the directory of the file with the #include line is not searched.</td>
</tr>
<tr>
<td>M</td>
<td>Generates make dependencies.</td>
</tr>
<tr>
<td>m</td>
<td>Expands macros everywhere. This is the same as specifying <code>macro=yes</code>.</td>
</tr>
<tr>
<td>macro={yes</td>
<td>no_com</td>
</tr>
<tr>
<td>macro_expand={vc</td>
<td>cpp}</td>
</tr>
<tr>
<td>MF=\textit{file}</td>
<td>Makes fpp append dependencies to <code>file</code>.</td>
</tr>
<tr>
<td>noB</td>
<td>Specifies that C++-style comments should be recognized.</td>
</tr>
<tr>
<td>noC</td>
<td>Specifies that C-style comments should be recognized. This is the same as <code>c_com=yes</code>.</td>
</tr>
<tr>
<td>noJ</td>
<td>Specifies that F90-style comments should be recognized in a #define line. This is the same as <code>f_com=no</code>.</td>
</tr>
<tr>
<td>no-fort-cont</td>
<td>Specifies that IDL style format should be recognized. This option is only for the IDE. Note that macro arguments in IDL may have a C-like continuation character \ which is different from the Fortran continuation character &amp;. The fpp preprocessor should recognize the C-like</td>
</tr>
<tr>
<td><strong>fpp Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------</td>
</tr>
<tr>
<td><strong>P</strong></td>
<td>Tells the compiler that line-numbering directives should not be added to the output file. This line-numbering directive appears as <code>#line-number file-name</code></td>
</tr>
</tbody>
</table>
| **Unname**    | Removes any initial definition of name, where name is an fpp variable that is predefined on a particular preprocessor. The following shows an example of symbols that may be predefined, depending upon the architecture of the system:  
  Operating System: __APPLE__, __unix, and __linux  
  Hardware: __i386, __x86_64 |
| **undef**     | Removes initial definitions for all predefined symbols. |
| **V**         | Displays the fpp version number. |
| **w[0]**      | Prevents warnings from being output. By default, warnings are output to standard error stream (stderr). |
| **what**      | Displays detailed version information. |
| **Xu**        | Converts uppercase letters to lowercase, except within character-string constants. The default is to leave the case as is. |
| **Xw**        | Tells the compiler that in fixed-format source files, the blank or space symbol " " is insignificant. By default, the space symbol is the delimiter of tokens for this format. |
| **Ydir**      | Adds directory dir to the end of the system include paths. |
Portability Library Overview

Intel® Fortran includes functions and subroutines that ease porting of code to or from a PC, or allow you to write code on a PC that is compatible with other platforms.

The portability library is called LIBIFPORT.LIB (Windows* OS) or libifport.a (Linux* OS and OS X*). Frequently used functions are included in a portability module called IFPORT.

The portability library also contains IEEE* POSIX library functions. These functions are included in a module called IFPOSIX.

You can use the portability library in one of two ways:

- Add the statement USE IFPORT to your program. This statement includes the IFPORT module.
- Call portability routines using the correct parameters and return value.

The portability library is passed to the linker by default during linking. To prevent this, specify the fpscomp compiler option with the nolibs keyword.

Using the IFPORT mod file provides interface blocks and parameter definitions for the routines, as well as compiler verification of calls.

Using the IMSL* Mathematical and Statistical Libraries Overview (Windows* OS)

The IMSL* libraries, a collection of nearly 1,000 mathematical and statistical functions easily accessible from the visual and command line development environments, are an optionally installed component provided with certain editions of the Intel® Fortran product. The IMSL libraries are provided in both static library and dynamic-link library (DLL) forms.

Install the compiler first and then install the IMSL libraries. For more information, see the install.htm file.

You can view the IMSL readme file and online help using the IMSL Fortran Library 6.0 program folder. The online documentation included with the IMSL Libraries includes text files and PDF files:

- Text files:
  - QuickStart - Brief instructions for setting up the command-line build environment
  - Read me - Full instructions for using the IMSL libraries from the command-line environment, plus reference information
  - Release notes - Information about changes from previous versions of the IMSL libraries
  - Readme (specific for your architecture) for IMSL Fortran Library - A series of Readme files with information on use of the IMSL libraries on a specific architecture

- PDF documentation
  The IMSL Adobe Acrobat* PDF documentation lets you quickly find details on the purpose and use of any IMSL Library routine. You can access the following topics through the IMSL Fortran Library User's Guide:

  - IMSL Math Library
  - IMSL Math Library Special Functions
  - IMSL Stat Library

  Click on any of the libraries to see a submenu of items grouped by subject. Within each category (for example, Linear Systems, Eigen system Analysis, and so on), click on a routine for more information.

The IMSL libraries have coding conventions regarding use of modules for interface declarations. For detailed information, read the Introduction section of the IMSL Fortran Library User's Guides.

For more information on the IMSL libraries, see:

- The IMSL readme file provided in the IMSL Fortran Library program folder.
- The IMSL online documentation PDF files provided in the IMSL Fortran Library program folder for the IMSL Routines Reference.

Using the IMSL Libraries from the Integrated Development Environment (Windows* OS)
Using the IMSL Libraries from the Command Line (Windows* OS)
IMSL Include File and Library Naming Conventions and Redistribution (Windows* OS)
Using IMSL Libraries in a Mixed-Language Environment (Windows* OS)

Using the IMSL Libraries from the Integrated Development Environment (Windows* OS)
To use the IMSL* libraries from the Microsoft Visual Studio* IDE:

1. Add the IMSL Include and Library directories to the list of directories searched:
a. Select Tools > Options.
b. Select Intel Compilers and Tools > Visual Fortran
c. Select Compilers.
d. Select the Target Platform for which you want to make changes. Select Win32 for IA-32 (32-bit) architecture. Select x64 for Intel® 64 (64-bit) architecture.

Make sure that the desired compiler version is selected.
e. At the right of Libraries, click the "..." button. This opens the list of libraries directories.
f. Add to the end of the list, one of the following:
   • For IA-32 architecture: $(FNL_DIR)\IA32\lib
   • For Intel® 64 architecture: $(FNL_DIR)\Intel64\lib
g. Click OK.
h. At the right of Includes, click the "..." button.
i. Add to the end of the list, one of the following:
   • For IA-32 architecture: $(FNL_DIR)\IA32\include\dll
   • For Intel® 64 architecture: $(FNL_DIR)\Intel64\include\dll
j. Click OK.
k. Repeat steps c through i for the other target architecture if desired.
l. Click OK to save the changes.

You need to reapply these changes if you install a new version of the compiler or use the installation option to keep an existing update installed when installing a new update.

2. To pass IMSL libraries to the Linker, add one of the following lines to your main program or any convenient source file for your application. This needs to be specified only once per application.

   • To use the static library form of the libraries:
     INCLUDE 'link_fnl_static.h'

   • To use the dynamic link library form of the libraries:
     INCLUDE 'link_fnl_shared.h'

   • To use the static library form of the libraries and the Intel® Math Kernel Library:
     INCLUDE 'link_fnl_static_hpc.h'

   • To use the dynamic link library form and the Intel® Math Kernel Library:
     INCLUDE 'link_fnl_shared_hpc.h'

   • To use the MPIC, the static library form of the libraries and the MPI* version of the error handler:
     INCLUDE 'link_mpi.h'

   • To use MPI, the static library form of the libraries, the MPI version of the error handler and the Intel® Math Kernel Library:
     INCLUDE 'link_mpi_hpc.h'

   • To use MPI, the static library form of the libraries, the scalar version of the error handler:
     INCLUDE 'link_mpi.h'

   • To use MPI, the static library form of the libraries, the scalar version of the error handler and the Intel® Math Kernel Library:
     INCLUDE 'link_mpi_hpc.h'

If you want to specify the libraries explicitly, select Project>Add Existing Item..., change Files of Type to All Files, browse to the IMSL Libraries folder, and add the appropriate libraries as explained in IMSL Include File and Library Naming Conventions and Redistribution.

3. Ensure that the following project properties are set to ensure correct operation with the IMSL libraries:

   • Fortran>External Procedures>Calling Convention>Default
   • Fortran>External Procedures>Name Case Interpretation>Upper Case
   • Fortran>External Procedures>String Length Argument Passing>After All Arguments
   • Fortran>External Procedures>Append Underscores to External Names>No
   • Fortran>Floating Point>Floating Point Exception Handling>Produce NaN, signed infinities, and denormal results
Using the IMSL Libraries from the Command Line (Windows® OS)

To use the IMSL® libraries from the command line:

1. Set the necessary Intel® Fortran environment variables for your development environment by executing the compilervars.bat file (see Using the compilervars File to Specify Location of Components). This sets the INCLUDE path and library (linker) search paths.

2. Add a reference to the FFLAGS environment variable to establish IMSL-compatible defaults and add a reference to the appropriate environment variable to the ifort commands used to build the sources:

   - %LINK_FNL_STATIC% for the static libraries
   - %LINK_FNL_SHARED% for the dynamic libraries
   - %LINK_FNL_STATIC_HPC% for the static libraries and Intel MKL
   - %LINK_FNL_SHARED_HPC% for the dynamic libraries and Intel MKL
   - %LINK_FNL_MPI% for the static libraries, the MPI version of error handler and MPI
   - %LINK_FNL_MPI_HPC% for the static libraries, the MPI version of error handler, MPI and Intel MKL
   - %LINK_FNL_MPIIS% for the static libraries, the scalar version of error handler, MPI and Intel MKL
   - %LINK_FNL_MPIIS_HPC% for the static libraries, the scalar version of error handler, MPI and Intel MKL

   For example, ifort %FFLAGS% example.f90 %LINK_FNL_STATIC%

3. Do not change the defaults for the compiler options /fpe and /iface.

4. Make IMSL routines and their interfaces available to your program. There are several options available for this; see the Introduction in the IMSL Fortran Library User's Guide for details.

The free-form Standard Fortran example program below invokes the function AMACH and the subroutine UMACH from the IMSL Libraries. The AMACH function retrieves real machine constants that define the computer's real arithmetic. A value for positive machine infinity is returned (Infinity). The subprogram UMACH retrieves the output unit number.

```fortran
! This free-form example demonstrates how to call
! IMSL routines from Intel(R) Visual Fortran.
!
PROGRAM SHOWIMSL
USE AMACH_INT
USE UMACH_INT
INTEGER NOUT
REAL RINFP
!
! The AMACH function and UMACH subroutine are
! declared in the AMACH_INT and UMACH_INT modules
CALL UMACH(2,NOUT)
RINFP = AMACH(7)
WRITE(NOUT,*) 'REAL POSITIVE MACHINE INFINITY = ',RINFP
END PROGRAM
```

For information on using the IMSL libraries from the IDE, see Using the IMSL Libraries from the Integrated Development Environment.
**IMSL Include File and Library Naming Conventions and Redistribution (Windows* OS)**

The IMSL* libraries provide sets of "include" files. By default, the standard set is installed at the following locations:

- C:\Program Files\VNI\imsl\fnl600\IA32\include\dll (for systems using IA-32 architecture)
- C:\Program Files\VNI\imsl\fnl600\Intel64\include\dll (for systems using Intel® 64 architecture)

The standard set is suitable for use when linking against either the static or dynamic libraries; however, some applications linking to the static libraries may see warnings from the linker due to the use of the DLLIMPORT directive for IMSL global variables. The warnings can be ignored, but if you want to avoid them, use the alternate set of "include" files in the include\ static folder.

The following libraries are supplied:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Library Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMSL and IMSL_DLL</td>
<td>IMSL Static and DLL Library; contains application-callable routines</td>
</tr>
<tr>
<td>IMSLMKL_DLL</td>
<td>IMSL DLL Library using Intel® Math Kernel Library; contains application-callable routines</td>
</tr>
<tr>
<td>IMSLS_ERR</td>
<td>IMSL Error Handler Library; scalar version</td>
</tr>
<tr>
<td>IMSLP_ERR</td>
<td>IMSL Error Handler Library, MPI version</td>
</tr>
<tr>
<td>IMSL_HPC_L</td>
<td>LAPACK enabled routines</td>
</tr>
<tr>
<td>IMSL_HPC_S</td>
<td>ScalaPACK enabled routines</td>
</tr>
<tr>
<td>IMSLSCALAR</td>
<td>Support routines</td>
</tr>
<tr>
<td>IMSLSUPERLU</td>
<td>Support routines</td>
</tr>
<tr>
<td>IMSLMPISTUB</td>
<td>Stub libraries</td>
</tr>
<tr>
<td>IMSLSPARSESTUB</td>
<td>Stub libraries</td>
</tr>
<tr>
<td>IMSLBLAS</td>
<td>Basic Linear Algebra Subroutine support library</td>
</tr>
</tbody>
</table>

For applications running on systems using IA-32 architecture, use the following combinations of libraries and compiler options:

**Static linking**

IMSL.LIB IMSLSUPERLU.LIB IMSLSCALAR.LIB IMSLBLAS.LIB IMSLS_ERR.LIB IMSLMPISTUB.LIB

**Dynamic linking**

IMSL_DLL.LIB /libs:dll

**Static linking, using Intel® Math Kernel Library for multiple processors**

IMSL.LIB IMSLSUPERLU.LIB IMSLHPC_L.LIB IMSLS_ERR.LIB IMSLMPISTUB.LIB MKL_INTEL_C.LIB MKL_INTEL_THREAD.LIB MKL_CORE.LIB LIBIOMP5MD.LIB

**Dynamic linking, using Intel® Math Kernel Library for multiple processors**

IMSLMKL_DLL.LIB /LIBS_DLL
Static linking, using MPI version of the error handler and MPI for multiple processors

<table>
<thead>
<tr>
<th>Static linking</th>
<th>IMSL.LIB IMSLSUPERLU.LIB IMSLSCALAR.LIB IMSLBLAS.LIB IMSLP_ERR.LIB</th>

The tables above document the libraries which must be redistributed with your IMSL application for it to function properly.

If your program is linked to any of the IMSL or Intel MKL DLLs, the folder containing the DLLs must be included in the definition of the PATH environment variable, or the DLLs must be in the same folder as the application .EXE file. See the table above for the names of IMSL and Intel MKL DLLs to accompany your application.

If your application is linked against the static IMSL libraries, no additional IMSL files need to be distributed along with your application. However, you may still need to distribute Intel® Fortran DLLs that are not provided in static library form, such as libiomp5md.dll.

Please refer to the IMSL End-User License Agreement for your rights and limitations regarding distribution of applications that use the IMSL library.

Using IMSL Libraries in a Mixed-Language Environment (Windows* OS)

You can use the IMSL Libraries in a mixed-language development environment with Intel® Visual Fortran and C or C++ native code.

Messages that IMSL routines write to standard output or to error output in a mixed-language application or an application for Windows* can be awkward if they are written to the screen. You can avoid this by calling UMACH from a Fortran routine to remap the output and error units to a file instead of to the screen. For example, the following free-form program writes the standard output from VHSTP to the file STD.TXT, and the error message from AMACH to the file ERR.TXT:

```fortran
PROGRAM fileout
! This program demonstrates how to use the UMACH routine to
! redirect the standard output and error output from IMSL
! routines to files instead of to the screen. The routines
! are declared in the interface modules
!
USE umach_int
USE amach_int
INTEGER STDU, ERRU
REAL x, frq(10)/3.0,1.0,4.0,1.0,5.0,9.0,2.0,6.0,5.0,3.0/
!
! Redirect IMSL standard output to STD.TXT at unit 8
!
CALL umach(-2, STDU)
OPEN (unit=STDU, file='std.txt')
CALL vhstp(10,frq,1,'Histogram Plot')
CLOSE(8)
!
! Redirect IMSL error output to ERR.TXT at unit 9
```
CALL umach(-3, ERRU)
OPEN (unit=ERRU, file='err.txt')
x = amach(0)   ! Illegal parameter error
CLOSE(9)  END

The standard output from IMSL routine VHSTP written to STD.TXT is:

```
1
Histogram Plot
Frequency-------------------------
  9 * I I *
  8 * I I *
  7 * I I *
  6 * I I I *
  5 * I I I I *
  4 * I I I I I *
  3 * I I I I I I *
  2 * I I I I I I I I *
  1 * I I I I I I I I I I *
-----------------------------------------------------------------------
Class            5        10
```

The error output from IMSL routine AMACH written to ERR.TXT is:

```
*** TERMINAL ERROR 5 from AMACH. The argument must be between 1 and 8
***          inclusive. N = 0
```

Consider the following simple Fortran example that uses the IMSL library:

```fortran
USE amach_int
real rinfp
rinfp = AMACH(7)
write(*,*) 'Real positive machine infinity = ',rinfp
end
```

The output is:

```
Real positive machine infinity = Infinity
```

The corresponding C example is:

```c
/* FILE CSAMP0.C */
#include <stdio.h>
#include <stdlib.h>
extern float AMACH(long *);
main()
{
    long n;
    float rinfp;
    n = 7;
    rinfp = AMACH(&n);
    printf("Real positive machine infinity = %16E\n", rinfp);
    fflush(stdout);
    _exit(0);
}
```

This C language example demonstrates the use of:

- The function prototype needed when calling the IMSL libraries.
- The & address operator passes the address of the variable to the subprogram (IMSL libraries expect arguments passed by reference).

The C example can be compiled by the icl or cl command to create an object file that can be linked using the ifort command. Note that the appropriate IMSL libraries must also be linked in. See IMSL Include File and Library Naming Conventions and Redistribution for details.
Using National Language Support (NLS) Routines Overview (Windows* OS)

Intel® Fortran provides a complete National Language Support (NLS) library of language-localization routines and multibyte-character routines. You can use these routines to write applications in many different languages.

In many languages, the standard ASCII character set is not enough because it lacks common symbols and punctuation (such as the British pound sign), or because the language uses a non-ASCII script (such as Cyrillic for Russian) or because the language consists of too many characters for each to be represented by a single byte (such as Chinese).

In the case of many non-ASCII languages, such as Arabic and Russian, an extended single-byte character set is sufficient. You need only change the language locale and codepage, which can be done at a system level or within your program. However, Eastern languages such as Japanese and Chinese use thousands of separate characters that cannot be encoded as single-byte characters. Multibyte characters are needed to represent them.

Character sets are stored in tables called code sets. There are three components of a code set: the locale, which is a language and country (since, for instance, the language Spanish may vary among countries), the codepage, which is a table of characters to make up the computer's alphabet, and the font used to represent the characters on the screen. These three components can be set independently. Each computer running Windows operating systems comes with many code sets built into the system, such as English, Arabic, and Spanish. Multibyte code sets, such as Chinese and Japanese, are not standard but come with special versions of the operating system (for instance, Windows NT-J comes with the Japanese code set).

The default code set is obtained from the operating system when a program starts up. When you install your operating system, you should install the system supplied code sets. Thereafter, they are always available. You can switch among them by:

1. Open the Control Panel (available from Settings)
2. Click the Regional Settings icon
3. Choose from the dropdown list of available locales (languages and countries).

When you select a new locale, it becomes the default system locale, and will remain the default locale until you change it. Each locale has a default codepage associated with it, and a default currency, number, and date format.

NOTE
The default codepage does not change when you select a new locale until you reboot your computer.

You can change the currency, number, and date format in the International dialog box or the Regional Setting dialog box independently of the locale.

The locale determines the character set available to the user. The locale you select becomes the default for the NLS routines described in this section, but the NLS routines allow you to change locales and their parameters from within your programs. These routines are useful for creating original foreign-language programs or different versions of the same program for various international markets. Changes you make to the locale from within a program affect only the program. They do not change the system default settings.

The codepage you select, which can be set independently, controls the multibyte (MB routines) character routines described in this section. Only users with special multibyte-character code sets installed on their computers need to use MB routines. The standard code sets all use single-byte character code sets.

Note that in Intel Fortran source code, multibyte characters can be used only in character strings and source comments. They cannot be used within variable names or statements. Like program changes to the locale, program changes to codepages affect only the program, not the system defaults.
To access the routines, the following statement should be present in any program unit that uses NLS or MB routines:

```fortran
USE IFNLS
```

- Program Units and Procedures Overview

**Understanding Single and Multibyte Character Sets (Windows* OS)**

The ASCII character set defines the characters from 0 to 127 and an extended set from 128 to 255. Several alternative single-byte character sets, primarily European, define the characters from 0 to 127 identically to ASCII, but define the characters from 128 to 255 differently. With this extension, 8-bit representation is sufficient for defining the needed characters in most European-derived languages. However, some languages, such as Japanese Kanji, include many more characters than can be represented with a single byte. These languages require multibyte coding.

A multibyte character set consists of both one-byte and two-byte characters. A multibyte-character string can contain a mix of single and double-byte characters. A two-byte character has a lead byte and a trail byte. In a particular multibyte character set, the lead and trail byte values can overlap, and it is then necessary to use the byte's context to determine whether it is a lead or trail byte.
Tools

PGO Tools

PGO Tools Overview
This section describes the tools that take advantage of or support the Profile-guided Optimizations (PGO) available in the compiler.

- Code coverage Tool
- Test prioritization Tool
- Profmerge and proforder Tools

Code Coverage Tool
The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are listed below:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- Code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate an HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on all supported Intel architectures on Linux*, Windows*, and OS X* operating systems.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.
Code Coverage Tool Requirements

To run the code coverage tool on an application, you must have the following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the -prof-gen=srcpos (Linux and OS X) or /Qprof-gen:srcpos (Windows) option.

**NOTE**

Use the -[Q]prof-gen:srcpos option if you intend to use the collected data for code coverage and profile feedback. If you are only interested in using the instrumentation for code coverage, use the /Qcov-gen option. Using the /Qcov-gen option saves time and improves performance. This option can be used only on Windows platform for all architectures.

- A pgopti.dpi file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge and proforder Tools tool. This file is also generated implicitly by the Intel® compilers when compiling an application with [Q]prof-use options with available .dyn and .dpi files.

Using the Tool

The tool uses the following syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov [-codecov_option]</td>
</tr>
</tbody>
</table>

where -codecov_option is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in the code coverage tools Options section. If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using -prof-gen=srcpos (Linux and OS X) or /Qprof-gen:srcpos (Windows), and/or /Qcov-gen (Windows) option.

   This step generates an instrumented executable and a corresponding static profile information (pgopti.spi) file when the -[Q]prof-gen=srcpos option is used. When the /Qcov-gen option is used, minimum instrumentation only for code coverage and generation of .spi file is enabled.

   **NOTE**

   You can specify both the /Qprof-gen=srcpos and /Qcov-gen options on the command line. The higher level of instrumentation needed for profile feedback is enabled along with the profile option for generating the .spi file, regardless of the order the options are specified on the command line.

2. Run the instrumented application.

   This step creates the dynamic profile information (.dyn) file. Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by the -prof-dir (Linux or OS/X) or -Qprof-dir (Windows) option, or PROF_DIR environment variable. On Windows, you can use the -Qcov-dir or COV_DIR environment variable. These have the same meaning as -Qprof-dir and PROF_DIR.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (pgopti.dpi) file.

   This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.

   You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the profmerge -a option. Select an alternate name for the output .dpi file using the profmerge -prof_dpi option.
CAUTION
The profmerge tool merges all .dyn files that exist in the given directory. Confirm that unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. The valid syntax and tool options are shown below.
This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.

NOTE
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

**Example: specify .dpi and .spi files**
```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

**Example: add contact information**
```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

**Example: export data to text**
```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

**Code Coverage Tool Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-bgcolor</td>
<td>#FFFF99</td>
<td>Specifies the HTML color name for code in the uncovered blocks.</td>
</tr>
<tr>
<td>-beginblkdsbl</td>
<td></td>
<td>Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-ccolor</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the covered code.</td>
</tr>
<tr>
<td>-comp</td>
<td></td>
<td>Specifies the file name that contains the list of files being (or not) displayed.</td>
</tr>
<tr>
<td>-counts</td>
<td></td>
<td>Generates dynamic execution counts.</td>
</tr>
<tr>
<td>-demang</td>
<td></td>
<td>Demangles both function names and their arguments.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-dpi <code>file</code></td>
<td>pgopti.dpi</td>
<td>Specifies the file name of the dynamic profile information file (.dpi).</td>
</tr>
<tr>
<td>-endblkdsbl <code>string</code></td>
<td></td>
<td>Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-fcolor <code>color</code></td>
<td>#FFCCCC</td>
<td>Specifies the HTML color name for code of the uncovered functions.</td>
</tr>
<tr>
<td>-help, -h</td>
<td></td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-icolor <code>color</code></td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.</td>
</tr>
<tr>
<td>-maddr <code>string</code></td>
<td>Nobody</td>
<td>Sets the email address of the web-page owner</td>
</tr>
<tr>
<td>-mname <code>string</code></td>
<td>Nobody</td>
<td>Sets the name of the web-page owner.</td>
</tr>
<tr>
<td>-nopartial</td>
<td></td>
<td>Treats partially covered code as fully covered code.</td>
</tr>
<tr>
<td>-nopmeter</td>
<td></td>
<td>Turns off the progress meter. The meter is enabled by default.</td>
</tr>
<tr>
<td>-onelinedsbl <code>string</code></td>
<td></td>
<td>Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-pcolor <code>color</code></td>
<td>#FAFAD2</td>
<td>Specifies the HTML color name or code of the partially covered code.</td>
</tr>
<tr>
<td>-prj <code>string</code></td>
<td></td>
<td>Sets the project name.</td>
</tr>
<tr>
<td>-ref</td>
<td></td>
<td>Finds the differential coverage with respect to ref_dpi_file.</td>
</tr>
<tr>
<td>-spi <code>file</code></td>
<td>pgopti.spi</td>
<td>Specifies the file name of the static profile information file (.spi).</td>
</tr>
<tr>
<td>-srcroot <code>dir</code></td>
<td></td>
<td>Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.</td>
</tr>
</tbody>
</table>

**NOTE**

In order for the substitution to take place, the sources need to be compiled with one of the following options: 

```
[Q]prof-src-root, [Q]prof-src-root-cwd. This option specifies the base directory that is to be treated as the project root directory.
```

An example of use is:

```
C:> ifort -Qprof-gen:srcpos -Qprof-src-root c:\workspaces\orig_project_dir test1.f90 test2.f90
C:> test1.exe
C:> profmerge
C:> cd \workspaces\
C:> mv orig_project_dir new_project_dir
C:> cd new_project_dir\src
C:> codecov -srcroot C:\workspaces\new_project_dir
```
Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application’s critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- **Top level (for a group of selected modules)**
- **Individual module source views**

**Top-Level Coverage**

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest.
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.
• By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  • Basic-block coverage
  • Function coverage
  • Function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.

![Coverage Summary](image)

The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. With one click you can see the least-covered function in the list, and with another click you can see the body of the function. You can scroll down in the source view and browse through the function body.

**Individual Module Source View**

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

• Number of blocks within uncovered functions
• Block coverage in the case of covered functions
• Function names

**Setting the Coloring Scheme for the Code Coverage**

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covered code</td>
<td>#FFFFFF</td>
<td>Indicates code was exercised by the tests. You can override the default color with the -ccolor tool option.</td>
</tr>
<tr>
<td>Uncovered basic block</td>
<td>#FFFF99</td>
<td>Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed during the tests. You can override the default color with the -bcolor tool option.</td>
</tr>
<tr>
<td>Uncovered function</td>
<td>#FFCCCC</td>
<td>Indicates functions that were never called during the tests. You can override the default color with the -fcolor tool option.</td>
</tr>
<tr>
<td>Partially covered code</td>
<td>#FAFAD2</td>
<td>Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the -pcolor tool option.</td>
</tr>
<tr>
<td>Ignored code</td>
<td>#90EE90</td>
<td>Indicates code that was specifically marked to be ignored. You can override this default color using the -xcolor tool option.</td>
</tr>
<tr>
<td>Information lines</td>
<td>#FFFFFF</td>
<td>Indicates basic-block markers and dynamic counts. You can override the default color with the -icolor tool option.</td>
</tr>
<tr>
<td>Unknown</td>
<td>#FFFFFF</td>
<td>Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the -ucolor tool option.</td>
</tr>
</tbody>
</table>

The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

**NOTE**

You need to interpret the colors in the context of the code. For example, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks.

**Dynamic Counters**

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the -counts option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.
If more than one basic block is generated for the code at a source position (for example, for macros), then
the total number of such blocks and the number of the blocks that were executed are also displayed in front
of the execution count. For example, line 11 in the code is an IF statement:

```
Example
11   IF ((N .EQ. 1).OR. (N .EQ. 0))
     10 (1/2)
12      PRINT N
     7
```

The coverage lines under code lines 11 and 12 contain the following information:

- The IF statement in line 11 was executed 10 times.
- Two basic blocks were generated for the IF statement in line 11.
- Only one of the two blocks was executed, resulting in the partial coverage color.
- Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as
one entity. In such cases, it is necessary to assume that all blocks generated for one source position are
covered when at least one of the blocks is covered. This assumption can be configured with the -nopartial
option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted
accordingly. The code lines 11 and 12 indicate that the print statement in line 12 was covered. However,
only one of the conditions in line 11 was ever true. With the -nopartial option, the tool treats the partially
covered code (like the code on line 11) as covered.

Differential Coverage

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run,
and a new run identifying the code that is covered by the new run but not covered by the reference run. Use
this feature to find the portion of the applications code that is not covered by the applications tests but is
executed when the application is run by a customer. It can also be used to find the incremental coverage
impact of newly added tests to an applications test space.

Generating Reference Data

Create the dynamic profile information for the reference data, which can be used in differential coverage
reporting later, by using the -ref option. The following command demonstrate a typical command for
generating the reference data:

```
Example: generating reference data
codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new
run but missed in the reference run. In such cases, the tool shows only the modules that included the code
that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code with the same coverage property (covered or not covered) on both runs is considered covered
code. Otherwise, if the new run indicates that the code was executed, while in the reference run the code
was not executed, then the code is treated as uncovered. Alternately, if the code is covered in the reference
run but not covered in the new run, the differential-coverage source view shows the code as covered.

Running Differential Coverage

To run the code coverage tool for differential coverage, you must have the application sources, the .spi file,
and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of
differential coverage analysis:
Example: specifying a component file

```plaintext
codecov -comp file
```

where `file` is the name of a text file containing strings that act as file/directory name masks for including and excluding file-level analysis. For example, assume the following:

- You want to include all files with the string "source" in the file name or directory name.
- You create a component text file named `myComp.txt` with the selective inclusion string "source".

Once you have a component file, enter a command similar to the following:

```
Example

codecov -comp myComp.txt
```

In this example, filenames with string "source" (like source1.f and source2.f) and all files within directories where the directory name contains the string "source" (like source/file1.f and source2\file2.f) are included in the analysis.

To exclude files or directories, add the tilde (~) prefix to the string. You can specify inclusion and exclusion in the same component file. For example, assume you want to analyze all individual files or files in a directory where the file/directory name includes the string "source", and you want to exclude all individual files and files in directories where the file/directory name includes the string "skip". You add content similar to the following to the component file (`myComp.txt`) and pass it to the `-comp` option:

```
Example: inclusion and exclusion strings in the myComp.txt file

source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file, `myComp.txt`, instructs the tool to:
• Include files with filename containing "source" (like source1.f and source2.f)
• Include all files in directories with the directory name containing "source" (like source/file1.f and source2/file2.f)
• Exclude all files with filename containing "skip" (like skipthis1.f and skipthis2.f)
• Exclude all files in directories with the directory name containing "skip" (like skipthese1/debug1.f and skipthese2/debug2.f)

Excluding Coverage at the Line and Function Level

You can mark individual lines for exclusion by passing string values to the -onelinedsbl option. For example, assume that you have some code similar to the following:

**Sample code**

```fortran
print*, "ERROR: n = ", n ! NO_COVER
print*, " n2 = ", n2 ! INF IA-32 architecture
```

If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following.

**Example**

```bash
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.

**Sample code**

```fortran
subroutine dumpInfo (n)
    integer n ! NO_COVER
    ...
end subroutine
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the -onelinedsbl and -xcolor options. The following example commands demonstrate the combination:

**Example: combining tool options**

```bash
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

Excluding Code by Defining Arbitrary Boundaries

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the -beginblkdsbl and -endblkdsbl options to mark the beginning and end (respectively) of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.
For example assume that you have the following code:

```fortran
integer n, n2
n = 123
n2 = n**n
if (n2 .lt. 0) then
   ! /* BINF */
   print*, "ERROR: n = ", n
   print*, "       n2 = ", n2
   ! // EINF
else if (n2 .eq. 0) then
   print*, "zero: n = ", n, " n2 = ", n2
else
   print*, "positive: n = ", n, " n2 = ", n2
endif
end
```

The following example commands demonstrate how to use the -beginblkdsbl option to mark the beginning and the -endblkdsbl option to mark the end of code to exclude from the sample shown above.

```bash
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF
codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the -xcolor option.

### Exporting Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool.

- **Quick export**: The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The -xmlfcvrg, -txtfcvrg, -xmlbcvrg and -txtbcvrg options support the first method.

- **Combined export**: The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The -xmlbcvrgfull and -txtbcvrgfull options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

#### Quick Export
The profile of covered functions of an application can be exported quickly using the \texttt{-xmlfcvrg}, \texttt{-txtfcvrg}, \texttt{-xmlbcvrg}, and \texttt{-txtbcvrg} options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

**Example: quick export of function data**

```
codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function, together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report.

**XML-formatted report example**

```xml
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.F">
    <FUNCTION name="f0" freq="2">
      <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
    </FUNCTION>
    ...
  </MODULE>
  <MODULE name = "D:\SAMPLE2.F">
    ...
  </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.f, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33\% basic block coverage.

You can also export the data in text format using the \texttt{-txtfcvrg} option. The generated text report, using this option, for the above example would be similar to the following example:

**Text-formatted report example**

```
Covered Functions in File: "D:\SAMPLE.F"
"f0"    2       6       5        83.33
"f1"    1       6       4        66.67
"f2"    1       6       3        50.00
...
```

In the text formatted version of the report, the each line of the report should be read in the following manner:

<table>
<thead>
<tr>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
<th>Column 4</th>
<th>Column 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function name</td>
<td>Execution frequency</td>
<td>Line number of the start of the function definition</td>
<td>Column number of the start of the function definition</td>
<td>Percentage of basic-block coverage of the function</td>
</tr>
</tbody>
</table>

Additionally, the tool supports exporting the block level coverage data using the \texttt{-xmlbcvrg} option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

**Example: quick export of block data to XML**

```
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```
The example command shown above would generate XML-formatted results similar to the following:

**XML-formatted report example**

```xml
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.F90">
    <FUNCTION name="f0" freq="2">
      ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1"> </INSTANCE>
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2"> </INSTANCE>
        <INSTANCE id="2" freq="1"> </INSTANCE>
      </BLOCK>
    </FUNCTION>
  </MODULE>
</PROJECT>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.f90. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column 3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

**Combined Exports**

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.

Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formats in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

**Dynamic Call Graphs**

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

**Test Prioritization Tool**

The test prioritization tool, also known as the tselect tool, enables the profile-guided optimizations on all supported Intel® architectures, on Linux®, Windows®, and OS X® operating systems, to select and prioritize tests for an application based on prior execution profiles.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool
Features and Benefits

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application. The tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing. Instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests’ execution time.

See Understanding Profile-guided Optimization and Profile an Application topics for general information on creating the files needed to run this tool.

Test Prioritization Tool Requirements

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the -prof-gen=srcpos (Linux* and OS X*) or /Qprof-gen:srcpos (Windows*) option.
- The .dpi files generated by the promerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. Run the promerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.
- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
  1. Name each test .dpi file so the file names uniquely identify each test.
  2. Create a .dpi list file, which is a text file that contains the names of all .dpi test files.

  Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.

  For example: Test1.dpi 00:00:60:35 states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.

  The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

  **CAUTION**
  The promerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code. The tool uses the following general syntax:

  **Tool Syntax**

  ```
tselect -dpi_list file
  
  -dpi_list is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.
  
  **NOTE**
  Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").```
**Usage Model**

The following figure illustrates a typical test prioritization tool usage model.

**Test Prioritization Tool Options**

The tool uses the options that are listed in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-dpi_list file</td>
<td>Required. Specifies the name of the file that contains the names of the dynamic profile information (.dpi) files. Each line of the file must contain only one .dpi file name, which can be followed by its execution time (optional). The name must uniquely identify the test.</td>
</tr>
<tr>
<td>-spifile</td>
<td>Specifies the file name of the static profile information file (.SPI). Default is pgopti.spi</td>
</tr>
<tr>
<td>-ofile</td>
<td>Specifies the file name of the output report file.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-comp&lt;file&gt;</td>
<td>Specifies the file name that contains the list of files of interest.</td>
</tr>
<tr>
<td>-cutoff&lt;value&gt;</td>
<td>Instructs the tool to terminate when the cumulative block coverage reaches</td>
</tr>
<tr>
<td></td>
<td>a preset percentage, as specified by &lt;value&gt;, of pre-computed total</td>
</tr>
<tr>
<td></td>
<td>coverage. &lt;value&gt; must be greater than 0.0 (for example, 99.00) but not</td>
</tr>
<tr>
<td></td>
<td>greater than 100. &lt;value&gt; can be set to 100.</td>
</tr>
<tr>
<td>-nototal</td>
<td>Instructs the tool to ignore the pre-compute total coverage process.</td>
</tr>
<tr>
<td>-mintime</td>
<td>Instructs the tool to minimize testing execution time. The execution time</td>
</tr>
<tr>
<td></td>
<td>of each test must be provided on the same line of &lt;dpi_list&gt; file, after</td>
</tr>
<tr>
<td></td>
<td>the test name in dd:hh:mm:ss format.</td>
</tr>
<tr>
<td>-srcbasedir&lt;dir&gt;</td>
<td>Specifies a different top-level project directory than was used during</td>
</tr>
<tr>
<td></td>
<td>compiler instrumentation run with the prof-src-root compiler option to</td>
</tr>
<tr>
<td></td>
<td>support relative paths to source files in place of absolute paths.</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to generate more logging information about program</td>
</tr>
<tr>
<td></td>
<td>progress.</td>
</tr>
</tbody>
</table>

**Running the Tool**

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

   **Example**
   ```
   set PROF_DIR=c:\myApp\prof-dir
   ```

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

   **Operating System** | **Command** |
   ----------------------|-------------|
   Linux and OS X        | ifort -prof-gen=srcpos myApp.f90 |
   Windows                | ifort /Qprof-gen:srcpos myApp.f90 |

   The commands shown above compile the program and generate instrumented binary myApp, as well as the corresponding static profile information pgopti.spi.

3. Confirm that unrelated .dyn files are not present by issuing a command similar to the following:

   **Example**
   ```
   rm prof-dir \*.dyn
   ```

4. Run the instrumented files by issuing a command similar to the following:

   **Example**
   ```
   myApp < data1
   ```
The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by the -prof-dir step above.

5. Merge all .dyn file into a single file by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test1.dpi
```

The profmerge tool merges all the .dyn files into one file (Test1.dpi) that represents the total profile information of the application on Test1.

6. Confirm again there are no unrelated .dyn files present a second time by issuing a command similar to the following:

```
Example
rm prof-dir \*.dyn
```

7. Run the instrumented application, and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified in the prof-dir step above by issuing a command similar to the following:

```
Example
myApp < data2
```

8. Merge all .dyn files into a single file by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test2.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test2.dpi) that represents the total profile information of the application on Test2.

9. Confirm that there are no unrelated .dyn files present for the final time by issuing a command similar to the following:

```
Example
rm prof-dir \*.dyn
```

10. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified by -prof-dir by issuing a command similar to the following:

```
Example
myApp < data3
```

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test3.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test3.dpi) that represents the total profile information of the application on Test3.

12. Create a file named tests_list with three lines. The first line contains Test1.dpi, the second line contains Test2.dpi, and the third line contains Test3.dpi.

**Tool Usage Examples**

When these items are available, the test prioritization tool may be launched from the command line in the prof-dir directory as described in the following examples.
### Example 1: Minimizing the Number of Tests

The following example describes how minimize the number of test runs.

**Example Syntax**

```
tselect -dpi_list tests_list -spi pgopti.spi
```

where the `-spi` option specifies the path to the `.spi` file.

The following sample output shows typical results.

**Sample Output**

```
Total number of tests = 3
Total block coverage ~ 52.17
Total function coverage ~ 50.00
```

<table>
<thead>
<tr>
<th>num</th>
<th>%RatCvrg</th>
<th>%BlkCvrg</th>
<th>%FncCvrg</th>
<th>Test Name @ Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>87.50</td>
<td>45.65</td>
<td>37.50</td>
<td>Test3.dpi</td>
</tr>
<tr>
<td>2</td>
<td>100.50</td>
<td>52.17</td>
<td>50.00</td>
<td>Test2.dpi</td>
</tr>
</tbody>
</table>

In this example, the results provide the following information:

- By running all three tests, you achieve 52.17% block coverage and 50.00% function coverage.
- Test3 alone covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, you achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

### Example 2: Minimizing Execution Time

Assume you have the following execution time of each test in the `tests_list` file:

```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `-mintime` option:

**Sample Syntax**

```
tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:
Sample Output

<table>
<thead>
<tr>
<th>num</th>
<th>elapsedTime</th>
<th>%RatCvrg</th>
<th>%BlkCvrg</th>
<th>%FncCvrg</th>
<th>Test Name</th>
<th>@ Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10:15</td>
<td>75.00</td>
<td>39.13</td>
<td>25.00</td>
<td>Test2.dpi</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>41:00</td>
<td>100.00</td>
<td>52.17</td>
<td>50.00</td>
<td>Test3.dpi</td>
<td></td>
</tr>
</tbody>
</table>

In this case, the results indicate that running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests when based on minimizing time (first Test2, then Test3) may be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

Using Other Options

The -cutoff enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to use the option:

```
Example

tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The -cutoff enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

Profmerge and Proforder Tools

Profmerge Tool

Use the profmerge tool to merge dynamic profile information (.dyn) files and any specified summary files (.dpi). The compiler executes profmerge automatically during the feedback compilation phase when you specify the [Q]prof-use option.

The command-line usage for profmerge is as follows:

```
Syntax

profmerge [-prof_dir dir_name]
```

The tool merges all .dyn files in the current directory, or the directory specified by -prof_dir, and produces a summary file: pgopti.dpi.
You can use profmerge tool to merge .dyn files into a .dpi file without recompiling the application. You can run the instrumented executable file on multiple systems to generate .dyn files, and optionally use profmerge with the -prof_dpi option to name each summary .dpi file created from the multiple .dyn files.

Because the profmerge tool merges all the .dyn files that exist in the given directory, confirm that unrelated .dyn files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

**Profmerge Options**

The profmerge tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dump</td>
<td>Displays profile information.</td>
</tr>
<tr>
<td>-help</td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-exclude_funcsfunctions</td>
<td>Excludes functions from the profile. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot;) as a wild card character in function names.</td>
</tr>
<tr>
<td>-prof_dir</td>
<td>Specifies the directory from which to read .dyn and .dpi files, and write the .dpi file. Alternatively, you can set the environment variable PROF_DIR.</td>
</tr>
<tr>
<td>-prof_dpi</td>
<td>Specifies the name of the .dpi file being generated.</td>
</tr>
<tr>
<td>-prof_file</td>
<td>Merges information from file matching: dpi_file_and_dyn_tag.</td>
</tr>
<tr>
<td>-src_olddir-src_newdir</td>
<td>Changes the directory path stored within the .dpi file.</td>
</tr>
<tr>
<td>-src_no_dir</td>
<td>Uses only the file name and not the directory name when reading dyn/dpi records. If you specify -src_no_dir, the directory name of the source file will be ignored when deciding which profile data records correspond to a specific application routine, and the -src-root option is ignored.</td>
</tr>
<tr>
<td>-src-rootdir</td>
<td>Specifies a directory path prefix for the root directory where the user's application files are stored. This option is ignored if you specify -src_no_dir.</td>
</tr>
<tr>
<td>-file1.dpi...fileN.dpi</td>
<td>Specifies and merges available .dpi files.</td>
</tr>
<tr>
<td>Tool Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to display full information during merge.</td>
</tr>
<tr>
<td>-weighted</td>
<td>Instructs the tool to apply an equal weighting (regardless of execution times) to the .dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.</td>
</tr>
<tr>
<td>-gen_weight_spec file</td>
<td>Instructs the tool to generate a text file containing a list of the .dyn and .dpi file that were merged with default weight=1/run_count.</td>
</tr>
<tr>
<td></td>
<td>The text file is created in the directory specified by the prof_dir option.</td>
</tr>
<tr>
<td>-weight_spec weight_spec.txt</td>
<td>Instructs the profmerge tool to generate and use the text file, weight_spec.txt, listing individual .dyn/.dpi files or directory names along with weight values for them.</td>
</tr>
<tr>
<td></td>
<td>When the -weight_spec option is used:</td>
</tr>
<tr>
<td></td>
<td>• A new .dpi file is always created</td>
</tr>
<tr>
<td></td>
<td>• Only files called out by the specification file are merged</td>
</tr>
<tr>
<td></td>
<td>• .dyn timestamps are ignored and merge always takes place</td>
</tr>
<tr>
<td></td>
<td>The prof_dir option controls where the input/output weight_spec.txt is located, and the destination of the .dpi file.</td>
</tr>
<tr>
<td></td>
<td>The -weight_spec option overrides:</td>
</tr>
<tr>
<td></td>
<td>• Any values of -a option</td>
</tr>
<tr>
<td></td>
<td>• Any computation from using -weighted option</td>
</tr>
</tbody>
</table>

**Weighting the Runs**

Using the -weight_spec option results in a new .dpi file. Only the files listed in the text file are merged. No files in the current directory are used unless they are included in the text file.

**Relocating source files using profmerge**

The Intel® Fortran Compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (.dpi) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading .dyn/.dpi file records by specifying the profmerge option -src_no_dir. This profmerge option is the same as the compiler option -no-prof-src-dir (Linux® and OS X®) and /Qprof-src-dir- (Windows®).
To enable the movement of application sources, as well as the sharing of profile summary files, you can use the profmerge option -src-root to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair -src_old-src_new to modify the data in an existing summary dpi file. For example:

Example: relocation command syntax

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where <dir1> is the full path to dynamic information file (.dpi), <dir2> is the old full path to source files, and <dir3> is the new full path to source files. The example command (above) reads the pgopti.dpi file, in the location specified in <dir1>. For each routine represented in the pgopti.dpi file, whose source path begins with the <dir2> prefix, profmerge replaces that prefix with <dir3>. The pgopti.dpi file is updated with the new source path information.

You can run profmerge more than once on a given pgopti.dpi file. For example, you may need to do this if the source files are located in multiple directories:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command Examples</th>
</tr>
</thead>
</table>
| Linux* and OS X* | profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2  
profmerge -prof_dir -src_old /proj_1 -src_new /proj_2 |
| Windows*         | profmerge -src_old "c:/program files" -src_new "e:/program files"  
profmerge -src_old c:/proj/application -src_new d:/app |

In the values specified for -src_old and -src_new, uppercase and lowercase characters are treated as identical in Windows. Likewise, forward slash (/) and backward slash (\) characters are treated as identical.

NOTE
Because the source relocation feature of profmerge modifies the pgopti.dpi file, consider making a backup copy of the file before performing the source relocation.

Proforder Tool

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the /ORDER linker option in Windows. The tool uses the following syntax:

Syntax

```
proforder [-prof_dir dir] [-o file]
```

where dir is the directory containing the profile files (.dpi and .spi), and file is the optional name of the function order list file. The default name is proford.txt.

NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example [Q]prof-dir) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-"), unlike Windows* compiler options, which are preceded by a forward slash ("/").

Proforder Options

The proforder tool supports the following options:
<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td></td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td></td>
<td>Disables version information. This option is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>supported on Windows* only.</td>
</tr>
<tr>
<td>-omit_static</td>
<td></td>
<td>Instructs the tool to omit static functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from function ordering.</td>
</tr>
<tr>
<td>-prof_dir dir</td>
<td>dir</td>
<td>Specifies the directory where the .spi and .dpi</td>
</tr>
<tr>
<td></td>
<td></td>
<td>file reside.</td>
</tr>
<tr>
<td>-prof_file</td>
<td>file</td>
<td>Specifies the name of the .dpi file.</td>
</tr>
<tr>
<td>-prof_string</td>
<td>string</td>
<td>Selects the .dpi and .spi files that include the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>substring value in the file name matching the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>values passed as string.</td>
</tr>
<tr>
<td>-prof_spi file</td>
<td>file</td>
<td>Specifies the name of the .spi file.</td>
</tr>
<tr>
<td>-o file</td>
<td>proford.txt</td>
<td>Specifies an alternate name for the output file.</td>
</tr>
</tbody>
</table>

**Supported Environment Variables**

**Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations**

Instead of doing a full multi-file interprocedural build of your application by using the compiler option 
[Q]ipo, you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the procedures and data in your application. These optimizations are not supported on OS X* systems.

The following table lists each optimization, the type of procedures or global data it applies to, and the operating systems and architectures that it is supported on.

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type of Procedure or Data</th>
<th>Supported OS and Architectures</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function Order Lists:</strong> Specifies the order in which the linker should link the non-static routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging.</td>
<td>EXTERNAL procedures and library procedures only (not other types of static procedures).</td>
<td>Windows OS: all Intel architectures</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Linux OS: not supported</td>
</tr>
<tr>
<td><strong>Function Grouping:</strong> Specifies that the linker should place the extern and static routines (procedures) of your program into hot or cold program sections. This optimization can improve application performance by improving code locality and reduce paging.</td>
<td>EXTERNAL procedures and static procedures only (not library procedures).</td>
<td>Linux OS: IA-32 and Intel 64 architectures</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Windows OS: not supported</td>
</tr>
<tr>
<td>Optimization</td>
<td>Type of Procedure or Data</td>
<td>Supported OS and Architectures</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td><strong>Function Ordering:</strong></td>
<td>Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging.</td>
<td>EXTERNAL procedures and static procedures only (not library procedures) Linux and Windows OS: all Intel architectures</td>
</tr>
<tr>
<td><strong>Data Ordering:</strong></td>
<td>Enables ordering of static global data items (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.</td>
<td>Static global data (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) only Linux and Windows OS: all Intel architectures</td>
</tr>
</tbody>
</table>

You can only use one of the function-related ordering optimizations listed above on each application. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the prof-gen option keyword globdata (needed for Data Ordering) instead of srcpos (needed for function-related ordering).

The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the [Q]ipo or equivalent compiler option.

**Generating a Function Order List (Windows OS)**

This section provides an example of the process for generating a function order list. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called c:\profdata. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the /Qprof-gen:srcpos option. Use the /Qprof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

   **Example commands**
   ```
   ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90
   ```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

   **Example commands**
   ```
   myprog.exe
   ```

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the pgopti.dpi file. Use the /prof_dir option to specify the directory location of the .dyn files.
Example commands

profmerge /prof_dir c:\profdata

4. Generate the function order list using the proforder tool. By default, the function order list is produced in the file proford.txt.

Example commands

proforder /prof_dir c:\profdata /o myprog.txt

5. Compile the application with the generated profile feedback by specifying the ORDER option to the linker. Use the /Qprof-dir option to specify the directory location of the profile files.

Example commands

ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /link /ORDER:@MYPROG.txt

Using Function Grouping (Linux OS)

This section provides a general example of the process for using the function grouping optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called profdata. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the -prof-gen option. Use the -prof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands

ifort -o myprog -prof-gen -prof-dir ./profdata file1.f90 file2.f90

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

Example commands

./myprog

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the -prof-func-group option to request the function grouping as well as the -prof-use option to request feedback compilation. Again, use the -prof-dir option to specify the location of the profile files.

Example commands

ifort /exe:myprog file1.f90 file2.f90 -prof-func-group -prof-use -prof-dir ./profdata

Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.
1. Compile your program using the -prof-gen=srcpos (Linux) or /Qprof-gen:srcpos (Windows) option. Use the [Q]prof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.f90 file2.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90</td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
</tbody>
</table>

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the [Q]prof-func-order option to request the function ordering, as well as the [Q]prof-use option to request feedback compilation. Again, use the [Q]prof-dir option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-func-order prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-func-order /Qprof-use</td>
</tr>
</tbody>
</table>

**Using Data Ordering**

This section provides an example of the process for using the data order optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90, and that you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the -prof-gen=globdata (Linux) or /Qprof-gen:globdata (Windows) option. Use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-gen=globdata -prof-dir ./profdata file1.f90 file2.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-gen=globdata /Qprof-dir c:\profdata file1.f90 file2.f90</td>
</tr>
</tbody>
</table>
2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
</tbody>
</table>

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the [Q]prof-data-order option to request the data ordering as well as the [Q]prof-use option to request feedback compilation. Again, use the [Q]prof-dir option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-data-order -prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-data-order /Qprof-use</td>
</tr>
</tbody>
</table>

Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the /Qipo (Windows) compiler option

Each method has advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions (external and library functions whose names are exposed to the linker).

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Function Order List Effects

<table>
<thead>
<tr>
<th>Function Type</th>
<th>IPO Code Layout</th>
<th>Function Ordering with proforder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static</td>
<td>X</td>
<td>No effect</td>
</tr>
<tr>
<td>Extern</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Library</td>
<td>No effect</td>
<td>X</td>
</tr>
</tbody>
</table>

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
- You must compile with /Gy to enable function-level linking. (This option is active if you specify either option /O1 or /O2.)
Compiler Option Mapping Tool

The Intel compiler's Option Mapping Tool provides an easy method to derive equivalent options between Windows* and Linux* operating systems. For example, a Windows OS developer who is developing an application may want to know the Linux OS equivalent for the /Oy- option. Likewise, the Option Mapping Tool provides Windows OS equivalents for Intel compiler options supported on Linux OS.

**NOTE**
The Compiler Option Mapping Tool does not support selecting OS* X. However, because Linux and OS X* use the same options in almost all cases, specify "tlinux" if targeting OS X*.

Using the Compiler Option Mapping Tool

You can start the Option Mapping Tool from the command line by:

- Invoking the compiler and using the /Qmap-opts option
- Invoking the compiler and using the -map-opts option
- Executing the tool directly

**NOTE**
The Compiler Option Mapping Tool only maps compiler options on the same architecture. It will not map an option that is specific to the Intel® 64 architecture to a like option available on the IA-32 architecture.

Calling the Option Mapping Tool with the Compiler

If you use the compiler to execute the Option Mapping Tool, the following syntax applies:

```bash
<compiler command> <map-opts option> <compiler option(s)>
```

**Example:** Finding the Linux equivalent for /Oy-

```bash
ifort /Qmap-opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows OS options to Linux OS for Fortran
'-Qmap-opts' Windows OS option maps to
  --> '-map-opts' option on Linux OS
  --> '-map_opts' option on Linux OS
'-Oy-' Windows OS option maps to
  --> '-fomit-frame-pointer-' option on Linux OS
  --> '-fno-omit-frame-pointer' option on Linux OS
  --> '-fp' option on Linux OS
```

**Example:** Finding the Windows OS equivalent for -fp

```bash
ifort -map-opts -fp
Intel(R) Compiler option mapping tool
mapping Linux OS options to Windows OS for Fortran
'-map-opts' Linux OS option maps to
  --> '-Qmap-opts' option on Windows OS
  --> '-Qmap_opts' option on Windows OS
'-fp' Linux OS option maps to
  --> '-Oy-' option on Windows OS
```

**NOTE**
Output from the Option Mapping Tool also includes:
When you call the Option Mapping Tool with the compiler, the source file is not compiled.

**Calling the Option Mapping Tool Directly**

Use the following syntax to execute the Option Mapping Tool directly from a command line environment where the full path to the `map_opts` executable is known (compiler bin directory):

```
map_opts -t<target OS> -l<language> -opts <compiler option(s)>
```

where values for:

- `<target OS>` = {l|linux|w|windows}
- `<language>` = {f|fortran|c}

**Example: Finding the Linux OS equivalent for /Oy-**

```
map_opts -tl -lf -opts /Oy-
```

Intel(R) Compiler option mapping tool
mapping Windows OS options to Linux OS for Fortran
'Oy-' Windows OS option maps to
  --> '-fomit-frame-pointer-' option on Linux OS
  --> '-fno-omit-frame-pointer' option on Linux OS
  --> '-fp' option on Linux OS

**Example: Finding the Windows equivalent for -fp**

```
map_opts -tw -lf -opts -fp
```

Intel(R) Compiler option mapping tool
mapping Linux OS options to Windows OS for Fortran
'-fp' Linux OS option maps to
  --> '-Oy-' option on Windows OS

---

**Offload Extract Tool**

This topic only applies to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**Description**

The Offload Extract tool is a standalone tool that extracts embedded target objects from fat objects and embedded target binaries from fat executables on Windows* and Linux* systems. The tool can be used for Intel® MIC Architecture related offload extraction. For simplicity, in this topic, the Intel® MIC Architecture target objects and executables will be referred to as MIC target objects and executables.

**Features and Benefits**

By default, you cannot use analyzing and debugging tools like `objdump` and `readelf` to directly examine offload MIC objects/binaries because they are embedded in the host object or binary.

Use the Offload Extract tool to extract MIC object/binary from a fat object/binary on 64-bit Linux* or 64-bit Windows* systems. The extracted object/binary is an ELF object that can be analyzed with `objdump` or `readelf` analyzing tools.

**Using the Tool**

To extract the target object files, invoke the offload extract tool as follows:

```
offload_extract  <fat host object>
```
The MIC target objects are extracted into object files with the same name as the input object file but with the substring MIC appended to the filename. Since the target objects are in ELF format the object file name extension will be .o. For example,

**offload_extract host.obj => hostMIC.o**

To extract the target executables, invoke the offload extract tool as follows:

```
offload_extract <fat host binary>
```

The MIC target executables are extracted into target executable files with the same name as the input object file but with the file extension MIC added. For example,

**offload_extract host.exe => hostMIC.mic**

---

**NOTE**

To extract the target object files from an archived library, you must first extract the individual fat objects from the fat archived library and then invoke the offload extract tool on the individual fat objects. For example:

```
ar -x libhost.a
offload_extract <individual fat host object>
```

---

**Using Options**

There are two options you can use to fine tune your extraction of offload binaries or executables.

Use the `-o` option to specify target filename or output directory. The syntax for the option is as follows:

```
offload_extract <fat host object|binary> [-o <output filename>]
offload_extract <fat host object|binary> [-o <output directory>]
```

When you use the `-o` option the target output filename and directory are generated without the MIC substring.

Use the `-target` option to select specific target MIC objects/executables to be extracted. The syntax for the option is as follows:

```
offload_extract <fat host object|binary> [-target mic]
```

Portability Considerations Overview

This section presents topics to help you understand how language standards, operating system differences, and computing hardware influence your use of Intel® Fortran and the portability of your programs.

Your program is portable if you can implement it on one hardware-software platform and then move it to additional systems with minimum changes to the source code. Correct results on the first system should be correct on the additional systems. The number of changes you might have to make when moving your program varies significantly. You might have no changes at all (strictly portable), or enough that it is more efficient to design or implement a new program (non-portable customization). Most programs in their lifetime will need to be ported from one system to another, and this section can help you write code that makes this easy.

Understanding Fortran Language Standards Overview

A language standard specifies the form and establishes the interpretation of programs expressed in the language. Its primary purpose is to promote portability of programs across a variety of systems among vendors and users.

The vendor-user community has adopted a series of major Fortran language standards. The primary organizations that develop and publish the standards are the InterNational Committee for Information Technology Standards (INCITS) and International Standards Organization (ISO).

The major Fortran language standards are:

- **Draft Fortran 2015**
  The Fortran Standards group is working on a revision to Fortran 2008, which is tentatively called Fortran 2015. There is a draft Fortran 2015 document in progress, which introduces further support for interoperability with the C language, including assumed type and assumed rank arrays, C descriptors, and the RANK intrinsic.

- **Fortran 2008**
  American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2010, Information technology -- Programming languages -- Fortran. This standard introduces support for submodules and coarrays, and includes various performance enhancements such as the DO CONCURRENT construct. For more information on supported Fortran 2008 language features, see the Fortran Language Reference Manual.

- **Fortran 2003**

- **Fortran 95**

- **Fortran 90**

- **FORTRAN 77**
  American National Standard Programming Language FORTRAN, ANSI X3.9-1978. This standard added new features based on vendor extensions to FORTRAN IV and addressed problems associated with large-scale projects, such as improved control structures.

- **FORTRAN IV**
  American National Standard Programming Language FORTRAN, ANSI X3.9-1966. This was the first attempt to standardize the languages called FORTRAN by many vendors.
Although a language standard seeks to define the form and the interpretation uniquely, a standard may not cover all areas of interpretation. It may also include some ambiguities. You need to carefully craft your program in these cases to insure that you get the desired answers when producing a portable program.

Language Standards Conformance

Using Standard Features and Extensions

Standard Features

Use standard language features to achieve the greatest degree of portability for your Intel® Fortran programs. You can design a robust implementation to improve the portability of your program, or you can choose to use extensions to the standard to increase the readability, functionality, and efficiency of your programs.

You can request that the compiler warn you about program syntax that violates the standard's numbered syntax rules and constraints. While this does not insure that the program as a whole is standard-conforming, it can help to avoid many possible compatibility issues. The /stand (Windows*) or -std (Linux* and OS X*) options enable this checking, and you can specify the desire standard to check against. If you do not specify a standard, Fortran 2003 is used.

You can use the standard-semantics compiler option to enable all of the options that implement the current Fortran Standard behavior of the compiler where those differ from the compiler's default.

Standard Extensions

Not all extensions to the Fortran standard cause problems when porting to other platforms. Many extensions are supported on a wide range of platforms, and if a system you are porting a program to supports an extension, there is no reason to avoid using it. There is no guarantee, however, that the same feature on another system will be implemented in the same way as with Intel® Fortran. Only the Fortran standard is guaranteed to coexist uniformly on all platforms.

The Intel® Fortran Compiler supports many language extensions on multiple platforms, including Linux*, OS X*, and Microsoft Windows* operating systems. The Intel® Fortran Language Reference Manual identifies whether each language element is supported on other platforms.

It is a good programming practice to declare any external procedures either in an EXTERNAL statement or in a procedure interface block, for the following reasons:

- The newer Fortran standards have added many new intrinsic procedures to the language.
  Programs that conformed to earlier Fortran Standards (such as FORTRAN 77) may include non-intrinsic functions or subroutines having the same name as new Fortran Standard procedures.
- Some processors include nonstandard intrinsic procedures that might conflict with procedure names in your program.

If you do not explicitly declare the external procedures and the name duplicates an intrinsic procedure, the processor calls the intrinsic procedure, not your external routine. For more information on how the Intel® Fortran Compiler resolves name definitions, see Resolving Procedure References.

Using Compiler Optimizations

Many Fortran compilers perform code-generation optimizations to increase the speed of execution or to decrease the required amount of memory for the generated code. Although the behaviors of both the optimized and non-optimized programs fall within the language standard specification, different behaviors can occur in areas not covered by the language standard. Compiler optimization can influence floating-point numeric results.

The Intel® Fortran Compiler can perform optimizations to increase execution speed and to improve floating-point numerical consistency.

Floating-point consistency refers to obtaining results consistent with the IEEE binary floating-point standards. For more information, see the fltconsistency option.

Unless you properly design your code, you may encounter numerical difficulties when you optimize for fastest execution. The nofltconsistency option uses the floating-point registers, which have a higher precision than stored variables, whenever possible. This tends to produce results that are inconsistent with the precision of stored variables. The fltconsistency option can improve the consistency of generated code by rounding results of statement evaluations to the precision of the standard data types, but it does produce slower execution times.

Language Standards Conformance

The Fortran standard has undergone several revisions since its initial publication as FORTRAN IV (also known as FORTRAN 66). Subsequent revisions have been FORTRAN 77, Fortran 90, Fortran 95, Fortran 2003, Fortran 2008, and draft Fortran 2015. Each revision has added new features; some revisions have labeled features as "deprecated" (or obsolescent) or they have removed them. Intel Fortran continues to support deprecated and deleted features.

It also includes support for many features in the Fortran 2008 standard (ISO/IEC 1539-1:2010) and some features from the draft Fortran 2015 standard.

The Fortran Standards committee is currently answering questions of interpretation on Fortran 2008 language features. Any answers given by the committee that are related to features implemented in Intel Fortran may result in changes in future releases of the Intel Fortran compiler, even if the changes produce incompatibilities with earlier releases of Intel Fortran.

Intel Fortran provides a number of extensions to the Fortran 2008 Standard. In the language reference, extensions (non-standard features) are displayed in this color.

Language Compatibility

Intel® Fortran is highly source-compatible with Compaq* Visual Fortran on supported systems, and it is substantially source-compatible with DEC* Fortran 90 and VAX* FORTRAN 77.

Draft Fortran 2015 Features

*Short Description*

The following Fortran 2015 feature is new in this release:

- Further Interoperability of Fortran with C, including assumed-type, assumed-rank, C descriptors, and the RANK intrinsic

Fortran 2008 Features

The following Fortran 2008 features are new in this release:

- Submodules

The following Fortran 2008 features are also supported:

- IMPURE keyword

\(^1\) This is the same as International Standards Organization standard ISO/IEC 1539-1:1997 (E).

\(^2\) This is the same as International Standards Organization standard ISO/IEC 1539:1991 (E).
The EXECUTE_COMMAND_LINE subroutine
The BLOCK construct
The FUNCTION and SUBROUTINE keywords on the END statement are optional for internal procedures and module procedures.
A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign
Generic resolution of procedures where one dummy argument has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN), or where one is a procedure and the other is a data object.
The ENTRY statement is an obsolescent feature.
A source statement can begin with one or more semicolon characters.
Coarray intrinsic routines: ATOMIC_DEFINE and ATOMIC_REF
A polymorphic MOLD= specifier for ALLOCATE
Coarrays (Windows* and Linux* only)
Image control statements: SYNC ALL, SYNC IMAGES, SYNC MEMORY, CRITICAL, LOCK, and UNLOCK
Coarray intrinsic routines: IMAGE_INDEX, LCOBOUND, NUM_IMAGES, THIS_IMAGE, and UCOBOUND
CRITICAL construct
Maximum array rank of 15 (Intel® Fortran allows 31 dimensions)
G0 and G0.d format edit descriptors
FINAL routines
GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
A generic interface may have the same name as a derived type
Bounds specification and bounds remapping list on a pointer assignment
In formatting, a * indicates an unlimited repeat count
NEWUNIT= specifier in OPEN
A CONTAINS section can be empty
Attributes CODIMENSION and CONTIGUOUS
Coarrays can be specified in ALLOCATABLE, ALLOCATE, and TARGET statements
MOLD keyword in ALLOCATE
DO CONCURRENT statement
ERROR STOP statement
Intrinsic functions BESSEL_J0, BESSEL_J1, BESSEL_JN, BESSEL_Y0, BESSEL_Y1, BESSEL_YN, BGE, BGT, BLE, BLT, DSHIFTL, DSHIFTR, ERF, ERFC, ERFC_SCALED, GAMMA, HYPOT, IALL, IANY, IPARITY, IS_CONTIGUOUS, LEADZ, LOG_GAMMA, MASKL, MASKR, MERGE_BITS, NORM2, PARITY, POPCNT, POPPAR, SHIFTL, SHIFTR, STORAGE_SIZE, TRAILZ
ISO_FORTRAN_ENV module constants ATOMIC_INT_KIND, ATOMIC_LOGICAL_KIND, CHARACTER_KINDS, INTEGER_KINDS, INT8, INT16, INT32, INT64, LOGICAL_KINDS, REAL_KINDS, REAL32, REAL64, REAL128, STAT_LOCKED, STAT_LOCKED_OTHER_IMAGE, STAT_UNLOCKED
ISO_FORTRAN_ENV type LOCK_TYPE
SCALAR keyword for ALLOCATED

See Also
New Language Features
Fortran 2003 Features

Fortran 2003 Features
Fortran 2003 is fully supported, including the following features:
Parameterized derived types with KIND and LENGTH type parameters and the %KIND and %LEN type parameter designators
A polymorphic dummy argument that has the attribute INTENT(OUT) becomes UNDEFINED or it will have DEFAULT INITIALIZATION applied.
User-Defined Derived-Type I/O
- A polymorphic SOURCE= specifier for ALLOCATE
- Bounds specification and bounds remapping list on a pointer assignment
- FINAL routines
- GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
- Enumerators
- Type extension (not polymorphic)
- Type-bound procedures
- Allocatable scalar variables (not deferred-length character)
- ERRMSG keyword for ALLOCATE and DEALLOCATE
- SOURCE= keyword for ALLOCATE
- Character arguments for MAX, MIN, MAXVAL, MINVAL, MAXLOC, and MINLOC
- Intrinsic modules IEEE_EXCEPTIONS, IEEE_ARITHMETIC and IEEE_FEATURES
- ASSOCIATE construct
- DO CONCURRENT construct
- PROCEDURE declaration
- Procedure pointers
- ABSTRACT INTERFACE
- PASS and NOPASS attributes
- CONTIGUOUS attribute
- Structure constructors with component names and default initialization
- Array constructors with type and character length specifications
- I/O keywords BLANK, DECIMAL, DELIM, ENCODING, IOMSG, PAD, ROUND, SIGN, and SIZE
- Format edit descriptors DC, DP, RD, RC, RN, RP, RU, and RZ
- The COUNT_RATE argument to the SYSTEM_CLOCK intrinsic may be a REAL of any kind.
- NAMELIST I/O for internal files
- Intrinsic functions EXTENDS_TYPE_OF and SAME_TYPE_AS
- SELECT TYPE construct
- CLASS declaration
- PUBLIC types with PRIVATE components and PRIVATE types with PUBLIC components
- RECORDTYPE setting STREAM_CRLF
- A file can be opened for stream access (ACCESS='STREAM')
- Specifier POS can be specified in an INQUIRE, READ, or WRITE statement
- BIND attribute and statement
- Language binding can be specified in a FUNCTION or SUBROUTINE statement, or when defining a derived type
- IS_IOSTAT_END intrinsic function
- IS_IOSTAT_EOR intrinsic function
- INTRINSIC and NONINTRINSIC can be specified for modules in USE statements
- ASYNCHRONOUS attribute and statement
- VALUE attribute and statement
- Specifier ASYNCHRONOUS can be specified in an OPEN, INQUIRE, READ, or WRITE statement
- An ID can be specified for a pending data transfer operation
- FLUSH statement
- WAIT statement
- IMPORT statement
- NEW_LINE intrinsic function
- SELECTED_CHAR_KIND intrinsic function
- Intrinsic modules ISO_C_BINDING and ISO_FORTRAN_ENV
- Specifiers ID and PENDING can be specified in an INQUIRE statement
- User-defined operators can be renamed in USE statements
- MOVE_ALLOC intrinsic subroutine
- PROTECTED attribute and statement
- Pointer objects can have the INTENT attribute
- GET_COMMAND intrinsic
- GET_COMMAND_ARGUMENT intrinsic
- COMMAND_ARGUMENT_COUNT intrinsic
- GET_ENVIRONMENT_VARIABLE intrinsic
- Allocatable components of derived types
- Allocatable dummy arguments
- Allocatable function results
- VOLATILE attribute and statement
- Names of length up to 63 characters
- Statements up to 256 lines
- A named PARAMETER constant may be part of a complex constant
- In all I/O statements, the following numeric values can be of any kind: UNIT=, IOSTAT=
- The following OPEN numeric values can be of any kind: RECL=
- The following READ and WRITE numeric values can be of any kind: REC=, SIZE=
- The following INQUIRE numeric values can be of any kind: NEXTREC=, NUMBER=, RECL=, SIZE=
- Recursive I/O is allowed when the new I/O being started is internal I/O that does not modify any internal file other than its own
- IEEE infinities and Nans are displayed by formatted output as specified by Fortran 2003
- In an I/O format, the comma after a P edit descriptor is optional when followed by a repeat specifier
- The following intrinsics take an optional KIND= argument: ACHAR, COUNT, IACHAR, ICHAR, INDEX, LBOUND, LEN, LEN_TRIM, MAXLOC, MINLOC, SCAN, SHAPE, SIZE, UBOUND, VERIFY
- Square brackets [ ] are permitted to delimit array constructors instead of (/ /)
- The Fortran character set has been extended to contain the 8-bit ASCII characters ~ \ [ ] ^ { } | # @

New Language Features
Fortran 2008 Features
Minimizing Operating System-Specific Information

The operating system influences your program both externally and internally. For increased portability, you need to minimize the amount of operating-system-specific information required by your program. The Fortran language standards do not specify this information.

Operating-system-specific information consists of non-intrinsic extensions to the language, compiler and linker options, and possibly the graphical user interface of Windows*. Input and output operations use devices that may be system-specific and may involve a file system with system-specific record and file structures.

The operating system also governs resource management and error handling. You can depend on default resource management and error handling mechanisms or provide mechanisms of your own. For information on special library routines to help port your program from one system to another, see Portability Library Overview and related topics.

The minimal interaction with the operating system is for input/output (I/O) operations and usually consists of knowing the standard units preconnected for input and output. You can use default file units with the asterisk (*) unit specifier.

To increase the portability of your programs across operating systems, consider the following:

• Do not assume the use of a particular type of file system.
• Do not embed filenames or paths in the body of your program. Define them as constants at the beginning of the program or read them from input data.
• Do not assume a particular type of standard I/O device or the "size" of that device (number of rows and columns).
• Do not assume display attributes for the standard I/O device. Some environments do not support attributes such as color, underlined text, blinking text, highlighted text, inverse text, protected text, or dim text.
Storing and Representing Data

The Fortran language standard specifies little about the storage of data types. This loose specification of storage for data types results from a great diversity of computing hardware. This diversity poses problems in representing data and especially in transporting stored data among a multitude of systems. The size (as measured by the number of bits) of a storage unit (a word, usually several bytes) varies from machine to machine. In addition, the ordering of bits within bytes and bytes within words varies from one machine to another. Furthermore, binary representations of negative integers and floating-point representations of real and complex numbers take several different forms.

The simplest and most reliable means of transferring data between dissimilar systems is in *character* and not binary form. Simple programming practices ensure that your data as well as your program is portable.
Data Portability

Formatting Data for Transportability

You can achieve the highest transportability of your data by formatting it as 8-bit character data. Use a standard character set, such as the ASCII standard, for encoding your character data. Although this practice is less efficient than using binary data, it will save you from shuffling and converting your data.

If you are transporting your data by means of a record-structured medium, it is best to use the Fortran sequential files. See Record Types in the reference guide for more information.

Remember also that some systems use a carriage return/linefeed pair as an end-of-record indicator, while other systems use linefeed only. There might be system-dependent values embedded within your data that complicate its transport.

Implementing a strictly portable solution requires a careful effort. Maximizing portability may also mean making compromises to the efficiency and functionality of your solution. If portability is not your highest priority, you can use some of the techniques that appear in later sections to ease your task of customizing a solution.

Supported Native and Nonnative Numeric Formats

Supported Native and Nonnative Numeric Formats

Data storage in different computers uses a convention of either little endian or big endian storage. The storage convention generally applies to numeric values that span multiple bytes, as follows:

Little endian storage occurs when:
- The least significant bit (LSB) value is in the byte with the lowest address.
- The most significant bit (MSB) value is in the byte with the highest address.
- The address of the numeric value is the byte containing the LSB. Subsequent bytes with higher addresses contain more significant bits.

Big endian storage occurs when:
- The least significant bit (LSB) value is in the byte with the highest address.
- The most significant bit (MSB) value is in the byte with the lowest address.
- The address of the numeric value is the byte containing the MSB. Subsequent bytes with higher addresses contain less significant bits.

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte).
The following figures show the difference between the two byte-ordering schemes:

**Little and Big Endian Storage of an INTEGER Value**

The following figure illustrates the difference between the two conventions for the case of addressing bytes within words.

**Byte Order Within Words: (a) Big Endian, (b) Little Endian**

Data types stored as subcomponents (bytes stored in words) end up in different locations within corresponding words of the two conventions. The following figure illustrates the difference between the representations of several data types in the two conventions. Letters represent 8-bit character data, while numbers represent the 8-bit partial contribution to 32-bit integer data.

**Character and Integer Data in Words: (a) Big Endian, (b) Little Endian**
If you serially transfer bytes now from the big endian words to the little endian words (BE byte 0 to LE byte 0, BE byte 1 to LE byte 1, and so on), the left half of the figure shows how the data ends up in the little endian words. Note that data of size one byte (characters in this case) is ordered correctly, but that integer data no longer correctly represents the original binary values. The right half of the figure shows that you need to swap bytes around the middle of the word to reconstitute the correct 32-bit integer values. After swapping bytes, the two preceding figures are identical.

Data Sent from Big to Little: (a) After Transfer, (b) After Byte Swaps

You can generalize the previous example to include floating-point data types and to include multiple-word data types.

Moving unformatted data files between big endian and little endian computers requires that the data be converted.

Intel Fortran provides the capability for programs to read and write unformatted data (originally written using unformatted I/O statements) in several nonnative floating-point formats and in big endian INTEGER or floating-point format. Supported nonnative floating-point formats include Compaq* VAX* little endian.
floating-point formats supported by Digital* FORTRAN for OpenVMS* VAX Systems, standard IEEE big endian floating-point format found on most Sun Microsystems* systems and IBM RISC* System/6000 systems, IBM floating-point formats (associated with the IBM's System/370 and similar systems), and CRAY* floating-point formats.

Converting unformatted data instead of formatted data is generally faster and is less likely to lose precision of floating-point numbers. For unformatted files that contain record lengths before and after the data, specifying big-endian conversion will interpret the lengths as big-endian.

**Caution:**

Intel Fortran support of data conversion applies only to I/O list items of instrinsic type (REAL, INTEGER, and so on). I/O list items of derived type are not converted.

The native memory format includes little endian integers and little endian IEEE floating-point formats, S_float for REAL(KIND=4) and COMPLEX(KIND=4) declarations, T_float for REAL(KIND=8) and COMPLEX(KIND=8) declarations, and X_float for REAL(KIND=16) and COMPLEX(KIND=16) declarations.

The keywords for supported nonnative unformatted file formats and their data types are listed in the following table:

### Nonnative Numeric Formats, Keywords, and Supported Data Types

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG_ENDIAN</td>
<td>Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian IEEE floating-point formats for REAL and COMPLEX single-, double-, and extended-precision numbers. INTEGER(KIND=1) data is the same for little endian and big endian.</td>
</tr>
<tr>
<td>CRAY</td>
<td>Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian CRAY proprietary floating-point format for REAL and COMPLEX single- and double-precision numbers.</td>
</tr>
</tbody>
</table>
| FDX       | Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats:  
  • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
  • VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8)  
  • IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16) |
| FGX       | Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats:  
  • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
  • VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8)  
  • IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16) |
| IBM       | Big endian integer data of the appropriate INTEGER size (one, two, or four bytes) and big endian IBM proprietary (System/370 and similar) floating-point format for REAL and COMPLEX single- and double-precision numbers. |
| LITTLE_ENDIAN | Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following native little endian IEEE floating-point formats:  
  • S_float for REAL (KIND=4) and COMPLEX (KIND=4)  
  • T_float for REAL (KIND=8) and COMPLEX (KIND=8)  
  • IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16) |
| NATIVE    | No conversion occurs between memory and disk. This is the default for unformatted files. |
| VAXD      | Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: |
Keyword | Description
--- | ---
| • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
• VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8)  
• VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16) | 

VAXG | Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats:
• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)  
• VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8)  
• VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16)

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a run-time message is displayed.

Environment Variable F_UFMTENDIAN Method

Porting non-Native Data
When porting nonnative data, consider the following:

• Vendors might use different units for specifying the record length (RECL specifier) of unformatted files. While formatted files are specified in units of characters (bytes), unformatted files are specified in longword units for Intel® Fortran (default) and some other vendors.

  To allow you to specify the RECL units (bytes or longwords) for unformatted files without source file modification, use the assume byterecl compiler option.
• Certain vendors apply different OPEN statement defaults to determine the record type. The default record type (RECORDTYPE) with Intel® Fortran depends on the values for the ACCESS and FORM specifiers for the OPEN statement.
• Certain vendors use a different identifier for the logical data types, such as hex FF and hex 00 instead of 01 to denote .TRUE. and .FALSE. See the assume byterecl compiler option.
• Source code being ported may be coded specifically for big endian use.

See Also
assume compiler option

Specifying the Data Format

Methods of Specifying the Data Format
There are a number of methods for specifying a nonnative numeric format for unformatted data:

• Set an environment variable for a specific unit number before the file is opened. The environment variable is named FORT_CONVERT\(n\), where \(n\) is the unit number.
• Set an environment variable for a specific file name extension before the file is opened. The environment variable is named FORT_CONVERT\_ext or FORT_CONVERT_{ext}, where \(\text{ext}\) is the file name extension (suffix).
• Set an environment variable for a set of units before the application is executed. The environment variable is named F_UFMTENDIAN.
• Specify the CONVERT keyword in the OPEN statement for a specific unit number.
• Compile the program with an OPTIONS statement that specifies the CONVERT=\textit{keyword} qualifier. This method affects all unit numbers using unformatted data specified by the program.
• Compile the program with the appropriate compiler option, which affects all unit numbers that use unformatted data specified by the program. Use the convert compiler option.
If none of these methods are specified, the native LITTLE_ENDIAN format is assumed (no conversion occurs between disk and memory).

Any keyword listed in \textit{Supported Native and Nonnative Numeric Formats} can be used with any of these methods, except for the Environment Variable \texttt{F\_UFMTENDIAN Method}, which supports only LITTLE_ENDIAN and BIG_ENDIAN.

If you specify more than one method, the order of precedence when you open a file with unformatted data is below:

1. Check for an environment variable \texttt{(F\_CONVERTn)} for the specified unit number (applies to any file opened on a particular unit).
2. Check for an environment variable \texttt{(F\_CONVERT\_ext} is checked before \texttt{F\_CONVERT\_ext}) for the specified file name extension (applies to all files opened with the specified file name extension).
3. Check for an environment variable \texttt{(F\_UFMTENDIAN)} for the specified unit number (or for all units).

\textbf{NOTE}

This environment variable is checked only when the application starts executing.

4. Check the \texttt{OPEN} statement \texttt{CONVERT} specifier.
5. Check whether an \texttt{OPTIONS} statement with a \texttt{CONVERT:keyword} qualifier was present when the program was compiled.
6. Check whether the \texttt{convert} compiler option was present when the program was compiled.

\textit{convert}

\texttt{Environment Variable F\_UFMTENDIAN Method}

\texttt{Environment Variable F\_CONVERT\_ext or F\_CONVERT\_ext Method}

\texttt{Environment Variable F\_CONVERTn Method}

\texttt{OPEN Statement CONVERT Method}

\texttt{OPTIONS Statement Method}

\textit{Supported Native and Nonnative Numeric Formats}

\texttt{Environment Variable F\_CONVERT\_ext or F\_CONVERT\_ext Method}

Use this method to specify a non-native numeric format for each specified file name extension (suffix). Specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit \texttt{OPEN} to one or more unformatted files. Use the format \texttt{F\_CONVERT\_ext} or \texttt{F\_CONVERT\_ext} (where \texttt{ext} is the file extension or suffix). The \texttt{F\_CONVERT\_ext} environment variable is checked before \texttt{F\_CONVERT\_ext} environment variable (if \texttt{ext} is the same).

For example, assume you have a previously compiled program that reads numeric data from one file and writes to another file using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from a file with a \texttt{.dat} file extension and write that data in native little endian format to a file with an extension of \texttt{.data}. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format (\texttt{S\_float} and \texttt{T\_float}) when read from \texttt{file.dat}, and then written without conversion in native little endian IEEE format to the file with a suffix of \texttt{.data}, assuming that environment variables \texttt{F\_CONVERT\_DATA} and \texttt{F\_CONVERTn} (for that unit number) are not defined.

Without requiring source code modification or recompilation of a program, the following command sets the appropriate environment variables before running the program:

\begin{tabular}{|l|}
\hline
\textbf{Example} \\
\hline
// Linux*  
\texttt{setenv F\_CONVERT\_DAT BIG\_ENDIAN} \hline
// Windows*  
\texttt{set F\_CONVERT\_DAT=BIG\_ENDIAN} \\
\hline
\end{tabular}

The \texttt{F\_CONVERTn} method takes precedence over this method. When the appropriate environment variable is set when you open the file, the \texttt{F\_CONVERT\_ext} or \texttt{F\_CONVERT\_ext} environment variable is used if a \texttt{F\_CONVERTn} environment variable is not set for the unit number.
The FORT_CONVERTn and the FORT_CONVERT_.ext or FORT_CONVERT_ext environment variable methods take precedence over the other methods. For instance, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

You can set the appropriate environment variable using the format FORT_CONVERT_.ext or FORT_CONVERT_ext. If you also use Intel® Fortran on Linux* systems, consider using the FORT_CONVERT_.ext form, because a dot (.) cannot be used for environment variable names on certain Linux* command shells. If you do define both FORT_CONVERT_.ext and FORT_CONVERT_ext for the same extension (ext), the file defined by FORT_CONVERT_.ext is used.

On Windows* systems, the file name extension (suffix) is not case-sensitive. The extension must be part of the file name (not the directory path).

**Environment Variable FORT_CONVERTn Method**

You can use this method to specify a nonnative numeric format for each specified unit number. You specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit OPEN to that unit number.

When the appropriate environment variable is set when you open the file, the environment variable is always used because this method takes precedence over the other methods. For example, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

For example, assume you have a previously compiled program that reads numeric data from unit 28 and writes it to unit 29 using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from unit 28 and write that data in native little endian format to unit 29. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format when read from unit 28, and then written without conversion in native little endian IEEE format to unit 29.

Without requiring source code modification or recompilation of this program, the following command sequence sets the appropriate environment variables before running a program.

**Linux:**

```bash
setenv FORT_CONVERT28 BIG_ENDIAN
setenv FORT_CONVERT29 NATIVE
```

**Windows:**

```cmd
set FORT_CONVERT28=BIG_ENDIAN
set FORT_CONVERT29=NATIVE
```

The following figure shows the data formats used on disk and in memory when the program is run after the environment variables are set.

**Sample Unformatted File Conversion**
This method takes precedence over other methods.

Environment Variable F_UFMTENDIAN Method

This little-endian-big-endian conversion feature is intended for Fortran unformatted input/output operations. It enables the development and processing of files with little-endian and big-endian data organization.

The F_UFMTENDIAN environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units or for all units continues for the rest of the execution.

Specify the numbers of the units to be used for conversion purposes by setting F_UFMTENDIAN. Then, the READ/WRITE statements that use these unit numbers will perform relevant conversions. Other READ/WRITE statements will work in the usual way.

General Syntax for F_UFMTENDIAN

In the general case, the variable consists of two parts divided by a semicolon. No spaces are allowed inside the F_UFMTENDIAN value:

\[ F_{\text{UFMTENDIAN}} = \text{MODE} \mid \{\text{MODE;}\} \text{ EXCEPTION} \]

where:

- **MODE** = big | little
- EXCEPTION = big:ULIST | little:ULIST | ULIST
- ULIST = U | ULIST,U
- U = decimal | decimal -decimal

- **MODE** defines current format of data, represented in the files; it can be omitted.
  
  The keyword little means that the data has little endian format and will not be converted. This is the default.

  The keyword big means that the data has big endian format and will be converted.

- **EXCEPTION** is intended to define the list of exclusions for MODE.EXCEPTION keyword (little or big) defines data format in the files that are connected to the units from the EXCEPTION list. This value overrides MODE value for the units listed.

  The EXCEPTION keyword and the colon can be omitted. The default when the keyword is omitted is big.

  - Each list member U is a simple unit number or a number of units. The number of list members is limited to 64.
  - decimal is a non-negative decimal number less than 232.

Converted data should have basic data types or arrays of basic data types. Derived data types are disabled. Error messages may be issued during the little-endian-to-big-endian conversion. They are all fatal.

On Linux* systems, the command line for the variable setting in the shell is:

Sh: export F_UFMTENDIAN=MODE;EXCEPTION

**NOTE**

The environment variable value should be enclosed in quotes if the semicolon is present.

The environment variable can also have the following syntax:

\[ F_{\text{UFMTENDIAN}} = u[,u] . . . \]

Examples

1. F_UFMTENDIAN=big

   All input/output operations perform conversion from big-endian to little-endian on READ and from little-endian to big-endian on WRITE.
2.  \texttt{F\_UFMTENDIAN="little;big:10,20"}
    \texttt{or F\_UFMTENDIAN=big:10,20}
    \texttt{or F\_UFMTENDIAN=10,20}
    The input/output operations perform big-endian to little endian conversion only on unit numbers 10 and 20.

3.  \texttt{F\_UFMTENDIAN="big;little:8"}
    No conversion operation occurs on unit number 8. On all other units, the input/output operations perform big-endian to little-endian conversion.

4.  \texttt{F\_UFMTENDIAN=10-20}
    The input/output operations perform big-endian to little-endian conversion on units 10, 11, 12, ... 19, 20.

5.  Assume you set \texttt{F\_UFMTENDIAN=10,100} and run the following program.

\begin{verbatim}
integer*4   c4
integer*8   c8
integer*4   cc4
integer*8   cc8
cc4 = 456
cc8 = 789

! prepare a little endian representation of data
open(11,file='lit.tmp',form='unformatted')
write(11) c8
write(11) c4
close(11)

! prepare a big endian representation of data
open(10,file='big.tmp',form='unformatted')
write(10) c8
write(10) c4
close(10)

! read big endian data and operate with them on little endian machine.
open(100,file='big.tmp',form='unformatted')
read(100) cc8
read(100) cc4

! Any operation with data, which have been read
! ...
close(100)
stop
end
\end{verbatim}

Now compare \texttt{lit.tmp} and \texttt{big.tmp} files with the help of the \texttt{od} utility:

\begin{verbatim}
> od -t x4 lit.tmp
00000000 00000008 00000315 00000000 00000008
00000020 00000004 000001c8 00000004
00000034
> od -t x4 big.tmp
74 2463
\end{verbatim}
You can see that the byte order is different in these files.

**OPEN Statement CONVERT Method**

Use this method to specify a nonnative numeric format for each specified unit number. This method requires an explicit file `OPEN` statement to specify the numeric format of the file for that unit number.

This method takes precedence over the `OPTIONS` statement and the compiler option `CONVERT[: ]` keyword method, but has a lower precedence than the environment variable methods.

For example, the following source code shows how the `OPEN` statement would be coded to read unformatted VAXD numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20 (the absence of the `CONVERT` keyword or environment variables `FORT_CONVERT20`, `FORT_CONVERT.dat`, or `FORT_CONVERT_dat` indicates native little endian data for unit 20):

```fortran
OPEN (CONVERT='VAXD', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
... 
OPEN (FILE='graph3_t.dat', FORM='UNFORMATTED', UNIT=20)
```

A hard-coded `OPEN` statement `CONVERT` keyword value cannot be changed after compile time. However, to allow selection of a particular format at run time, equate the `CONVERT` keyword to a variable and provide the user with a menu that allows selection of the appropriate format (menu choice sets the variable) before the `OPEN` occurs.

You can also select a particular format at run time for a unit number by using one of the environment variable methods (`Environment Variable FORT_CONVERTn Method`, `Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method`, or `Environment Variable F_UFMTENDIAN Method`), which take precedence over the `OPEN` statement `CONVERT` keyword method.

**See Also**

`OPEN` Statement: Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.

`Environment Variable FORT_CONVERTn Method`

`Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method`

`Environment Variable F_UFMTENDIAN Method`

**OPTIONS Statement Method**

You can only specify one numeric file format for all unformatted file unit numbers using this method unless you also use one of the environment variable methods or `OPEN` statement `CONVERT` keyword method.

You specify the numeric format at compile time and must compile all routines under the same `OPTIONS` statement `/ CONVERTr` keyword qualifier. You could use one source program and compile it using different `ifort` commands to create multiple executable programs that each read a certain format.

The environment variable methods and the `OPEN` statement `CONVERTr` keyword method take precedence over this method. For example, you might use the `FORT_CONVERTn environment variable` or `OPENCONVERTr` method to specify each unit number that will use a format other than that specified using the `ifort` option method.

This method takes precedence over the `ifortconvert[ ]` compiler option method.

You can use `OPTIONS` statements to specify the appropriate floating-point formats (in memory and in unformatted files) instead of using the corresponding `ifort` command qualifiers. For example, to use VAX `F_floating`, `G_floating`, and `X_floating` as the unformatted file format, specify the following `OPTIONS` statement:

```fortran
OPTIONS /CONVERT=VAXG
```
Because this method affects all unit numbers, you cannot read data in one format and write it in another format, unless you use it in combination with one of the environment variable methods or the OPEN statement CONVERT keyword method to specify a different format for a particular unit number.

For more information, see the OPTIONS Statement statement.

See Also

OPTIONS Statement: Overrides or confirms the compiler options in effect for a program unit.

Compiler Option -convert or /convert Method

You can only specify one numeric format for all unformatted file unit numbers using the convert compiler option unless you also use one (or more) of the previous methods shown in Methods of Specifying the Data Format.

You specify the numeric format at compile time and must compile all routines under the same convert keyword compiler option. You can use the same source program and compile it using different ifort commands (or the equivalent in the IDE) to create multiple executable programs that each read a certain format.

If you specify other methods, the other methods take precedence over using this method. For instance, you might use the environment variable or OPEN statement convertkeyword method to specify each unit number that will use a format different than that specified using the convertkeyword compiler option method for all other unit numbers.

For example, the following command compiles program file.for to use VAX D_floating (and F_floating) floating-point data for all unit numbers (unless superseded by one of the other methods). Data is converted between the file format and the little endian memory format (little endian integers, S_floating, T_floating, and X_floating little endian IEEE* floating-point format). The created file, vconvert.exe, can then be run:

```bash
// Windows*
ifort file.for /convert:vaxd /link /out:vconvert.exe
```

Because this method affects all unformatted file unit numbers, you cannot read data in one format and write it in another file format using the convertkeyword compiler option alone. You can if you use it in combination with the environment variable methods or the OPEN statement convertkeyword method to specify a different format for a particular unit number.

directive specifying default kind 1840

function returning kind type parameter for 1875

model for 1056

real data type

constants 710–712

default kind 709

function converting to double precision 1285

models for 1056

ranges for 551

storage 1030

real editing

conversion 930

E and D 926

EN 927

engineering notation 927

ES 929

F 924

G 930

scientific notation 929

with exponents 926

without exponents 924

real model

function returning exponent part 1 1364

function returning fractional part 1 1397

function returning largest number 1 1466

function returning number closest to unity 1 1350

function returning smallest number 2 2013

real numbers

directive specifying default kind 1840

function resulting in single-precision 1 1841

function returning absolute spacing 0 1938

function returning ceiling 0 1227

function returning class of IEEE 1396

function returning difference between 1299

function returning floor 0 1373

function returning fractional part for model 0 1888

function returning scale of model 0 1865

function rounding 1143

function truncating 1135

real values
transferring 924, 930
transferring in exponential form 926
transferring using engineering notation 927
transferring using scientific notation 929
real-coordinate graphics
  function converting to double precision 1285
  function converting to quad precision 1821
real-time clock
  subroutine returning data from 1986
REAL(16)
  constants 712
REAL(4)
  constants 711
REAL(8)
  constants 711
REAL*16709
REAL*4709
REAL*8709
REC
  specifier for READ 1836
  specifier for WRITE 2055
REC specifier 870, 873
reciprocal
  function returning 1860
RECL
  specifier for INQUIRE 970
  specifier for OPEN 989
RECORD 1842
record access 574
record I/O 583
record I/O statement specifiers 581
record length 574
record number
  identifying for data transfer 873
record position
  specifying 583
record specifier
  alternative syntax for 1040
record structure fields
  references to 1043
record structure items
  directive specifying starting address of 1692
record structures
  aggregate assignment 1045
  converting to Fortran 95/90 derived types 1041
  directive modifying alignment of data in 1684
  MAP declarations in 2032
  UNION declarations in 2032
record transfer 575
record type
  converting nonnative data using OPEN defaults 2459
record types 568
records
  function checking for end-of-file 1347
  option specifying padding for 409
  repositioning to first 1856
  rewriting 1857
  specifying line terminator for formatted files 568
  statement to delete 1295
  statement writing end-of-file 1344
  types of 568, 869
RECORDSIZE 991
RECORDTYPE
  specifier for INQUIRE 971
  specifier for OPEN 991
RECTANGLE 1843
RECTANGLE_W 1843
rectangles
  functions drawing 1843
  subroutines storing screen image defined by 1437
recursion 1844
RECURSIVE
  in functions 1404
  in subroutines 1978
recursive execution
  option specifying 329
recursive procedures
  as functions 1404
  as subroutines 1978
redistributable package 545
redistributing libraries 545
REDUCTION
  in DO directive 1324
  in PARALLEL directive 1693
  in PARALLEL DO directive 1697
  in PARALLEL SECTIONS directive 1699
  in SECTIONS directive 1870
  in SIMD OpenMP* Fortran directive 1923
  in TEAMS directive 2005
reentrancy protection
  function controlling 1389
REF 1847
REFERENCE
  option for ATTRIBUTES directive 1183
references
  function 821
  procedure 821
  to elemental intrinsic procedures 837
  to generic intrinsic functions 835
  to generic procedures 834
  to non-Fortran procedures 838
  to nonestablished names 1022
references to global function symbols
  option binding to shared library definitions 478
references to global symbols
  option binding to shared library definitions 477
register allocator
  option selecting method for partitioning 230
REGISTERMOUSEEVENT 1848
relational expressions 759
relational operators 759
relative error
  option defining for math library function results 300
  option defining maximum for math library function results 307
relative files
  statement to delete records from 1295
relative spacing
  function returning reciprocal of 1860
release configuration
  function returning reciprocal of 1860
remainder
  functions returning 1615
REMAPALLPALETTERGB 1849
REMPAAPALETTERGB 1849
Remapping RGB values for video hardware 1849
remote debugging 2150, 2152
removed compiler options 136
RENAME 1851
RENAMEFILE 1851
REPEAT 1852
repeat specification
  nested and group 948
repeatable edit descriptors 913, 918
replicated arrays
  function creating 1958
report generation
  dynamic profile counters 2319, 2322
Intel® Compiler extensions 2185
OpenMP* run-time routines 2181
profile information 2322
 timing 2181
 using xi* tools 2333
 RESHAPE 1853
 resolving generic references 1020
 resolving procedure references 1020
 resolving specific references 1022
 response Default Options 82
 Restore Default Options 82
 restricted expressions 763
 restrictions
 in using traceback information 2341
 restrictions on offloaded code 2285
 restrictions on offloaded code, Windows* 2286
 RESULT
 defining explicit interface 1844
 keyword in functions 1404
 result name
 in functions 1404
 result variables
 in ENTRY 1346
 requiring explicit interface 839
 RETURN
 retaining data after execution of 1862
 REWIND 1856
 REWRITE 1857
 RGB color
 subroutine converting into components 1535
 RGB color values
 function converting integer to 1858
 function remapping 1849
 function returning current 1416
 function returning for multiple pixels 1445
 function returning for pixel 1443
 function returning text 1450
 function setting current 1881
 function setting for multiple pixels 1903
 function setting for pixel 1901
 function setting text 1906
 RGB components
 subroutine converting color into 1535
 RGBTOINTEGER 1858
 right margin wrapping
 option disabling 414
 right shift
 function performing arithmetic 1550
 function performing circular 1551
 function performing logical 1553
 RINDEX 1859
 RN 941
 RN edit descriptor 941
 RNUM 1859
 root procedures
 table of 1095
 ROUND
 specifier for INQUIRE 971
 specifier for OPEN 992
 round editing
 DC 941
 DP 942
 RC 941
 RD 941
 RN 941
 RP 941
 RU 941

 rounding
 function performing 1629
 rounding during file connections 940
 routine entry
 option specifying the stack alignment to use on 425
 routine entry and exit points
 option determining instrumentation of 243
 routines
 calling Windows APIs 546
 comparing Intel(R) Fortran and Windows APIs 546
 MCBS module 1059
 module 1059
 NLS module 1059
 OpenMP Fortran 1067
 option passing arguments in registers 216
 storing in shareable libraries 546
 that handle MBCS characters 1062
 RP 941, 942
 RP edit descriptor 941
 RRSPACING 1860
 RSHIFT 1551
 RTC 1860
 RTL errors
 function letting you specify a handler for 1356
 RU 941
 RU edit descriptor 941
 run-time environment
 function cleaning up 1383
 function initializing 1384
 run-time environment variables 2093
 run-time error messages
 format 636
 locating 640
 locating cause 640
 using traceback information 2340
 where displayed 636
 run-time error processing
 default 635
 run-time errors
 functions returning most recent 1438
 Run-Time Library (RTL)
 error processing performed by 635
 function controlling reentrancy protection for 1389
 option searching for unresolved references in
 multithreaded 489, 490, 502
 option specifying which to link to 486
 requesting traceback 2340
 run-time performance
 improving 534
 run-time routines
